Preface

The *Solaris WBEM Services Administrator's Guide* explains Common Information Model (CIM) concepts and describes how to administer Web-Based Enterprise Management (WBEM) services in the Solaris[™] operating environment.

Solaris WBEM Services software makes it easier for software developers to create management applications that run on Solaris and makes the Solaris operating environment easier to manage.

Who Should Use This Book

This book is written for system administrators who manage WBEM-enabled networks and workstations, by running existing WBEM applications or writing new ones.

Before You Read This Book

This book requires knowledge of the following:

- Object-oriented programming concepts
- Java[™] programming
- WBEM Common Information Model (CIM) concepts
- Network management concepts

If you are unfamiliar with these areas, you might find the following references useful:

- Java[™] How to Program
 - H. M. Deitel and P. J. Deitel, Prentice Hall, ISBN 0-13-263401-5
- *The Java Class Libraries, Second Edition, Volume 1*, Patrick Chan, Rosanna Lee, Douglas Kramer, Addison-Wesley, ISBN 0-201-31002-3
- CIM Tutorial, provided by the Distributed Management Task Force

The following Web sites are useful resources when working with WBEM technologies.

■ Distributed Management Task Force (DMTF)

See this site at www.dmtf.org for the latest developments on CIM, information about various working groups, and contact information for extending the CIM Schema.

Rational Software

See this site at www.rational.com/uml for documentation on the Unified Modeling Language (UML) and the Rose CASE tool.

How This Book Is Organized

Chapter 1 provides an overview of Solaris WBEM Services and Web-Based Enterprise Management (WBEM).

Chapter 2 describes the CIM Object Manager and explains how to start and stop it.

Chapter 3 describes security features and how to set access rights on namespaces and users.

Chapter 4 describes the command syntax for the mofcomp command and how to compile a .mof file.

Chapter 5 describes the logging features.

Chapter 6 describes error messages generated by components of the Solaris WBEM Services product.

Appendix A provides information about general Common Information Model (CIM) concepts.

Appendix B describes the Solaris Schema files, Managed Object Format (MOF) files that describe managed objects in the Solaris operating environment.

Appendix C describes new and changed information in this release of the *Solaris WBEM Services Administrator's Guide*.

Glossary is a list of words and phrases found in this book and their definitions.

Ordering Sun Documents

Fatbrain.com, an Internet professional bookstore, stocks select product documentation from Sun Microsystems, Inc.

For a list of documents and how to order them, visit the Sun Documentation Center on Fatbrain.com at http://wwwl.fatbrain.com/documentation/sun.

Accessing Sun Documentation Online

The docs.sun.comSM Web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. The URL is http://docs.sun.com.

Typographic Conventions

The following table describes the typographic changes used in this book.

TABLE P-1 Typographic Conventions

Typeface or Symbol	Meaning	Example
AaBbCc123	The names of commands, files, and directories; on-screen computer output	Edit your .login file. Use ls -a to list all files. machine_name% you have mail.
AaBbCc123	What you type, contrasted with on-screen computer output	machine_name% su Password:

 TABLE P-1
 Typographic Conventions (continued)

Typeface or Symbol	Meaning	Example
AaBbCc123	Command-line placeholder: replace with a real name or value	To delete a file, type rm filename.
AaBbCc123	Book titles, new words, or terms, or words to be emphasized.	Read Chapter 6 in <i>User's</i> Guide.
		These are called <i>class</i> options. You must be <i>root</i> to do this.

Overview

This chapter provides an overview of Web-Based Enterprise Management (WBEM) and Solaris WBEM Services, software that makes it easier for software developers to create management applications that run on Solaris and make the Solaris operating environment easier to manage.

This chapter covers the following topics.

- About WBEM
- About the Common Information Model
- Solaris WBEM Services Software
- Sun WBEM Software Development Kit

About WBEM

Web-Based Enterprise Management (WBEM) is an industry-wide initiative that includes standards for web-based management of systems, networks, and devices on multiple platforms. This standardization enables system administrators to manage desktops, devices, and networks.

WBEM is designed to be compatible with all major existing management protocols, including Simple Network Management Protocol (SNMP), Distributed Management Interface (DMI), and Common Management Information Protocol (CMIP).

WBEM encompasses the following standards:

- Common Information Model (CIM) Information model for describing managed resources.
- Managed Object Format (MOF) Language for defining CIM classes and instances.

 eXtensible Markup Language (XML) – Markup language for describing managed resources on the web.

The Distributed Management Task Force (DMTF), a group representing corporations in the computer and telecommunications industries, is leading the effort to develop management standards. The goal of the DMTF is to develop an integrated approach to managing networks across platforms and protocols, resulting in cost-effective products that interoperate as flawlessly as possible. For information about DMTF initiatives and outcomes, see the DMTF web site at www.dmtf.org.

About the Common Information Model

This section provides a brief introduction to basic CIM terms and concepts as they are used in the Solaris WBEM Services product. For more information on CIM, see Appendix A.

CIM is an object-oriented information model for describing managed resources such as disks, CPUs, and operating systems. A CIM object is a representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application.

Basic CIM Elements

CIM objects with similar properties and purposes are represented as CIM classes. Properties are attributes that describe a unit of data for a class. An instance is a representation of a managed object that belongs to a particular class. Instances contain actual data. For example, Solaris_ComputerSystem is a CIM class that represents a computer running the Solaris operating environment. The Solaris software running your workstation is an instance of the Solaris_OperatingSystem class. ResetCapability and InstallDate are examples of properties of the Solaris_ComputerSystem class.

CIM classes are grouped into meaningful collections called schemas. A schema is a group of classes with a single owner. A class must belong to only one schema. Schemas are used for administration and class naming. All class names must be unique within a particular schema. The schema name is the determining factor in differentiating classes and properties from others that may have the same name. The naming of schema, class, and property follow this syntax:

Schemaname_classname.propertyname

The CIM Models

The Common Information Model categorizes information from general to specific. Specific information, such as a representation of the Solaris environment, extends the model. CIM consists of the following three layers of information:

- Core Model A subset of CIM not specific to any platform.
- Common Model Information model that visually depicts concepts, functionality, and representations of entities related to specific areas of network management, such as systems, devices, and applications.
- Extensions Information models that support the CIM Schema and represent a very specific platform, protocol, or corporate brand.

Collectively, the Core Model and the Common Model are referred to as the CIM Schema.

The Core Model

The Core Model provides the underlying, general assumptions of the managed environment—for example, that specific, requested data must be contained in a location and distributed to requesting applications or users. These assumptions are conveyed as a set of classes and associations that conceptually form the basis of the managed environment. The Core Model is meant to introduce uniformity across schemas intended to represent specific aspects of the managed environment.

For applications developers, the Core Model provides a set of classes, associations, and properties that can be used as a starting point to describe managed systems and determine how to extend the Common Model. The Core Model establishes a conceptual framework for modeling the rest of the managed environment.

The Core Model provides classes and associations to extend specific information about systems, applications, networks, devices, and other network features through the Common Model and extensions.

The Common Model

Areas of network management depicted in the Common Model are independent of a specific technology or implementation but provide the basis for the development of management applications. This model provides a set of base classes for extension into the area of five designated technology-specific schemas: Systems, Devices, Applications, Networks, and Physical.

CIM Extensions

Extension schemas are built upon CIM to connect specific technologies to the model. By extending CIM, a specific operating environment such as Solaris can be made available to a greater number of users and administrators. Extension schemas provide classes for software developers to build applications that manage and administer the extended technology. The Solaris Schema is an extension of the CIM Schema.

Solaris WBEM Services

Solaris WBEM Services software provides Web-Based Enterprise Management (WBEM) services on the Solaris operating environment. These services make it easier for software developers to create management applications that run in the Solaris operating environment, and makes the Solaris operating environment easier to manage.

Solaris WBEM Services software provides secure access and manipulation of management data. The product includes a built-in Solaris provider that allows management applications to access information about managed resources (devices and software) in the Solaris operating environment.

The CIM Object Manager accepts connections from management applications using either RMI or XML/HTTP protocols, and provides the following services to connected clients:

- Management services, in the form of a CIM Object Manager that checks the semantics and syntax of CIM data and distributes data between applications, the CIM Repository, and managed resources.
- Security services that enable administrators to control user access to CIM information.
- Logging services that consist of classes developers can use to create applications that dynamically record event data to a log record and retrieve data from a log record. Administrators can use this data to track and determine the cause of events.
- XML services that convert XML data into CIM classes, enabling XML/HTTP-based WBEM clients to communicate with the CIM Object Manager.

Once connected to a WBEM-enabled system, WBEM clients can request WBEM operations, such as, creating, viewing, and deleting CIM classes and instances, querying for properties that have a specified value, enumerating (getting a list of) instances or classes in a specified class hierarchy.

Software Components

Solaris WBEM Services software consists of software components that function at three layers: Application, Management, and Provider. These components interact with the operating system and hardware layers. Figure 1–1 shows the software components and their interaction at each layer.

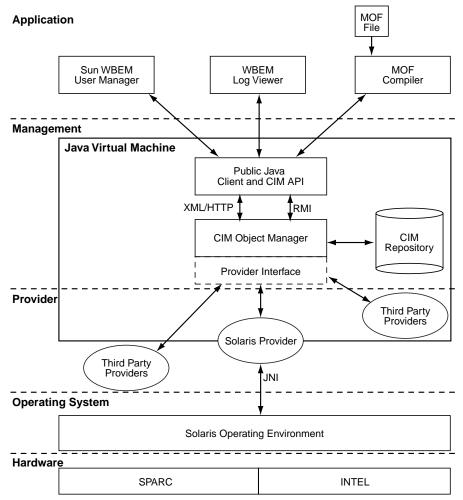

Figure 1–1 Solaris WBEM Services Architecture

- Application Layer WBEM clients process and display data from managed resources. Solaris WBEM Services includes the following applications.
 - Sun WBEM User Manager and Solaris Management Console (SMC) Users Tool
 Applications that allow system administrators to add and delete authorized users and to set their access privileges to managed resources.

- Solaris Management Console (SMC) Log Viewer An application that displays log files. Using the log viewer, a user can view details of a log record, including the name of the user who issued a logged command and the client computer on which a logged event occurred.
- Managed Object Format (MOF) Compiler Program that parses a file containing MOF statements, converts the classes and instances defined in the file to Java classes, and then adds the Java classes to the CIM Object Manager Repository, a central storage area for management data.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a representation, or model, of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the mofcomp command to compile MOF files at any time after installation. For more information about MOF, see the DMTF web page at http://www.dmtf.org.

- Management Layer Components at this layer provide services to connected WBEM clients.
 - Common Information Model (CIM) Object Manager Software that manages CIM objects on a WBEM system. CIM objects are stored internally as Java classes. The CIM Object Manager transfers information between WBEM clients, the CIM Object Manager Repository, and managed resources.
 - CIM Object Manager Repository Central storage area for CIM class and instance definitions.
 - Client and CIM Application Programming Interfaces (APIs) WBEM client applications use these Java interfaces to request operations, such as creating or viewing classes or instances of managed resources, from the CIM Object Manager.
 - Provider Interface Providers use these interfaces to transfer information about managed resources to the CIM Object Manager. The CIM Object Manager uses the provider interfaces to transfer information to locally installed providers.
- Provider Layer Providers act as intermediaries between the CIM Object Manager and one or more managed resources. When the CIM Object Manager receives a request from a WBEM client for data that is not available from the CIM Object Manager Repository, it forwards the request to the appropriate provider.
 - Solaris Provider Provides the CIM Object Manager with instances of managed resources in the Solaris operating environment. Providers get and set information on managed devices. A native provider is a machine-specific program written to run on a managed device. For example, a provider that

accesses data on a Solaris system will most likely include C functions to query the Solaris system. The Java Native Interface (JNI) is the native programming interface for Java that is part of the JDK. By writing programs using the JNI, you ensure that your code is completely portable across all platforms. The JNI allows Java code that runs within a Java Virtual Machine (VM) to operate with applications and libraries written in other languages, such as C, C++, and assembly.

 Solaris Schema – A collection of classes that describe managed objects in the Solaris operating environment. The CIM and Solaris Schema classes are stored in the CIM Object Manager Repository. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment.

The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment. Users can also use the MOF compiler (mofcomp) to add CIM Schema, Solaris Schema, or other classes to the CIM Object Manager Repository.

- Operating System Layer The Solaris provider allows management applications to access information about managed resources (devices and software) in the Solaris operating environment.
- Hardware Layer A management client can access management data on any supported Solaris platform.

Namespaces

One or more schemas can be stored in directory-like structures called namespaces. A CIM namespace is a directory-like structure that can contain other namespaces, classes, instances, and qualifier types. The names of objects within a namespace must be unique.

In Solaris WBEM Services, when WBEM client application connects to a particular namespace, all subsequent operations occur within that namespace. When connected to a namespace, the client can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace. For example, if you create a namespace called <code>child</code> in the <code>root\cimv2</code> namespace, you could connect to <code>root\cimv2</code> and access the classes and instances in the <code>root\cimv2</code> and <code>root\cimv2\child</code> namespaces.

An application can connect to a namespace within a namespace. This is similar to changing to a subdirectory within a directory. Once the application connects to the new namespace, all subsequent operations occur within that namespace. If you open a new connection to root\cimv2\child, you can access any classes and instances

in that namespace but cannot access the classes and instances in the parent namespace, root\cimv2.

Three namespaces are created by default during installation:

- root The top-level namespace that contains other namespaces.
- root\cimv2 Contains the default CIM classes and instances that represent objects on your system, such as, LogicalDisk and Netcard. This is the default namespace.
- root\security Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

Providers

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a user is granted read access to the CIM and Solaris Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

Providers are classes that communicate with managed objects to access data. Providers forward this information to the CIM Object Manager for integration and interpretation. When the CIM Object Manager receives a request from a management application for data that is not available from the CIM Object Manager Repository, it forwards the request to a provider.

The CIM Object Manager uses object provider APIs to communicate with providers. When an application requests dynamic data from the CIM Object Manager, the CIM Object Manager uses the provider interfaces to pass the request to the provider.

Providers perform the following functions in response to a request from the CIM Object Manager:

- Map the native information format to CIM classes
 - Get information from a device
 - Pass the information to the CIM Object Manager in the form of CIM classes
- Map the information from CIM classes to native device format
 - Get the required information from the CIM class
 - Pass the information to the device in native device format

Interoperability with Other WBEM Systems

A WBEM client and WBEM system can run on the same system or on different systems. Multiple WBEM clients can establish connections to the same WBEM system. A typical WBEM system can serve four or five WBEM clients.

Solaris WBEM Services supports the Version 1.0 Specification for CIM Operations over HTTP. This specification uses XML to model CIM objects and messages. XML is a standard markup language for describing data on the Web. This standard extends XML markup to define CIM objects and operations. Because XML provides a standard way of describing data that can be sent across the Web, any WBEM client can access CIM data on any WBEM system that can parse XML data.

Sun WBEM Software Development Kit

The Sun WBEM Software Development Kit (SDK) contains the components required to write management applications that can communicate with any WBEM-enabled management device. Developers can also use this tool kit to write providers, programs that communicate with managed objects to access data. All management applications developed using the Sun WBEM SDK run on the Java platform.

A WBEM client application is a program that uses Sun WBEM SDK APIs to manipulate CIM objects. A client application typically uses the CIM API to construct an object (for example, a namespace, class, or instance) and then initialize that object. The application then uses the Client APIs to pass the object to the CIM Object Manager and request a WBEM operation, such as creating a CIM namespace, class, or instance.

The Sun WBEM SDK installs and runs in any Java environment. It may be used as a standalone application or with Solaris WBEM Services. The Sun WBEM SDK is available for download from http://www.sun.com/solaris/wbem.

CIM Object Manager

The Common Information Model (CIM) Object Manager is software that transfers CIM data between WBEM client applications and managed resources.

This chapter includes the following topics:

- "About the CIM Object Manager" on page 29
- "The init.wbem Command" on page 30
- "Upgrading the CIM Object Manager Repository" on page 32
- "Setting the Solaris Provider CLASSPATH" on page 34
- "Exception Messages" on page 35

About the CIM Object Manager

The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.

When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data. When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.

At startup, the CIM Object Manager performs the following functions:

■ Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 80

- Sets up a connection to the CIM Object Manager Repository
- Waits for incoming requests

During normal operations, the CIM Object Manager performs these functions:

- Performs security checks to authenticate user login and authorization to access namespaces.
- Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.
- Routes requests to the appropriate provider or to the CIM Object Manager Repository.
- Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.

A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to the CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.

The init.wbem Command

/etc/init.d/init.wbem start | stop | status

The init.wbem utility is run automatically during installation and each time the system is rebooted. This utility starts the CIM Object Manager and Solaris Management Console (SMC) server, both of which run combined in a single process. It can be also be used to stop the CIM Object Manager and SMC server, or to retrieve status from the server.

Generally, you do not need to stop the CIM Object Manager. However, if you change an existing provider, you must stop and restart the CIM Object Manager before using the updated provider.

The init.wbem command has three options:

- start Starts the CIM Object Manager and SMC server on the local host.
- stop Stops the CIM Object Manager and SMC server on the local host.
- status Gets status for the CIM Object Manager and SMC server on the local host

Solaris Management Console Server

The Solaris Management Console (SMC) server is the back end to the front-end GUI, smc(1M). The SMC front-end GUI provides Solaris management applications such as a User Manager, Disk Manager, and Log Viewer. The SMC server provides tools for the console to download and performs common services for the console and its tools, such as authentication, authorization, logging, messaging, and persistence.

System Booting

The init.wbem script is installed in the /etc/init.d directory. A link to the script exists in /etc/rc2.d/S90wbem, which is run with the start option when init state 2 is entered (normally at boot time). Other links to it exist in /etc/rc0.d/ K36wbem, /etc/rc1.d/K36wbem, and /etc/rc3.d/K36wbem, which are run with the stop option when init states 0, 1, and S are entered (normally at system halt, or when entering "system administrator mode" or single-user mode).

Stopping and Restarting the CIM Object Manager

If you change a provider, you must stop and restart the CIM Object Manager before using the updated provider.

▼ To Stop the CIM Object Manager

- 1. Become root by typing the following command at the system prompt:
 - % su
- 2. Type the root password when you are prompted.
- 3. Stop the CIM Object Manager by typing the following command:

```
# /etc/init.d/init.wbem stop
```

▼ To Restart the CIM Object Manager

- 1. Become root by typing the following command at the system prompt:
 - % su
- 2. Type the root password when you are prompted.

Upgrading the CIM Object Manager Repository

If you are upgrading from Solaris 8 10/00 (WBEM Services 2.2) or earlier to Solaris 8 1/01 (WBEM Services 2.3), you must upgrade the CIM Object Manager Repository datastore format.

Datastore Format for	Datastore Format for
Solaris 8 10/00 (WBEM Services 2.2) or earlier	Solaris 8 1/01 (WBEM Services 2.3)
JavaSpaces™	Reliable Log

To upgrade a JavaSpaces datastore to the newer Reliable Log repository format, you use the wbemconfig convert command. This command successfully converts any proprietary custom MOF data, but not any CIM or Solaris MOF data you have modified—these will be destroyed. To recompile any modified CIM or Solaris MOF data into the new repository, run the mofcomp compiler on the MOF files containing the class definitions.

The wbemconfig convert command creates a directory named /var/sadm/wbem/logr/ that contains the converted data.

Warning - To prevent corruption of your data, only use the wbemconfig convert command after stopping the CIM Object Manager with the init.wbem stop command.

Note - Because the wbemconfig convert command invokes the JVM (Java Virtual Machine) to perform conversion of the repository, you must be running the same version of the JVM as was used to create the original JavaSpaces datastore. After the wbemconfig convert command is completed, you can change to any version of the JVM you want.

Upgrading the CIM Repository datastore format is a two-part process:

■ Steps you must perform before installing your new version of Solaris.

■ Steps you must perform after installing your new version of Solaris.

▼ Before Installing Your New Version of Solaris

1. Log in as superuser (root) and save the JavaSpaces software. Type the following command:

```
# cp /usr/sadm/lib/wbem/outrigger.jar /usr/sadm/lib/wbem/
outrigger.jar.tmp
```

2. Check and record the version of the JDK installed on your machine. For example:

```
# /usr/bin/java -version
java version "1.2.1"
Solaris VM (build Solaris_JDK_1.2.1_04c, native threads,
sunwjit)
```

You must be running the same version of the JDK as was used when the original JavaSpaces datastore was created.

▼ After Installing Your New Version of Solaris

1. Log in as superuser and stop the CIM Object Manager:

```
# /etc/init.d/init.wbem stop
```

2. Restore the JavaSpace software that you saved in Step 1 of "Before Installing Your New Version of Solaris".

```
# mv /usr/sadm/lib/wbem/outrigger.jar /usr/sadm/lib/wbem/
outrigger.jar.2
# mv /usr/sadm/lib/wbem/outrigger.jar.tmp /usr/sadm/lib/wbem/
outrigger.jar
```

- 3. Install the old version of the JDK that was on your machine previously, in a separate location from the current (newly installed) JDK. You can download a JDK from http://java.sun.com/products/.
- 4. Change the symbolic link /usr/java to point to the location of the old version of the JDK. For example, if you installed Solaris_JDK_1.2.1_04c in /old_sdk:

```
# rm /usr/java
# ln -s /old_sdk/Solaris_JDK_1.2.1_04c /usr/java
```

- 5. Convert the JavaSpaces datastore to Reliable Log format.
 - # /usr/sadm/lib/wbem/wbemconfig convert
- 6. Restore the outrigger. jar file included in the new version of Solaris.

mv /usr/sadm/lib/wbem/outrigger.jar.2 /usr/sadm/lib/wbem/
outrigger.jar

7. Change the symbolic link /usr/java to point to the location of the new JDK that came in the new version of Solaris:

```
# rm /usr/java
# ln -s /usr/java1.2 /usr/java
```

- 8. Restart the CIM Object Manager.
 - # /etc/init.d/init.wbem start

Setting the Solaris Provider CLASSPATH

To set the Solaris provider's CLASSPATH, use the client APIs to create an instance of the Solaris_ProviderPath class and set its pathurl property to the location of your provider class files. The Solaris_ProviderPath class is stored in the \root\system namespace.

You can also set the provider CLASSPATH to the location of your provider class files. You can set the class path to the <code>jar</code> file or to any directory that contains the classes. Use the standard URL format that Java uses for CLASSPATHs.

Provider CLASSPATH	Syntax
Absolute path to directory	file:///a/b/c/
Relative path to directory from which the CIM Object Manager was started (/)	file://a/b/c

▼ To Set the Provider CLASSPATH

1. Create an instance of the Solaris_ProviderPath class. For example:

```
/* Create a namespace object initialized with root\system
(name of namespace) on the local host. */
CIMNameSpace cns = new CIMNameSpace("", "root\system");

// Connect to the root\system namespace as root.
cc = new CIMClient(cns, "root", "root_password");

// Get the Solaris_ProviderPath class
cimclass = cc.getClass(new CIMObjectPath("Solaris_ProviderPath");

// Create a new instance of Solaris_ProviderPath.
class ci = cimclass.newInstance();
```

2. Set the pathurl property to the location of your provider class files. For example:

```
...
/* Set the provider CLASSPATH to //com/mycomp/myproviders/.*/
ci.setProperty("pathurl", new CIMValue(new String("//com/mycomp/myproviders/"));
...
```

3. Update the instance. For example:

```
// Pass the updated instance to the CIM Object Manager
cc.setInstance(new CIMObjectPath(), ci);
```

Exception Messages

The CIM Object Manager generates exception messages to indicate incorrect MOF syntax and semantics. For an explanation of exception messages, see Chapter 6.

Administering Security

This chapter describes the security features enforced by the CIM Object Manager, including the following topics:

- Overview
- Using the Sun WBEM User Manager to Set Access Control
- Using the APIs to Set Access Control
- CIM Exception Messages

Overview

There are two separate mechanisms for administering security within the Solaris operating environment, WBEM ACL (access control list) based and Solaris RBAC (role-based access control) .

The classes defined in the Solaris_Acll.0.mof file are used to implement ACL-based security. This provides a default authorization scheme for the Solaris WBEM Services, and applies to all CIM operations. This feature is specific to the Solaris WBEM Services.

Instances of the Solaris_Acll.0.mof classes determine the default authorizations assigned to a WBEM user and/or namespace. Provider programs, however, are allowed to override this scheme for CIM operations relating to instance manipulation; the Sun Solaris providers use the RBAC scheme to do this.

You can use the WBEM User Manager (/usr/sadm/bin/wbemadmin) to add users to existing ACLs with either read or write permissions. See "Using the Sun WBEM User Manager to Set Access Control" on page 40. You can also write WBEM

applications using the Solaris_Acll.0.mof classes to set access control. See "Using the APIs to Set Access Control" on page 43.

The classes defined in the <code>Solaris_Users1.0.mof</code> file are used to implement Solaris RBAC security for defining user roles and priveleges, via the Users tool of the Solaris Management Console (SMC) . The SMC Users tool lets you add users to existing roles and grant RBAC rights to existing users. (An RBAC right is managed in the Rights portion of the SMC Users tool.) See "Solaris Management Console Users Tool" on page 39.

Sun WBEM Security Features

The CIM Object Manager validates a user's login information for the machine on which the CIM Object Manager is running. A validated user is granted some form of controlled access to the entire Common Information Model (CIM) Schema. The CIM Object Manager does not provide security for system resources such as individual classes and instances. However, the CIM Object Manager does allow control of global permissions on namespace and access control on a per-user basis.

The following security features protect access to CIM objects on a WBEM-enabled system:

- Authentication The process of verifying the identity of a user, device, or other entity in a computer system, often as a prerequisite to allowing access to the resources in a system.
- *Authorization* The granting to a user, program, or process the right of access.
- *Replay protection* The CIM Object Manager protects against a client picking up and sending another client's message to the server by validating a session key.

A client cannot copy another client's last message sent to a CIM Object Manager. The CIM Object Manager uses a MAC for each message, based on a negotiated session key, to guarantee that all communication in the client-server session is with the same client that initiated the session and participated in the client-server authentication.

A MAC is a token parameter added to a remote call which contains security information used to authenticate that single message. It is used to confirm that the message came from the client that was originally authenticated for the session, and that the message is not being replayed from some other client. This type of mechanism is used in WBEM for RMI messages. The session key negotiated in the user authentication exchange is used to encrypt the security information in the message's MAC token.

Note that no digital signing of messages is performed.

Authentication

When a user logs in and enters a user name and password, the client uses the password to generate an encrypted digest which the server verifies. When the user is authenticated, the CIM Object Manager sets up a client session. All subsequent operations occur within that secure client session and contain a MAC token which uses the session key negotiated during authentication.

Authorization

Once the CIM Object Manager has authenticated the user's identity, that identity can be used to verify whether the user should be allowed to execute the application or any of its tasks. The CIM Object Manager supports capability-based authorization, which allows a privileged user to assign read and write access to specific users. These authorizations are added to existing Solaris user accounts.

Solaris Management Console Users Tool

The SMC Users tool lets you add users to existing roles and grant RBAC rights to existing users. (An RBAC right is managed in the Rights portion of the SMC Users

To Start SMC and Users Tool

1. Change to the location of the SMC invocation command by typing the following:

cd /usr/sbin

2. Start SMC by typing the following command:

smc

- 3. Double-click on "This Computer" (or single-click the expand/compress icon next to it) in the left-hand Navigation panel to expand the tree beneath it. Do the same for "System Configuration", and you will see the Users icon underneath.
- 4. Click on the Users icon to start the application.

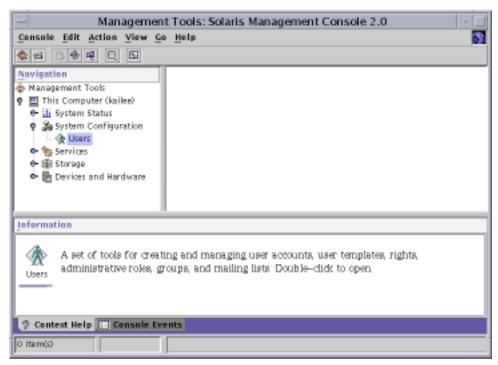

Figure 3–1 Solaris Management Console, with Users Tool Selected

For more information on the Solaris Management Console, see the man page smc(1M).

Using the Sun WBEM User Manager to Set Access Control

The Sun WBEM User Manager allows privileged users to add and delete authorized users and to set their access privileges. Use this application to manage user authentication and access to CIM objects on a WBEM-enabled system. A user must have a Solaris user account.

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in as root, you can set the following types of access to CIM objects:

- Read Only Allows read-only access to CIM Schema objects. Users with this
 privilege can retrieve instances and classes, but cannot create, delete, or modify
 CIM objects.
- Read/Write Allows full read, write, and delete access to all CIM classes and instances.
- Write Allows write and delete, but not read access to all CIM classes and instances.
- None Allows no access to CIM classes and instances.

▼ How to Start Sun WBEM User Manager

1. In a command window, type the command:

/usr/sadm/bin/wbemadmin

The Sun WBEM User Manager starts, and the Login dialog box opens. Context-help information is available in the Context Help panel when you click on the fields in the dialog box.

2. In the Login dialog box, do the following:

■ In the User Name field, type the user name.

You must have read access to the root\security namespace to log in. By default, Solaris users have guest privileges, which grant them read access to the default namespaces. Users with read access can view, but cannot change, user privileges.

You must log in as root or a user with write access to the root\security namespace to grant access rights to users.

■ In the Password field, type the password for the user account.

3. Click OK.

The User Manager dialog box opens with a list of users and their access rights to WBEM objects within the namespaces on the current host.

▼ How to Grant Default Access Rights to a User

1. Start Sun WBEM User Manager.

2. In the Users Access portion of the dialog box, click Add.

A dialog box opens that lists the available namespaces.

- 3. Type the name of a Solaris user account in the User Name text entry field.
- 4. Select a namespace from the listed namespaces.
- 5. Click OK.

The user name is added to the User Manager dialog box.

6. Click OK to save the changes and close the User Manager dialog box. Click Apply to save the changes and keep the dialog box open.

This action grants this user read access to CIM objects in the selected namespace.

▼ How to Change Access Rights for a User

- 1. Start Sun WBEM User Manager.
- 2. Select the user whose access rights you want to change.
- 3. To grant the user read-only access, click the Read check box. To grant the user write access, click the Write check box.
- 4. Click OK to save the changes and close the User Manager dialog box. Click Apply to save the changes and keep the dialog box open.

▼ How to Remove Access Rights for a User

- 1. Start Sun WBEM User Manager.
- 2. In the Users Access portion of the dialog box, select the user name for which you want to remove access rights.
- 3. Click Delete to delete the user's access rights to the namespace.

A confirmation dialog box asks you to confirm your decision to delete the user's access rights. Click OK to confirm.

4. Click OK to save the changes and close the User Manager dialog box. Click Apply to save the changes and keep the dialog box open.

How to Set Access Rights for a Namespace

- 1. Start Sun WBEM User Manager.
- 2. In the Namespace Access portion of the dialog box, click Add.

A dialog box opens that lists the available namespaces.

- 3. Select the namespace for which you want to set access rights.
 - By default, users have read-only access to a namespace.
 - To allow no access to the namespace, make sure the Read and Write check boxes are not selected.
 - To allow write access, click the Write check box.
 - To allow read access, click the Read check box.
- 4. Click OK to save the changes and close the User Manager dialog box. Click Apply to save the changes and keep the dialog box open.

How to Remove Access Rights for a Namespace

- 1. Start Sun WBEM User Manager.
- 2. In the Namespace Access portion of the dialog box, select the namespace for which you want to remove access control, and then click Delete.
 - Access control is removed from the namespace, and the namespace is removed from the list of namespaces on the User Manager dialog box.
- 3. Click OK to save the changes and close the User Manager dialog box. Click Apply to save the changes and keep the dialog box open.

Using the APIs to Set Access Control

You can use the Sun WBEM SDK APIs to set access control on a namespace or on a per-user basis. The following security classes are stored in the root\security namespace:

■ Solaris_Acl - Base class for Solaris Access Control Lists (ACL). This class defines the string property *capability* and sets its default value to r (read only).

- Solaris_UserAcl Represents the access control that a user has to the CIM objects within the specified namespace.
- Solaris_NamespaceAcl Represents the access control on a namespace.

You can set access control on individual users to the CIM objects within a namespace by creating an instance of the <code>Solaris_UserACL</code> class and then using the APIs to change the access rights for that instance. Similarly, you can set access control on namespaces by creating an instance of the <code>Solaris_NameSpaceACL</code> class and then using APIs, such as the <code>setInstance</code> method, to set the access rights for that instance.

An effective way to combine the use of these two classes is to first use the <code>Solaris_NameSpaceACL</code> class to restrict access to all users to the objects in a namespace. Then use the <code>Solaris_UserACL</code> class to grant selected users access to the namespace.

The Solaris_UserAcl Class

The Solaris_UserAcl class extends the Solaris_Acl base class, from which it inherits the string property *capability* with a default value r (read only).

You can set the capability property to any of the following values for access privileges.

Access Right	Description
r	Read
rw	Read and Write
w	Write
none	No access

The Solaris_UserAcl class defines the following two key properties. Only one instance of the namespace-username ACL pair can exist in a namespace.

Property	Data Type	Purpose
nspace	string	Identifies the namespace to which this ACL applies.
username	string	Identifies the user to which this ACL applies.

How to Set Access Control on a User

1. Create an instance of the Solaris_UserAcl class. For example:

```
/* Create a namespace object initialized with root\security
(name of namespace) on the local host. */
CIMNameSpace cns = new CIMNameSpace("", "root\security");
// Connect to the root\security namespace as root.
cc = new CIMClient(cns, "root", "root_password");
// Get the Solaris_UserAcl class
cimclass = cc.getClass(new CIMObjectPath("Solaris_UserAcl");
// Create a new instance of the Solaris_UserAcl
class ci = cimclass.newInstance();
```

2. Set the capability property to the desired access rights. For example:

```
/* Change the access rights (capability) to read/write for user Guest
on objects in the root\molly namespace.*/
ci.setProperty("capability", new CIMValue(new String("rw"));
ci.setProperty("nspace", new CIMValue(new String("root\molly"));
ci.setProperty("username", new CIMValue(new String("guest"));
```

3. Update the instance. For example:

```
// Pass the updated instance to the CIM Object Manager
cc.setInstance(new CIMObjectPath(), ci);
```

The Solaris_NamespaceAcl Class

The Solaris_NamespaceAcl extends the Solaris_Acl base class, from which it inherits the string property *capability* with a default value r (read-only for GUEST and all users). The Solaris_NamespaceAcl class defines the following key property.

Property	Data Type	Purpose
nspace	string	Identifies the namespace to which this access control list applies. Only one instance of the namespace ACL can exist in a namespace.

▼ How to Set Access Control on a Namespace

1. Create an instance of the Solaris_namespaceAcl class. For example:

```
/* Create a namespace object initialized with root\security
(name of namespace) on the local host. */
CIMNameSpace cns = new CIMNameSpace("", "root\security");

// Connect to the root\security namespace as root.
cc = new CIMClient(cns, "root", "root_password");

// Get the Solaris_namespaceAcl class
cimclass = cc.getClass(new CIMObjectPath("Solaris_namespaceAcl");

// Create a new instance of the Solaris_namespaceAcl
class ci = cimclass.newInstance();
...
```

2. Set the capability property to the desired access rights. For example:

```
/* Change the access rights (capability) to read/write
to the root\molly namespace. */
ci.setProperty("capability", new CIMValue(new String("rw"));
ci.setProperty("nspace", new CIMValue(new String("root\molly"));
...
```

3. Update the instance. For example:

```
// Pass the updated instance to the CIM Object Manager
cc.setInstance(new CIMObjectPath(), ci);
```

MOF Compiler

This chapter describes the Managed Object Format (MOF) Compiler, including the following topics.

- About the MOF Compiler
- The mofcomp Command
- Compiling a MOF File

About the MOF Compiler

The Managed Object Format (MOF) Compiler parses a file containing MOF statements, converts the classes and instances defined in the file to Java classes, and adds the Java classes to the CIM Object Manager Repository, a central storage area for management data. The compiler loads the Java classes into the default namespace, root\cimv2, unless a #pragma namespace(``namespace_path'') statement appears in the MOF file.

The mofcomp command, which starts the MOF compiler, is executed before installation to compile MOF files that describe the CIM and Solaris Schemas. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java

Virtual Machine can interpret and exchange this information. You can also use the mofcomp command to compile MOF files at any time after installation.

Note - If you recompile the CIM_Schema23.mof file or the Solaris_Schema1.0.mof file, you must change to become root user before compiling. For example:

% /usr/sadm/bin/mofcomp -v -u root -p [root-password] /usr/sadm/ mof/Solaris_Schemal.0.mof

The mofcomp Command

The mofcomp command compiles the specified MOF file into CIM classes and instances that are stored in the CIM Object Manager Repository as Java classes and passed to the CIM Object Manager.

You must run the mofcomp command as root or as a user with write access to the namespace in which you are compiling.

/usr/sadm/bin/mofcomp [-help] [-v] [-sc] [-si] [-sq] [-version] [-c cimom_hostname] [-u username] [-p password] file

-help List the arguments to the mofcomp command.

-c *cimom hostname* Specify a system running the CIM Object Manager.

-p **password** Specify a password for connecting to the CIM Object

Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both –p and –u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify –u but not

−p, so that the compiler will prompt for the password.

-sc Run the compiler with the set class option, which updates

a class if it exists and contains no instances, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class

already exists.

-si	Run the compiler with the set instance option, which
	updates an instance if it exists, and returns an error if the
	instance does not exist. If you do not specify this option,
	the compiler adds a CIM instance to the connected
	namespace, and returns an error if the instance already

exists.

Run the compiler with the set qualifier types option,

which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if

the qualifier type already exists.

-u **username** Specify user name for connecting to the CIM Object

Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both –p and –u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify –u but not –p, so that the compiler will prompt for the password.

-v Run the compiler in verbose mode, which displays

compiler messages.

-version Display the version of the MOF compiler.

The mofcomp command will exit with 0 upon success and a positive integer upon failure.

Compiling a MOF File

You can compile a MOF file with or without a .mof extension. The MOF files that describe the CIM and Solaris Schemas are located in /usr/sadm/mof.

▼ How to Compile a MOF File

1. To run the MOF Compiler with no options, type the following:

mofcomp filename

For example,

```
# mofcomp /usr/sadm/mof/Solaris_Application1.0.mof
```

The MOF file is compiled into the CIM Object Manager Repository.

Security Advisory

If you run the mofcomp command with the -p option or -u and -p options, and you include a password on the command line, another user can run the ps command or the history command to see your password.

Note - If you run a command that requires you to provide your password, immediately change your password after running the command.

The following examples show unsafe (insecure) usage, running the mofcomp command with its -p option and then with its -up options:

```
% mofcomp -p Log8Rif
% mofcomp -up molly Log8Rif
```

You should change your password immediately after running the mofcomp command in this way.

System Logging

Logging is a service that enables WBEM administrators to track system events to determine how they occurred. You might want to record events such as the inaccessibility of a serial port, an error message generated by the mounting of a file system, or a system disk having reached capacity.

This chapter covers the following topics:

- About Logging
- Log Files
- Log Classes
- Using the APIs to Enable Logging
- Viewing Log Data

About Logging

The logging service records all actions that the service provider has been programmed to return and that are completed by Solaris WBEM Services components. Informational content and errors can be recorded to a log. For example, if a user disables a serial port, this information can be logged automatically by a serial port provider. Or, if a system error or other failure occurs, the administrator can check the log record to trace the cause of the occurrence.

All components, applications, and providers start logging automatically, in response to system events. For example, the CIM Object Manager automatically logs events after it is installed and started.

You can set up logging for applications and providers that you write for the WBEM environment. For information, see "Using the APIs to Enable Logging" on page 55.

You can view log data in the Solaris Management Console (SMC) Log Viewer to debug the logging functionality that you have set up. For more information on the SMC, see the man page smc(1M).

Log Files

When you set up an application or a provider to log events, its events are recorded in log files. All log records are stored in the path: /var/sadm/wbem/logr. Log files use the following naming convention:

```
wbem_log.#
```

where # is a number appended to indicate the version of the log file. A log file appended with a .1, such as wbem_log.1, is the most recently saved version. A log file appended with a .2 is the next oldest version. Larger file extensions, for example, wbem_log.16, indicate older versions of the file. Previous versions of the log file and the most recent version co-exist as an archive in /usr/sadm/wbem/log.

Log files are saved and renamed with a .1 filename extension when one of the following two conditions are met:

- The current file reaches the file size limit specified by the Solaris_LogServiceProperties class. Default values are set in the /usr/sadm/lib/wbem/WbemServices.properties file.
 - For information about how the properties of the Solaris_LogServiceProperties class control how a log file is used, see "Log File Rules" on page 52.
- The clearLog() method of the Solaris_LogService class is invoked on the current log file.

For information about the Solaris_LogService class and its methods, see "Solaris_LogService Class" on page 54.

Log File Rules

The Solaris_LogServiceProperties class is defined in Solaris_Corel.O.mof. The Solaris_LogServiceProperties class has properties that control the following attributes of a log file:

- Directory where the log file is written
- Name of the log file
- Size allowed for a log file before it is saved and renamed with a .1 file extension.

- Number of log files you can have in the archive
- Ability to write log data to syslog, the default logging system of the Solaris operating environment

To specify any of these attributes for an application that writes data to a log file, create a new instance of Solaris_LogServiceProperties and set the values of its associated properties. See Code Example 5-2 for detailed information about how to set the property values of the new instance.

Log File Format

The logging service provides three categories of log records: application, system, and security. Log records may be informational, or may record data derived from errors or warnings. A standard set of fields are defined for the data that can be presented in logs. Logs do not necessarily use all the fields, however. For example, an informational log may provide a brief message describing an event. An error log may provide a more detailed message.

Some log data fields are required to identify data in the CIM Repository. These fields are properties flagged with a read-only key qualifier in the Solaris_LogRecord class. You cannot set the values of these fields. You can, however, set the values of any of the following fields in your log files:

- Category Type of log record
- Severity Severity of conditions that caused data to be written to a log file
- AppName Name of the application from which the data was obtained
- UserName Name of the individual who was using the application when log data was generated
- ClientMachineName Name of the computer on which an incident occurred that generated log data
- ServerMachineName Name of the server on which an incident occurred that generated log data
- SummaryMessage Brief message describing the occurrence
- DetailedMessage Detailed message describing the occurrence
- Data Context information that applications and providers can present to interpret a log message

Log Classes

Logging involves the use of two Solaris Schema classes: Solaris_LogRecord and Solaris_LogService.

Solaris_LogRecord Class

The Solaris_LogRecord class is defined in Solaris_Core1.0.mof to model an entry in a log file. When an application or provider calls the Solaris_LogRecord class in response to an event, the Solaris_LogRecord class causes all data generated by the event to be written to a log file. To see the definition of the Solaris_LogRecord class as part of the Solaris Provider, use a text editor to view the Solaris_Core1.0.mof file. The Solaris_Core1.0.mof file is located in / usr/sadm/mof/.

The Solaris_LogRecord class uses a vector of properties and key qualifiers to specify attributes of the events, system, user, and application or provider that generate data. Read-only qualifier values are generated transparently for use between the application and the CIM Repository. For example, the value RecordID uniquely identifies the log entry but is not displayed as part of the log format when you view generated data.

You can set the values of writable qualifier values. For example, you can set the qualifier values of properties such as ClientMachineName and ServerMachineName, which identify the system on which an event occurs.

When the SysLogFlag property is set to true, then a detailed message of the log record is automatically sent to the syslog daemon on Solaris systems.

Solaris_LogService Class

The Solaris_LogService class controls the operation of the logging service and defines the ways in which log data is handled. This class has a set of methods that an application can use to distribute data about a particular event to the CIM Object Manager from the issuing application. The data becomes a trigger that generates a response from the CIM Object Manager, such as a retrieval of data from the CIM Repository.

The Solaris_LogService class has the following methods:

- clearLog Saves and renames a current log file or deletes a saved log file
- getNumRecords Returns the number of records in a particular log file
- listLogFiles Returns a list of all log files stored in /usr/sadm/wbem/log

- getCurrentLogFileName Returns the name of the most recent log file
- getNumLogFiles Returns the number of log files stored in /usr/sadm/wbem/ log
- getLogFileSize Returns the size, in megabytes, of a particular log file
- getSyslogSwitch Enables log data to be sent to syslog, the logging service of the Solaris operating environment
- getLogStorageName Returns the name of the host computer or device where log files are stored
- getLogFileDir Returns the path and name of the directory where log files are stored

The Solaris_LogServiceProperties class lets you set logging properties. See "Setting Logging Properties" on page 61.

You can view the definition of the Solaris_LogService class in the Solaris_Corel.0.mof file, which is located in /usr/sadm/mof/.

Using the APIs to Enable Logging

You can view log file contents in the Solaris Management Console (SMC) Log Viewer. For more information on the Solaris Management Console, see the man page smc(1M).

You can also develop your own log viewer if you prefer to view log files in a customized manner. You can use the WBEM logging APIs to develop a logging program which will:

- Write data from an application to a log file
- Read data from a log file to your log viewer
- Set logging properties that specify how logging is handled

Writing Data to a Log File

Enabling an application to write data to a log file involves the following main tasks:

- Creating a new instance of the Solaris_LogRecord class
- Specifying the properties that will be written to the log file and setting values for the property qualifiers

Setting the new instance and properties to print

▼ How to Create an Instance of Solaris_LogRecord To Write Data

1. Import all the necessary Java classes. The classes listed in Code Example 5–1 are the minimum classes that are required.

CODE EXAMPLE 5-1 Creating an Instance of Solaris_LogRecord To Write Data

```
import java.rmi.*;
import com.sun.wbem.client.CIMClient;
import com.sun.wbem.cim.CIMInstance;
import com.sun.wbem.cim.CIMValue;
import com.sun.wbem.cim.CIMProperty;
import com.sun.wbem.cim.CIMNameSpace;
import com.sun.wbem.cim.CIMObjectPath;
import com.sun.wbem.cim.CIMClass;
import com.sun.wbem.cim.CIMException;
import com.sun.wbem.solarisprovider.*;
import java.util.*;
```

- 2. Declare the public class CreateLog and the following values:
 - CIMClient instance
 - CIMObjectPath instance
 - CIMNameSpace instance

```
public class CreateLog {
    public static void main(String args[]) throws CIMException {

if ( args.length != 3) {
    System.out.println("Usage: CreateLog host username password");
    System.exit(1);
}

CIMClient cc = null;
CIMObjectPath cop = null;
try {
    CIMNameSpace cns = new CIMNameSpace(args[0]);
    cc = new CIMClient(cns, args[1], args[2]);
```

3. Specify the vector of properties to be returned. Set values for the properties of the qualifiers.

```
Vector keys = new Vector();
CIMProperty logsvcKey;
logsvcKey = new CIMProperty("category");
logsvcKey.setValue(new CIMValue(new Integer(2)));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("severity");
logsvcKey.setValue(new CIMValue(new Integer(2)));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("AppName");
logsvcKey.setValue(new CIMValue("SomeApp"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("UserName");
logsvcKey.setValue(new CIMValue("molly"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("ClientMachineName");
logsvcKey.setValue(new CIMValue("dragonfly"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("ServerMachineName");
logsvcKey.setValue(new CIMValue("spider"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("SummaryMessage");
logsvcKey.setValue(new CIMValue("brief_description"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("DetailedMessage");
logsvcKey.setValue(new CIMValue("detailed_description"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("data");
logsvcKey.setValue(new CIMValue("0xfe 0x45 0xae 0xda"));
keys.addElement(logsvcKey);
logsvcKey = new CIMProperty("SyslogFlag");
logsvcKey.setValue(new CIMValue(new Boolean(true)));
keys.addElement(logsvcKey);
```

4. Declare the new instance of the CIMObjectPath class for the log record.

```
CIMObjectPath logreccop = new CIMObjectPath("Solaris_LogRecord", keys);
```

5. Declare the new instance of Solaris_LogRecord. Set the vector of properties to write to a file.

```
CIMInstance ci = new CIMInstance();
  ci.setClassName("Solaris_LogRecord");
  ci.setProperties(keys);
  //System.out.println(ci.toString());
  cc.setInstance(logreccop,ci);
}
```

(continued)

```
catch (Exception e) {
   System.out.println("Exception: "+e);
   e.printStackTrace();
}
```

6. Close the session after data has been written to the log file.

```
// close session.
if(cc != null) {
        cc.close();
}
}
}
```

Reading Data From a Log File

Enabling an application to read data from a log file to a log viewer involves the following tasks:

- Enumerating instances of the Solaris_LogRecord class
- Getting the desired instance
- Printing properties of the instance to an output device, typically a user interface for the log viewer

▼ How to Get an Instance of the Solaris_LogRecord Class and Read Data

1. Import all the necessary Java classes. The classes listed below are the minimum required.

```
import java.rmi.*;
import com.sun.wbem.client.CIMClient;
import com.sun.wbem.cim.CIMInstance;
import com.sun.wbem.cim.CIMValue;
import com.sun.wbem.cim.CIMProperty;
import com.sun.wbem.cim.CIMNameSpace;
import com.sun.wbem.cim.CIMObjectPath;
import com.sun.wbem.cim.CIMClass;
import com.sun.wbem.cim.CIMException;
import com.sun.wbem.solarisprovider.*;
import java.util.*;
import java.util.Enumeration;
```

2. Declare the class ReadLog.

3. Set the CIMClient, CIMObjectPath, and CIMNameSpace values of the ReadLog class.

```
}
CIMClient cc = null;
CIMObjectPath cop = null;
try {         CIMNameSpace cns = new CIMNameSpace(args[0]);
cc = new CIMClient(cns, args[1], args[2]);
cop = new CIMObjectPath("Solaris_LogRecord");
```

4. Enumerate the instances of Solaris_LogRecord.

```
Enumeration e = cc.enumInstances(cop, true);
    for (; e.hasMoreElements(); ) {
```

5. Send the property values to an output device.

```
System.out.println("-----
  CIMObjectPath op = (CIMObjectPath)e.nextElement();
   CIMInstance ci = cc.getInstance(op);
   System.out.println("Record ID : " +
      (((Long)ci.getProperty("RecordID").getValue().
      getValue()).longValue()));
   System.out.println("Log filename : " + \,
      ((String)ci.getProperty("FileName").getValue().
      getValue()));
   int categ = (((Integer)ci.getProperty("category").
      getValue().getValue()).intValue());
   if (categ == 0)
   System.out.println("Category : Application Log");
   else if (categ == 1)
   System.out.println("Category : Security Log");
   else if (categ == 2)
   System.out.println("Category : System Log");
   int severity = (((Integer)ci.getProperty
      ("severity").getValue().getValue()).intValue());
   if (severity == 0)
   System.out.println("Severity : Informational");
   else if (severity == 1)
   System.out.println("Severity : Warning Log!");
   else if (severity == 2)
   System.out.println("Severity : Error!!");
   System.out.println("Log Record written by :" +
      ((String)ci.getProperty("AppName").getValue().
      getValue()));
   System.out.println("User : " + ((String)ci.
      getProperty("UserName").getValue().getValue()));
   System.out.println("Client Machine : " + ((String)ci.
      getProperty("ClientMachineName").getValue().getValue()));
   System.out.println("Server Machine : " + ((String)ci.
      getProperty("ServerMachineName").getValue().getValue()));
   System.out.println("Summary Message : " + ((String)
      ci.getProperty("SummaryMessage").getValue().getValue()));
   System.out.println("Detailed Message : " + ((String)
      ci.getProperty("DetailedMessage").getValue().getValue()));
   System.out.println("Additional data : " + ((String)
      ci.getProperty("data").getValue().getValue()));
```

(continued)

```
boolean syslogflag =((Boolean)ci.getProperty("syslogflag").getValue().
  getValue()).booleanValue();
 if (syslogflag == true) {
System.out.println("Record was written to syslog as well");
System.out.println("Record was not written to
  syslog");
System.out.println("----");
```

6. Return an error message to the user if an error condition occurs.

```
catch (Exception e) {
   System.out.println("Exception: "+e);
e.printStackTrace(); }
```

7. Close the session when the data has been read from the file.

```
// close session.
if(cc != null) {
    cc.close();
```

Setting Logging Properties

You can create an instance of the Solaris_LogServiceProperties class and set property values for the instance to control how your application or provider handles logging. The following code example shows how to set logging properties. Properties are stored in the /usr/sadm/lib/wbem/WbemServices.properties file.

CODE EXAMPLE 5–2 Setting Logging Properties

```
public class SetProps {
   public static void main(String args[]) throws CIMException {
 if (args.length != 3) {
     System.out.println("Usage: SetProps host username password");
     System.exit(1);
 CIMClient cc = null;
 try {
     CIMNameSpace cns = new CIMNameSpace(args[0]);
     cc = new CIMClient(cns, args[1], args[2]);
   CIMObjectPath logpropcop = new CIMObjectPath("Solaris_Log
   ServiceProperties");
    Enumeration e = cc.enumInstances(logpropcop, true);
  for (; e.hasMoreElements(); ) {
  CIMObjectPath op = (CIMObjectPath)e.nextElement();
   CIMInstance ci = cc.getInstance(op);
  ci.setProperty("Directory", new CIMValue("/tmp/bar1/"));
   ci.setProperty("FileSize", new CIMValue("10"));
  ci.setProperty("NumFiles", new CIMValue("2"));
   ci.setProperty("SyslogSwitch", new CIMValue("off"));
  cc.setInstance(logpropcop,ci);
 catch (Exception e) {
     System.out.println("Exception: "+e);
  e.printStackTrace();
 // close session.
 if(cc != null) {
     cc.close();
```

Viewing Log Data

You can view all details of a log record in the Solaris Management Console (SMC) Log Viewer, an application that provides a graphical user interface for viewing recorded data. For more information on the SMC, see the man page smc(1M).

Starting Log Viewer

After you have created a log record, you can start the SMC and then its Log Viewer.

How to Start SMC and Log Viewer

1. Change to the location of the SMC invocation command by typing the following:

cd /usr/sbin

2. Start SMC by typing the following command:

smc

- 3. In the Navigation panel, double-click This Computer (or single-click the expand/compress icon next to it) to expand the tree beneath it. Double-click System Status and the Log Viewer icon will be displayed.
- 4. Click the Log Viewer icon to start the application.

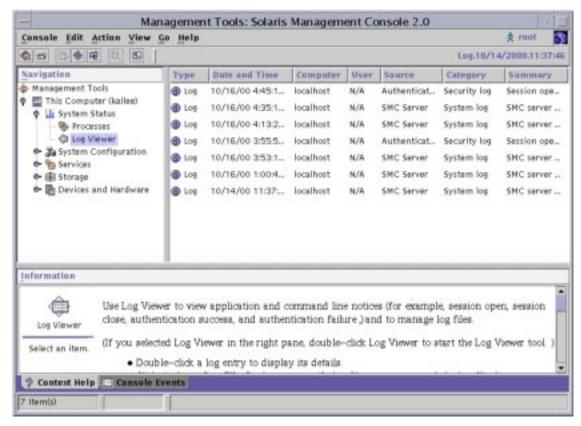

Figure 5-1 Solaris Management Console, with Log Viewer Selected

CIM Exception Messages

This chapter describes the exception messages generated by the CIM Object Manager in the Solaris WBEM Services, including the following topics.

- How CIM Exceptions are Generated
- Parts of CIM Exceptions
- Finding Information About CIM Exceptions
- Generated CIM Exceptions

How CIM Exceptions are Generated

The CIM Object Manager generates exception messages that are used by all the clients. The MOF Compiler appends a line to the exception indicating where in a .mof file the error occurred. From these exceptions, client applications can generate error messages that are more meaningful to the end-user.

CIM clients can be used as XML or RMI clients. Currently, XML supports only a subset of these exceptions. If you choose to use an XML client, be aware that you may not receive all the information contained in the exception message, and that you may loose parameter information.

Parts of CIM Exceptions

CIM exception messages are made up of the following parts:

- Unique identifier Character string that differentiates the error message from other error messages
- One or more parameters Placeholders for the specific classes, methods, and qualifiers that are cited in the exception message

Exception Message Example

For example, the MOF Compiler may return the following exception message:

REF_REQUIRED CIM_Docked

where

- REF_REQUIRED is the unique identifier.
- CIM_Docked is the parameter. A parameter can be replaced with the name of any appropriate class, property, method, or qualifier.

This exception message can be turned into a more user-friendly message such as:

Finding Information About CIM Exceptions

The following section provides a detailed explanation of each CIM exception. The exception messages are organized by unique identifiers in alphabetical order. For each exception message, the following types of information are provided, when applicable:

- Unique identifier, displayed as a heading
- Description of the parameters used in the exception message
- Example of the exception or message as it is displayed to a user, often the output of the MOF compiler or the CIM Object Manager
- Cause, or reason why the exception message was generated, and background or reference information that is helpful for understanding the error message

 Solution, including steps you can take to resolve the error are provided when available

Generated CIM Exceptions

The following section lists and describes the CIM exceptions generated by the MOF Compiler, CIM Object Manager, and WBEM client applications.

ABSTRACT_INSTANCE

Description

The ABSTRACT_INSTANCE exception has one parameter, which is the name of the abstract class.

Example

ABSTRACT_INSTANCE = Abstract class ExampleClass cannot have instances.

Cause

A client application tried to create an instance for the specified class. However, the specified class is an abstract class, and abstract classes cannot have instances.

Solution

Remove the programmed instances, as the client application cannot create such instances.

CHECKSUM_ERROR

Description

The CHECKSUM_ERROR exception has no parameters.

Example

CHECKSUM_ERROR = Checksum not valid.

Cause

The message could not be sent because it was damaged or corrupted. The damage could have occurred accidentally in transit or by a malicious third party.

Solution

Resend the message.

Note - This error message is displayed when the CIM Object Manager receives an invalid checksum. A checksum is the number of bits in a packet of data passed over the network. This number is used by the sender and the receiver of the information to ensure that the transmission is secure and that the data has not been corrupted or intentionally modified during transit.

An algorithm is run on the data before transmission, and the checksum is generated and included with the data to indicate the size of the data packet. When the message is received, the receiver can recompute the checksum and compare it to the sender's checksum. If the checksums match, the transmission was secure and the data was not corrupted or modified.

CIM_ERR_ACCESS_DENIED

Description

The CIM_ERR_ACCESS_DENIED exception does not have parameters.

Example

CIM_ERR_ACCESS_DENIED = Insufficient privileges.

Cause

This exception is displayed when a user does not have the appropriate privileges to complete an action.

Solution

See your WBEM administrator to request privileges to complete the operation.

CIM_ERR_FAILED

Description

The CIM_ERR_FAILED exception has one parameter which is replaced by a character string, a message that explains the error condition and its possible cause.

Example

CIM_ERR_FAILED=Invalid entry.

Cause

The CIM_ERR_FAILED exception is a generic message that can be displayed for a large number of different error conditions.

Solution

Because CIM_ERR_FAILED is a generic exception, many types of conditions can cause the message. The solution varies depending on the error condition.

Description

The CIM_ERR_INVALID_PARAMETER exception has one parameter which gives more information about the parameter that caused the error.

CIM_ERR_INVALID_PARAMETER = Class System has no schema prefix.

Cause

An operation was performed and the parameter was invalid. For example, a class was created without providing a schema prefix in front of the class name. The Common Information Model requires that all classes are provided with a schema prefix. For example, classes developed as part of the CIM Schema require a CIM prefix: CIM_Container. Classes developed as part of the Solaris Schema require a Solaris prefix: Solaris_System.

Solution

Provide the correct parameter. In the example above, the correct parameter would be CIM_Container. Find all instances of the class missing the prefix and replace them with the class name and prefix.

CIM_ERR_INVALID_SUPERCLASS

Description

The parameter CIM_ERR_INVALID_SUPERCLASS has two parameters:

- The name of the specified super class.
- The name of the sub class which caused the error.

Example

CIM_ERR_INVALID_SUPERCLASS = Superclass CIM_Chassis for class CIM_Container does not exist.

Cause

A class is specified to belong to a particular superclass, but the superclass does not exist. The specified superclass may be misspelled, or a non-existent superclass name may have been specified accidentally in place of the intended superclass name. Or, the superclass and the subclass may have been interpolated: the specified superclass actually may be a subclass of the specified subclass. In the previous example, CIM_Chassis is specified as the superclass of CIM_Container, but CIM_Chassis is a subclass of CIM_Container.

Solution

Check the spelling and the name of the superclass to ensure it is correct. Ensure that the superclass exists in the namespace.

CLASS_REFERENCE

Description

The CLASS_REFERENCE exception has two parameters.

- The name of the class that contains the reference.
- The name of the reference property.

Example

CLASS_REFERENCE = Class SolarisExample1 must be declared as an association to have reference SolarisExample2

Cause

A class has been defined with a reference property. However, the class is not an association. A class can only be defined to have a reference property if it is an association.

Solution

Declare the class as an association by using the -association qualifier.

INVALID CREDENTIAL

Description

The INVALID_CREDENTIAL exception does not have parameters.

Example

INVALID_CREDENTIAL = Invalid credentials.

Cause

This exception is displayed when an invalid password has been entered.

Solution

Retype the command and type the correct password.

INVALID OUALIFIER NAME

Description

The INVALID_QUALIFIER_NAME exception has one parameter which is replaced by the Managed Object Format notation that depicts an empty qualifier name.

Example

INVALID_QUALIFIER_NAME = Invalid qualifier name ' ' ''

Cause

A qualifier was created for a property, but a qualifier name was not specified.

Solution

Include the qualifier name in the context of the qualifier definition.

KEY_OVERRIDE

Description

The KEY_OVERRIDE exception has two parameters:

- The overriding property.
- The overridden property.

Example

KEY_OVERRIDE = Non-key Qualifier SolarisCard cannot override key Qualifier SolarisLock.

Cause

The client has defined a class where a non-Key property is trying to override a Key property. In CIM, all concrete classes require at least one Key property, and a non-Key class cannot override a class that has a Key.

Solution

The operation is not allowed as specified in the CIM specification.

KEY_REQUIRED

Description

The $\mathtt{KEY_REQUIRED}$ exception has one parameter which is the name of the class that requires the key.

Example

KEY_REQUIRED = Concrete (non-abstract) class ClassName needs at least one key.

Cause

A Key qualifier was not provided for a concrete class. In CIM, all non-abstract classes, referred to as concrete classes, require at least one Key qualifier.

Solution

Create a Key qualifier for the class.

Description

The METHOD_OVERRIDDEN command has three parameters:

- The name of the overriding method.
- The name of the overridden method.
- The name of the method that has overridden the second parameter.

Example

 $\label{eq:method_override} \mbox{METHOD_OVERRIDDEN} = \mbox{Method Resume () } \mbox{cannot override Stop() } \mbox{which is already overridden by Start()}$

Cause

A method is specified to override another method that has already been overridden by a third method. Once a method has been overridden, it cannot be overridden again.

Solution

This operation is illegal.

NEW_KEY

Description

The NEW_KEY exception has two parameters.

- The name of the key.
- The name of the class that is trying to define a new key.

Example

NEW_KEY = Class CIM_PhysicalPackage cannot define new key [Key]

Cause

A class is trying to define a new key when keys already have been defined in a superclass. Once keys have been defined in a superclass, new keys cannot be introduced into the subclasses.

Solution

No action can be taken.

NO_CIMOM

The NO_CIMOM exception has one parameter, which is the name of the host that is expected to be running the CIM Object Manager.

Example

NO_CIMOM = CIMOM molly not detected.

Cause

The CIM Object Manager is not running on the specified host.

Solution

Start the CIM Object Manager by typing the command init.wbem start or connect to a host that is running the CIM Object Manager.

NO_INSTANCE_PROVIDER

Description

The NO_INSTANCE_PROVIDER exception has two parameters:

- The name of the class for which the instance provider cannot be found.
- The name of the instance provider class that was specified.

Example

NO_INSTANCE_PROVIDER = Instance provider RPC_prop for class RPC_Agent not found.

Cause

The Java class of the specified instance provider is not found. This error message indicates that the class path of the CIM Object Manager does not contain one or more of the following:

- Name of the provider class
- Parameters of the provider class
- CIM class for which the provider is defined

Solution

Make sure the instance provider is present in the CIM Object Manager class path.

NO_METHOD_PROVIDER

The NO_METHOD_PROVIDER exception has two parameters:

- The name of the class for which the method provider cannot be found.
- The name of the method provider class that was specified.

Example

NO_METHOD_PROVIDER = Method provider Start_prop for class RPC_Agent not found.

Cause

The Java class of the specified method provider is not found. This error message indicates that the class path of the CIM Object Manager does not contain one or more of the following:

- Name of the provider class
- Parameters of the provider class
- CIM class for which the provider is defined

Solution

Make sure the method provider is present in the CIM Object Manager class path.

NO_OVERRIDDEN_METHOD

Description

The NO_OVERRIDDEN_METHOD exception has two parameters:

- The name of the overriding method.
- The name of the overridden method.

Example

 $\label{eq:no_overridden} \mbox{NO_OVERRIDDEN_METHOD} = \mbox{Method Write overridden by Read does not exist in class hierarchy.}$

Cause

The method of a subclass is trying to override a method of the superclass which does not exist anywhere in the class hierarchy.

Solution

Ensure that the method exists in the class hierarchy

The NO_OVERRIDDEN_PROPERTY exception has two parameters.

- The name of the overriding property.
- The name of the overridden property.

Example

NO_OVERRIDDEN_PROPERTY = Property A overridden by B does not exist in class hierarchy.

Cause

The property of a subclass is trying to override the property of the superclass which does not exist anywhere in the class hierarchy.

Solution

Ensure that the property exists in the superclass hierarchy.

NO_PROPERTY_PROVIDER

Description

The NO_PROPERTY_PROVIDER error message uses two parameters:

- The name of the class for which the property provider cannot be found.
- The name of the property provider class that was specified.

Example

NO_PROPERTY_PROVIDER = Property provider Write_prop for class RPC_Agent not found.

Cause

The Java class of the specified property provider is not found. This error message indicates that the class specified in the path of the CIM Object Manager does not contain the class specified in the second parameter.

Solution

Set the CIM Object Manager class path.

The NO_QUALIFIER_VALUE exception has two parameters:

- The name of the qualifier causing the error.
- The element to which the qualifier refers. Depending on the qualifier, the second parameter can be a class, property, method, or reference.

Example

NO_QUALIFIER_VALUE = Qualifier [SOURCE] for Solaris_ComputerSystem has no value.

Cause

A qualifier was specified for a property or method, but values were not included for the qualifier. For example, the qualifier VALUES requires a string array to be specified. If the VALUES qualifier is specified without the required string array, the NO_QUALIFIER_VALUE error message is displayed.

Solution

Specify the required parameters for the qualifier. For information about what attributes are required for which qualifiers, see the CIM Specification by the Distributed Management Task Force at the following URL: http://dmtf.org/spec/cims.html.

NO_SUCH_METHOD

Description

The NO_SUCH_METHOD exception has two parameters:

- The name of the specified method
- The name of the specified class

Example

NO_SUCH_METHOD = Method Configure() does not exist in class Solaris_ComputerSystem

Cause

Most likely, the method was not defined for the specified class. If the method is defined for the specified class, another method name may have been misspelled or typed differently in the definition.

Solution

Define the method for the specified class. Otherwise, ensure that the method name and class name were typed correctly.

NO_SUCH_PRINCIPAL

Description

The NO_SUCH_PRINCIPAL exception has one parameter which is the name of the principal, a user account.

Example

NO_SUCH_PRINCIPAL = Principal molly not found.

Cause

The specified user account cannot be found. The user name may have been mistyped upon login, or a user account has not been set up for the user.

Solution

Ensure that the user name is spelled and typed correctly upon login. Ensure that a user account has been set up for the user.

NO_SUCH_QUALIFIER1

Description

The ${\tt NO_SUCH_QUALIFIER1}$ exception has one parameter which is the name of the undefined qualifier.

Example

NO_SUCH_QUALIFIER1 = Qualifier [LOCAL] not found.

Cause

The qualifier does not exist in the namespace.

Solution

Define the qualifier. For information about standard CIM qualifiers and the usage of qualifiers in the CIM schema, see the CIM Specification by the Distributed Management Task Force at the following URL: http://www.dmtf.org/spec/cims.html.

NO_SUCH_QUALIFIER2

Description

The NO_SUCH_QUALIFIER2 exception has two parameters:

■ The name of the class, property, or method that the qualifier modifies.

■ The name of the qualifier that cannot be found.

Example

NO_SUCH_QUALIFIER2 = Qualifier [LOCAL] not found for CIM_LogicalElement

Cause

A qualifier was specified to modify a property or method of a particular class. The qualifier was not defined as part of the any schema. The qualifier is required to be defined as part of the CIM schema or an extension schema to be recognized as a valid qualifier.

Solution

Define the qualifier as part of the extension schema or use a standard CIM qualifier. For information about standard CIM qualifiers and the usage of qualifiers in the CIM schema, see the CIM Specification by the Distributed Management Task Force at the URL, http://www.dmtf.org/spec/cims.html.

NO_SUCH_SESSION

Description

The NO_SUCH_SESSION exception has one parameter which is the session identifier.

Example

NO_SUCH_SESSION = No such session 4002.

Cause

The exception is displayed when the client session cannot be found. The CIM Object Manager removes the session for security reasons. Chapter 3.

Solution

Ensure that your CIM environment is secure.

NOT_HELLO

Description

The NOT_HELLO exception has no parameters.

Example

 $NOT_HELLO = Not a Hello message.$

Cause

This error message is displayed if the data in the hello message—the first message sent to the CIM Object Manager—is corrupted.

Solution

Try to reconnect.

NOT_INSTANCE_PROVIDER

Description

The NOT_INSTANCE_PROVIDER exception has two parameters:

- The name of the class for which the InstanceProvider is defined.
- The name of the offending Java class.

Example

NOT_INSTANCE_PROVIDER = device_prop_provider for class Solaris_Provider does not implement InstanceProvider.

Cause

The path to the Java class specified as the provider does not implement the InstanceProvider interface.

Solution

Ensure that the Java class in the second parameter implements the InstanceProvider interface.

NOT_METHOD_PROVIDER

Description

The NOT_METHOD_PROVIDER exception has two parameters:

- The name of the method for which the MethodProvider interface is defined.
- The name of the offending Java class.

Example

NOT_METHOD_PROVIDER = Provider device_method_provider for class Solaris_Provider does not implement MethodProvider.

Cause

The path to the Java method specified in the second parameter does not implement the MethodProvider interface.

Solution

Ensure that the Java class in the second parameter implements the MethodProvider interface.

NOT_PROPERTY_PROVIDER

Description

The NOT_PROPERTY_PROVIDER exception has two parameters:

- The name of the method for which the PropertyProvider interface is defined.
- The name of the offending Java class.

Example

NOT_PROPERTY_PROVIDER = Provider device_property_provider for class Solaris_Provider does not implement PropertyProvider.

Cause

The path to the Java class in the second parameter does not implement the PropertyProvider interface.

Solution

Ensure that the Java class in the second parameter implements the PropertyProvider interface.

NOT_RESPONSE

Description

The NOT_RESPONSE exception has no parameters.

Example

NOT_RESPONSE = Not a response message.

Cause

This exception is displayed when the data in a first response message from the CIM Object Manager is corrupted.

Solution

Try to reconnect.

The PROPERTY_OVERRIDDEN exception has three parameters:

- The name of the overriding property.
- The name of the overridden property.
- The name of the method that has overridden the second parameter.

Example

PROPERTY_OVERRIDDEN = Property Volume cannot override MaxCapacity which is already overridden by RawCapacity

A property is specified to override another method that has already been overridden by a third method. Once a property has been overridden, it cannot be overridden again.

Solution

Specify a different property to override.

PS_UNAVAILABLE

Description

The PS_UNAVAILABLE exception has one parameter which is a message that describes why the persistent store became unavailable.

Example

PS_UNAVAILABLE = The persistent store is unavailable.

Cause

When the repository becomes unavailable, the first parameter gives more information on the cause.

Solution

As this exception is a general error condition, try to use the description details to see what causes the error.

REF_REQUIRED

Description

The REF_REQUIRED exception has one parameter which is the name of the association.

Example

REF REQUIRED = Association class CIM Chassis needs at least two references.

Cause

An association was defined without the necessary references. The rules of the Common Information Model specify that an association must contain two or more references.

Solution

Add the required references to the association in the first parameter.

SCOPE_ERROR

Description

The SCOPE_ERROR exception has three parameters:

- The name of the element the specified qualifier modifies.
- The name of the specified qualifier.
- The Meta element type of the first parameter.

Example

SCOPE_ERROR = Qualifier [UNITS] for CIM_Container does not have a Property scope.

Cause

A qualifier was specified in a manner that conflicts with the requirements of the scope definition. For example, in the CIM Specification, the <code>[READ]</code> qualifier is defined with a scope property. Hence, if you use <code>[READ]</code> to qualify a class, you will get a scope exception.

Note - The CIM Specification defines the types of CIM elements that a CIM qualifier can modify. This definition of the way in which a qualifier can be used is referred to as its scope. Most qualifiers, by definition, have a scope that directs them to modify properties or methods or both. Many qualifiers have a scope that directs them to modify parameters, classes, associations, indications, or schemas.

Solution

Confirm the scope of the specified qualifier. Refer to the section, "1.Qualifiers" of the CIM Specification by the Distributed Management Task Force at the following URL:http://www.dmtf.org/spec/cim_spec_v20 for the standard definitions of CIM qualifiers. Use a different qualifier for the results you want to achieve, or change your program to use the qualifier according to its CIM definition.

The SIGNATURE_ERROR exception has no parameters.

Example

SIGNATURE_ERROR = Signature not verified

Cause

This exception is displayed when a message is corrupted either accidentally or maliciously. It differs from the checksum error in that the message has a valid checksum, but the signature cannot be verified by the public key of the client. This protection ensures that even though the session key has been compromised, only the initial client which created the session is authenticated.

Solution

No action is provided for this message, which is displayed when a session has been infringed upon by an intruder. For information about Solaris WBEM Services security features, see Chapter 3.

TYPE_ERROR

Description

The TYPE_ERROR exception has five parameters:

- The name of the specified element, such as a property, method, or qualifier.
- The name of the class to which the specified element belongs.
- The type defined for the element.
- The type of value assigned.
- The actual value assigned.

Example

TYPE ERROR = Cannot convert sint16 4 to a string for VolumeLabel in class Solaris_DiskPartition

Cause

The value of a property or method parameter and its defined type are mismatched.

Solution

Match the value of the property or method with its defined type.

UNKNOWNHOST

The UNKNOWNHOST exception has one parameter which is the name of the host.

Example

UNKNOWNHOST = Unknown host molly

Cause

The client tried to connect to a host that cannot be located.

Solution

Check the spelling of the host name or contact your administrator.

VER_ERROR

Description

The VER_ERROR exception has one parameter which is the version number of the CIM Object Manager to which the client tried to connect.

Example

VER_ERROR = Unsupported version 0.

Cause

The CIM Object Manager you are trying to connect to does not support the client version.

Solution

Either upgrade the client API or upgrade the CIM Object Manager.

Common Information Model (CIM) Terms and Concepts

CIM Concepts

The following sections describe basic CIM terms and concepts that are essential to understanding how network entities and management functions are described and related within the context of CIM. For more detailed information about the Common Information Model and object-oriented modeling practices, including how to model your own schema, refer to the CIM Tutorial at http://dmtf.org/spec/cim_tutorial provided by the Distributed Management Task Force.

Object-Oriented Modeling

CIM uses the principles of Object-Oriented Modeling, a way to represent an object, entity, concept, or function that has a physical or logical existence. The goal of Object-Oriented Modeling is to set a representation of a physical entity into a framework, or model, to express the qualities and functions of the entity and its relationships with other entities. In the context of CIM, Object-Oriented Modeling is used to model hardware and software elements.

Uniform Modeling Language

Models are expressed in the form of visual representation and language. CIM conventions for rendering the model are based on the diagrammatic concepts of Uniform Modeling Language (UML). UML uses shapes to represent physical entities

and lines to represent relationships. For example, in UML, classes are represented as rectangles. Each rectangle contains the name of the class it represents. A line between two rectangles represents a relationship between the two. A line that forks to join two classes to a higher-level class represents an association.

CIM diagrams add color to the diagrams to further express relationships:

- Red lines→Associations
- Blue lines→Inheritance relationships
- Green lines→Aggregation

CIM Terms

The following terms are innate to the CIM Schema.

Schema

The terms model, schema, and framework are synonymous. Each is an abstract representation of an entity that has a physical or logical existence. In CIM, a schema is a named collection of classes used for class naming and administration. Within a schema, classes and their subclasses are represented hierarchically using the following syntax: Schemaname_classname. Each class name in a schema must be unique. Solaris WBEM Services includes a Solaris Schema. It contains all classes specific to the Solaris extension to CIM.

Class and Instance

In WBEM, a class is a collection of objects that represents the most basic unit of management. For example, in Solaris WBEM Services, the three main functional classes include CIMClass, CIMProperty, and CIMInstance.

Abstractly, classes are used to create managed objects. Class characteristics are inherited by the child objects, or instances, that are created from a class. For example, using CIMClass, you can create an instance, CIMClass (Solaris_Computer_System).

This instance of CIMClass answers the question, "What is the computer system?" The value of the instance is Solaris_Computer_System. All instances of the same class type are created from the same class template. In the example, the name of the computer system provides a template to create managed objects of the type Computer_System.

Classes can be static or dynamic. Instances of static classes are stored by the CIM Object Manager and can be retrieved from the CIM Repository when a request is made. Instances of dynamic classes—classes containing data that changes regularly, such as system usage—are created by provider applications as the data changes.

Custom Classes: Extensions to CIM

For extensions to CIM, custom classes can be developed to support managed objects that are specific to their managed environment. The CIM Object Manager API provides new classes to extend CIM for the Solaris operating environment.

Property

A property defines a characteristic of a class, represented hierarchically as Schemaname_classname.propertyname. For example, using the CIMProperty class, you can define a key as a property of a particular CIM class. Values of properties can be passed back from the CIM Object Manager as a string or as a vector for a range of properties. Each property has a unique name and only one domain—the class that owns the property. A property of a given class can be overridden by a property of its subclass.

An example of a property is the CIMProperty, which denotes the properties of a CIMClass.

Method

Like properties, methods belong to the class that owns them. A method is an action the objects of a given class are programmed to complete. For example, the method <code>public String getName()</code> returns the name of an instance as a concatenation of its keys and their values. Collectively, these actions describe the behavior of the class. Methods can belong only to the class that owns them. Within the context of a class, each method must have a unique name. A method of a given class can be overridden by a method of its subclass.

New classes inherit the definition of the method from the superclass, but not the implemented method. The definition of the method, indicated by a qualifier, serves as a placeholder in which a new implemented method can be provided. The CIM Object Manager checks for methods by starting from the lowest-level class and moving up the tree to the root class searching for a qualifier type that indicates a method.

Domain

Properties and methods are declared within a class. The class that owns the property or method is referred to as the domain of the property or method.

Qualifier and Flavor

A CIM qualifier is a modifier used to characterize CIM classes, properties, methods, and parameters. Qualifiers have unique attributes, including Name, Type, and Value, that are inherited by new classes.

Indication

An indication, an object and a type of class, is created as a result of the occurrence of an event. Indications can be arranged in a type hierarchy. Indications may have properties, methods, and triggers. Triggers are system operations, such as a change made to an existing class, or events that result in the creation of new instances of an indication.

Association

An association is a class that represents a relationship between two or more classes. Associations enable the creation of multiple relationship instances for a given class. System components can be related in many different ways, and associations provide a way of representing the relationships of these components.

Because of the way associations are defined, it is possible to establish a relationship between classes without affecting any of the related classes. The addition of an association does not affect the interface of the related classes. Only associations can have references.

Reference and Range

A reference is a type of property that defines the roles of objects involved in an association. The reference specifies the role name of the class in the context of the association. The domain of a reference is an association. The range of a reference is a character string that indicates the reference type.

Override

The override relationship is used to indicate the substitution of a property or method inherited from a subclass for a property or method inherited from the superclass. In CIM, guidelines determine what qualifiers of properties and methods can be overridden. For example, if the qualifier type of a class is flagged as a key, then the key cannot be overridden, because CIM guidelines specify that a key property cannot be overridden.

Core Model Concepts

The following sections provide descriptive information about the Core Model of CIM.

System Aspects of the Core Model

The Core Model provides classes and associations you can use to develop applications in which systems and their functions are represented as managed objects. These classes and associations embody the characteristics unique to all elements that comprise a system: physical and logical elements. Physical characteristics refer to the qualities of occupying space and conforming to the elementary laws of physics. Logical characteristics represent abstractions used to manage and coordinate aspects of the physical environment, such as system state or the capabilities of a system.

In the Core Model, logical elements can include the following.

TABLE A-1 Core Model Elements

Element Name	Description
Systems	A grouping of other logical elements. Because systems are themselves logical elements, a system can be composed of other systems.
Network Components	Classes that provide a topological view of a network.
Services and Access Points	Provide a mechanism for organizing the structures that provide access to the capabilities of a system.
Devices	An abstraction or emulation of a hardware entity, that may or may not be realized in physical hardware.

The following sections describe the classes and associations provided by the Core Model to emulate the qualities of systems.

System Classes Provided by the Core Model

The following table lists the classes that represent system aspects of the Core schema. The instances of these classes will most often belong to the descendents of the objects contained within the class.

TABLE A-2 Core Model System Classes

Class Name	Description	Example
Managed System	Base class for the system element hierarchy. Any distinguishable component of a system is a candidate for inclusion in this class.	Software components, such as files; and devices, such as disk drives and controllers, and physical components, such as chips and cards.
Logical Element	Base class for all the components of the system that represent abstract system components	Profiles, processes, or system capabilities in the form of logical devices.
System	Logical Element that aggregates a set of ManagedSystemElements. The aggregation operates as a functional whole. Within any particular subclass of System, there is a well-defined list of Managed System Element classes, whose instances must be aggregated.	Local Area Network, Wide Area Network, subnet, intranet
Service	Logical Element that contains the information necessary to represent and manage the functionality provided by a Device and/or SoftwareFeature. A Service is a general-purpose object to configure and manage the implementation of functionality. It is not the functionality itself.	Printer, modem, fax machine

System Associations Provided by the Core Model

Associations are classes that define the relationships shared by other classes. Association classes are flagged with an ASSOCIATION qualifier that denotes the purpose of the class. An association class must have at least two references, the names of the classes that share a particular relationship. Instances of an association always belong to the association class.

Associations can have the following types of relationships:

- One to one
- One to many
- One to zero
- Aggregation, such as a containment relationship between a system and its parts

Associations express the relationship between a system and the managed elements that make up the system. Two broad types of associations are used to define the relationships between classes:

The CIM Schema defines two basic types of associations:

- Component associations, which indicate that one class is part of another
- Dependency associations, which indicate that a class cannot function or exist without another class

These association types are abstract, which means that association classes do not have instances alone. Instances must belong to one of their descendent classes.

Component Associations

Component associations express the relationship between the parts of a system and the system itself. Component associations describe what elements make up a system. Abstract classes that express component associations are used to create concrete associations of this type in descendent classes. The descendent concrete associations answer the question: "What composition relationships does the component, or class, have with other components?"

In its most specialized role, the component association expresses the relationship between a system and its logical and physical parts.

Dependency Associations

Dependency associations establish the relationships between objects that rely on one another. The Core Model provides for the following types of dependencies:

■ Functional – the dependent object cannot function without the object on which it depends

■ Existence – the dependent object cannot exist without the object on which it depends

The following types of dependencies are included in the Core Model.

TABLE A-3 Core Model Dependencies

Dependency Association	Description
HostedService	An association between a Service and the System on which the functionality resides. The cardinality of this association is one-to-many. A System may host many Services. Services are weak with respect to their hosting System.
	Generally speaking, a Service is hosted on the System where the LogicalDevices or SoftwareFeatures that implement the Service are located. The model does not represent Services hosted across multiple systems. This is modeled as an ApplicationSystem that acts as an aggregation point for Services that are each located on a single host.
HostedAccessPoint	An association between a ServiceAccessPoint (SAP) and the System on which it is provided. The cardinality of this association is one-to-many and is weak with respect to the System. Each System may host many SAPs.
	A feature of the model is that the access point of a service can be located on the same or a different host from the system to which the service provides access. This allows the model to depict both distributed systems (an ApplicationSystem with component Service on multiple hosts) and distributed access (a Service with access points hosted on other systems).
ServiceSAPDependency	An association between a Service and a ServiceAccessPoint indicating that the referenced SAP is required for the Service to provide its functionality.
SAPSAPDependency	An association between a SAP and another SAP indicating that the latter is required in order for the former to utilize or connect with its Service.
ServiceAccessBySAP	An association that identifies the access points for a Service. For example, a printer may be accessed by Netware, Apple Macintosh, or Windows ServiceAccessPoints, potentially hosted on different Systems.

Example of an Extension into the Core Model

It is possible to develop many extensions into the Core Model. One possible extension includes the addition of a Managed Element class as an abstraction of the Managed System Element class. Descendents of this Managed Element class—classes

that represent objects outside the managed system domain, such as Users or Administrators—may be added to the Core Model.

Common Model Schemas

The Common Model provides a set of base classes for the following technology-specific schemas.

Systems

The Systems Model describes the computer, application, and network systems that comprise the top-level system objects that make up the managed environment.

Devices

The Devices Model is a representation of the discrete logical units on the system that provide the basic capabilities of the system, such as storage, processing, communication, and input/output functions. There is a strong temptation to identify the system devices with the physical components of the system. This approach is incorrect because what is being managed is not the physical components themselves but rather the operating system's representation of the devices.

The representation provided by the operating system does not have a one-to-one correspondence with the physical components of the system. For example, a modem may correspond to a discrete physical component. It may just as well be provided by a multi-function card that supports a LAN adapter as well as a modem, or the modem may be provided by an ordinary process running on the system. It is very important in using or making extensions to the model to understand this distinction between Logical Devices and Physical Components and not to get them confused.

Applications

The CIM Application Management Model is an information model designed to describe a set of details that is commonly required to manage software products and applications. This model can be used for various application structures, ranging from stand-alone desktop applications to a sophisticated, multiplatform, distributed, Internet-based application. Likewise, the model can be used to describe a single software product as well as a group of interdependent applications that form a business system.

A fundamental characteristic of the application model is the idea of the application life cycle. An application may be in one of four states: Deployable, Installable, Executable, and Executing. The interpretation and characteristics of the various objects used to represent applications are largely tied to the mechanisms used to transform applications from one state to another.

Networks

The Networks Model represents the various aspects of the network environment. This includes the topology of the network, the connectivity of the network, and the various protocols and services necessary to drive and provide access to the network.

Physical

The Physical Model provides a representation of the actual physical environment. Most of the managed environment is represented by logical objects, that is, objects that represent informational aspects of the environment rather than actual physical objects. Most of systems management is concerned with manipulating information that represents and controls the state of the system. Any impact on the actual physical environment (such as the movement of a read head on a physical drive, or the starting of a fan) is likely to only happen as an indirect consequence of the manipulation of the logical environment. As such, the physical environment is typically not of direct concern.

Apart from anything else, physical parts of the system are not instrumented. Their current state (and possibly even their very existence) can only be indirectly inferred from other information about the system. In the CIM, the physical model is a representation of this aspect of the environment and it is expected that it will differ dramatically from system to system and over time as technology evolves. It is also expected that the physical environment will always be very difficult to track and instrument, spawning the opportunity for a separate specialty, that of deploying applications, tools, and environments specifically aimed at providing information about the physical aspect of the managed environment.

The Solaris Schema

During installation, the CIM Object Manager compiles MOF files that describe the CIM Schema and the Solaris Schema in the directory /usr/sadm/mof/. CIM Schema files, which implement the Core and Common Models of the Common Information Model, are denoted by the use of CIM in their associated file names. The Solaris Schema files, denoted by the use of Solaris in their file names, provide the implementation of the Solaris extension into the Common Information Model. This appendix describes the Solaris Schema files.

- "The Solaris_Schema1.0.mof File" on page 96
- "The Solaris_CIMOM1.0.mof File" on page 97
- "The Solaris_Corel.0.mof File" on page 98
- "The Solaris_Application1.0.mof File" on page 101
- "The Solaris_System1.0.mof File" on page 103
- "The Solaris_Device1.0.mof File" on page 104
- "The Solaris_Acl1.0.mof File" on page 106
- "The Solaris_Network1.0.mof File" on page 106
- "The Solaris_Users1.0.mof File" on page 106

Solaris Schema Files

The following table provides a brief overview of the Solaris Schema files located in /usr/sadm/mof.

TABLE B-1 Solaris Schema Files

Solaris Schema File	Description of What it Provides
Solaris_Schemal.0.mof	Lists all of the MOF files of the Solaris Schema, in #pragma Include statements. Specifies the order in which the MOF files are read and compiled.
Solaris_CIMOM1.0.mof	Contains all the system properties that the CIM Object Manager uses.
Solaris_Corel.0.mof	Enables WBEM core features to be implemented. Lets you set locales, qualifiers, and providers.
Solaris_Application1.0.mof	Models Solaris packages and patches in CIM.
Solaris_System1.0.mof	Models the Solaris Schema components for a system, including the operating system and processes of the system. Extends CIM Schema definitions through the definition of the Solaris_Process and Solaris_OperatingSystem classes.
Solaris_Device1.0.mof	Enables a description of your system's processor, serial ports, printing devices, and time settings to make your computer work with the CIM Object Manager.
Solaris_Acl1.0.mof	Sets the base class and qualifiers for user ACLs.
Solaris_Network1.0.mof	Defines classes pertaining to network domains, IP subnets, and naming services (including NIS, NIS+, LDAP, DNS, and server /etc files).
Solaris_Users1.0.mof	Defines classes for working with user accounts.

For more detailed information about each file, see the following sections.

The Solaris_Schema1.0.mof File

The <code>Solaris_Schemal.o.mof</code> file is the high-level container of all other MOF files comprised by the Solaris Schema. It lists the MOF files in the order in which they must be compiled. The Java classes generated from each compilation are then sent to the CIM Object Manager, where they are either enacted as events or sent to the CIM Repository for storage as objects. The following listing of the

 ${\tt Solaris_Schemal.0.mof}$ file shows the Include statements in the order required for compilation.

```
Title:
         Solaris Master MOF 1.0
Description: Include pragmas for all other mofs
Date:
             05/09/00
Version:
             1.0
Copyright (c) 2000 Sun Microsystems, Inc. All Rights Reserved.
#pragma Include ("usr/sadm/mof/Solaris_Core1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_Application1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_System1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_Device1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_Network1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_Users1.0.mof")
#pragma Include ("usr/sadm/mof/Solaris_CIMOM1.0.mof")
// This must be the last include since it changes the CIM namespace
#pragma Include ("usr/sadm/mof/Solaris_Acl1.0.mof")
```

The compiler parses a line of the Solaris_Schemal.0.mof file, compiles the file specified in the Include statement, and then parses the next line of the Solaris_Schemal.0.mof file, until all included files are compiled.

The Solaris_CIMOM1.0.mof File

The Solaris_CIMOM1.0.mof file contains all the system properties used by the CIM Object Manager.

(continued)

```
Scope(property, reference),
      Flavor(DisableOverride);
Qualifier Override : string = null,
      Scope(property, method, reference);

class Solaris_CIMOM {
   [key]
    string name;
    [Description("Shuts down the CIMOM")]
    sint8 shutdown();
};
```

The Solaris_Core1.0.mof File

The Solaris_Core1.0.mof file is the first of the Solaris Schema files to be compiled after the Solaris_Schema1.0.mof file. This file provides the definition of the Solaris_ComputerSystem class of the Solaris Provider, and also the Solaris_LogRecord, Solaris_LogService,

Solaris_LogServiceProperties, and Solaris_LogServiceSetting classes.

Solaris ComputerSystem Class

The first section of Solaris_Corel.O.mof sets the definition of Solaris_ComputerSystem as an extension of the CIM_UnitaryComputerSystem class.

```
[Provider("com.sun.wbem.solarisprovider.computersystem.Solaris_ComputerSystem")]
class Solaris_ComputerSystem:CIM_UnitaryComputerSystem
};
```

Logging Definitions

The Solaris_LogRecord defines the types of data that can be written to WBEM system logs.

```
[Provider ("com.sun.wbem.solarisprovider.logsvc.Solaris_LogRecord")]
class Solaris_LogRecord
```

WBEM system logs fall into three general categories: application logs, system logs, and security logs. Log records may be assigned different severities, including informational, warning, and error logs. For information about using the Solaris_LogRecord call to enable logging in your applications, see "Using the APIs to Enable Logging" on page 55 in Chapter 5.

All log records use a standard format that is defined in the Solaris_LogRecord class. The properties of Solaris LogRecord indicate the types of data that are passed from an application into a log record. Some of the data passed is required by the CIM Object Manager and CIM Repository to identify the recorded data. These properties are flagged with a [read, key] qualifier to show that they are read-only. You can view the data but not change the values of these properties. You can change the values of properties assigned [read, write] qualifiers. The following list shows the properties as they are assigned to Solaris_LogRecord in

```
Solaris_Core1.0.mof.
[read, key]
sint64 RecordID;
[read, kev]
sint32 RecordHashCode;
[read, key]
string Filename;
[read]
datetime RecordDate;
[read, write]
sint32 category;
[read, write]
sint32 severity;
[read, write]
string AppName;
[read, write]
string UserName;
[read, write]
```

```
string ClientMachineName;
[read, write]
string ServerMachineName;
[read, write]
string SummaryMessage;
[read, write]
string DetailedMessage;
[read, write]
string data;
[read, write]
boolean SyslogFlag;
};
```

After properties are defined for <code>Solaris_LogRecord</code>, the <code>Solaris_LogService</code> class is defined as an extension of <code>CIM_Service</code>. This class controls the operation of the logging service.

```
[Provider ("com.sun.wbem.solarisprovider.logsvc.Solaris_LogService")]
class Solaris_LogService:CIM_Service
{
```

Each of the functions specified by the <code>Solaris_LogService</code> class defines how data is handled in a log file. For example, the <code>clearLog()</code> method specifies that all data is deleted from the log file and the log file is refreshed to accept new data.

```
{
sint32 clearLog([IN] string fileName);
sint64 getNumRecords([IN] string fileName, [OUT] sint64 numRec);
sint32 listLogFiles([OUT]string logFiles[]);
sint32 getCurrentLogFileName([OUT] string fileName);
sint32 getNumLogFiles([OUT] sint32 numFiles);
sint64 getLogFileSize([OUT] sint64 fileSize);
sint32 getSyslogSwitch([OUT] string switch);
sint32 getLogStorageName([OUT] string fileName);
sint32 getLogFileDir([OUT] string dirName);
};
```

The Solaris_LogServiceProperties class is defined as an extension of CIM_Setting:

```
[Provider ("com.sun.wbem.solarisprovider.logsvc.Solaris_LogServiceProperties")] class Solaris_LogServiceProperties:CIM_Setting {
```

The properties of this class control the following characteristics of a log file:

■ Directory—Directory to where the log file is written

- FileSize—Size allowed for a log file before it is renamed and saved
- NumFiles—Number of log files you can have in the archive
- SyslogSwitch—Ability to write log data to syslog, the default logging system of the Solaris operating environment

The Solaris_Application1.0.mof File

The Solaris Application 1.0. mof file lets you set up packages and patches for your applications that extend the Solaris Schema.

Packages

The Solaris_Application1.0.mof file contains classes that represent standard Solaris packages. These packages can be individually installed in and removed from the Solaris operating environment.

The following table lists the attributes you can set for your application packages, shows the field in which the package attribute is displayed when you run the pkginfo command, and describes the package attribute.

TABLE B-2 Package Information You Can Provide

Package Attribute	pkginfo Field	Description
Name	PKGINST	The name you assign to your package. Names typically take the form of 3 to 4 uppercase characters indicating the vendor, and up to 5 lowercase characters to uniquely identify the package.
Description	DESC	A brief description of the package in the form of a character string.
Caption	NAME	An additional brief description of the package in the form of a character string.

TABLE B-2 Package Information You Can Provide (continued)

Category	CATEGORY	Type of information contained in the package, for example, if the package contains video, graphic, or Java applications. The category is formed by a free-form string that usually contains the term <i>system</i> or <i>application</i> . The category string can be comprised of multiple terms separated by commas. Possible values include: <i>ALE</i> , <i>graphics</i> , <i>java</i> , <i>video</i> , <i>JFP</i> , <i>SyMON</i> .
Architecture	ARCH	System architecture to which the package applies. The Architecture attribute can be a string or an enumeration. Use all to specify a generic text package such as a package that consists of man pages. Specify sparc or i386 to represent a binary (represented by its processor type), or sparc.sun4u to specify a kernel (represented as a subclass of its processor type).
Base Directory	BASEDIR	Valid UNIX path that indicates the top-level directory where the package was installed.
Manufacturer	VENDOR	Manufacturer of the product.
Build Number	PSTAMP	String showing the build host name followed by a time stamp.
Install Date	INSTDATE	Date and time values that indicate when the operating system was installed.
Support Information	HOTLINE	Character string that provides information about who to call for support.

Patches

The Solaris_Application1.0.mof file also lets you provide fixes to problems and updated versions of your applications in the form of patches. The following table lists and describes the patch attributes that you can provide. All of the information contained in the patch attributes can be obtained with the showrev -p command.

TABLE B-3 Patch Information You Can Provide

Patch Attribute	Description
Obsoletes	Provides a description of patches that are obsolete or that have been integrated into the current patch.
Requires	Lists the patches required to make the current patch work.
Incompatibles	Lists patches that conflict with the current patch.
Packages	List of packages that this patch fixes.
Manufacturer	Lists the manufacturer's name.
Installation Date	Provides a date/time value indicating the date and time the patch was installed.

The Solaris_System1.0.mof File

The Solaris_System1.0.mof file defines the following classes:

- Solaris_Process
- Solaris_OperatingSystem
- Solaris_InstalledOS
- Solaris_RunningOS
- Solaris_OSProcess
- Solaris_LocalFileSystem
- Solaris_UFS
- Solaris_HSFS
- Solaris_NFS
- Solaris_Directory
- Solaris_ScheduledJob
- Solaris_ScheduledJob_Cron
- Solaris_JobScheduler
- Solaris_JobScheduler_Cron
- Solaris_DisklessClient
- Solaris_OsService

In addition, the Solaris_System1.0.mof file defines the following association classes:

- Solaris_Mount
- Solaris_NFSMount
- Solaris_NFSExport
- Solaris_UFSMount
- Solaris_HSFSMount
- Solaris_OwningJobScheduler
- Solaris_HostedJobScheduler
- Solaris_SystemDevice

The Solaris_Device1.0.mof File

The Solaris_Device1.0.mof file defines the following classes:

- Solaris_Processor
- Solaris_Environment
- Solaris_DiskDrive
- Solaris_DiskPartition
- Solaris_SerialPort
- Solaris_SerialPortConfiguration
- Solaris_SerialPortSetting
- Solaris_EthernetAdapter
- Solaris_SoundDevice
- Solaris_Keyboard
- Solaris_TimeZone
- Solaris_Printer
- Solaris_PrintJob
- Solaris_PrintService
- Solaris_PrintQueue
- Solaris_PrintSAP

In addition, the Solaris_Device1.0.mof file defines the following association classes:

- Solaris_MediaPresent
- Solaris_QueueForPrintService
- Solaris_OwningPrintQueue
- Solaris_PrinterServicingQueue
- Solaris_SystemTimeZone

Serial Ports

The Solaris_SerialPort class is defined with Boolean properties that let you control how serial port characteristics, such as baud rate and parity, are handled by the port. The Solaris PortConfiguration class properties let you specify data values that a user can view or modify.

Solaris_Printer Class and Printing Definitions

The properties of the Solaris Printer class and related classes are inherited from the CIM_Printer class and allow you to specify values for printers and printing services.

Solaris TimeZone Class

The Solaris_TimeZone class properties allow you to specify values for setting and changing the date.

The Solaris_SystemTimeZone class is an association between the ${\tt Solaris_ComputerSystem} \ and \ {\tt Solaris_TimeZone} \ classes. \ Its \ properties \ are$ Element, which holds the value of a CIM_ObjectPath to a Solaris_ComputerSystem instance, and Setting, which holds the value of a CIM_ObjectPath to a Solaris_TimeZone instance.

```
[Association,
        Provider ("com.sun.wbem.solarisprovider.tz.Solaris_SystemTimeZone")]
class Solaris_SystemTimeZone:Solaris_SystemSetting
        [override("Element")]
   Solaris_ComputerSystem REF Element;
        [override("Setting")]
   Solaris_TimeZone REF Setting; };
```

The Solaris_Acl1.0.mof File

This file specifies the Solaris WBEM Services security classes. It defines the following base classes for access control lists, users, and namespaces:

- Solaris_Acl
- Solaris_UserAcl
- Solaris_NamespaceAcl

For information about these classes, see "Using the APIs to Set Access Control" on page 43 in Chapter 3.

The Solaris_Network1.0.mof File

The Solaris_Network1.0.mof file defines classes pertaining to network domains, IP subnets, and naming services (including NIS, NIS+, LDAP, DNS, and server /etc files). The following classes are defined:

- Solaris_AdminDomain
- Solaris_SystemAdminDomain
- Solaris_NisAdminDomain
- Solaris_NisplusAdminDomain
- Solaris_LdapAdminDomain
- Solaris_DnsAdminDomain
- Solaris_IPProtocolEndpoint
- Solaris_IPSubnet

The Solaris_Users1.0.mof File

The Solaris_Users1.0.mof file defines the following classes:

- Solaris_UserAccount
- Solaris_UserGroup
- Solaris_UserTemplate

- Solaris_UserHomeDirectory
- Solaris_AuthorizationAttribute
- Solaris_ExecutionProfile
- Solaris_ProfileAttribute
- Solaris_MailBox
- Solaris_EmailAlias

Solaris 8 1/01 Updates

The following provides an overview of new and changed information provided in this release of the *Solaris WBEM Services Administrator's Guide*.

Chapter 2, CIM Object Manager, was updated as follows:

- Updated description of init.wbem command, which now starts the Solaris Management Console (SMC) server as well as the CIM Object Manager. For details, see "The init.wbem Command" on page 30.
- Added section describing how to upgrade the CIM Object Manager repository. For details, see "Upgrading the CIM Object Manager Repository" on page 32.

Chapter 3, Administering Security, was updated to describe how the classes defined in the $Solaris_Users1.0.mof$ file are used to implement standard Solaris and RBAC security, via the Users tool of the Solaris Management Console (SMC) .

Chapter 5, System Logging, was updated as follows: wbemlogviewer application replaced with the Solaris Management Console (SMC) Log Viewer.

Appendix B, The Solaris Schema, was updated as follows:

- The Solaris_SerialPortSettingclass moved from the Solaris_Corel.0.mof file to the Solaris_Devicel.0.mof file.
- Description of the Solaris_Application1.0.mof file was changed, removing this package attribute: Package Status. One patch attribute was added: Packages.
- Description of the Solaris_System1.0.mof file updated, adding a complete list of classes defined in this file. For details see "The Solaris_System1.0.mof File" on page 103.
- Added description of the Solaris_Network1.0.mof file. See "The Solaris_Network1.0.mof File" on page 106.
- Added description of the Solaris_Users1.0.mof file. See "The Solaris_Users1.0.mof File" on page 106.

Glossary

This Glossary defines terms used in the Solaris WBEM Services documentation. Many of these terms are familiar to developers, but have new or altered meaning in the WBEM environment.

object located elsewhere in a MOF file. Alias names follow the same rules as instance and class names. Aliases are typically used as

shortcuts to lengthy paths.

aggregation relationship

A relationship in which one entity is made up of the aggregation of

some number of other entities.

association class A class that describes a relationship between two classes or between

instances of two classes. The properties of an association class include pointers, or references, to the two classes or instances. All WBEM classes can be included in one or more associations.

Backus-Naur Form

(BNF)

A metalanguage that specifies the syntax of programming languages.

cardinality The number of values that may apply to an attribute for a given

entity.

class A collection or set of objects that have similar properties and fulfill

similar purposes.

CIM Object

Manager Repository

A central storage area managed by the Common Information Model Object Manager (CIM Object Manager). This repository contains the

definitions of classes and instances that represent managed objects

and the relationships among them.

CIM Schema A collection of class definitions used to represent managed objects

that occur in every management environment.

See also core model, common model, and extension schema.

The CIM is divided into the metamodel and the standard schema. The metamodel describes what types of entities make up the schema. It also defines how these entities can be combined into objects that represent managed objects.

common model

The second layer of the CIM schema, which includes a series of domain-specific but platform-independent classes. The domains are systems, networks, applications, and other management-related data. The common model is derived from the core model.

See also extension schema.

core model

The first layer of the CIM schema, which includes the top-level classes and their properties and associations. The core model is both domain- and platform-independent.

See also common model and extension schema.

Distributed Management Task Force (DMTF) domain

An industry-wide consortium committed to making personal computers easier to use, understand, configure, and manage.

The class to which a property or method belongs. For example, if status is a property of Logical Device, it is said to belong to the Logical Device domain.

dynamic class

A class whose definition is supplied by a provider at runtime as needed. Dynamic classes are used to represent provider-specific managed objects and are not stored permanently in the CIM Object Manager Repository. Instead, the provider responsible for a dynamic class stores information about its location. When an application requests a dynamic class, the CIM Object Manager locates the provider and forwards the request. Dynamic classes support only dynamic instances.

dynamic instances

An instance that is supplied by a provider when the need arises and is not stored in the CIM Object Manager Repository. Dynamic instances can be provided for either static or dynamic classes. Supporting instances of a class dynamically allows a provider to always supply up-to-the-minute property values.

enumeration

Java term for getting a list of objects. Java provides an Enumeration interface that has methods for enumerating a list of objects. An individual object on this list to be enumerated is called an element.

extension schema The third layer of the CIM Schema, which includes platform-specific

extensions of the CIM Schema such as Solaris and UNIX.

See also common model and core model.

flavor See qualifier flavor.

indication An operation executed as a result of some action such as the

> creation, modification, or deletion of an instance, access to an instance, or modification or access to a property. Indications can also result from the passage of a specified period of time. An indication

typically results in an event.

inheritance The relationship that describes how classes and instances are

> derived from parent classes or superclasses. A class can spawn a new subclass, also called a child class. A subclass contains all the methods and properties of its parent class. Inheritance is one of the features that allows WBEM classes to function as templates for

actual managed objects in the WBEM environment.

instance A representation of a managed object that belongs to a particular

class, or a particular occurrence of an event. Instances contain actual

data.

instance provider A type of provider that supports instances of system- and

> property-specific classes. Instance providers can support data retrieval, modification, deletion, and enumeration. Instance

providers can also invoke methods.

See also property provider.

interface class The class used to access a set of objects. The interface class can be

an abstract class representing the scope of an enumeration.

See also enumeration and scope.

Interface Definition

A generic term for a language that lets a program or object written Language (IDL) in one language communicate with another program written in an

unknown language.

A property that is used to provide a unique identifier for an instance key

of a class. Key properties are marked with the Key qualifier.

Key qualifier A qualifier that must be attached to every property in a class that

serves as part of the key for that class.

managed object A hardware or software component that is represented as a WBEM

class. Information about managed objects is supplied by data and event providers as well as the CIM Object Manager Repository.

Managed Object Format (MOF)

management

application

A compiled language for defining classes and instances. The MOF compiler (mofcomp) compiles .mof text files into Java classes and adds the data to the CIM Object Manager Repository. MOF eliminates the need to write code, thus providing a simple and fast

technique for modifying the CIM Object Manager Repository.

An application or service that uses information originating from one or more managed objects in a managed environment. Management

applications retrieve this information through calls to the CIM Object

Manager API from the CIM Object Manager and from providers.

management information base

A database of managed objects.

metamodel A CIM component that describes the entities and relationships

representing managed objects. For example, classes, instances, and

associations are included in the metamodel.

metaschema A formal definition of the Common Information Model, which

defines the terms used to express the model, its usage, and its

semantics.

method A function describing the behavior of a class. Including a method in

a class does not guarantee an implementation of the method.

MOF file A text file that contains definitions of classes and instances using the

Managed Object Format (MOF) language.

Named Element An entity that can be expressed as an object in the metaschema.

namespace A directory-like structure that can contain classes, instances, and

other namespaces.

object path A formatted string used to access namespaces, classes, and

instances. Each object on the system has a unique path which identifies it locally or over the network. Object paths are conceptually similar to Universal Resource Locators (URLs).

override Indicates that the property, method, or reference in the derived class

overrides the similar construct in the parent class in the inheritance

tree or in the specified parent class.

polymorphism

The ability to alter methods and properties in a derived class without changing their names or altering interfaces. For example, a subclass can redefine the implementation of a method or property inherited from its superclass. The property or method is thereby redefined even if the superclass is used as the interface class.

Thus, the LogicalDevice class can define the variable status as a string, and can return the values "on" or "off." The Modem subclass of LogicalDevice can redefine (override) status by returning "on," "off." and "connected." If all LogicalDevices are enumerated, any LogicalDevice that happens to be a modem can return the value

"connected" for the status property.

property A value used to characterize the instances of a class. Property names

> cannot begin with a digit and cannot contain white space. Property values must have a valid Managed Object Format (MOF) data type.

A program that communicates with managed objects to access data property provider

and event notifications from a variety of sources, such as the Solaris operating environment or a Simple Network Management Protocol (SNMP) SNMP device. Providers forward this information to the

CIM Object Manager for integration and interpretation.

qualifier A modifier containing information that describes a class, an

instance, a property, a method, or a parameter. The three categories of qualifiers are: those defined by the Common Information Model (CIM), those defined by WBEM (standard qualifiers), and those

defined by developers. Standard qualifiers are attached

automatically by the CIM Object Manager.

qualifier flavor An attribute of a CIM qualifier that governs the use of a qualifier.

WBEM flavors describe rules that specify whether a qualifier can be propagated to derived classes and instances and whether or not a derived class or instance can override the qualifier's original value.

range A class that is referenced by a reference property.

reference A special string property type that is marked with the reference

qualifier, indicating that it is a pointer to other instances.

required property A property that must have a value.

schema A collection of class definitions that describe managed objects in a

particular environment.

scope An attribute of a CIM qualifier that indicates which CIM elements

can use the qualifier. Scope can only be defined in the Qualifier

Type declaration; it cannot be changed in a qualifier.

selective inheritance The ability of a descendant class to drop or override the properties

of an ancestral class.

Simple Network Management Protocol (SNMP) A protocol of the Internet reference model used for network

management.

singleton class A WBEM class that supports only a single instance.

Solaris Schema A Sun extension to the CIM Schema that contains definitions of

classes and instances to represent managed objects that exist in a

typical Solaris operating environment.

standard schema A common conceptual framework for organizing and relating the

various classes representing the current operational state of a system, network, or application. The standard schema is defined by the Distributed Management Task Force (DMTF) in the Common

Information Model (CIM).

static class A WBEM class whose definition is persistent. The definition is

stored in the CIM Object Manager Repository until it is explicitly deleted. The CIM Object Manager can provide definitions of static classes without the help of a provider. Static classes can support

either static or dynamic instances.

static instance An instance that is persistently stored in the CIM Object Manager

Repository.

subclass A class that is derived from a superclass. The subclass inherits all

features of its superclass, but can add new features or redefine

existing ones.

subschema A part of a schema owned by a particular organization. The Win32

and Solaris Schemas are examples of subschemas.

superclass The class from which a subclass inherits.

transitive In a relation having at least three attributes R (A, B, C), the situation

dependency in which A determines B, B determines C, but B does not determine

A.

trigger A recognition of a state change (such as create, delete, update, or

access) of a class instance, and update or access of a property. The WBEM implementation does not have an explicit object representing a trigger. Triggers are implied either by the operations on basic objects of the system (create, delete, and modify on classes, instances

and namespaces) or by events in the managed environment.

Unified Modeling Language (UML)

A notation language used to express a software system using boxes

and lines to represent objects and relationships.

Unicode A 16-bit character set capable of encoding all known characters and

used as a worldwide character-encoding standard.

UTF-8 An 8-bit transformation format that may also serve as a

transformation format for Unicode character data.

virtual function table (VTBL)

A table of function pointers, such as an implementation of a class. The pointers in the VTBL point to the members of the interfaces that

an object supports.

Win32 Schema A Microsoft extension to the CIM Schema that contains definitions

of classes and instances to represent managed objects that exist in a

typical Win32 environment.
