## Preface

This manual, Writing FCode Programs, replaces both Writing FCode Programs for SBus Cards and Writing FCode 2.0 Programs.

## Who Should Use This Book

This manual is written for designers of SBus interface cards and other devices that use the FCode interface language. It assumes that you have some familiarity with SBus card design requirements and Forth programming.

The material covered in this manual is specifically for those developing FCode applications on OpenBoot 2.0 or later SPARCsystems, and those developing SBus cards for either OpenBoot 2.0 only or both OpenBoot 1.0 and OpenBoot 2.0 and later systems.

This manual also assumes that you have read and understood SBus Specification B. 0 (or later) and OpenBoot Command Reference.

## How This Book Is Organized

- Chapter 1, "SBus Cards and FCode", introduces the basic relationships between FCode device drivers and the hardware that they control.
- Chapter 2, "Elements of FCode Programming", introduces the basic elements of FCode, stack notation, and programming style.
- Chapter 3, "Producing FCode", describes the process of producing FCode programs, from source file to testing working programs.
- Chapter 4, "Packages", describes the basic units of FCode program function.
- Chapter 5, "Properties", describes properties, which define how an FCode device driver program "sees" the hardware that it controls.
- Chapter 6, "Block and Byte Devices" through Chapter 10, "Serial Devices" describe currently-defined device types, programming requirements, and give some examples of device drivers for the various device types.
- Chapter 11, "FCode Dictionary", describes currently-defined FCode words, their functions and use, with brief programming examples.
- Appendix A, "FCode Reference", lists all currently-defined Fcode words according to functional grouping, name, and byte value.
- Appendix B, "OpenBoot Interrupt Testing", describes how to go about dealing with interrupts when testing SBus devices, including programming examples.
- Appendix C, "FCode Memory Allocation", describes guidelines for memory allocation and deallocation in FCode.
- Appendix D, "Changes in OpenBoot 1 FCode Usage", describes differences in programming style between OpenBoot 1 and OpenBoot 2 practice, and changes in usage of FCode words that have changed between OpenBoot 1 and OpenBoot 2.

## Related Books

This manual does not pretend to cover everything you need to know to write FCode drivers for SBus cards. You'll have to read some other books, too.

For information about SBus, OpenBoot 2.0, SBus device drivers, and writing device drivers for Sun workstations, see the following Sun manuals:

- OpenBoot Command Reference, 801-7042-10
- OpenBoot Quick Reference, 800-5675-11
- Writing SBus Device Drivers, 800-4455-10

For more information about Forth and Forth programming and SBus, see:

- Mastering Forth, Anita Anderson and Martin Tracy. Brady Communication Company, Inc., 1989.
- Forth: A Text and Reference, Mahlon G. Kelly and Nicholas Spies. Prentice Hall.
- Starting FORTH, Leo Brody. FORTH, Inc., second edition, 1987.
- Forth: a New Model, Jack Woehr. M \& T Books, 1992.
- OpenBoot Command Reference, 801-7042-10
- IEEE Standard for a Chip and Module Interconnect Bus: Sbus, IEEE Std 14961993

Some programs specifically mentioned in this manual for use in developing FCode programs are included on a diskette in the SBus Developer's Kit. Instructions for using these programs are included on the diskette.

If you don't have access to a complete SBus Developer's Kit, or if your SPARCstation doesn't have a diskette drive, contact the Sun SBus Technical Support Group (sbustech@Sun.com) for the software.

## What Typographic Changes and Symbols Mean

The following table describes the typeface changes and symbols used in this book.

Table P-1 Typographic Conventions

| Typeface or Symbol | Meaning | Example |
| :---: | :---: | :---: |
| AaBbCc123 | The names of commands, files, and directories; on-screen computer output | Edit your . login file. Use ls -a to list all files. system\% You have mail. |
| AaBbCc123 | What you type, contrasted with on-screen computer output | system\% su Password: |
| AaBbCc123 | Command-line placeholder: replace with a real name or value | To delete a file, type rm filename. |
| AaBbCc123 | Book titles, new words or terms, or words to be emphasized | Read Chapter 6 in User's Guide. These are called class options. <br> You must be root to do this. |
| Code samples are included in boxes and may display the following: |  |  |
| \% | UNIX C shell prompt | system\% |
| ok | OpenBoot command prompt | ok |
| \$ | UNIX Bourne and Korn shell prompt | system\$ |
| \# | Superuser prompt, all UNIX shells | system\# |

This manual follows a number of typographic conventions:

- Text beginning with a capitalized letter indicates a key name or a panel button on a window-based program. For example:

Press the Control-C key.
When you see two key names separated by a dash, press and hold the first key down, then press the second key. For example:

To press Control-C, press and hold Control, then press C.

- In a command line, square brackets indicate an optional entry and italics indicate an argument that you must replace with the appropriate text. For example:

```
cd [directory]
```

## SBus Cardsand FCode

Each SBus card must have a PROM whose contents identify the device and its characteristics.

The SBus card's PROM may also include an optional software driver that lets you use the card as a boot device or a display device during booting. The software driver may also include diagnostic selftest code.

In addition to designing hardware, the process of developing SBus devices may include writing, testing, and installing FCode drivers for the device. These drivers, if present, serve three functions:

- To exercise the device during development, and to verify its functionality.
- To provide the necessary driver to be used by the system boot PROM during power-up.
- To provide device configuration information.

In practice, these functions overlap substantially. The same code needed by the system boot PROM usually serves to significantly test the device as well, although additional code may be desired to fully verify proper behavior of the device. The PROM code is used before and during the boot sequence. After the boot sequence finishes, and while not using the OpenBoot Forth Monitor, most SBus device use is through SunOS drivers.

SBus device PROMs must be written in the FCode programming language, which is similar to Forth-83. FCode is described in more detail in Chapter 2, "Elements of FCode Programming".

## FCode PROM Format

An FCode PROM begins at address 0 within the SBus card's physical address space. Its size can range from 30 bytes up to 32 K bytes. Typical sizes are 60 bytes (for a simple card that identifies itself but does not need a driver) and 14 K bytes (for a card with a boot driver). It is good practice to make FCode boot drivers as short as is practical.

An FCode PROM must be organized as follows:

- Header ( 8 bytes: consisting of magic number, version number, length, checksum).
- Body (FCode program; 0 or more bytes).
- End Token (either End0, a zero byte, or End1, an alternative all 1's byte).

## Interpreting FCode

## For each SBus slot, the FCode program is interpreted during bootup as follows:

- Location 0 of the SBus PROM is read with an 8 -bit or 32 -bit access. If there is no response (as when there is no card in that slot), the slot is subsequently ignored.
- If the high-order byte of the value returned from the first access is not the FCode magic numbers $0 x f d$ or $0 x f 1$, the slot is subsequently ignored.
- If the high-order byte is $0 \times f d$ or $0 x f 1$, the PROM is assumed to contain a valid FCode program. The FCode is then interpreted by starting at location 0 and reading one byte at a time, executing a procedure associated with each FCode value.
- Interpretation ceases when the FCode $0 \times 00$ or $0 x f f$ (End0 or End1) is encountered.

## Device Identification

An FCode PROM must identify its device. This identification must include, at a minimum, the driver name, used to link the device to its SunOS driver. Identification information may include additional characteristics of the device for the benefit of the operating system and the CPU boot PROM.

In most systems, the CPU's FCode interpreter will store each device's identification information in a device tree that has a node for each device. Each device node has a property list that identifies and describes the device. The property list is created as a result of interpreting the program in the FCode PROM.

Each property must have a name and a value. The name is a string and the value is an array of bytes, which may encode strings, numbers, and various other data types.

See Chapter 5, "Properties" for more information.

## Creating and Executing FCode Definitions

Many FCode programs create executable routines, called colon definitions (or methods) that typically read from and write to device locations to control device functions. These definitions are also stored in the device tree node for that device.

Once defined, these routines may typically be executed under any of the following circumstances:

- Interactively at the OpenBoot ok prompt (for selftest or other purposes).
- By the OpenBoot system (for using this boot or display system during system start-up).
- Automatically during FCode interpretation (for power-on initialization or other purposes).

三1

## Elements of FCode Programming

FCode is based on the Forth- 83 dialect of the Forth language, with the following major differences:

- The FCode tokenizer program uses normal textfiles, rather than the BLOCKs and block editing of Forth-83, and contains its own predefined words for file transfers.
- Forth-83 is designed for 16 -bit machines. FCode is designed for 32 -bit machines, so FCode handles 16 and 32-bit quantities differently than Forth83.

FCode has these characteristics:

- The source format is machine and system independent.
- The binary format (FCode) is machine, system, and position independent.
- The binary format is compact.
- The binary format may be interpreted easily and efficiently.
- Programs are easy to develop and debug.
- The source format can easily be translated to binary format.
- The binary format can be untranslated back to a source format.

Forth commands are called words, and are roughly analogous to procedures in other languages. Unlike other languages, such as C, which have operators and syntactic characters and procedures, in Forth every word is a procedure.

Forth words consist of one to 31 printable characters, separated by one or more spaces from subsequent words.

Forth uses a left-to-right reverse Polish notation, like some scientific calculators. The basic structure of Forth is: do this, now do that, now do something else, and so on.

New Forth words are defined as sequences of previously existing words. Subsequently, new words may be used to create still more words.

FCode is a byte-coded translation of a Forth program. Translating Forth source code to FCode involves replacing the Forth word names (stored as text strings) with their equivalent FCode numbers. The tokenized FCode takes up less space in PROM than the original ASCII textfile form of the Forth program from which it was derived.

For purposes of this manual, the term FCode indicates both binary-coded FCode and the Forth programs written as ASCII text files for later conversion to binary-coded FCode.

Except where a distinction between the two forms is explicitly stated, the use of FCode in this manual can be assumed to apply equally to both FCode and Forth.

## Colon Definitions

Two concepts are critical to understanding FCode (or Forth):

- A colon definition creates a new word with the same behavior of a sequence of existing words. A colon definition begins with a colon and ends with a semicolon.
- Most parameter passing is done through a pushdown, last-in, first-out stack.

Normally, the action associated with an FCode word is performed when the FCode word is encountered. This is called interpret state. However, you can switch from interpret state to compile state.

In interpret state, FCode words are executed as they are encountered. Interpret state operates until encountering a " $:$ ". The word " $:$ " does the following:

- Allocates a new FCode word and associates it with the name immediately following the colon
- Switches to compile state

During compile state operation, FCodes are saved for later execution, rather than being executed immediately. The sequence thus compiled is installed in the action tables as a new word, and can be later used in the same way as if it were a built-in word.

Compile state continues until a ";" is read, switching operation back to interpret state.

FCode words encountered after the colon are compiled into RAM for later use, until a semicolon is encountered. The word ";"does the following:

- Compiles an end-of-procedure FCode word
- Switches to interpret state

After compilation, the newly-assigned FCode word can be either interpreted or compiled as part of yet another new word.

If you define a new word having the same spelling as an existing word, the new definition supersedes the older one(s), but only for subsequent usages of that word.

Here's an example of a colon definition, defining a new FCode word dac!:
: dac! ( data addr reg\# -- ) swap dac ! dac + ! ;

## Stack Operations

Each FCode word is specified by its effect on the stack and any side effects, such as accessing memory. Most FCode words affect only the stack, by removing arguments from the stack, performing some operation on them, and putting the result or results back on the stack.

The stack effects of an FCode word is described by a stack comment, included in the colon definition.

In the previous example, the stack comment, beginning with "( " and ending with ")", shows that dac! takes three parameters from the stack, and doesn't replace them with anything when it's done.

You can place stack comments anywhere in a colon definition, and you should include them anywhere that they will enhance clarity.

The rightmost argument is on top of the stack, with any preceding arguments beneath it. In other words, arguments are pushed onto the stack in left to right order, leaving the most recent one (the rightmost one in the diagram) on the top.

Following the stack comment in the preceding example are a series of words that describe the behavior of dac!. Executing dac! is the same as executing the list of words in its colon definition.

Note that FCode words are separated by spaces, tabs, or newlines;" ( data " is not the same as " (data ". Any visible character is part of a word, and not a separator.

While case is not significant, by convention FCode is written in lower case.

## Additional Information

For more information about Forth programming, needed to use available FCode primitives, refer to the Forth-related books listed in "Related Books," on page xvi.

## Programming Style

Some people have described Forth as a write-only language. While it sometimes ends up that way, it is possible to write Forth (and FCode) programs that can be read and understood by more than just the original programmer.

## Commenting Code

Comment code extravagantly, then consider adding more comments. The comments can help you and others maintain your code, and they don't add to the final size of the resulting FCode PROM.

Typical practice is to use " ( )" for stack comments and " $\backslash$ " for other descriptive text and comments.

## Short Definitions

Keep word definitions short. If your definition exceeds half a page, try to break it up into two or more definitions. If it grows to a page or longer, you should break it up, if only to make the code easier to support in the future.

A good size for a word definition is one or two lines of code.

## Stack Comments

Always include stack comments in word definitions. It can be useful to compare intended function with what the code really does. Here's an example of a word definition with acceptable style.

```
\ xyz-map establishes a virtual-to-physical mapping for each of the
\ useful addressable regions on the board
: xyz-map ( -- )
\ Base-address Offset Size create-mapping
\ then save virtual address
    my-address 40.0000 + 4 map-sbus ( virtaddr )
    is status-register ( )
    my-address 80.0000 + frame-buf-size map-sbus (virtaddr )
    is frame-buffer-adr ( )
;
```

Stack items are generally written using descriptive names to help clarify correct usage. See the table below for stack item abbreviations used in this manual.

Table 2-1 Stack Item Notation

| Notation | Description |
| :--- | :--- |
| $\mid$ | Alternate stack results, for example: (input -- adr len false $\mid$ result true ). |
| $?$ | Unknown stack items (changed from ???). |
| $? ? ?$ or $[\ldots]$ | Unknown stack items. |
| acf | Code field address. |
| adr | Memory address (generally a virtual address). |
| byte b $x x x$ | 8-bit value (smallest byte in a 32-bit word). |

Table 2-1 Stack Item Notation (Continued)

| Notation | Description |
| :--- | :--- |
| char | 7-bit value (smallest byte), high bit unspecified. |
| cnt <br> len <br> size | Count or length. |
| flag $x x x$ ? |  |
| long Lxxx | $0=$ false; any other value = true (usually -1). |
| $\mathrm{n} \mathrm{n1} \mathrm{n2} \mathrm{n3}$ | 32-bit value. |
| n u | Normal signed values (32-bit). |
| $\mathrm{n}[64]$ <br> (n.low n. hi) | Unsigned, positive values (32-bit). |
| phys | Extended-precision (64-bit) numbers (2 stack items). |
| pstr | Physical address (actual hardware address). |
| virt | Packed string (adr len means unpacked string). |
| word w $x x x$ | Virtual address (address used by software). |

## A Minimum FCode Program

If an SBus card is not needed during the boot process, a minimal FCode program that merely declares the name of the device will often suffice. Here is an example of an acceptable minimum program:

```
fcode-version1
" SUNW,bison" xdrstring " name" attribute
my-address h# 20.0000 +
my-space h# 100
" reg" attribute
end0
```

This program creates a "name" property called "SUNW, bison" that will be used by the SunOS driver's identify routine to identify this device, and declares the location and size of on-board registers. The name that you use should always begin with your company name.

Note - To avoid name conflicts between different companies' products, use your company's public stock symbol.

You can also use the following shorthand form. The FCode program generated will be equivalent to the minimum program given above.

```
fcode-version1
" SUNW,bison" name
my-address h# 20.0000 + my-space h# 100 reg
end0
```

You might also want to include additional code to declare additional properties, create selftest routines, or to initialize the device after power-on.

## FCode Classes

There are four general classes of FCode source words:

- Primitives. These words generally correspond directly to conventional Forth words, and implement functions such as addition, stack manipulation, and control structures.
- System. These are extension words implemented in the boot PROMs, and implement functions such as memory allocation and device attribute reporting.
- Interface. These are specific to particular types of devices, and implement functions such as draw-character.
- Local. These are private words definitions, implemented and used by devices.

Each FCode primitive is represented in the SBus card's PROM as a single byte. Other FCodes are represented in the SBus PROM as two consecutive bytes. The first byte, a value from 1 to $0 x f$, may be thought of as an escape code.

One-byte FCode numbers range in value from $0 \times 10$ to $0 \times f e$. Two-byte FCode numbers begin with a byte in the range $0 \times 01$ to $0 \times 0 f$, and end with a byte in the range $0 \times 00$ to $0 x f f$. The single-byte values $0 \times 00$ and $0 x f f$ signify "end of program" (either value will do; conventionally, $0 \times 00$ is used):
Currently-defined FCodes are listed according to both functional groups and in numeric order in Appendix A, "FCode Reference".

## Primitive FCodes

There are more than 300 primitive FCode words, most of which exactly parallel Forth-83 words, divided into three groups:

- FCode words that generate a single FCode byte
- tokenizer macros
- tokenizer directives

Primitive FCode words that have an exact parallel with standard Forth- 83 words are given the same name as the equivalent Forth-83 word. Chapter 11, "FCode Dictionary", contains further descriptions of primitive FCodes.

There are about another 70 tokenizer macros, most of which also have direct Forth-83 equivalents. These are convenient source code words translated by the tokenizer into short sequences of FCode primitives.
tokenizer directives are words that generate no FCodes, but are used to control the interpretation process. Cross-compiler directives include the words

- binary, decimal, hex, and octal
- b\#, d\#, h\#, and o\#
- headers and headerless
- \and (
- . (
- alias

## System FCodes

System FCodes are used by all classes of FCode drivers for various systemrelated functions. System FCodes may be either service words or configuration words.

- Service words are available to the device's FCode driver when needed for functions such as memory mapping or diagnostic routines.
- Configuration words are included in the driver to document characteristics of the driver itself. These "properties" are passed up to the device's SunOS driver.

## Interface FCodes

Interface FCodes are standard routines used by the workstation's CPU to perform the functions of the SBus card's device. Different classes of devices will each use only the appropriate set of interface FCodes.

For example, if the system wants to paint a character on the display screen, it does it by calling the interface FCode routine draw-character. This requires the frame buffer's FCode driver to assign its own definition into the drawcharacter interface word. It does this as follows

```
: my-draw ( char -- ) \ "local" word to draw a character.
    ... \ Definition contents.
\ end of my-draw definition.
: my-install ( -- ) \ local word to install all interfaces.
    ['] my-draw is draw-character
    ...
;
```

When my-install executes, draw-character has the behavior of my-draw.

## Local FCodes

Local FCodes are assigned, where needed, to words defined within the body of SBus driver code. There are over 2000 FCode byte values allocated for local FCodes. The byte values are meaningful only within the context of a particular driver. Different drivers reuse the same set of byte values.

三2

## Producing FCode

## FCode Source

An FCode source file is essentially a Forth language source code file. The basic Forth words available to the programmer are listed in the FCode Dictionary chapter of this manual. Typically Forth source files are named with a .fth suffix. FCode source files follow the same convention.

FCode programs have the following format:

```
\(\backslash\) Title comment describing the program that follows
fcode-version1
< body of the FCode program >
endo
```

fcode-version1 is a macro which directs the tokenizer to create an FCode header. For a description of the FCode header see "FCode Binary Format" on page 17. fcode-version1 produces a header including the version1 FCode. The macro fcode-version2 is similar except it produces a header containing the start 1 FCode. This macro may also be used to begin the FCode source. However since OpenBoot version 1 systems only recognize version1, plug-in device FCode that must run in OpenBoot version 1 systems must use fcode-version1.

See Appendix D, "Changes in OpenBoot 1 FCode Usage" for more information on differences between version 1 and version 2 FCode usage.
endo is an FCode that marks the end of an FCode program. It must be at the end of the program or erroneous results may occur. end1 is an alternative but endo is recommended.

The comment in the first line is not strictly necessary in many cases but it is recommended since some OpenBoot tools require it.

## Tokenizing FCode Source

The process of converting FCode source to FCode binary is referred to as tokenizing. A tokenizer program coverts FCode source words to their corresponding byte-codes, as indicated in the FCode Dictionary chapter. A tokenizer program together with instructions describing its use is available from the Sun SBus Support Group.

An FCode program's source may reside across multiple files. The fload tokenizer directive may be used to direct the tokenizer input stream to another file. fload acts like an \#include statement in C. When fload is encountered the tokenizer begins processing the file named by the fload directive. When the named file is completed, tokenizing continues with the file that issued the fload. fload directives may be nested.

Typically, the tokenizer produces a file in the following format based on the UNIX ${ }^{\text {tm }}$ a.out format:

- Header - 32 bytes
- FCode header - 8 bytes
- FCode binary - remainder of file

The header has the following format:

- 4 bytes - 0x01030107 (hexadecimal)
- 4 bytes - Size in bytes of the FCode binary
- 4 bytes $-0 x 0$
- 4 bytes - 0x0
- 4 bytes - 0x0
- 4 bytes - Load point of the file
- 4 bytes - 0x0
- 4 bytes - 0x0

You can use this file to load either an FCode PROM or system memory for debugging as described in "Using the Forth Monitor to Download FCode" on page 20.

The load point of the file is not used when burning an FCode PROM, but is used by Forth Monitor commands that load FCode files into system memory. The tokenizer available from the SBus Support Group sets the load point to be the recommended $0 \times 4000$ address.

By convention, the file output by the tokenizer has the suffix .fcode.

## FCode Binary Format

The format of FCode binary that is required by the OpenBoot FCode evaluator is as follows:

Table 3-1 FCode Binary Format

| Element | Structure |
| :--- | :--- |
| FCode header | eight bytes |
| Body | 0 or more bytes |
| End byte-code | 1 byte either the end0 or end1 byte-code |

The format of the FCode header is:
Table 3-2 FCode Header Format

| Byte(s) | Content |
| :--- | :--- |
| 0 | One of the FCodes: version1, start1, start2, start3, start 4 |
| 1 | reserved |
| 2 and 3 | 16-bit checksum of the FCode body |
| 4 through 7 | count of bytes in the FCode binary image including the header |

## Testing FCode on the Target Machine

Once you have created the FCode binary you may test it using the OpenBoot Forth Monitor. The Forth Monitor provides facilities to allow you to load your program into system memory and direct the FCode evaluator to interpret it from there. This allows you to avoid having to burn a PROM and attach it to your plug-in board with each FCode revision during the debug process. See the OpenBoot Command Reference for complete documentation on the use of the Forth Monitor.

The FCode testing process generally involves the following steps:

1. Configuring the target machine. This includes installing the hardware associated with the FCode program into the target machine and poweringup the machine to the OpenBoot Forth Monitor.
2. Loading the FCode program into memory from a serial line, a network, a hard disk, or a floppy disk.
3. Interpreting the FCode program to create a device node(s) on the OpenBoot device tree.
4. Browsing the device node(s) to verify proper FCode interpretation.
5. Exercising the FCode program's device driver methods complied into the device node, if any.

If the FCode program does not include any methods which involve using the actual hardware then the program may be tested without installing the hardware.

## Configuring the Target Machine

## Setting Appropriate Configuration Parameters

Before powering-down the target machine to install the target hardware, a few NVRAM parameters should be set to appropriate values. You can set them from the Forth Monitor as follows:

```
ok setenv auto-boot? false
ok setenv fcode-debug? true
```

Setting auto-boot? to false tells OpenBoot not to boot the OS upon a machine reset but rather to enter the Forth Monitor at the ok prompt.

Setting fcode-debug? to true tells the OpenBoot FCode evaluator to save the names of words created by interpreting FCode words which were tokenized with headers on. This is in addition to words defined with external on - whose names are always saved. fcode-debug? defaults to false to conserve RAM space in normal machine operation. With the names saved, the debugging methods described in later sections will be easier since it will be easier to read decompiled FCode.

## Modifying The Expansion Bus Probe Sequence

The start-up sequence in the machine's OpenBoot implementation will be programmed to examine all expansion buses at well-known locations for the presence of plug-in devices and their onboard FCode PROM program. It then invokes the FCode evaluator to interpret the program. This process is called probing the device.

When using the Forth Monitor to load and interpret an FCode program in system memory, it is better to configure OpenBoot to not automatically try to probe the device. The probing will be done manually (as explained later) from the Forth Monitor after the FCode program is loaded into memory.
Configuring an OpenBoot implementation not to probe a given slot on a given expansion bus may be done in various ways which are implementation dependent. That is, they will be different for different systems and different expansion buses.

Many machines have an NVRAM parameter called sbus-probe-list which defines which SBus card slots will be probed during start up and the order in which they will be probed.

For example, on the SPARCstation2, sbus-probe-list has a default value of 0123. Setting sbus-probe-list to 013 directs OpenBoot during start-up to probe first SBus slots 0 (built-in devices), then slot 1, and finally slot 3. This leaves SBus slot 2 unprobed, free for use by the device under development.

Methods to prevent probing a given slot for other types of expansion buses may involve using the nvramrc. An nvramrc script could be used to patch an implementation specific OpenBoot word which defines the bus's probe sequence or to modify a property of the expansion buses device node which describes the sequence.

After the FCode program is debugged and programmed in PROM on the device and you want to do a full system test (including automatic probing of the new device), restore the expansion bus probing configuration to the default.

## Getting to the Forth Monitor

After completing the configuration described above, power-down the machine and install the device. Then power-up the system and it should stop at the ok prompt ready for Forth Monitor commands.

Note - On the SPARCstation1 and SPARCstation1+, SBus slot 3 may be used only for SBus slave devices, such as framebuffers. Unlike slots 1 and 2, it may not be used for SBus master devices, such as disk drive or network interfaces.

## Using the Forth Monitor to Download FCode

Complete directions for using the Forth Monitor to download files to system memory are provided in the OpenBoot Command Reference. This chapter contains a synopsis for FCode program files. FCode words used to help download and execute FCode source files are shown below.

Table 3-3 File Download/Execute-related Toolkit Commands

| FCode | Stack Notation | Function |
| :--- | :--- | :--- |
| begin-package | ( arg-adr arg-len reg-adr reg-len path-adr path-len -- ) | Initialize device tree for executing FCode. |
| select-dev | ( path-adr path-len -- ) | Open specified device node and make it the <br> current node. |
| set-args | ( arg-adr arg-len reg-adr reg-len -- ) | Sets values returned by my-args, my-space <br> and my-address for the current node. |
| end-package | ( -- ) | Complete device tree entry and return to <br> Forth Monitor environment. |
| unselect-dev | ( -- ) | Closes current node and return to Forth <br> Monitor environment. |
| new-slot-node <br> (1.x only) | ( -- ) | Prepare device tree for new entry. |
| execute- <br> device-method | ( ... path-adr path-len cmd-adr cmd-len -- ... ok? ) | Execute named command within the <br> specified device tree node. |
| probe-slot <br> (1.x only) | ( slot\# -- ) | Setup and execute FCode in the given SBus <br> slot. |

## Using dload to Load from Ethernet

dload loads files over Ethernet at a specified address, as shown below.
ok 4000 dload filename
In the above example, filename must be relative to the server's root. Use 4000 (hex) as the address for dload input.

FCode programs loaded with dload must be in the format described in "Tokenizing FCode Source". The tokenizer provided by the SBus Support Group can output these files.
dload uses the trivial file transfer protocol (TFTP), so the server may need to have its permissions adjusted for this to work.

## Using dlbin to Load From Serial Port A

dlbin may be used to load files over serial line A. Connect the target system's serial port A to a machine that is able to transfer a file on request. The following example assumes a tip window setup on a Sun system which will provide the FCode file. (See the OpenBoot Command Reference for information on setting tip connections.)

1. At the ok prompt, type:
```
ok dlbin
```

2. In the tip window of the other system, send the file:
```
~C (local command) cat filename
(Away two seconds)
```

The ok prompt will reappear on the screen of the target system.
FCode programs loaded with dlbin must be in the format described in "Tokenizing FCode Source". dlbin loads the files at the entry point indicated in the file header. It is recommended that this address be $0 \times 4000$.

## Using boot to Load From Hard Disk, Floppy Disk, or Ethernet

You can also load an FCode program with boot, the command normally used to boot the operating system. Use the following format:
ok boot [device-specifier] [filename] -h
device-specifier is either a full device path name or a device alias. See the OpenBoot Command Reference for information on device path names and aliases.

For a hard disk or floppy partition, filename is relative to the resident file system. See the OpenBoot Command Reference for information on creating a bootable floppy disk. For a network, filename is relative to the system's root partition on its root server. In both cases, the leading / must be omitted from the file path.

The -h flag specifies that the program should be loaded, but not executed. This flag must be included since otherwise boot will attempt to automatically execute the file assuming it is executable binary.
boot uses intermediate booters to accomplish its task. When loading from a hard disk or floppy disk, the OpenBoot firmware first loads the disk's boot block, which in turn loads a second-level booter. When loading over a network, the firmware uses TFTP to load the second-level booter. In both cases, filename and -h are passed to these intermediate booters.

The output file produced by a tokenizer may need to be converted to the format required by the secondary boot program. For example, Solaris $2 . x$ intermediate booters require ELF format. fakeboot, a program available from the Sun SBus Support Group, may be useful in this process.

The location in memory where the FCode program is loaded depends on the secondary boot program and the fakeboot program.

## Using the Forth Monitor to Interpret an FCode Program

FCode program interpretation involves creating a device node on the device tree.
There are some basic differences between the device tree of version 2 and of version 1. Improvements were made in version 2 that involve the form of physical addresses associated with device nodes and the ability to include
device driver methods in device nodes. Thus use of the FCode evaluator to interpret an FCode Program differs for OpenBoot version 2 and OpenBoot version 1 systems.

## Interpretation Under OpenBoot 2

For version 2, device nodes are also known as packages. Creating a device node from downloaded FCode involves the following steps:

## 1. Setting up the environment with begin-package.

For example, a begin-package call for creating a device node for an SBus card installed in slot \#3 of a SPARCstation2 looks like:
ok 00 " 3,0" " /sbus" begin-package
In the example, the string, /sbus, indicates that the device node which will be created by the FCode program is to be a child node of the / sbus node in the device tree.

In general, any device node which supports child nodes - called parent nodes may be used as this argument to begin-package. The device node defined by the FCode program will be made a child of that node. The full device pathname from the root node must be given. Another example of an SBus parent node is on a SPARCstation10 where its device pathname is /iommu/sbus.

In the example, the string, " 3,0 " indicates the SBus slot number, 3 , and byteoffset, 0 , within the slot's address space where the device node is to be based.

In general, this string is a pair of values separated by a comma which identify the physical address associated with the expansion slot. The form of this physical address depends on the physical address space defined by the parent node. For children of an SBus node, the form is slot-number, byte-offset. Other parent nodes will define different address spaces.

The physical address pair value is retrieved within the FCode program with both the my-address and my-space FCodes.

In the example, the initial 00 represents a null argument string passed to the FCode program.

This argument string is retrieved within the FCode program with the my-args FCode. Generally, FCode programs do not take arguments at interpretation time so this will usually be the null string. (For the SPARCstation2, when the FCode PROM on an SBus card is automatically interpreted during system power-on, this is set to a null string).
begin-package is defined as:
: begin-package select-dev new-device set-args ;
select-dev ( adr len -- ) - Opens the input device node (the parent node) and makes it the current instance.
new-device ( -- ) - Initializes a new device node as a child of the currently active node and makes it the current instance.
set-args ( arg-adr arg-len reg-adr reg-len -- ) - Sets the values returned by my-args, my-space, and my-address for the current instance.

## 2. Interpreting the loaded FCode with byte-load

byte-load is the Forth Monitor command that invokes the FCode evaluator to compile the FCode program into the current instance.

For FCode programs downloaded with dload or dlbin use:
ok 40001 byte-load

4000 is the load address recommended to be used as input to dload and as the entry point in the file loaded by dlbin. The argument, 1 , is the byte spacing between FCode byte-codes which byte-load is to expect. For FCode loaded into memory this is always 1 .

For FCode programs downloaded with boot, the address at which the FCode is loaded depends on the second level booter and the program that is used to convert the FCode file to a format accepted by the booter, such as fakeboot. For example, if the file is loaded with the FCode binary starting at 4030 use:
ok 40301 byte-load

## 3. Closing the environment with end-package.

end-package finishes up the creation of the device tree node.
ok end-package

It is defined as:

```
: end-package finish-device unselect-dev ;
```

finish-device ( -- ) Completes the device tree node initialized by newdevice and changes the current instance to be the parent node.
unselect-dev (-- ) Closes the parent device tree node and returns to the normal Forth Monitor environment. That is, there is no longer a current instance or active package.

## Interpretation Under OpenBoot 1

OpenBoot Version 1 was only implemented in early SPARCstations which only contain the SBus expansion bus. Thus the following discussion assumes an FCode program for an SBus plug-in device on early SPARCstations.

## 1. Setting up the environment

In version 1, the user sets only the value of my-address. Unlike version 2, my-address is defined as the offset - from the base of the SBus in the systems root address space - of the SBus slot in which the device is installed.

Set my-address as in the following example for SBus slot 1 :

```
ok 200.0000 is my-address
```

Hexadecimal slot offsets for the SPARCstation1/1+, SPARCstation IPC and SPARCstation 1E are:

- 0x200.0000 - Slot 1
- 0x400.0000 - Slot 2
- 0x600.0000 - Slot 3

In version 1 the user prepares the device tree for a new entry by issuing the new-slot-node command. This command assumes that the new device will be the child of the SBus nexus node in the slot indicated by my-address.

[^0]new-slot-node is not in OpenBoot versions 1.0 or 1.1, but you can download it with the reheader.fth file available from the Sun SBus Support Group, or enter the following patch directly:

```
\ For OpenBoot version 1.0
: new-slot-node ( -- )
    ffe9b192 execute
    my-address ffe93da0 execute
    slot# ffe9bd6e execute
;
\ For OpenBoot version 1.1
: new-slot-node ( -- )
    ffe9b152 execute
    my-address ffe9499c execute
    slot# ffe9bd56 execute
;
```

## 2. Interpreting the downloaded FCode with byte-load

For version 1, use byte-load to interpret the FCode program as described for version 2.

## Using the Forth Monitor to Browse a Device Node

The capability to view device nodes as well as what is contained in device nodes is different in OpenBoot versions 1 and 2. In version 2, the Forth Monitor has built-in many more commands to navigate the device tree.

Table 3-4 lists available OpenBoot commands supporting device node browsing:

Table 3-4 Commands for Browsing the Device Tree

| Command | Description |
| :--- | :--- |
| .attributes | Display the names and values of the current node's properties. |
| cd device-path | Select the indicated device node, making it the current node. |
| cd node-name | Search for a node with the given name in the subtree below the current node, and select <br> the first such node found. |

Table 3-4 Commands for Browsing the Device Tree

| Command | Description |
| :--- | :--- |
| cd .. | Select the device node that is the parent of the current node. |
| cd / | Select the root machine node. |
| device-end | De-select the current device node, leaving no node selected. |
| find-device | (path-adr path-len -- ) Select device node, like cd. |
| get-attribute | ( name-adr name-len -- true \| value-adr value-len false ) Returns property value. |
| ls | Display the names of the current node's children. |
| pwd | Display the device path name that names the current node. |
| show-devs [device-path] | Display all the devices known to the system directly beneath a given level in the device <br> hierarchy. show-devs used by itself shows the entire device tree. |
| words | Display the names of the current node's methods. |

## Device Node Browsing Under OpenBoot 2

Once a device node has been created, you may use the Forth Monitor to browse the node. See the OpenBoot Command Reference for a more complete discussion on this. Below is a brief synopsis of the available commands.

- show-devs displays all known devices in the device tree.
- cd sets the active package to a named node so its contents may be viewed. For example, to make the ACME company's SBus device named "ACME,widget" the active package on a SPARCstation2:

```
ok cd /sbus/ACME,widget
```

- find-device is essentially identical to cd differing only in the way the input pathname is passed.

```
ok " /sbus/ACME,widget" find-device
```

- . attributes displays the names and values of all the properties created for the active package.
- get-attribute returns the value of the specified property from the active package.
- ls displays the names of all child nodes, if any, of the active package.
- words shows the names of the device node methods, if any, created by the FCode program. It shows all words which were defined with external and, if fcode-debug? was true when the FCode was interpreted, the words defined with headers.
- see wordname decompiles wordname.
- device-end undoes the effects of the cd or find-device command putting the system back into the normal Forth Monitor environment.
- pwd displays the device pathname of the active package.

## Device Node Browsing Under OpenBoot 1

For version 1, only device node properties are included in device nodes and there are no commands built in the Forth Monitor to view them. Here is some Forth code which may be loaded into a version 1 system to view device nodes and their properties. It defines the command, . dev, with the following usage:

```
Forth program to display device node properties
/l* constant /prop
printable? ( char -- flag ) bl h# 7e between ;
.cstring ( adr -- ) begin dup c@ dup while emit 1+ repeat 2drop ;
xtype ( adr len -- )
    bounds ?do i c@ dup printable? if emit else drop then loop
xdump ( adr len -- ) bounds ?do i unaligned-@ .h /l +loop ;
to-column ( column# -- ) #out @ - 1 max spaces ;
.props ( prop-adr -- )
    begin dup l@ while
        dup l@ .cstring
        dup la1+ l@ over 2 la+ l@ swap
        d# 16 to-column 2dup xtype
        d# 32 to-column xdump cr
        /prop +
    repeat drop
.dev ( adr -- [ next-adr' ] [ child-adr ] )
    ." Node at: " dup .h cr
    dup 2 la+ l@ ?dup if .props then
    dup >r l@ ?dup if ." Next: " dup .h then
    r> la1t l@ ?dup if ." Child: " dup .h then cr
ok root-info .dev
```

;
;
;

```
(displays root node)
ok .dev
(displays next node)
ok .dev
```

## Using the Forth Monitor to Test a Device Node Driver

The Forth Monitor provides the capability to test the device node driver methods of an FCode program by allowing the user to execute individual methods from the Forth Monitor prompt.

OpenBoot version 2 has much more robust support for device node methods than version 1. In version 2 , there are basically two ways to invoke device node methods. They are described below. For version 1 considerations see the third part of this section.

## Device Node Methods Under OpenBoot 2

## Using select-dev

select-dev initializes an execution environment for the methods of the input device node methods. It allows the user to subsequently execute the methods directly by name.

For example, on a SPARCstation2 execute this command as follows:
ok " /sbus/ACME,widget" select-dev
select-dev performs the following:

- It effectively calls "cd /sbus/ACME, widget" to make the named device the active package. This makes all the device methods "visible" to the Forth Monitor.
- Establishes a chained set of package instances for each node in the path. In particular, this makes an instance of all data items of the device node available to its methods.
- Opens all device nodes in the path by calling the open method of each. select-dev assumes open (and close) methods in each node in the path and so the device node under test must have one.

Once these steps are performed the current device node methods may be executed by simply typing their name at the prompt. For example:

```
ok clear-widget-register
    fetch-widget-register .
O
ok
```

As is generally true of the Forth language, if execution of the method exposes an error in the code, the error may be isolated by executing the component words of the method step-by-step. Use see to decompile the method. And then type the component words individually until the error is evident. For example:

```
ok see clear-widget-register
: clear-widget-register
    enable-register-write
    O widget-register rl!
    disable-register-write
;
ok enable-register-write
ok O widget-register rl!
ok disable-register-write
```

This process may be performed recursively by decompiling the component words and then individually executing their component words. This is much easier if most of the words were defined with the headers directive. Use showstack to enable automatic printing of the Forth stack after the execution of each step to ensure correct stack behavior.

Device nodes may also be modified "on-the-fly" by any of the following:

- Entering new methods definitions. These methods are compiled into the device node like the methods in the FCode program that created the node.
- Redefining a method to include some function neglected in the first definition. (Only subsequent uses of the method are affected.) For example:

```
ok : open open initialize-widget-register-2 ;
```

- Use patch to edit word definitions. See the OpenBoot Command Reference for information on how to use this command.

Of course these modifications only stay in effect until the machine is reset and once they are working you'll probably want to include the modifications to the FCode program source.
unselect-dev reverses the effects of select-dev by calling the close method of each device in the path of the current active node, destroying the package instance of each node, and returning to the normal Forth Monitor environment. Execute unselect-dev as follows:
ok unselect-dev

## Using execute-device-method

 execute-device-method is used to execute a method directly from the normal Forth Monitor environment. That is, it is not necessary to manually make the device node the current instance before executing the method. For example:```
ok " /sbus/ACME,widget" " test-it" execute-device-method
```

execute-device-method returns true if it successfully executes the method; false, if not.
execute-device-method performs the following steps before invoking the method:

- Temporarily sets the named device node to be the active package.
- Temporarily establishes a chained set of package instances for each node in the path. In particular, this makes an instance of all data items of the device node available to its methods.
- Temporarily opens all device nodes in the name device path except the last device node in the pathname.

Note that the last item in the above list is a significant departure from how select-dev works. Since the device open method is not executed, any method invoked in this manner must be able to stand alone - not requiring any preestablished state which normally is created by open.

In summary, execute-device-method is provided to allow execution of device node methods which have been designed to provide their own state initialization and therefore to execute without previous execution of the open method. A typical example is a selftest method.

## Device Node Methods Under OpenBoot 1

With the exception of framebuffer device drivers, it not recommended to make use of device node methods in version 1. Since booting from plug-in boards is not supported in version 1 the only beneficial methods would be for device diagnostics.

Some reasons to avoid device methods in version 1 are:

1. There are several FCode words not supported in version 1. Therefore methods designed to run on version 2 and version 1 must use the old, less functional, set of FCodes.
2. Plug-in board device methods are not compiled into the associated device node. They are compiled into the main Forth vocabulary. This makes it impossible to provide a standard way for users to invoke diagnostic methods across different devices. The methods must be named specially and users must be informed of that name in order to pick them out of the many OpenBoot Forth words.
3. There is limited dictionary space in many version 1 systems.

## Testing FCode in Source Form

The Forth Monitor provides the capability to skip the tokenizer and download FCode program source directly. This practice is not recommended since there is not much advantage to this except to save a small amount of time tokenizing the program. And, in fact, there are some down sides:

- It may cause problems in the long run since generally the Forth Monitor recognizes a larger number of words that does the FCode evaluator. So the FCode program developer who tests with FCode source may develop and test a program only to find that some of the words he used are not FCode words and will not be accepted by the tokenizer and the FCode evaluator. This will require the developer to rewrite code.
- To load source you should comment out fcode-version1 and end0.
- Since the download commands accept only one file any floaded files must be put in-line.

To load an ASCII Forth source file over serial line A you use the command, dl . In addition to loading the file over the serial line it compiles the Forth source while it is loading without requiring a extra command. Therefore the developer must execute begin-package before downloading. See the OpenBoot Command Reference for details on the use of dl .

To load a program over a network with dload or from a disk with boot follow the instructions in the OpenBoot Command Reference. These commands do not evaluate the Forth source so downloading may be done before beginpackage. dload requires that the source file begin with the two characters, " $\backslash$ " (backslash space).

For OpenBoot version 1, using source code directly may cause problems since some FCode words do not have name headers and will thus be unrecognized. A file named reheader.fth, available from the Sun SBus Support Group, may be downloaded and executed to provide the missing words.

## Producing an FCode PROM

The output of the tokenizer program is used to make an actual FCode PROM. If your PROM burning tools do not accept the format, you may need to develop a format conversion utility.

## Exercising an Installed FCode PROM

You may either let OpenBoot automatically evaluate the FCode program from the PROM or you may remove the device from the OpenBoot probing as discussed earlier in "Configuring the Target Machine".

The same process discussed for testing FCode programs which are loaded to system memory may be used to test FCode programs already loaded into PROM on the device.

## Exercising FCode Under OpenBoot 2

If you take the device out of the probing sequence, a device node may be built manually as in the following example for a SPARCstation2 with the device installed in SBus slot 1:

```
ok 10000 constant rom-size
ok " /sbus" select-dev
ok " 1,0" decode-unit ( offset space )
ok rom-size map-in (fcode-vadr )
ok new-device ( fcode-vadr )
ok " " " 1,0" set-args ( fcode-vadr )
ok dup 1 byte-load ( fcode-vadr )
ok finish-device ( fcode-vadr )
ok rom-size map-out
ok unselect-dev
```

This is essentially the same sequence as outlined for evaluating FCode loaded into system memory except that the user must map in and map out the FCode PROM by using the decode-unit and use the map-in and map-out methods of the parent device node. For more information about these methods, see Chapter 8, "Hierarchical Devices".

You may browse the device node and exercise the device methods in the same way as described earlier. You may also define new methods and patch existing ones. Of course these modifications will only remain until a system reset.

## Exercising FCode Under OpenBoot 1

If you take the device out of the probing sequence, a device node may be built manually as in the following example with the device installed in SBus slot 2:

```
ok 2 probe-slot
```

In this case, probe-slot is equivalent to:

```
ok 400.0000 is my-address
ok new-slot-node
ok my-address 10000 map-sbus ( fcode-vadr)
ok dup 1 byte-load ( fcode-vadr )
ok 10000 free-virtual
```

三3

## Packages

A package is a group of functions, or methods, that implements a specific interface. A package implements a library of functions that may then be called, as needed, by FCode programs.

For many devices, this is not particularly useful, but it will be useful for FCode programs that:

- implement bootable devices
- call functions or properties from other packages, or
- implement functions intended to be called from other packages

A plug-in package is a package that is not permanently resident in the main OpenBoot PROM. Plug-in packages are written in FCode. Since FCode is represented with a machine-independent binary format, it lets the same plugin packages be used on machines with different CPU instruction sets.

A package's references to OpenBoot PROM system functions are resolved and the functions defined by the package are made available to other parts of the OpenBoot during the linking process. This is performed at run-time, when OpenBoot interprets (probes) the package. Thus, plug-in packages do not need to be pre-linked with a particular OpenBoot implementation.

OpenBoot only needs to know the beginning address of the package in order to probe it. Once probed, the package becomes a working part of OpenBoot, until the system is reset or turned off. A package exports its interface to OpenBoot, and to other packages, as a vocabulary of Forth words.

Many packages implement a specific interface; a standard set of functions. Different packages may implement the same interface. For example, there may be two display device driver packages, each implementing the standard display device interface, but for two different display devices.

There may also be multiple instances of a single package. For example, a plugin disk driver may have as many instances as there are disks of that type.

## Package Definitions, Package Instances, and Device Nodes

A package consists of

- methods (software procedures)
- properties (externally-visible information describing the package), and - data (information used internally by the package).

Package data consists of uninitialized data, corresponding to Forth buffers, and initialized data, corresponding to Forth variables, values and deferred words. The initial values of the initialized data are stored within the package.

Each package is associated with exactly one device node, so you can use the terms package and device node interchangeably.

The active package is the package whose methods are currently visible.
An instance is a set of values for a package's data. Before a package's methods may be executed, an instance must be created. You create an instance from a package by allocating memory for the package's data and setting the contents of that memory to the initial values stored in the package. Multiple instances may be created from the same package, and may exist simultaneously.

The current instance is whatever instance is in use at a given time. When a package method accesses a data item, it refers to the copy of that data item that is associated with the current instance.

Plug-in device drivers are plug-in packages implementing simple device drivers. The interfaces to these drivers are designed to provide a primitive I/O capability.

Plug-in drivers are used for such functions as booting the operating system from that device, or displaying text on the device before the operating system has activated its own drivers. Plug-in drivers are made available to other parts of the OpenBoot PROM during the probing phase of the OpenBoot PROM start-up sequence.

Plug-in drivers must be programmed to handle portability problems, such as hardware alignment restrictions and byte ordering of external devices. With care, you can write a driver so that it is portable to a variety of systems in which the device could conceivably operate.

Plug-in drivers are intended to be stored in ROM located on the device itself, so that the act of installing the device automatically makes its plug-in driver available to the OpenBoot PROM.

For devices with no provision for such a plug-in driver ROM, the plug-in driver could be located elsewhere, perhaps in ROM located on a different device or in an otherwise unused portion of the main OpenBoot PROM.

## Package Methods

## Required Methods

A package that is intended for use by OpenBoot (bootable, for example) must always implement the two following methods:

## open ( -- ok? )

Prepare the package for subsequent use. open typically allocates resources, maps, initializes devices, and performs a brief sanity check (no check at all may be acceptable). true is returned if successful, false if not. When open is called, the parent instance chain has already been opened, so this method may call its parent's methods.

```
close( -- )
```

Restore the package to its "not in use" state. close typically turns off devices, unmaps, and deallocates resources. close is executed before its parent is closed, so the parent's methods are available to close. It is an error to close a package which is not open.

## Recommended Methods

The following methods are highly recommended. If possible, they should be present even if they are only stubs.

## reset -- )

Put the package into a "quiet" state. reset is primarily for packages that do not automatically assume a quiet state after a hardware reset, such as devices that turn on with interrupt requests asserted.
selftest ( -- error\# )
Test the package. selftest is invoked by the OpenBoot test word. It returns 0 if no error found or a package-specific error number if a failure is noticed.
test does not open the package before executing selftest, so selftest is responsible for establishing any state necessary to perform its function prior to starting the tests, and for releasing any resources allocated after completing the tests. There should be no user interaction with selftest, as the word may be called from a program with no user present.

If the device was already open when selftest is called, a new instance will still be created and destroyed. A well-written selftest should handle this possibility correctly, if appropriate.

If the device is already open, but it is not possible to perform a complete selftest without destroying the state of the device, the integrity of the open device should take precedence, and the selftest process should test only those aspects of the device that can be tested without destroying device state. The inability to fully test the device should not be reported as an error result; an error result should occur only if selftest actually finds a device fault.

The "device already open" case happens most commonly for display devices, which are often used as the console output device, and thus remain open for long periods of time. When testing a display device that is already open, it is not necessary to preserve text that may already be on the screen, but the device state should be preserved to the extent that further text output can occur and be visible after selftest exits. Any error messages that are displayed by the selftest method will be sent to the console output device, so when testing an
already-open display device, such error messages should be avoided during times when selftest has the device in a state where it is unable to display text.
selftest is not executed within an open/close pair. When selftest executes, a new instance is created (and destroyed). It will have its own set of variables, values, and so forth. These quantities are not normally shared with an instance opened with the normal open routine for the package.

Note - selftest should be written to do its own mapping and unmapping.

## Package Data Definitions

The usual Forth words can be used to create and use package data areas:

```
variable bar
5 value grinch
defer stub
create ival x , y , z ,
7 buffer: foo
ival foo 7 move
```

The data areas defined above are shared among all open instances of the package. If a value is changed, for instance, the new value will persist until it is changed again, independent of the creation and destruction of package instances.

All open instances of a package can access and change the value, which changes it for all other instances.

Usually a package does not share values among open instances. Consequently, you will usually want to use the following constructions to define package data areas local to a given package instance:

```
instance variable bar
5 instance value grinch
instance defer stub
7 instance buffer: foo
```

You should use the instance approach whenever possible. Using instance defines data areas that are re-initialized every time a package instance is created (usually by opening the package), so each instance gets its own copy of the data area. For example, changes to bar in one instance will not affect the contents of bar in another instance. (Note that create operates across all the instances, and cannot be made instance-specific.)

The total amount of data space consumed by that package is remembered as part of the package definition when finish-device executes to finish the package definition. Also, the contents of all the variables, values, and defers at the time finish-device executes are also stored as part of the package definition.

An instance of the package is created when that package is later opened. Data space is allocated for that instance (the amount of which was remembered in the package definition). The portion of that data space corresponding to the initialized variables, values, and defers is initialized from the values stored in the package definition. Data space associated with buffer:'s is not initialized.

You can add new methods and new properties to a package definition at any time, even after finish-device has been executed for that package. To do so, select the package and proceed to create definitions or properties.

However, it is not possible to add new data items to a package definition after finish-device has been executed for that package. finish-device sets the size of the data space for that package, and from then on it is fixed.

## Accessing Other Packages

A particular package can often use the support of other, previously defined packages. There are two types of packages whose methods can be used directly:

- the parent of the package being defined
- standard support packages in the /packages node of the device tree

Phandles and Ihandles
A package definition is identified by its phandle. find-package returns the phandle of a package definition in the /packages node. The phandle is then used to open that support package. For example:
" deblocker" find-package
returns either false (not found), or phandle true.
Opening a support package with open-package returns an ihandle. This ihandle is used primarily to call the methods of the support package, and to close the support package when it is no longer needed.

An instance argument string must be supplied when opening any package (it may be null). The instance argument string can then be accessed from within the opened package with the my-args FCode (see below for details). For example (assume that phandle has already been found):
" 5,3,0" phandle open-package (ihandle)
If the package cannot be opened, an ihandle of 0 is returned.
The following FCodes are used to find and open packages (within the /packages node):

Table 4-1 Package Access FCodes

| Name | Stack Comment | Description |
| :--- | :--- | :--- |
| find-package | ( name-adr name-len -- false \\| phandle true ) | Find the package specified by the string <br> name-adr name-len within /packages. <br> Returns the phandle of the package, if <br> found. |
| open-package | ( arg-adr arg-len phandle -- ihandle \\| 0) | Open an instance of the package phandle, <br> return the ihandle of the opened package, <br> or 0 if unsuccessful. The package is <br> opened with an instance argument string <br> specified by arg-adr arg-len. |
| \$open-package | (arg-adr arg-len name-adr name-len -- ihandle \|0) | Shortcut word to find and open a package <br> within the /packages node in one |
|  |  | operation. |

An example of using \$open-package follows:

```
" 5,3,0" " deblocker"
    $open-package ( ihandle 0 )
```

Table 4-2 Manipulating phandles and ihandles

| Name | Stack Comment | Description |
| :--- | :--- | :--- |
| my-self | (-- ihandle ) | Return the instance handle of the currently-executing package <br> instance. |
| my-parent | Return the instance handle of the parent of the currently-executing <br> package instance. |  |
| ihandle>phandle | ( ihandle -- phandle ) | Convert an instance handle to a package handle. |
| close-package | ( ihandle -- ) | Close an instance of a package. |

Don't confuse phandle with ihandle. Here's how to use them:

1. Find the phandle of a package.
2. Use this phandle to open an instance of the package; this will give an ihandle.
3. Use the ihandle to access the methods of the package.
4. When done accessing the methods of the package, use the ihandle to close the instance of the package with close-package.

Use ihandle>phandle to open another instance of the current package or its parent. my-self and my-parent return ihandles, which can be converted into phandles with ihandle>phandle.

To open another instance of the current package, use:

## my-self ihandle>phandle open-package

To open another instance of the parent package, use:

[^1]
## Instance Arguments and Parameters

An instance argument (my-args) is a string that is passed to a package when it is opened. The string may contain parameters of any sort, based on the needs of the package, or can simply be a null-string if no parameters are needed. A null string is generated either with " " or 00.

The instance argument passed may be accessed from inside the package with the my-args FCode.

Note - A package is not required to inspect the passed arguments.

If the argument string contains several parameters separated by a common character, you can pick off the pieces from within the package with left-parse-string. You can use any character as the separator; a comma is commonly used for this.

Note - Avoid using blanks or the / character, since these will confuse the parsing of any pathname.

A new value for my-args is passed every time a package is opened. This can happen under a number of circumstances:

1. The my-args string will be null when FCode on an SBus card is interpreted automatically by the OpenBoot system at power-on.
2. The my-args string is determined by a parameter to the begin-package tool used to set up the device tree when FCode is downloaded and interpreted interactively.
3. The my-args string can be set with set-args before a particular slot is probed, if SBus probing is being controlled from nvramrc.

The above three instances happen only once, when the package FCode is interpreted for the first time. If you want to preserve the initial value for myargs, the FCode program should copy it into a local buffer to preserve the information.

Whenever a package is reopened, a new value for my-args is supplied at that time. The method for supplying this new value depends on the method used to open the package, as described below.
4. The instance argument (my-args) is supplied as a string parameter to the commands open-package or \$open-package.
5. Monitor commands, such as select-dev, test, and execute-devicemethod, supply the entire pathname to the device being opened. This approach lets an instance argument be supplied as part of the pathname itself. For example, to open the SBus device "SUNW,bwtwo" with the argument string " $5,3,0$ ", enter:

```
ok " /sbus/SUNW,bwtwo:5,3,0" select-dev
ok
```

A more complicated (and fictitious) example is the following:

```
ok " /sbus/SUNW,fremly:test/grumpin@7,32:print/SUNW, fht:1034,5"
ok select-dev
ok
```

Here the string "test" is passed to the SUNW, fremly package as it is opened, the string "print" is passed to the grumpin package as it is opened, and the string " 1034,5 " is passed to the SUNW, fht package as it is opened.

## Package Addresses

Another piece of information available to a package is its address relative to its parent package. Again, there are two main ways to pass this address to the package:

- Part of the pathname of the package
- A string parameter given to the probe words

As an example of the first method, suppose the following package is being opened:

## ok "/sbus/esp/sd@3,0:b" select-dev

Then the address of the /sd package relative to the /esp package is 3,0 . Note that this address must match the initial value of the "reg" property (if present) of the /sd package.

The package can find its relative address with my-unit, which returns the address as a pair of numbers. The first number (high) is the number before the comma in the example above, and the second number (low) is the number after the comma. Note that these are numbers, not strings.

As an example of the second method, suppose a test version of an FCode package is being interpreted:

```
ok 0 0 " 3,0" " /sbus" begin-package
ok
```

Here the my-args parameters for the new FCode are null, the initial address is 3,0 and it will be placed under the /sbus node.

The initial address can be obtained through my-address and my-space. Typically, you use my-space and my-address (plus an offset) to create the package's "reg" property, and also to map in needed regions of the device.

## Executing Methods

A method is identified by its execution token, which is returned by findmethod for other packages. The token is actually the Forth acf for the word. For words in the package being defined, the Forth word ['] returns an execution token.

The execution token is used to execute a method in another package, and also to schedule a method for automatic, repeated execution by the system clock interrupt. See the alarm FCode.

Accessing the methods of a package can be done in one of the following ways (there are other ways as well, but these cover the common cases), with the last approach generally the best:

```
$open-package $call-method
find-package open-package $call-method
find-package open-package find-method call-package
```

Because finding is inherently a slow process, if a method is to be used repeatedly, the last technique is recommended. The idea is to save the ihandle and phandle of the package in question, together with the execution token of the method needed, so that the overhead of finding them gets paid only one time, instead of every time the method is executed.

For example, the following method is simple, but if slow called repeatedly:

```
: add-offset ( x.byte# -- x.byte#' )
    my-args " disk-label" $open-package (ihandle)
    " offset" rot (name-adr name-len ihandle)
    $call-method
;
```

A more complex, but if called repeatedly, much faster construct:

```
value label-ihandle \ place to save the other package's ihandle
O value offset-method \ place to save found method's acf
: init ( -- )
        my-args " disk-label" $open-package ( ihandle ) is label-ihandle
        " offset" label-ihandle ihandle>phandle ( name-adr name-len phandle ) find-method if
            ( acf ) is offset-method
        else ." Error: can't find method"
    then
;
: add-offset ( d.byte# -- d.byte#' )
    offset-method label-ihandle call-package
;
```

Because device access time often dominates I/O operations, the benefit of this extra code probably won't be noticed. It is only justified if the particular method will be called often.

A shortcut word to call a method in the parent package is $\$ c a l l-p a r e n t$. This is equivalent to using my-parent \$call-method.

Table 4-3 Method-Access Words

| Name | Stack Comment | Description |
| :--- | :--- | :--- |
| find-method | (adr len phandle -- false $\mid$ acf <br> true ) | Find the method named adr len within the package phandle. <br> Returns false if not found. |
| call-package | $([\ldots]$ acf ihandle -- [...] ) | Execute the method acf within the instance ihandle. |
| \$call-method | $([\ldots]$ adr len ihandle -- [...]) | Shortcut word to find and execute the method adr len within <br> the package instance ihandle. |
| \$call-parent | $([\ldots]$ adr len -- [...]) | Execute the method adr len within the parent's package <br> instance. Exactly equivalent to calling my-parent \$call- <br> method. |

## Debugging Packages

## Package Mappings

Mappings set up by a package persist across instances (unless explicitly unmapped). Passing the mapped addresses between instances is not usually worth the convolutions involved. It is usually better for each new instance to do its own mappings, being sure to unmap resources as they are no longer needed.

If you save virtual addresses into a value, be sure to use the instance declarations (see "Package Data Definitions" on page 41).
nvramrc
Machines that support packages will generally also support the nvramrc facility. nvramrc is a special area in the NVRAM that can contain Monitor commands to be executed by OpenBoot as the machine powers on. These commands can be used to specify behavior during start up or to define changes for later execution.

For example: assume a card in SBus slot\#2 (named XYZ, me) needs custom attributes set by the user. nvramrc contents would include:

```
probe-all
cd /sbus/XYZ,me
" type5" xdrstring " xyzmode" attribute
device-end
install-console
banner
```

After editing nvramrc, turn on the nvram parameter use-nvramrc? and reset the machine to activate the contents of nvramrc. See OpenBoot Command Reference for more about editing nvramrc contents.

## Modifying Package Properties

To modify the properties of a package, first probe the package to get it into memory. Normally, probing is done automatically after the nvramrc commands are executed.

See Chapter 5, "Properties", for more information about properties.

## Standard Support Packages

The /packages node of the device tree is special. It is a hierarchical node, but instead of describing a physical bus, /packages serves as a parent node for some software package nodes. The children of /packages are generalpurpose software packages not attached to any particular hardware device. The "physical address space" defined by /packages is a trivial one: all addresses are the same - 0,0 . Its children are distinguished by name alone.

The children of /packages are used by other packages to implement commonly used functions. They may be opened with the FCodes openpackage or \$open-package, and closed with close-package. There are three support packages that are included as standard children of /packages.

## Sun Disk-Label Support Package

Disk (block) devices are random-access, block-oriented storage devices with fixed-length blocks. Disks may be subdivided into several logical "partitions", as defined by a disk label-a special disk block, usually the first one, containing information about the disk. The disk driver is responsible for appropriately interpreting a disk label. The driver may use the standard support package /disk-label if it does not implement a specialized label.
/disk-label interprets a standard Sun disk label, reading any "partitioning" information contained in it. It includes a first stage disk boot protocol for the standard label. load is the most important method defined by this package.

This package uses the read and seek methods of its parent (in practice, the package which opens this one to use the support routines). /disk-label defines the following methods:

Table 4-4 Sun Disk Label Package Methods

| Name | Stack diagram | Description |
| :---: | :---: | :---: |
| open | (-- flag) | Reads and verifies the disk label accessed by the read and seek methods of its parent instance. Selects a disk partition based upon the text string returned by my-args. For the standard Sun disk label format, the argument is interpreted as follows: |
|  |  | Argument ${ }^{\text {P }}$ Partition |
|  |  | <none> ${ }^{\text {¢ }}$ |
|  |  | a or A 0 |
|  |  | b or B 1 |
|  |  | ... |
|  |  | g or G |
|  |  | Returns - 1 if the operation succeeds. As a special case, if the argument is the string "nolabel", open returns -1 (success) without attempting to read or verify the label. |
| close | (--) | Frees all resources that were allocated by open. |
| load | (adr -- size) | Reads a stand-alone program from the "standard" disk boot block location for the partition specified when the package was opened. Places the program at memory address adr, returning its length size. For the standard Sun disk format, the stand-alone program is 7.5 K bytes beginning 512 bytes from the start of the partition. |
| offset | (x.rel-- x.abs) | Returns the 64-bit absolute byte offset x . abs corresponding to the 64-bit partition-relative byte offset x.rel. In other words, adds the byte location of the beginning of the selected partition to the number on the stack. |

## TFTP Booting Support Package

The / obp-tftp package implements the Internet Trivial File Transfer Protocol (TFTP) for use in network booting. It is typically used by a network device driver for its first stage network boot protocol. Again, load is the most important method defined by this package.

This package uses the read and write methods of its parent, and defines the following methods:

Table 4-5 TFTP Package Methods

| Name | Stack diagram | Description |
| :--- | :--- | :--- |
| open | $(--$ flag) | Prepares the package for subsequent use, returning -1 if the operation <br> succeeds and 0 otherwise. |
| close | $(--)$ | Frees all resources that were allocated by open. |
| load | Reads the default stand-alone program from the default TFTP server, <br> placing the program at memory address adr and returning its length size. <br> For the standard Sun TFTP booting protocol, RARP (Reverse Address <br> Resolution Protocol) is used to acquire the IP address corresponding to the <br> system's MAC address (equivalent to its Ethernet address). From the IP <br> address, the default file name is constructed, of the form <Hex-IP- <br> Address>.<architecture> (for example, C0092E49. SUN4C). Then obp-tftp <br> tries to TFTP read that file, first trying the server that responded to the <br> RARP request, and if that fails, then broadcasting the TFTP read request. |  |

## Deblocker Support Package

The / deblocker package makes it easy to implement byte-oriented device methods, using the block-oriented or record-oriented methods defined by devices such as disks or tapes. It provides a layer of buffering between the high-level byte-oriented interface and the low-level block-oriented interface. /deblocker uses the max-transfer, block-size, read-blocks and write-blocks methods of its parent, and defines the following methods:

Table 4-6 Deblocker Package Methods

| Name | Stack diagram | Description |
| :--- | :--- | :--- |
| open | $(--$ flag) | Prepares the package for subsequent use, allocating the buffers used by the <br> deblocking process based upon the values returned by the parent instance's max- <br> transfer and block-size methods. Returns -1 if the operation succeeds, 0 <br> otherwise. |
| close | $(--)$ | Frees all resources that were allocated by open. |

## Table 4-6 Deblocker Package Methods

| Name | Stack diagram | Description |
| :--- | :--- | :--- |
| read | (adr len -- actual) | Reads at most len bytes from the device into the memory buffer beginning at adr. <br> Returns actual, the number of bytes actually read, or 0 if the read operation <br> failed. Uses the parent's read-blocks method as necessary to satisfy the request, <br> buffering any unused bytes for the next request. |
| write | (adr len -- actual) | Writes at most len bytes from the device into the memory buffer beginning at adr. <br> Returns actual, the number of bytes actually read, or 0 if the write operation <br> failed. Uses the parent's write-blocks method as necessary to satisfy the <br> request, buffering any unused bytes for the next request. |
| seek | (x.position -- flag) | Sets the device position at which the next read or write will take place. The <br> position is specified by the 64-bit number x.position. Returns 0 if the operation <br> succeeds or -1 if it fails. |

三 4

## Properties

Properties are created by FCode PROMs. The CPU's boot PROM understands certain property names that tell it things such as the type of the device (disk, tape, network, display, and so on). The CPU boot PROM may use this information to determine how to use the device (if at all) during the boot process.

SunOS understands other property names that give information used for configuring the operating system automatically. These properties include the driver name, the addresses and sizes of the device's registers, and interrupt levels and interrupt vectors used by the device.

Other properties may be used by individual SunOS device drivers. The names of such properties and the interpretation of their values is subject to agreement between the writers of the FCode PROM and the SunOS driver, but may otherwise be arbitrarily chosen. For example, a display device might declare width, height, and depth properties to allow a single SunOS driver to automatically configure itself for one of several similar but different devices.

A package's properties identify the characteristics of the package and its associated physical device, if any. You can create a property either with the attribute FCode, or with the name, reg, intr, model, and device-type FCodes, described below.

For example, a framebuffer package might export its register addresses, interrupt levels, and framebuffer size. Every package has an associated property list, which is arbitrarily extensible. Use the Forth Monitor command . attributes to display the names and values of the current node's properties.

Each property has a property name and a property value.

- The property name identifies the particular property. This name is composed of a string of printable characters. Uppercase characters should not be used in the name string since some systems may convert them to lower case.
- The property value specifies the contents, or value, of a particular property. The value is an array of bytes that may be used to encode integer numbers, text strings, or other forms of information.

Many derived data types can be encoded into the primitive "array of bytes" data type, for example:

- integer. Encoded as 4 bytes, big endian
- text string. Encoded as a null-terminated sequence of bytes
- physical address range. Encoded as 3 integers: space, offset, size
- structure. The concatenation of other types, with no padding or internal alignment
- array. The concatenation of $n$ examples of some type

If an FCode program tries to create the same property (with the same name) more than once for a given package, the new property supercedes the old one.

You can add new properties during the lifetime of a product. For backward compatibility, an FCode or device driver program that needs the value of a particular property should consider the possibility that the property does not exist, in which case the program should supply its own default value.

## Standard FCode Properties

A number of FCode properties have been defined and used by some or all current implementations of OpenBoot. These are listed below.

A package should never create any property using any of the following names, unless the defined meanings and structures are used. Doing otherwise can result in system errors occurring.

## Standard FCode Properties For Cards (General)

- address
- device_type
- interrupts
- intr
- model
- name
- params
- parity-generated
- reg
- slave-burst-sizes
- status

## Device-type Specific Properties For SBus Cards

- address-bits, (network)
- character-set, (display)
- down-burst-sizes, (sbus)
- local-mac-address, (network)
- mac-address, (network)
- max-frame-size, (network)

General Properties For Parent Nodes

- clock-frequency
- ranges
- scsi-initiator-id

## Properties For SBus Parent Nodes

- burst-sizes
- bus-parity-generated
- one-pending-retry
- slave-only
- slot-address-bits
- up-burst-sizes

## Standard Properties

## "address"

This is an optional property that declares currently-mapped device virtual addresses. It is generally used to declare large regions of existing mappings, in order to enable the SunOS device driver to reuse those mappings to conserve system resources.

The contents of the property are an arbitrary number of virtual addresses. The correspondence between declared addresses and the set of mappable regions of a particular device is device-dependent.

```
-1 value my-buffers
-1 value my-dma-adr
: map-me ( -- )
    my-address 10.0000 + my-space 1.0000 "map-in" $call-parent ( virt1 )
    is my-buffers
    2000 " dma-alloc" $call-parent ( virt2 ) is my-dma-adr
    my-buffers xdrint my-dma-adr xdrint xdr+ " address" attribute
;
: unmap-me ( -- )
    my-dma-adr 2000 " dma-free" $call-parent
    my-buffers 1.0000 " map-out" $call-parent
    " address" delete-attribute
;
```

See also: free-virtual, attribute

## "address-bits"

This optional property, when declared in "network" devices, indicates the number of address bits needed to address this device on its network. Used as:
d\# 48 xdrint " address-bits" attribute

See also: attribute and Chapter 9, "Network Devices".

## "burst-sizes"

This required property is located in every SBus controller node in the system. Its value is a bit mask of burst transfer sizes supported by this SBus implementation. If bit $n$ is 1 , then transfer size $2^{n}$ bytes is supported. For instance, 9 means that 8 -byte and 1-byte transfers are supported.

Support for the extended (64-bit) SBus protocol is also indicated by this property, using the next-higher 16 bits of the value.

Thus, an SBus controller which supports transfer sizes of 1,2,4,8,16,32,64 bytes would have a "burst-sizes" value of 0x007f. An SBus controller which also supports extended ( 64 -bit) transfers of $8,16,32,64,128$ bytes would have a "burst-sizes" value of 0x00f8007f.

Notice that particular destination devices may be more restrictive in the allowed transfer sizes. This property only describes the transfer sizes allowed by the SBus controller itself.

It is acceptable for an SBus controller to omit this property, as long as some parent node is assured of having the correct value. A plug-in device should use get-inherited-attribute to query this property.

Some early systems only support 16-byte bursts (as well as 1,2,4 byte transfers), but do not declare the "burst-sizes" property at all. Thus, a missing "burst-sizes" should be assumed to be equivalent to a "burstsizes" value of $0 \times 0017$. Used as:
h\# 7f xdrint " burst-sizes" attribute
See also: slave-burst-sizes, attribute, Chapter 8, "Hierarchical Devices".

## "bus-paritygenerated"

This optional property, when present on an SBus controller node, indicates that this SBus is generating parity on SBus transactions. A null value is used.

See also Chapter 8, "Hierarchical Devices".

## "character-set"

This optional property, when declared in "display" or "serial" devices, indicates the recognized character set for this device. The contents are a text string.

A typical value is "ISO8859-1". 8859-1 is the number of the ISO specification for that particular character set, which essentially covers the full range of western European languages. To get a list of possible values, consult the $X$ registry. There is an address for it in the X11R5 documentation.

Used as:
" ISO8859-1" xdrstring " character-set" attribute

See also: attribute, Chapter 7, "Display Devices" and Chapter 10, "Serial Devices".

## "clock-frequency"

This property may be queried (using get-inherited-attribute) by a plugin device, to determine the clock frequency for this bus (if appropriate). The value is returned in Hertz (cycles per second).

Any bus nexus node implementing a bus with a basic clock frequency (such as SBus) must either publish this property, or ensure that the correct value will be returned if a child queries for this value using get-inherited-attribute. For example:

```
d# 2.000.000 xdrint
" clock-frequency" attribute
```

See also: Chapter 8, "Hierarchical Devices".

## "device_type"

This optional property declares the type of this plug-in device. The type need not be declared, unless this device is intended to be usable for booting. If this property is declared, using one of the following key values listed next, then the

FCode program must follow the required conventions for that particular type of device, by implementing a specified set of properties and procedures (methods). Used as:
" display" xdrstring " device_type" attribute
Defined key values for this property are:
Table 5-1 Standard Device Types

| Device Type | Device Characteristics |
| :--- | :--- |
| display | Framebuffer or other similar display device, usable for message display during booting. See <br> Chapter 7, "Display Devices" for the requirements of this type of device. |
| network | Packet-oriented network device, such as Ethernet, usable as a boot file source. See Chapter 9, <br> "Network Devices" for the requirements of this type of device. |
| block | Random-access, block-oriented device, such as a disk drive, usable as a boot file source. See <br> Chapter 6, "Block and Byte Devices" for the requirements of this type of device. |
| byte | Random-access, byte-oriented device, such as a tape drive, usable as a boot file source. See <br> Chapter 6, "Block and Byte Devices" for the requirements of this type of device. |
| serial | Byte-oriented device, such as a serial port, usable for console input and/or console output. See <br> Chapter 10, "Serial Devices" for the requirements of this type of device. <br> SBus controller node, which lets you attach plug-in SBus devices. Some SBus controller nodes set <br> their "device_type" "hierarchical" and set their "name" to "sbus". See Chapter 8, <br> "Hierarchical Devices" for the requirements of this type of device. |

See also: device-type, attribute

## "down-burst-sizes"

This optional property, when declared in an SBus slave acting as a bus bridge (such as an "sbus" device), denotes transfer sizes allowed to the subordinate bus. The value is encoded similarly to "burst-sizes".

See also Chapter 8, "Hierarchical Devices".

## "interrupts"

This optional property declares the interrupt level(s) for this plug-in device. The contents are one or more integers. Note that the bus-level interrupt (not the CPU-level interrupt) is specified.

For SBus devices, SBus interrupt levels 1-7 are allowed. The correct choice for your interrupt level will depend on your latency requirements. Typical usage is: video - SBus level 5, Ethernet - SBus level 4, SCSI and DMA - SBus level 3. SBus levels 6 and 7 should only be used with great care, otherwise significant system performance degradation may occur.

Because of previous usage of the "intr" property instead of the "interrupts" property in earlier systems, we recommend that both "intr" and "interrupts" be declared in FCode for SBus cards. However, cards which only declare "intr" should continue to work, as current systems automatically generate the "interrupts" property for you as required.

To declare a single interrupt (level 5), used as:

```
5 xdrint " interrupts" attribute
5 0 intr
```

To declare two interrupts (levels 3 and 5), used as:

```
xdrint 3 xdrint xdr+ " interrupts" attribute
sbus-intr>cpu xdrint \ Interrupt#1
    xdrint xdr+ \ Null vector#1
sbus-intr>cpu xdrint xdr+ \ Interrupt#2
    xdrint xdr+ \ Null vector#2
intr" attribute
```

See also: "intr", intr, attribute

## "intr"

This property was used in early systems, but has now been superceded by the "interrupts" property.

Creation of this property automatically creates an "interrupts" property in most systems, except in the case where an "interrupts" property has already been created by the FCode for this device.

See also: "interrupts", intr, attribute

## "local-mac-address"

This optional property, when declared in "network" devices, indicates the built-in Media Access Control address for this device (if any). The system may or may not use this address in order to access this device.

Used as:
" "(08,04,fe,23,46,9e)" xdrbytes " local-mac-address" attribute

See also: mac-address, "mac-address", attribute, and Chapter 9, "Network Devices".

## "mac-address"

This property must be declared in "network" devices, to indicate the Media Access Control (MAC) address that this device is currently using. This value may or may not be the same as the "local-mac-address" property, if any.

Here's how it all fits together.

1. If a plug-in device has an assigned MAC address from the factory, this address is published as the value for "local-mac-address".
2. The system (based on various factors such as presence or absence of "local-mac-address" and/or the value of the NVRAM parameter "local-mac-address?") decides which address it prefers the plug-in device to use. The value returned by the mac-address FCode is set to this address.
3. The plug-in device then reports the address which it is actually using, by publishing the "mac-address" property.

Following are code examples for three typical situations.
For a well-behaved plug-in "network" device (which has a factory-unique MAC address but can use another system-supplied MAC address if desired by the system), the FCode would appear as:

```
" "(08,04,fe,23,46,9e)" xdrbytes " local-mac-address" attribute
mac-address xdrbytes " mac-address" attribute
(plus code to "assign" the correct mac-address value into registers)
```

For a plug-in "network" device that has a factory-unique MAC address and is unable to alter its behavior to a different address, the FCode would appear as:

| " "(08,04,fe, 23, 46,9e)" | xdrbytes | " local-mac-address" | attribute |
| :--- | :--- | :--- | :--- | :--- |
| " "(08,04,fe, $23,46,9 e) "$ | xdrbytes | " mac-address" | attribute |

For a plug-in "network" device which does not have any built-in MAC address, the FCode would appear as:

| mac-address |  |
| :--- | :--- |
| (plus code to "assign" the correct mac-address value into registers) | attribute |

See also: mac-address, "local-mac-address", attribute and Chapter 9, "Network Devices".

## "max-frame-size"

This optional property, when declared in "network" devices, indicates the maximum allowable size of a packet (in bytes). Used as:

$$
4000 \text { xdrint " max-frame-size" attribute }
$$

See also: attribute and Chapter 9, "Network Devices".

## "model"

This optional property identifies the model name/number for a plug-in card, for manufacturing and field-service purposes.

The "model" property is useful to identify the specific piece of hardware (the plug-in card), as opposed to the "name" property (since several different but functionally-equivalent cards would have the same "name" property, thus calling the same device driver). Although the "model" property is good to have in general, it generally does not have any other specific purpose.

Used as:

[^2]See also: model, attribute

## "name"

This property is used to match a particular SunOS device driver with the appropriate plug-in device. All device nodes must publish this property.

The contents are an arbitrary string. Any combination of printable characters is allowed, except for "@", ":" or "/". Embedded spaces are not allowed. The convention is to use a string of the form SUNW, xxxxxx.
(In place of SUNW, use your company's over-the-counter stock symbol. If you're not a publicly-traded company, pick a name that isn't being used.) This technique greatly reduces the chance that the value for your name property will accidentally collide with a name chosen by someone else.

Used as:
" SUNW,bison-printer" xdrstring " name" attribute

The name command may also be used to create this property.
See also: name, attribute, device-name.

## "one-pending-retry"

This optional property, if present in the SBus controller node, indicates a system restriction on the use of SBus retry cycles. A null value is used.

If this property is present, the SBus controller restricts retries from a particular slot to use the same address until the retry cycle is completed, as opposed to being able to interleave retries with different addresses.

Any SBus master capable of interleaving pending retries with accesses to other addresses, must check for the absence of this property in the parent before enabling that feature. Used as:

```
0 0 " one-pending-retry" attribute
```

See also: Chapter 8, "Hierarchical Devices".

## "params"

This optional property contains the information to be passed when the myparams FCode is executed. This feature is obsolescent and should not be used.

See also: my-params, attribute.

## "parity-generated"

This optional property, if present, indicates that this SBus device is currently generating correct parity on the SBus. This means that whenever this device presents data (or a virtual address) on the SBus data lines, the Parity signal is also driven to correct (odd) parity. The value of the property is null.

This does not deal with the methods for enabling or disabling parity checking. Presence of this property merely provides the necessary information to determine that parity is being generated, so that any decision as to whether or not to check parity can be made with adequate information.

If the device has the capability to turn parity-generation on and off, this property should be created and deleted accordingly. Used as:

## 0 0 " parity-generated" attribute

See also: attribute.

## "ranges"

The ranges property is a list of child-to-parent physical address correspondences required for most hierarchical devices.
ranges is a property for bus devices, particularly those buses whose children can be accessed with CPU load and store operations (as opposed to buses like SCSI, whose children are accessed with a command protocol).

The ranges property value describes the correspondence between the part of the physical address space of the bus node's parent available for use by the bus node (the parent address space), and the physical address space defined by the bus node for its children (the child address space).

The ranges property value is a sequence of

> child-phys parent-phys size
specifications.

- child-phys is a starting address in the child physical address space defined by the bus node
- parent-phys is a starting address in the physical address space of the parent of the bus node
- size is the length in bytes of the address range.

The specification means that there is a one-to-one correspondence between the child addresses and the parent addresses within that range. The parent addresses given are always relative to the parent's address space.

Each starting address is represented using the physical address representation as two 32 -bit numbers (one for space and one for offset). size is encoded as an unsigned integer.

The total size of each such specification is five 32-bit numbers (two for each of the two addresses, plus one for the size). Successive specifications are encoded sequentially. A space with length $2^{* *}$ (number of bits in a machine word) is represented with a size of 0 .

The specifications should be sorted in ascending order of the child address. The address ranges thus described need not be contiguous in either the child space or the parent space. Also, the entire child space must be described in terms of parent addresses, but not all of the parent address space available to the bus device need be used for child addresses (the bus device might reserve some addresses for its own purposes, for instance).

For example, suppose that a 4 -slot 25 -bit SBus is attached to a machine whose physical address space consists of a 32-bit "memory" space (space=0) and a 32bit "io" space (space=1). The SBus slots appear in "io" space at address 0xf800.0000, 0xfa00.0000, 0xfc00.0000, and 0xfe00.0000. In terms of the SBus's parent address space, the SBus device has available for its purposes the offsets from 0xf800.0000 through 0xffff.ffff in space 1 of its parent.

The SBus device defines for its children the spaces $0,1,2$, and 3 , all starting at offset 0 and running for $0 \times 200.0000$ bytes. In this case the SBus device uses all the address space given to it by its parent for the SBus children, and reserves none of the addresses for itself. The ranges property for the SBus device would contain the encoded form of the following sequence of numbers:

Table 5-2 Child-Parent Address Relationships

| Child Address |  | Parent Address |  |  |
| :---: | :---: | :---: | :---: | :--- |
| Space, Offset |  | Space, | Offset |  |
| 0, | 0 | 1, | f800.0000 | 200.0000 |
| 1, | 0 | 1, | fa0.00000 | 200.0000 |
| 2, | 0 | 1, | fc00.0000 | 200.0000 |
| 3, | 0 | 1, | fe00.0000 | 200.0000 |

Here the high components of the child address represent the SBus slot numbers, and the high component of the parent address represents "io space."

If ranges exists but its value is of 0 length, the bus's child address space is identical to its parent address space.

If the ranges property for a particular bus device node is nonexistent, code using that device should use an appropriate default interpretation. Some examples include the following:

- SBus node: Missing ranges means that the version of OpenBoot was created before the ranges property came into existence. Code should supply the correct ranges based on the machine type, from the finite set of machines that existed before ranges came into existence.
- Machine node: The machine node has no parent. Therefore the correspondence between its child and parent address spaces is meaningless, and there is no need for ranges.
- SCSI host adapter node: The child address space is not directly addressable, thus ranges would be meaningless.

The distinction between reg and ranges is as follows:

- reg is supposed to represent the actual device registers in the parent address space. For a bus adapter, this would be such as configuration/mode/initialization registers.
- ranges represents the correspondence between a bus adapter's child and parent address spaces.

Most packages do not need to be concerned with ranges. These properties are mainly to communicate with stand-alone programs. One exception could be a bus extender or adaptor.

See also: Chapter 8, "Hierarchical Devices".

## "reg"

This property declares the location and size of onboard registers for its device. The FCode program for every plug-in SBus device must declare this property.
The contents are one or more (phys, size) pairs. Each pair specifies an addressable region of the device. An FCode PROM at location 0 of the device is generally not declared, except in the case where there are no other regions to declare.

For example, to declare two register fields at 10.0000-10.00ff and 20.000020.037f, use the following:

In some cases, the reg command may also be used to create this property.
See also: reg, attribute.

## "scsi-initiator-id"

This optional property is located in one of the parent nodes of the system. It may be queried (using get-inherited-attribute) by a plug-in device. Its value is an integer, $0-15$, indicating the address of the main SCSI host adapter of this system (if any). The value also indicates the suggested address for the host adapter for any plug-in SCSI controller.

The SCSI controller node for a plug-in SCSI controller may also publish this property, to indicate the current address of this host adapter. Used as:

7 xdrint " scsi-initiator-id" attribute
See also: attribute.

## "slave-burst-sizes"

This optional property uses a bitmask to indicate the set of SBus transfer sizes which this device will accept. It contains a set of integer values. The number of entries is the same as the number of (phys,size) entries in the "reg" property, and each entry in "slave-burst-sizes" describes the transfer sizes accepted by the corresponding "reg" entry. The encoding of each "slave-burst-sizes" entry is the same as the encoding for the "burstsizes" property.

This property may be defined for any device which is capable of acting as an SBus slave. The value is a "hint" to the operating system, or to other devices which may desire to access this SBus device. Used as:

```
h# 3f xdrint h# 17 xdrint xdr+ " slave-burst-sizes" attribute
```

See also: burst-sizes, reg, attribute

## "slave-only"

This optional property, if present in the SBus controller node or other parent nodes, uses a bitmask to indicate that certain SBus slots support slave-only access. If bit n is 1 , then slot\#2 $\wedge^{\wedge} \mathrm{n}$ is slave-only. For example, a value of 8 indicates that slot\#3 is slave-only.

A plug-in device should use get-inherited-attribute to query this property.

If this property is not found (for example, if the system contains a version 1 boot PROM that was released before this property was defined), then slot\#3 is slave-only.

This affects SPARCstation1 and SPARCstation 1+ only (SPARCstation IPC only has two slots). Used as:
8 xdrint " slave-only" attribute

See also: attribute and Chapter 8, "Hierarchical Devices".

## "slot-address-bits"

This required property in the SBus controller node specifies the number of address lines available to each SBus card. Typical values are either 25 or 28. It is acceptable for an SBus controller to omit this property, as long as some parent node is assured of having the correct value. A plug-in device should use get-inherited-attribute to query this property.

If this property is not found (for example, if the system contains a version 1 boot PROM that was released before this property was defined), then a value of 25 should be assumed. Used as:

```
d# 25 xdrint " slot-address-bits" attribute
```

See also: attribute.

## "status"

This optional property indicates that this device has failed an internal selftest and is thus unavailable for use.

Absence of this property means that this device is believed to be operational.
If this property is present, the value is a string indicating the status of the device, as follows:

Table 5-3 status Property Values

| Status Value | Meaning |
| :--- | :--- |
| "okay" | The device is believed to be operational. <br> "disabled" <br> The device represented by this node is not operational, but it might become operational in the <br> future (e.g. an external switch is turned off, or something isn't plugged in). |
| "fail- $x x x$ " | The device represented by this node is not operational because a fault has been detected, and it is <br> unlikely that the device will become operational without repair. No additional failure details are <br> available. |
| The device represented by this node is not operational because a fault has been detected, and it is <br> unlikely that the device will become operational without repair. "xxx" is additional human- <br> readable information about the particular fault condition that was detected. |  |

Used as:
" disabled" xdrstring " status" attribute

See also: attribute.

## "up-burst-sizes"

This optional property, when present on an SBus controller node, indicates the set of allowed transfer sizes up though the node to its parent bus. The value is encoded similarly to that of "burst-sizes".

See also: Chapter 8, "Hierarchical Devices".

## Manipulating Properties

## Property Creation and Modification

By far the most common activity done with a property is to create or modify one. The FCode attribute is the general property publishing word. It will create a new property or change the value of an existing property for the current package.

There are some special property publishing FCodes, designed for use in common situations:

- reg is used to create a "reg" property that describes where the package's physical resources are located.
- intr creates "intr" and "interrupts" properties to describe what interrupts and vectors are used by the physical hardware of the package.
- model can be used to create the "model" property to differentiate among similar packages.
- name is an FCode macro for creating the "name" property.
- device-name can also be used to create the "name" property.
- Use delete-attribute to completely remove a property.

## Property Values

Various kinds of information may be stored in a property value byte array by using an external data representation (xdr) encoding/decoding method. The encoding format is machine-independent; the representation of the property values is independent of the byte organization and word alignment characteristics of particular processor.

Note - This encoding is not related to xdr-type encodings described in architecture documents for various other computer systems.

The data type of any particular property must be implicitly known by any software that wishes to use it. In other words, property value data types are not self-identifying. Furthermore, the presence or absence of a property with a particular name can encode a true/false flag; such a property may have a zerolength property value.

## Property Encoding

The second most common activity in connection with properties is to encode the value for a property in the external data representation, usually in preparation for publishing the property using attribute. There are four FCodes used to encode a basic piece of data, and one FCode for amalgamating the basic pieces for a property that has multiple values.
xdrint encodes a number. xdrstring encodes a string. xdrphys encodes a physical address (hiding all the relative addressing information). And finally, xdrbytes encodes a sequence of bytes.
$x d r+$ is used to amalgamate two basic pieces of data.

## Property Retrieval

Somewhat less common is for a package to retrieve the value of a property. There are three property value retrieving words, get-my-attribute, get-inherited-attribute, and get-package-attribute.

- Use get-inherited-attribute if the property in question is one that exists somewhere in the chain of parent instances between the package being defined and the root node of the machine.
- Use get-my-attribute if the property desired already exists for the package being defined.
- Use get-package-attribute if the property exists in some other support package. In this last case, you must find the support package first to get its phandle.

For an example, suppose a particular SBus FCode package wants to use DVMA to transfer some data between a device and memory.

It could use get-inherited-attribute to find the value of a property named slave-only. slave-only will be a property of one of the parent nodes of the package being defined, if it exists.

The value of the property is a bitmask of the SBus slots that do not support DVMA. Then the package would look at my-unit or my-space to get its slot number. The two pieces of information will tell the package whether or not it can use DVMA.

## Property Decoding

Once a package has searched for and found the value of a property of interest, it must decode the value to forms it can understand. Usually the value is the representation of an integer; use xdrtoint to generate the actual number as a binary number on the stack. Occasionally the value of interest is the representation of a string, in which case use xdrtostring. Both of these FCodes act as parsers - they will also return the unused portion of the value for further decoding.

Other kinds of values can be decoded by left-parse-string or packagespecific decoders. Note that the package must know how to decode the value of a property it wishes to use.

## Property-Specific FCodes

Following is a summary of attribute-specific FCodes. Those introduced with OpenBoot 2.0 are noted by V2. See the individual dictionary entries in Chapter 11, "FCode Dictionary" for more information.

Table 5-4 Property-specific FCodes

| Name | Stack Comment | Description |
| :---: | :---: | :---: |
| Property Creation |  |  |
| attribute | ( xdr-adr xdr-len name-adr name-len -- ) | Create an property named name-adr name-len, with the value xdr -adr xdr -len. |
| device-type | ( adr len -- ) | Shorthand word to create the "device_type" property, with the value adr len. |
| intr | ( intr-level vector -- ) | Shorthand word to create the "intr" and "interrupts" properties. |
| model | ( adr len -- ) | Shorthand word to create the "model" property, with the value $a d r$ len. |
| name | ( adr len -- ) | Shorthand macro to create the "name" property, with the value adr len. |
| reg | ( phys space size -- ) | Shorthand word to create the "reg" property. |
| device-name | ( adr len -- ) | Shorthand word to create the "name" property, with the value adr len. Similar to name, but uses only one FCode instead of creating a macro. V2. |
| delete-attribute | ( name-adr name-len -- ) | Delete the desired property. V2. |
| xdr Encoding |  |  |
| xdrint | ( n -- xdr-adr xdr-len ) | Converts an integer to xdr-format. |
| xdrphys | ( phys space -- xdr-adr xdr-len ) | Converts a physical unit pair to xdr-format. |
| xdrstring | ( adr len -- xdr-adr xdr-len ) | Converts a text string to xdr-format. |
| xdr+ | ( xdr-adr1 xdr-len1 xdr-adr2 xdr-len2 --xdr-adr xdr-len1+2 ) | Merge two xdr-format structures. They must have been created sequentially. |
| xdrbytes | ( adr len -- xdr-adr xdr-len ) | Converts a byte array to xdr-format. Similar to xdrstring, except no trailing null is appended. <br> V2. |

Table 5-4 Property-specific FCodes (Continued)

| Name | Stack Comment | Description |
| :---: | :---: | :---: |
| xdr Decoding |  |  |
| xdrtoint | ( xdr-adr xdr-len -- xdr-adr2 xdr-len2 n ) | Converts an xdr-format string to an integer. V2. |
| xdrtostring | ( xdr-adr xdr-len -- xdr-adr2 xdr-len2 adr len ) | Converts an xdr-format string to a normal string. V2. |
| Attribute Retrieval |  |  |
| get-my-attribute | ( adr len -- true \| xdr-adr xdr-len false ) | Returns the xdr-format contents for the property adr len within the current instance, or true if not found. V2. |
| get-packageattribute | ```( adr len phandle -- true \| xdr-adr xdr- len false )``` | Returns the xdr-format contents for the property adr len within the package phandle, or true if not found. V2. |
| get-inheritedattribute | ( adr len -- true \| xdr-adr xdr-len false ) | Returns the xdr-format contents for the property adr len, or true if not found. The current package instance is searched first. If not found, the parent is searched next, then the parent's parent, and so on. V2. |

## Blockand Byte Devices

## Block Devices

Block devices are nonvolatile mass storage devices whose information can be accessed in any order. Examples of block devices include hard disks, floppy disks, and CD-ROMs. OpenBoot firmware typically uses block devices for booting.

This device type generally applies to disk devices, but as far as OpenBoot is concerned, it simply means that the device "looks like a disk" at the OpenBoot software interface level.

The block device FCode must declare the block device-type, and must implement the methods open and close, as well as the methods described below in "Required Methods" on page 78 ".

Although packages of the block device type present a byte-oriented interface to the rest of the system, the associated hardware devices are usually blockoriented i.e. the device reads and writes data in "blocks" (groups of, for example, 512 or 2048 bytes). The standard / deblocker support package assists in the presentation of a byte-oriented interface "on top of" an underlying block-oriented interface, implementing a layer of buffering that "hides" the underlying "block" length.

Block devices are often subdivided into several logical "partitions", as defined by a disk label - a special block, usually the first one, containing information about the device. The driver is responsible for appropriately interpreting a disk label. The driver may use the standard disk label support package if it does not
implement a specialized label. The /disk-label support package interprets a system-dependent label format. Since the disk booting protocol usually depends upon the label format; the standard disk label support package also implements a load method for the corresponding boot protocol.

## Byte Devices

Byte devices are sequential-access mass storage devices, for example tape devices. OpenBoot firmware typically uses byte devices for booting.

The byte device FCode program must declare the byte device type, and must implement the open and close methods in addition to those described in "Required Methods".

Although packages of the byte device type present a byte-oriented interface to the rest of the system, the associated hardware devices are usually recordoriented; the device reads and writes data in records containing more than one byte. The records may be fixed length or variable length. The standard /deblocker support package assists in presenting a byte-oriented interface on top of anderlying record-oriented interface, implementing a layer of buffering that hides the underlying record structure.

## Required Methods

## block-size( -- bytes )

All data transfers to or from the device are in records of $n$ bytes each. The most common value for n is 512 .

This method is only required if the / deblocker support package is used.
load( adr -- len )
load works a bit differently for block and byte devices:
With block devices, it loads a stand-alone program from the device into memory at adr. len is the size in bytes of the program loaded. If the device can contain several such programs, the instance arguments returned by myargs can be used to select the specific program desired. open is executed before load is invoked.

With byte devices, load reads a stand-alone program from the tape file specified by the value of the argument string given by my-args. That value is the string representation of a decimal integer. If the argument string is null, tape file 0 is used. load places the program in memory at adr, returning the size len of the read-in program in bytes.

```
max-transfer( -- bytes )
```

The size in bytes of the largest single transfer that the device can perform. max-transfer is expected to be a multiple of block-size.

This method is only required if the /deblocker support package is used.

```
read( adr len -- actual )
```

Read at most len bytes from the device into memory at adr. actual is the number of bytes actually read. If the number of bytes read is 0 or negative, the read failed. Note that len need not be a multiple of the device's normal block size.
read-blocks( adr block\# \#blocks -- \#read )
Read \#blocks records of length block-size bytes each from the device, starting at device block block\#, into memory at address adr. \#read is the number of blocks actually read.

This method is only required if the / deblocker support package is used.
seek ( poslow poshigh -- error? ) for block
( offset file\# -- error? ) for byte
seek works a bit differently depending on whether it's being used with a block or byte device.

For block devices, seek sets the device position for the next read or write. The position is the byte offset from the beginning of the device specified by the 64bit number which is the concatenation of poshigh and poslow. error? is 1 if the seek fails, and 0 if it succeeds.

For byte devices, it seeks to the byte offset within file file\#. If offset and file\# are both 0 , rewind the tape. error? is -1 if seek fails, and 0 if seek succeeds.
write ( adr len -- actual )
Write len bytes from memory at adr to the device. actual is the number of bytes actually written. If actual is less than len, the write did not succeed. If actual is -1 , some other error occurred. len need not be a multiple of the device's normal block size.
write-blocks ( adr block\# \#blocks -- \#written )
Write \#blocks records of length block-size bytes each to the device, starting at block block\#, from memory at adr. \#written is the number of blocks actually written.

This method is only required if the / deblocker support package is used.

## Required Properties

Table 6-1 Required Block Device Properties

| Property Name | Sample Value |  |
| :--- | :--- | :--- | :--- | :--- |
| name | "SUNW, googly" |  |
| reg | my-address h\# $12.0000+$ my-space $\mathrm{h} \#$ | 20 |
| device_type | " block" or " byte" |  |

## Device Driver Examples

The structure of the device tree for the sample card supported by the sample device drivers in this chapter is as follows:

Figure 6-1 Sample Device Tree

## Simple Block Device Driver

```
\ This is at a stage where each leaf node can be used only as a
\ non-bootable device.
\ It only creates nodes and publishes necessary properties
\ to identify the device.
fcode-version1
hex
    " SUNW,my-scsi" xdrstring " name" attribute
    3 xdrint " interrupts" attribute
    3 0 intr
    h# 20.0000 constant scsi-offset
    h# 40 constant /scsi
    my-address scsi-offset + my-space /scsi reg
    d# 25.000.000 xdrint " clock-frequency" attribute
    new-device \ missing "reg" indicates a SCSI "wild-card" node
        " sd" xdrstring " name" attribute
```

```
        finish-device
        new-device \ missing "reg" indicates a SCSI "wild-card" node
            " st" xdrstring " name" attribute
        finish-device
end0
```

## Extended Block Device Driver

```
\ sample driver for "my-scsi" device.
\ It is still a non-bootable device.
\ The purpose is to show how an intermediate stage of driver can
\ be used to debug board during development.
\ In addtion to publishing the properties, this sample driver
\ shows methods to access, test and control "SUNW,my-scsi" device.
\ Following main methods are provided for "SUNW,my-scsi" device.
\ open ( -- success? )
\ close ( -- )
\ reset ( -- )
\ selftest ( -- fail? )

## Display Devices

$7 \equiv$

This device type applies to framebuffers and other devices that appear to be memory to the processor with associated hardware to convert the memory image to a visual display. Display devices can be used as console output devices.

## Required Methods

The display device FCode must declare the display device-type, and must implement the methods open and close.

System defer words are loaded by appropriate routines. is-install, isremove and is-selftest are used to create the open, close and selftest routines.

For display devices, created methods interact with OpenBoot commands in a way that is different from that of other device types. Other device types provide methods that are found by dictionary searches looking for specific names.

Some FCodes are specifically designed for display devices. See Table A-35 through Table A-41 in Appendix A, "FCode Reference".

## Required Properties

Table 7-1 Required Display Device Properties

| Property Name | Typical Value |  |
| :--- | :--- | :--- |
| name | SUNW,cgsix | \{any name chosen by the manufacturer] |
| device_type | display | \{required for display devices $\}$ |
| reg | list of registers | \{depends on the device $\}$ |

## Device Driver Examples

## Simple Display Device Driver

This is a sample FCode program for a display device that does not need to be usable as a console display device during system power-up.

```
\ Basic display device driver
\ cg6 (Lego) frame buffer driver
\ This version doesn't use the graphics accelerator because of
\ conflicts with the window system's use of same.
hex
fcode-version1
    " SUNW,cgsix" name
    " SUNW,501-xxxx" model
    h# 20.0000 constant dac-offset h# 10 constant /dac
    h# 30.0000 constant fhc-offset h# 10 constant /fhc
    h# 30.1800 constant thc-offset h# 20 constant /thc
    h# 70.0000 constant fbc-offset h# 10 constant /fbc
    h# 70.1000 constant tec-offset h# 10 constant /tec
    h# 80.0000 constant fb-offset h# 10.0000 constant /frame
    : >reg-spec ( offset size -- xdrreg )
        >r my-address + my-space xdrphys r> xdrint xdr+
    ;
    dac-offset /dac >reg-spec
```

```
Basic display device driver
    fhc-offset /fhc >reg-spec xdr+
    thc-offset /thc >reg-spec xdr+
    fbc-offset /fbc >reg-spec xdr+
    tec-offset /tec >reg-spec xdr+
    fb-offset /frame >reg-spec xdr+
    " reg" attribute
    5 0 intr
    5 xdrint " interrupts" attribute
end0
```

## Extended Display Device Driver

This sample FCode program has added code to initialize and test the device, but still is not usable as a console display device during system power-up.

```
            Extended Display device driver
\ cg6 (Lego) frame buffer driver
\ This version doesn't use the graphics accelerator because of
\ conflicts with the window system's use of same.

## Hierarchical Devices

This device type generally applies to random access or memory mapped buses, for which the children of the bus can be mapped into the CPU address space and accessed like memory.

Hierarchical devices include such buses as SBus and VMEbus.
Not all bus devices fall into this category. For example, SCSI is not a memory mapped bus; SCSI targets are not accessed with load or store instructions.

## Required Methods

The hierarchical device package code must implement the open, close, reset, and selftest methods, as well as the following:
decode-unit ( adr len -- low high )
Convert adr len, a text string representation, to low high, a numerical representation of a physical address within the address space defined by this package.
dma-alloc( size -- virt )
Allocate a virtual address range of length size bytes that is suitable for direct memory access by a bus master device. The memory is allocated according to the most stringent alignment requirements for the bus. virt is an 32-bit address that the OpenBoot-based system can use to access the memory.

Note that dma-map-in must also be called to generate a suitable DMA address.

A child of a hierachical device calls dma-alloc using

```
" dma-alloc" $call-parent
```

For example:

```
-1 value my-reg
: my-dma-alloc ( size -- )
    " dma-alloc" $call-parent is my-reg
;
```

See Appendix C, "FCode Memory Allocation" for more information.

```
dma-free( virt size -- )
```

Free size bytes of memory previously allocated by dma-alloc at the virtual address virt.

A child of a hierachical device calls dma-free by using
" dma-free" \$call-parent

For example:

```
2000 value my-size
: my-dma-free ( -- )
    my-reg my-size " dma-free" $call-parent
    -1 is my-reg
;
```

See Appendix C, "FCode Memory Allocation" for more information.
dma-map-in ( virt size cacheable? -- devaddr )
Convert the virtual address range virt size, previously allocated by dmaalloc, into an address devaddr suitable for DMA on the bus. dma-map-in can also be used to map application-supplied data buffers for DMA use if the bus allows. If cacheable? is true, the calling child desires to use any available
fast caches for the DMA buffer. If access to the buffer is required before the buffer is mapped out, the child must call dma-sync or dma-map-out to ensure cache coherency with memory.

A child of a hierachical device calls dma-map-in using
" dma-map-in" \$call-parent
For example:

```
: my-reg-dma-map ( -- )
    my-reg my-size false " dma-map-in" $call-parent ( devaddr )
    is my-reg-dma
```

;

See Appendix C, "FCode Memory Allocation" for more information.

```
dma-map-out( virt devaddr size -- )
```

Remove the DMA mapping previously created with dma-map-in. Flush all caches associated with the mapping.

A child of a hierachical device calls dma-map-in by using
" dma-map-out" \$call-parent
For example:

```
$call-parent
: my-reg-dma-free ( -- )
    my-reg my-reg-dma my-size " dma-map-out" $call-parent
    -1 is my-reg-dma
;
```

See Appendix C, "FCode Memory Allocation" for more information.
dma-sync( virt devaddr size -- )
Synchronize (flush) any memory caches associated with the DMA mapping previously established by dma-map-in. You must interleave calls to this method (or dma-map-out) between DMA and CPU accesses to the memory region, or errors may result.

For example, a child of a hierachical device calls dma-sync by using \$callparent. This method is valid for FCode version 2.1 or later. Some early version 2 systems do not define this method in the / sbus node. Those systems automatically synchronize DMA and CPU access. The following example will give correct results in all cases.

```
: my-dma-sync ( virt devadr size -- )
    " dma-sync" ['] $call-parent catch if
        \ Parent does not have dma-sync
        \ cleanup the stack and return
        2drop 3drop
    then
;
```

See Appendix C, "FCode Memory Allocation" for more information.

```
probe-self( arg-adr arg-len reg-adr reg-len fcode-adr fcode-len -- )
```

Probe for a child of this node. fcode-adr fcode-len is a unit-address text string that locates the FCode program for the child. reg-adr reg-len is a unit-address text string that identifies the address of the child itself. arg-adr arg-len is a string for any device arguments for the child. probe-self checks whether there is indeed FCode at the indicated location, perhaps using cpeek.

If the FCode exists, probe-self creates a new child device node and interprets the FCode. If the interpretation of the FCode fails in some way, the new device node may be empty, containing no properties or methods.

For example, to probe FCode for SBus slot \#1:

```
" /sbus" select-dev
0 0 " 1,0" 2dup probe-self
unselect-dev
```

map-in( low high size -- virt )
Create a mapping associating the range of physical addresses beginning at low high, extending for size bytes, within the package's physical address space, with a processor virtual address virt.

For example, a child of a hierachical device calls map-in with " map-in" \$call-parent:

```
: map-reg ( -- )
    my-address xx-offset + my-space xx-size ( adr space size )
    " map-in" $call-parent ( virt )
    is xx-reg ( )
```

;
map-out ( virt size -- )
Destroy the mapping set by map-in at virtual address virt of length size bytes.

For example, a child of a hierachical device calls map-out with " map-out" \$call-parent:

```
: unmap-reg ( virt -- )
    xx-reg xx-size ( virt size )
    " map-out" $call-parent ( )
    -1 is xx-reg
;
```

unique-key ( -- byte )
Returns a unique "key" byte value in the range $0 \times 01$.. 0xef each time it is called.

Used for implementing "write to zero" transparent SBus-to-SBus bridge devices, an SBus-to-SBus bridge must implement unique-key by calling its parent's unique-key method. Doing this assures the uniqueness of the returned key's value throughout the chain of interconnected SBuses.

For example, a child of a hierachical SBus device calls unique-key with " unique-key" \$call-parent:

[^3]
## SBus Addressing

The SBus uses geographical addressing with numbered slots.
An SBus physical address is represented numerically by the SBus slot number as the high number and the offset from the base of that slot as the low number. The text string representation is slot\#, offset, where both slot\# and offset are the ASCII representations of hexadecimal numbers.

## SBus Required Properties

Table 8-1 Required SBus Properties

| Property Name | Sample Value |
| :--- | :--- |
| name | "SUNW, finagle" |
| burst-sizes |  |
| device-type | " sbus" |
| ranges |  |
| slot-address-bits |  |

## VMEBus Addressing

VMEBus has a number of distinct address spaces represented by a subset of the 64 possible values encoded by the six "address modifier" bits. The maximum size of one of these address spaces is 32 bits. An additional bit is used to select between 16 -bit and 32 -bit data.

A VMEBus physical address is represented numerically as follows. The high number is made up of the six address modifier bits AM0-5 in bits 0-5 and the data width bit ( $0=16$-bit data, $1=32$-bit data) in bit 6 . The low number is the offset within the selected address space. The text string representation is $a s$, offset, where both as and offset are ASCII representations of a hexadecimal numbers; as encodes the data width and address modifier bits.

## VMEBus Required Properties

Table 8-2 Required VMEbus Properties

| Property Name | Sample Value |
| :--- | :--- |
| name | "SuNW, vizzy" |
| device-type | " vmebus" |
| ranges |  |

## Device Driver Examples

The following examples of a hierarchical FCode driver are based on Sun's SBus expansion hardware called "XBox". XBox increases the number of SBus slots available in a system by providing a bus-bridge between the platform's onboard SBus and an SBus in the XBox hardware. XBox includes an SBus card called the XAdaptor card which plugs into the host platform's SBus and includes an expansion chassis called the XBox Expansion Box. Therefore XBox is an example of a hierarchical device which, in fact, implements an SBus interface to child plug-in devices.

The example is divided into three parts: the basic device driver, the extended device driver, and the complete device driver. In the case of a hierarchical device, in practice, one would only want to develop and ship a driver with the complete functionality. Otherwise, plug-in cards which rely on a full set of parent services generally would not be able to function. The three stage presentation of the driver simply shows how a driver might grow through the development cycle.

## Basic Hierarchical Device Driver

The basic driver simply declares most of the important properties of the device, particularly the addresses of the various registers. A driver in this state might be used to support the develoment of the OS driver which would attach to the device name and configure itself based on the device properties published by the FCode driver.

## Extended Hierarchical Device Driver

The extended driver adds methods allowing access to various device registers in addtion to the functions of the basic driver. It provides methods to:

- map in the registers
- fetch from and store to the registers
- program one of the registers which control the allocation of address space across the various SBus slots.

Such an extended driver provides methods that a developer can use to read and write registers and verify correct hardware responses. Note that the complete driver does not use all of the device registers; read/write access methods were included for all of them to allow easy testing during development.

## Complete Hierarchical Device Driver

The complete driver includes all the required device node methods. It also includes code to initalize the hardware at system reset. In particular, it configures the allocation of address space across slots. It does this by either performing an autoconfiguration or by accepting a manual override via a property in its parent. During the configuration process, the driver interprets the FCode of any SBus card plugged into the XBox. This results in devices being added to the device tree.

\ The XBox slot configuration may be forced by the user. The mechanism
\ for doing this is a string which specifies megs/slot (eg. "16,8,8,0").
\ This string is processed into the config bits array. Then the
\ slot-sizes-array is searched for a configuration which matches or
\ exceeds the requested number for each slot. If the request is
\ unreasonable the default-slot-config is used.
\ Then the configuration is set in the XBox hardware.
\ Finally each slot is probed based on the config.

## Network Devices

Network devices are packet-oriented devices capable of sending and receiving packets addressed according to IEEE 802.2 (Ethernet). OpenBoot firmware typically uses network devices for diskless booting. The standard obp-tftp support package assists in the implementation of the load method for this device type.

This chapter describes how to implement network device drivers. First, the developer of a network driver needs to cooperate with the developers of OS driver to agree on the structure of the device tree, based on the functionalities of the drivers. Then they need to define all necessary properties used by OS or OpenBoot firmware.

Normally the network device driver could have a one level tree or a two level tree. While it is unlikely it will have more than two level tree, if necessary, the user can create more than a two level tree by applying new-device and finish-device.

A one level tree could have several nodes, depending on how many net channels the SBus card can support, each node corresponds to one net channel.

For a two level tree, it could have one "control" node on the top level, one or more nodes at the bottom level, depending on the number of net channels it supports. The simplest driver is to support has only one net channel and will only create one node, all properties and all methods being under this node.

This chapter shows three sample network device drivers for the Quad Ethernet device card. The structure of the device tree for the examples is as follows:

Each QED SBus card defines two levels:

- one qec device node
- four qe device nodes

Figure 9-1 QED Device Tree
The general pathname (after sbus or sbi) for a qe node is
qec@S,20000/qe@c,0
where $S$ is the SBus slot number, $C$ is the network channel number.

## Required Methods

The network device FCode must declare the network device-type, and must implement the methods open and close, as well as the following methods:
load( adr -- len )
Read the default stand-alone program into memory starting at adr using the default network booting protocol. len is the size in bytes of the program read in.
read ( adr len -- actual )
Receive a network packet, placing at most the first len bytes in memory at adr. Return the actual number of bytes received (not the number copied), or 0 if no packet is currently available. Packets with hardware-detected errors are discarded as though they were not received. Do not wait for a packet (nonblocking).
write ( adr len -- actual )
Transmit the network packet of size len bytes starting at memory address adr. Return the number of bytes actually transmitted. The packet must be complete with all addressing information, including source hardware address.

## Required Device Properties

The required properties for a network device are
Table 9-1 Required Network Device Properties

| Name | Typical Value |
| :--- | :--- |
| name | "SUNW,my-net" \{any name chosen by the manufacturer\} |
| reg | list of registers \{depends on the device\} |
| device_type | "network" |
| mac-address | $800 \times 200 \times 0 \mathrm{c}$ 0xea $0 \times 41$ \{the currently using MAC address.\} |

## Optional Device Properties

Several other properties may be declared for network devices:
Table 9-2 Optional Network Device Properties

| Property Name | Typical Property Value |
| :--- | :--- |
| max-frame-size | $0 \times 4000$ |
| address-bits | 48 |
| slave-burst-sizes | $0 \times 7 \mathrm{f}$ \{depends on the number of entries in the reg property\} |
| local-mac-address | $800 \times 20$ 0x0c 0xea $0 \times 41$ \{the built-in Media Access Control addr.\} |

## Device Driver Examples

If the network device is not to be bootable, it likely needs only one level tree. The examples below, however, show device drivers for two-level trees.

## Simple Network Device Example

At minimum, a network device driver need only provide the desired tree structure and to publish all the necessary properties to identify the devices.

## Sample Driver With Test and Debugging Methods

This version of a network device driver is still non-bootable, but it shows how an intermediate step of driver can be used to debug and test the device during or after development.

The coding techniques shown in this and the following examples are:

- Each qe node has exactly the same set of instance variables as each of the other qe nodes.
- All the qe nodes share the same qe driver source code defined in the first qe node (qe0).

## Bootable Network Device Driver Example

The example below shows a complete version of a bootable network driver. It implements the selftest method callable by OpenBoot test and test-all commands and the watch-net method callable by OpenBoot watch-net and watch-net-all commands.

```
\ QED bootable driver
\ qed.fth
fcode-version1
    headers
    fload board.fth
```

```
\ QED bootable driver
    : copyright ( -- )
            ." QED 1.1 " cr
            ." Copyright 1992-1993 Sun Microsystems, Inc. All Rights Reserved" cr
    ;
\
\ ***** The following is the FCode driver for version2 CPU PROMs. *****

## Serial Devices

Serial devices are byte-oriented, sequentially-accessed devices such as asynchronous communication lines (often attached to a "dumb" terminal).

## Required Methods

The serial device driver must declare the serial device-type, and must implement the methods open and close, as well as the following:

## install-abort( -- )

Instruct the driver to begin periodic polling for a keyboard abort sequence. install-abort is executed when the device is selected as the console input device.
read ( adr len -- actual )
Read len bytes of data from the device into memory starting at adr. Return the number of bytes actually read, actual, or -2 if no bytes are currently available from the device. -1 is returned if other errors occur.
remove-abort( -- )
Instruct the driver to cease periodic polling for a keyboard abort sequence. remove-abort is executed when the console input device is changed from this device to another.
write ( adr len -- actual )
Write len bytes of data to the device from memory starting at $a d r$. Return the number of bytes actually written, actual.

## Required Properties

The standard properties of a serial driver are:
Table 10-1 Serial Driver Required Properties

| Property Name | Value |
| :--- | :--- |
| name | " sunw,thingy" |
| reg | \{device-dependent \} |
| device_type | $"$ serial" |

## Device Driver Examples

The three examples that follow are serial device drivers for the Zilog 8530 SCC (UART) chip.

- The first sample is a short driver which simply creates a device node and declare the properties for the device.
- The second sample is a more sophisticated driver that defines methods to control and access the device.
- The third sample shows the complete serial device driver.

## Simple Serial FCode Program

```

## Extended Serial FCode Program

```
\ Extended Serial FCode Program
\ In addition to publishing the properties, this sample driver
\ provides methods to access and control the serial ports.
\
\ The following main methods are provided:
\ - usea ( -- )
\ Selects serial port A. All subsequent operations will
\ be directed to port A
\ - useb ( -- )
\ Selects serial port B. All subsequent operations will
\ be directed to port B
\ - uemit ( char -- )
\ Emits a given character to the selected serial port.
\ - ukey ( -- key )
\ Retrieves a character from the selected serial port.
\ - read ( adr len -- #read )
\ Reads "len" number of characters from the selected port,
\ and store them at "adr".
\ - write ( adr len -- #written )
\ Writes "len" number of characters from the buffer located
\ at "adr" to the selected serial port.

## Complete Serial FCode Program

```
\ Complete Serial driver.
\ In addition to the methods defined in the above driver sample,
\ this version defines more methods to initialize, test, and access
\ the serial ports.
\ The new main methods are:
\ - inituarts ( -- )
\ Initializes both serial ports A and B.
\ - open ( -- okay? )
\Maps in the uart chip. Selects port A on default, then check
\ my-args, if port B was specified, then selects port B instead.
\ - close ( -- )
\ Unmap the uart chip.
\ - selftest ( -- )
\ Performs selftest on both Port A and B.
\ - install-abort ( -- )
\ Sets up alarm to do poll-tty every }10\mathrm{ miliseconds.
\ - remove-abort ( -- )
\ Removes the poll-tty alarm.

## FCodeDictionary

This dictionary describes the pre-defined FCode words that you can use as part of FCode source code programs. Appendix A, "FCode Reference", contains a command summary, with words grouped by function.

The words are given alphabetically in this chapter, sorted by the first alphabetic character in the word's name. For example, the words mod and */mod are adjacent to each other. Words having no alphabetic characters in their names are placed at the beginning of the chapter, in ASCII order.

The boot PROM and tokenizer are case-insensitive (all Forth words are converted to lowercase internally). The only exceptions are literal text, such as text inside " strings and text arguments to the ascii command, which are left in the original form. In general, you may use either uppercase or lowercase.

All arithmetic uses 32-bit signed values, unless otherwise specified.
Defining words create a header by calling external-token, named-token, or new-token. See these words for more details.

All FCode byte values listed in this chapter are given in hexadecimal. Version 2 FCodes cannot be used OpenBoot 1 systems, they are called out in the dictionary definitions by "Version 2 ".

The rest of this chapter contains definitions of the FCodes and tokenizer macros defined for use in the SPARCstation OpenBoot PROM.
! ( n adr -- )
Store $n$ at adr. For more portable code, use l! if you explicitly want a 32-bit access. adr must be aligned as given by variable.

```
" (text)" ( -- adr len ) code# 12 len xx xx xx ...
```

generates: b(") len text

This word is used to compile a text string, delimited by a ". At execution time, the address and length of the string is left on the stack. For example:

```
" SUNW,new-model" xdrstring " model" attribute
```

You can embed control characters and 8-bit binary numbers within strings. This is similar in principle to the $\backslash n$ convention in $C$, but syntactically tuned for Forth. This feature applies to the string arguments of the words " and ."

The escape character is ' $"$ '. Here is the list of escapes:
Table 11-1 Escape Sequences in Text Strings

| Syntax | Function |
| :---: | :---: |
| "" | quote (") |
| " n | newline |
| "r | carret |
| "t | tab |
| "f | formfeed |
| "1 | linefeed |
| "b | backspace |
| "! | bell |
| "^x | control x , where x is any printable character |
| "(hh hh) | Sequence of bytes, one byte for each pair of hex digits hh. Non-hex characters will be ignored |

"<whitespace> terminates the string, as usual.
" followed by any other printable character not mentioned above is equivalent to that character. This syntax is completely backwards compatible with old code, since the only legal previous usage was "<whitespace>

For example:

```
" This is "(01 32 8e) abc"nA test xyzzy "!"! abcdefg""hijk"^bl"
    ^^^^^^ ^ ^ ^ ^ ^
    3 bytes newline 2 bells " control b
```

The " ( hh hh hh hh ) form is useful for entering binary data.
Any non-hex characters (such as space or comma) are ignored within the data field of "( ...), and thus make useful delimiters. The "makearray" tool can be used in conjunction with this syntax to easily incorporate large binary data fields into any FCode program.

Note - The use of " n for line breaks is discouraged. The preferred method is to use cr , rather than embedding the line break character inside a string. Use of cr results in more accurate display formatting, because Forth updates its internal line counter when cr is executed.

When " is used outside a colon definition, current implementations permit only two interpreted strings to be active at any given time, a third interpreted string overwrites the first one. This limitation does not apply in colon definitions.

```
# ( +L1 -- +L2 )
code# 99
```

The remainder of +L 1 divided by the value of base is converted to an ASCII character and appended to the output string toward lower memory addresses. +L 2 is the quotient and is maintained for further processing. Typically used between <\# and \#>.
\#> ( L - adr +n )
code\# 97
Pictured numeric output conversion is ended dropping L. adr is the address of the resulting output array. +n is the number of characters in the output array. adr and +n together are suitable for type. See (.) and (u.) for typical usages.

```
name ( -- acf ) code# 11 FCode(name)
```

generates: b(')

Used to generate the code field address (acf) of the word immediately following the ' . ' should only be used outside of definitions. See ['] for more details.

For example:
defer opt-word ( -- ) ' noop is opt-word
( text) ( -- ) code\# none
Ignore subsequent text after the " ( " up to a delimiting ")". Note that a space is required after the (. Although either (or $\backslash$ may be used equally well for documentation, by common convention we use ( . . . ) for stack comments and \ . . . for all other text comments and documentation. See also (s .

For example:

```
: 4drop ( a b c d -- )
    2drop ( a b )
    2drop ( )
;
```

(.) ( $\mathrm{n}-\mathrm{adr}$ len )
generates: dup abs <\# \#s swap sign \#>

This is the numeric conversion primitive, used to implement display words such as "." It converts a number into a string. If $n$ is negative, the first character in the array will be a minus (-) sign.

For example:

```
: show-version ( -- )
    ." CPU bootprom version is " base @ d# 16 base ! ( old-base )
    firmware-version ( old-base version )
    lwsplit (.) type ascii . emit .h cr base ! ( )
;
```

```
* ( n1 n2 -- n3 )
code# 20
```

n 3 is the arithmetic product of n 1 times n 2 . If the result cannot be represented in one stack entry, the least significant bits are kept.

* / ( n1 n2 n3 -- n4 )
code\# $30 \quad 20 \quad 31 \quad 21$
generates: >r * r> /
Calculates $n 1 * n 2 / n 3$. The inputs, outputs and intermediate products are all 32-bit.
+ ( n1 n2 -- n3 ) code\# 1e n 3 is the arithmetic sum of n 1 plus n 2 .
+! ( n adr -- )
code\# 6c
n is added to the value stored at adr. This sum replaces the original value at adr. adr must be aligned as given by variable.
, ( n -- )
code\# d3
Compile a number into the dictionary. In current systems, the number of bytes compiled is 4 (same as $l$, ). See c, for limitations. The dictionary pointer must be two-byte aligned.

For example, to create an array containing integers 400040002345 6734:
create my-array 40004000 , 23 , 45 , 6734 ,

- ( n1 n2 -- n3 )
code\# 1f
n 3 is the result of subtracting n 1 minus n 2 .
-1 ( -- -1 )
Leave the value -1 on the stack. The only numbers that are not encoded using b (lit) are the values $-1,0,1,2$, or 3 . Because these numbers occur so frequently, these values are assigned individual FCodes to save space.
- ( n -- )
code\# 9d
The absolute value of n is displayed in a free field format with a leading minus sign if $n$ is negative, and a trailing space.

If the base is hexadecimal, . displays the number in unsigned format, since signed hex display is hardly ever wanted. Use s. to display signed hex numbers. See also s. .

```
." text" ( -- ) code# 12 len xx xx xx ... 90
generates: b(") len text type
```

This word compiles a text string, delimited by ". At execution time, the string is displayed, for example, in ." hello world"

This word is equivalent to using " text" type
. " is normally used only within a definition. The text string will be displayed later when that definition is called. You may wish to follow it with cr to flush out the text buffer immediately.

Use . ( to print anything while the FCode PROM is being interpreted.
See tokenizer [ for details about printing at tokenize time.

Gathers a text string, delimited by ), to be immediately displayed during probe time. For example:

```
.( hello world)
```

This word is equivalent to: " text " type
Use this to print out text at the time the FCode PROM is being interpreted (you may wish to follow it with a cr to flush out the text buffer immediately). This word may be called either inside or outside of definitions; the text is immediately displayed in either case.

Note that the string will typically be printed out of serial port A, since any framebuffer present may not yet be activated at the time that SBus slots are being probed. Use . " for any printing to be done when new words are later executed.

See tokenizer [ for details about printing at tokenize time.
/ ( n1 n2 -- quot )
code\# 21
Calculates n1 divided by n2. An error condition results if the divisor (n2) is zero. See /mod.

0
( -- 0 )
code\# a5
Leave the value 0 on the stack. The only numbers that are not encoded using b (lit) are the values $-1,0,1,2$, or 3 . Because these numbers occur so frequently, they are assigned individual FCodes to save space.

```
0< ( n -- flag )
code# 36
```

Flag is true if n is less than zero (negative).

```
0<= ( n -- flag )
code# 37
```

Flag is true if $n$ is less than or equal to zero.

```
O=( n -- flag )
code# 34
```

Flag is true if n is zero. This word will invert any flag.
$0<>$ ( n -- flag ) code\# 35
Flag is true if $n$ is not zero.
$0>(\mathrm{n}--\mathrm{flag}) \quad$ code\# 38
Flag is true if n is greater than zero.
$0>=(\mathrm{n}--\mathrm{flag}) \quad$ code\# 39
Flag is true if $n$ is greater than or equal to zero.

## 1 ( -- 1 )

code\# a6
Leave the value 1 on the stack. The only numbers that are not encoded using b (lit) are the values $-1,0,1,2$, or 3 . Because these numbers occur so frequently, these values are assigned individual FCodes to save space.

```
1+ ( n1 -- n2 )
code# a6 1e
generates: 1 +
```

n 2 is the result of adding one to n 1 .

1- ( n 1 -- n 2 ) code\# a6 1f
generates: 1 -
n 2 is the result of subtracting one from n 1 .

2 (-- 2 )
code\# a7
Leaves the value 2 on the stack. The only numbers that are not encoded using b (lit) are the values $-1,0,1,2$, or 3 . Because these numbers occur so frequently, these values are assigned individual FCodes to save space.

2! ( n1 n2 adr -- )
code\# 77
n1 and n2 are stored in consecutive 32-bit locations starting at adr. n2 is stored at the lower address.

2* ( n1 -- n2 )
code\# 59
n 2 is the result of shifting n1 left one bit. A zero is shifted into the vacated bit position. This is equivalent to multiplying by 2.

2+ ( n1 -- n2 ) code\# a7 1e generates: $2+$
n 2 is the result of adding 2 to n 1 .

```
2- ( n1 -- n2 ) code# a7 1f
    generates: 2 -
```

    n 2 is the result of subtracting 2 from n 1 .
    2/ ( n1 -- n2 )
code\# 57
n 2 is the result of arithmetically shifting n1 right one bit. The sign is included
in the shift and remains unchanged. This is equivalent to dividing by 2.
2@ ( adr -- n1 n2 )
n 1 and n 2 are two numbers stored in consecutive 32-bit locations starting at
adr. $n 2$ is the number that was stored at the lower address.
3 (-- 3 )
code\# a8

Leaves the value 3 on the stack. The only numbers that are not encoded using b (lit) are the values $-1,0,1,2$, or 3 . Because these numbers occur so frequently, these values are assigned individual FCodes to save space.

```
: name ( -- ) at creation code# (header) b7
```

        ( ?? -- ?? ) at execution
    generates: new header, \(b(t y p e)=b(:)\)
    Begin a new definition, terminated by ; Used in the form:
: newname ... ;

Later usage of newname is equivalent to usage of the contents of the definition. See named-token, new-token, and external-token for more information on header formats.
; ( -- )
code\# c2
generates: b(;)
Ends the compilation of a colon definition. See also : .

```
< ( n1 n2 -- flag )

Flag is true if \(n 1\) is less than \(n 2 . n 1\) and \(n 2\) are signed integers.
```

<\# ( -- )
code\# 96

```

Initialize pictured numeric output conversion. You can use the words:
<\# \# \#s hold sign \#>
to specify the conversion of a 32-bit number into an ASCII character string stored in right-to-left order. See (.) and (u.) for typical usages.
```

<<(n1 +n -- n2 )
code\# 27

```
n 2 is the result of logically left shifting n1 by +n places. Zeroes are shifted into the least-significant bits.

For example:
```

: bljoin ( byte.low byte.lowmid byte.highmid byte.high -- L )
8<< + 8<< + 8<< +
;

```
```

<= ( n1 n2 -- flag ) code\# 43

```

Flag is true if \(n 1\) is less than or equal to n2.n1 and n2 are signed integers.
```

<> ( n1 n2 -- flag ) code\# 3d

```

Flag is true if \(n 1\) is not equal to \(n 2 . n 1\) and \(n 2\) are signed integers.
```

=( n1 n2 -- flag )
code\# 3c

```

Flag is true if n 1 is equal to \(\mathrm{n} 2 . \mathrm{n} 1\) and n 2 are signed integers.
```

( n1 n2 -- flag )
code\# 3b

```

Flag is true if n 1 is greater than \(\mathrm{n} 2 . \mathrm{n} 1\) and n 2 are signed integers.

Flag is true if n 1 is greater than or equal to n 2 . n 1 and n 2 are signed integers.
\(\gg(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2)\)
code\# 28
n 2 is the result of logically right shifting n1 by +n places. Zeroes are shifted into the most-significant bits. Use >>a for signed shifting.

For example:
```

: wbsplit ( w -- b.low b.high )
dup h\# ff and swap 8 >>
h\# ff and
;

```
```

? ( adr -- )
code\# 6d 9d

```
generates: @.

Fetch and print the 32-bit value at the given address. An old standard Forth word, primarily used interactively.
```

@ ( adr -- n ) code\# 6d

```
\(n\) is the value stored at adr. For more portable code, use 1d if you explicitly want a 32-bit access. adr must be aligned as given by variable.
[`] name ( -- acf) code\# 11 FCode (name) generates: b(')
' or [ \({ }^{\prime}\) ] are used to generate the code field address (acf) of the word immediately following the \({ }^{\prime}\) or [ \(\left.{ }^{\prime}\right]\).
' should only be used outside definitions; ['] may be used either inside or outside definitions. Examples shown usually use ['] , since it will always generate the intended result:

\footnotetext{
: my-probe... [`] my-install is-install... ;
}
or
[`] my-install is-install

In normal Forth,' may be used within definitions for the creation of language extensions, but such usage is not applicable to FCode programs.
\rest-of-line ( -- ) code\# none
Ignore the rest of the input line after the \(\backslash\). It can occur anywhere on an input line. Note that a space must be present after the \. See ( or (s for another form for delimiting comments.

For example:

0 value his-ihandle \place to save someone's ihandle
```

<<a ( n1 +n -- n2 )
code\# 27

```
generates: <<

Arithmetic left-shift (left-shift with sign-extend), to round out the existing words \(\ll, \gg\), and \(\gg\) a . This word is useless, because the carry out from an arithmetic left shift is not accessible later.
```

>>a (n1 +n -- n2 )
code\# 29

```
n 2 is the result of arithmetically right shifting n 1 by +n places. The sign bit of n 1 is shifted into the most-significant bits.

For example:
\[
\text { ffff. } 00006 \text { >>a.h }
\]
shows: fffffc00, while
```

ffff.0000 6 >> .h

```
shows: 3fffc00.
```

abort ( -- )
code\# 2 16
version 2

```

Aborts program execution. Control returns to ok prompt. Called after encountering fatal errors.

For example:
```

: probe-loop ( adr -- )
\ generate a tight probe loop until any key is pressed.
begin dup l@ drop key? if abort then again
;

```

\section*{\(\operatorname{abs}(\mathrm{n}--\mathrm{u})\)}
code\# 2d
\(u\) is the absolute value of \(n\). If \(n\) is the maximum negative number, \(u\) is the same value (since the maximum negative number in two's complement notation has no positive equivalent).
```

again ( -- )
generates: bbranch -offset
Used in the form begin ... again to generate an infinite loop. Use Stop-A from the keyboard, or abort or exit, to exit from this loop. Use this word with caution!
For example:

```
```

: probe-loop ( adr -- )

```
: probe-loop ( adr -- )
    \ generate a tight probe loop until any key is pressed.
    \ generate a tight probe loop until any key is pressed.
    begin dup l@ drop key? if abort then again
    begin dup l@ drop key? if abort then again
;
```

code\# 13 offset
alarm ( acf $n--$ ) code\# 213
version 2

Arranges to periodically execute the package method acf at intervals of $n$ milliseconds (to the best accuracy possible).
acf is the compilation address, as returned by [']. Each time the method is called, the current instance will be the same as the current instance at the time that alarm was executed. If $n$ is 0 , stop the periodic execution of acf within the current instance context.

A common use of alarm would be to implement a console input device's polling function.

For example:

```
: my-checker ( -- ) test-dev-status if user-abort then ;
: install-abort ( -- ) ['] my-checker d# 10 alarm ;
```

alias
new-name old-name ( -- )
code\# none
alias creates a new name, with the exact behavior of some other existing name. The new name can then be used interchangeably with the old name and have the same effect.

The tokenizer does not generate any FCode for an alias command, but instead simply updates its own lookup table of existing words. Any occurrence of the new word causes the assigned FCode value of the old word to be generated. One implication is that the new word will not appear in the OpenBoot dictionary after the FCode program is compiled.

If the original FCode source text is downloaded and interpreted directly, without being tokenized or detokenized, then any new alias words will show up and be usable directly.

## For example:

```
alias pkg-attr get-package-attribute
```

aligned ( adr1 -- adr2 )
code\# ae
Increase adr1 to the next machine word boundary - to the next value evenly divisible by 4 . The correct boundary could vary on other CPU implementations.

```
alloc-mem ( #bytes -- virtual )
    code# 8b
```

Allocate some free physical memory from Forth, and return its virtual address. See free-mem.

For example:

```
h# 100 alloc-mem ( virt ) constant my-buff
```

```
and ( n1 n2 -- n3 )
code# 23
```

n 3 is the bit-by-bit logical and of n 1 with n 2 .
ascii
(-- n ) code\# 10000000 xx generates: b(lit) value

Interpret the next letter as an ASCII code. For example:

```
ascii C (equals hex 43)
ascii c (equals hex 63)
```

attribute ( value-xdr-adr value-xdr-len name-adr name-len -- ) code\# 110
attribute is the way to pass properties from an FCode program to a SunOS device driver. A property consists of two strings: a name string and a value string. The name string gives the name of the property, and the value string gives the value associated with that name. For example, a framebuffer may wish to declare a property named "hres" (for horizontal resolution) with a value of 1152.

The attribute command requires two strings on the stack - the value string and the name string. The name string is an ordinary Forth string, such as any string created with " . This string should be written in lower case, since the attribute name is stored only after converting uppercase letters, if any, to lower case. For example:

[^4]is stored as if entered

## " A21-b" xdrstring " new_version" attribute

The value string, however, must be in the xdr format. See Chapter 5, "Properties" for more information on creating xdr-format strings.

All properties created by an FCode program are stored in a "device tree" by OpenBoot. This tree may then be queried by a SunOS device driver, using getprop or getlongprop.

The FCode program and the SunOS device driver may agree on any arbitrary set of names and values to be passed, with virtually no restrictions. Several names, though, have special meaning. For many of them, a shorthand command also exists that makes the attribute declaration a bit simpler.

For example:
" SUNW, new-model" xdrstring " model" attribute

See also: name, reg, intr, model and Chapter 5, "Properties" for more information.

```
b# number ( -- n ) code# 10 xx xx xx xx
generates: b(lit) value
```

Interpret the next number in binary (base 2), regardless of any previous settings of hex, decimal, binary or octal. Only the immediately-following number is affected, the current numeric base setting is unchanged. For example:

```
hex
b# 100 (equals decimal 4)
100 (equals decimal 256)
```

See also d\#, h\#, and o\#.

```
b(") ( -- adr len ) code# 12 len xx xx xx ...
```

An internal word, generated by words such as " or ." to leave a text string on the stack. The FCode for b(") should always be followed by an 8-bit length, then by the appropriate number of bytes representing the desired test string. Never use the word b(") in source code.
$\mathbf{b} \mathbf{( '}^{\prime}$ ) ( -- acf ) code\# 11 FCode\#
An internal word, generated by ' or ['] to leave on the stack the code field address of the immediately following word. The FCode for $\mathrm{b}\left({ }^{\prime}\right)$ should always be followed by the FCode of the desired word. Never use the word b(') in source code.

## b(+loop)

( n -- ) code\# 16 -offset

An internal word, generated by + loop. The FCode for b ( + loop) should always be followed by a negative offset (either 8 -bit or 16 -bit, see offset16). Never use the word b(+loop) in source code.
b(:) ( -- )
code\# b7
An internal word, generated by the defining word : . This is the type entry for : needed by named-token or new-token. See these words for more details. Never use the word b(:) in source code.
b(;) (-- )
code\# c2
An internal word, generated by ; to end a colon definition. Never use the word b(; ) in source code.

```
b (<mark) ( -- )
code# b1
```

An internal word, generated by begin. Never use the word b(<mark) in source code.
b(>resolve) ( -- )
code\# b2
An internal word, generated by repeat, else, and then. Never use the word b (>resolve) in source code.
$\mathbf{b}$ (?do) ( end start -- ) code\# 18 +offset
An internal word, generated by ?do. The FCode for b (?do) should always be followed by a positive offset (either 8 -bit or 16 -bit, see offset16). Never use the word b (?do) in source code.

## b(buffer:)

( n -- )
code\# bd
An internal word, generated by the defining word buffer: . This is the type entry for buffer: needed by external-token, named-token, or newtoken. See these words for more details. Never use the word b (buffer:) in source code.

```
b(case) ( selector -- selector ) code# c4
```

An internal word, generated by case. Never use the word b (case) in source code.

```
b(constant) ( n -- ) code# ba
```

An internal word, generated by the defining word constant. This is the type entry for constant needed by external-token, named-token or newtoken. See these words for more details. Never use the word b (constant) in source code.
b(create) ( -- )
An internal word, generated by the defining word create. This is the type entry for create needed by external-token, named-token or new-token . See these words for more details. Never use the word b (create) in source code.

```
b(defer) ( -- )
code# bc
```

An internal word, generated by the defining word defer. This is the type entry for defer needed by external-token, named-token or new-token . See these words for more details. Never use the word b (defer) in source code.
b(do) ( end start -- ) code\# 17 +offset
An internal word, generated by do. The FCode for b(do) should always be followed by a positive offset (either 8 -bit or 16 -bit, see offset16). Never use the word b(do) in source code.
$\mathbf{b}$ (endcase) ( -- ) code\# c5
An internal word, generated by endcase. Never use the word b (endcase) in source code.

```
b(endof) ( -- ) code# c6 +offset
```

An internal word, generated by endof. Never use the word b(endof) in source code.

```
b(field) ( offset size -- offset+size ) code# be
```

An internal word, generated by the defining word field. This is the type entry for field needed by external-token, named-token or new-token . See these words for more details. Never use the word b(field) in source code.
b(is) ( n -- ) code\# c3
An internal word, generated by is .
Never use the word b(is) in source code.

## b(leave) ( -- )

code\# 1b
An internal word, generated by leave .
Never use the word b(leave) in source code.
b(lit) $\square$
Any input number, such as 205 or -14, will create the b (lit) FCode (code\#10), followed by 32-bits ( 4 bytes) with the actual binary value in two's-complement arithmetic. The number base (hex, decimal or any other chosen radix) is
controlled by any previous uses of the tokenizer directives hex, decimal, and so on, or by numeric input control words such as h\#, d\#, ascii, and so on. Thus,

$$
\text { decimal ... } 20
$$

would be encoded as the hex bytes $10 \begin{array}{lllll}100 & 00 & 00 & 14\end{array}$
The only numbers that are not encoded using $b$ (lit) are the values $-1,0,1,2$, or 3. Because these numbers occur so frequently, these values are assigned individual FCodes to save space.

Never use the word b (lit) in source code.
b(loop) ( n -- )
code\# 15 -offset
An internal word, generated by loop. The FCode for b (loop) should always be followed by a negative offset (either 8 -bit or 16 -bit, see offset 16 ).

Never use the word b(loop) in source code.

```
b(Of) ( testval -- ) code# 1c +offset
```

An internal word, generated by of. The FCode for b(of) should always be followed by a positive offset (either 8-bit or 16-bit, see offset 16 ). Never use the word $b$ (of) in source code.

## b(value)

( $n$-- )
code\# b8
An internal word, generated by the defining word value. This is the type entry for value needed by external-token, named-token or new-token . See these words for more details. Never use the word b (value) in source code.

## b(variable)

An internal word, generated by the defining word variable. This is the type entry for variable needed by external-token, named-token or newtoken. See these words for more details. Never use the word b (variable) in source code.

## b?branch ( flag -- )

An internal word, generated by until, while, and if. The FCode for b?branch should always be followed by an offset (either 8-bit or 16-bit, see offset16). Never use the word b?branch in source code.
base ( -- adr )
The address of a variable containing the current numeric conversion radix to be used when the FCode program is executing, such as 10 for decimal, 16 for hex, 8 for octal, and so on. For example, to print the current value of base, use:

```
base @ .d
```

The tokenizer words binary, decimal, hex, or octal are also available for changing the value in base as desired. However, these four words behave differently depending whether they occur within a definition or outside of a definition.

If any of binary, decimal, hex, or octal occur within a definition, then they will be compiled, later causing a change to the value in base when that definition is executed.

If any of binary, decimal, hex, or octal occur outside of a definition, however, then they are interpreted as commands to the tokenizer program itself, thus affecting the interpretation of all subsequent numbers in the text.

Note that changes to base affect the numeric base of the Toolkit itself, which can create much confusion for any user (the default value for base is hexadecimal). If you must change the base, Sun recommends that you save and then restore the original base, as in:

```
:.o ( n -- ) \ Print n in octal
    base @ swap ( oldbase n )
    octal . ( oldbase )
    base !
```

In general, only numeric output will be affected by the value in base. Fixed numbers in FCode source are interpreted by the tokenizer program. Most numeric input is controlled by binary, decimal, hex, octal, b\#, d\#, h\#, and o\#, but these words only affect the tokenizer input base; they but do not affect the value in base. For example:

```
    (assume initial value in base is 16, i.e. Toolkit is in hex)
    (no assumptions should be made about the initial tokenizer base)
fcode-version1
hex (tokenizer in base 16; later execution, using base, in base 16)
20. (compile decimal 32, later print "20" when FCode executes)
decimal (tokenizer is in base 10, later execution is in base 16)
20. (compile decimal 20, later print "14" since FCode executes in hex)
: TEST ( -- )
    octal (still compiling in decimal, later change base when TEST executes)
    20. (compiles decimal 20, prints "24" since base was just changed)
    h# 20 .d (compiles decimal 32, prints "32"; no permanent base changes)
    20. (compiles decimal 20, prints "24")
;
20. (compile decimal 20, later print "14"
TEST (prints "24 32 24"; has a side-effect of changing the base)
20. (compile decimal 20, later print 24 since TEST changed base)
hex (tokenizer is in base 16; later execution, using base, still in base 8)
20. (compile decimal 32, later print "40")
```

If this all seems confusing, simply follow these guidelines:
Good: initially declare hex just after fcode-version1, and make liberal use of b\#, d\#, o\#, h\#,.h and.d.

Bad: changing base either directly or by calling binary, decimal, hex, or octal from within a definition.
bbranch ( -- )
An internal word, generated by again, repeat, and else. The FCode for bbranch should always be followed by an offset (either 8 -bit or 16-bit,see offset16). Never use the word bbranch in source code.

```
    begin ( -- )
                                    code# b1
        generates: b(<mark)
```

Marks the beginning of a conditional loop, such as begin ... until, begin ... while ... repeat, or begin ... again. See these other words for more details.
bell ( -- n )
code\# ab
n is the ASCII code for the bell character; decimal 7.

```
between ( n min max -- flag ) code# 44
```

flag is true if $n$ is between min and max, inclusive of both endpoints (min <= $\mathrm{n}<=\max )$. See within for a different form of comparison.

```
binary ( -- ) code# none
    generates: 2 base ! or code# a7 a0 72
```

If outside of a definition, commands the tokenizer program to interpret subsequent numbers in binary (base 2). If within a definition, change the value in base affecting later numeric output when the FCode program is executed.
See base.
bl ( -- n )
code\# a9
The ASCII code for the space character; decimal 32, hex 20.
blank
( adr len -- ) fill code\# a9 79
generates: bl fil
len bytes of memory beginning at adr are set to the ASCII character value for space (hex 20). No action is taken if len is zero.

## blink-screen ( -- )

code\# 1 5b
A defer word, called by the terminal emulator when needed to flash the entire screen.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly.

This may be done with is, or it may be loaded automatically with fb1install or fb8-install (which loads fb1-blink-screen or fb8-blink-screen, respectively). These default routines invert the screen (twice) by xor-ing every visible pixel. This is quite slow.

A replacement routine simply disables the video for 20 milliseconds or so, i.e.

```
: my-blink-screen ( -- ) video-off 20 ms video-on ;
    \ load default behaviors with fbx-install, then:
    ['] my-blink-screen is blink-screen
```

Of course, this example assumes that your display hardware is able to quickly enable and disable the video without otherwise affecting the state.
bljoin ( byte.lo byte2 byte3 byte.hi -- n )
code\# 7f
Merge four bytes into a single 32-bit word. Incorrect results may be generated unless the high 24 bits of each stack item are zero.
body> ( apf -- acf )
code\# 85
Convert the parameter field address of a word to its code field address.
>body ( acf -- apf )
Convert the code field address of a word to its parameter field address.
bounds
$\qquad$
bounds ( start cnt -- start+ent start )
code\# ac
Convert a starting value and count into the form required for a do or ?do loop. For example, to perform a loop 20 times, counting up from 4000 to 401 f inclusive, use:

400020 bounds do ... loop

This is equivalent to:
$n$ is the ASCII code for the backspace character; decimal 8.

```
buffer: name ( size -- ) at creation code# (header)
    ( -- adr ) at execution
    generates: new header, where b(type) = b(buffer:)
```

Allocate some memory and create a name that, when executed, leaves on the stack the virtual address of the desired memory. Create with:

## 200 buffer: name

```
bwjoin ( byte.lo byte.hi -- word )
code# bo0
```

Merge two bytes into the low 16-bits of a stack entry (the upper bits are zero). Incorrect results may be generated unless the high 24 bits of each stack item are zero.

4-byte-id ( -- )
code\# fe
This byte (at location 0 ) followed by 3 more identifier bytes, was used during some of the early OpenBoot development as a replacement for actual FCode, by providing a single "magic" number to identify an SBus device. It was a temporary measure only, as it required the boot PROM to "know" the correct magic number for a given device.

This feature is no longer supported, and should not be used under any circumstances.

C! ( n adr -- )
The least significant 8 bits of $n$ are stored in the byte at adr.

C, ( n -- )
Compile a byte into the dictionary. This word may be used, in conjunction with create, to create an array-type structure, as:
create yellow $77 \mathrm{c}, 23 \mathrm{c}$, ff c, ff c, $47 \mathrm{c}, 22 \mathrm{c}$, ..

Later execution of yellow leaves the address of the first byte of the array (the address of the byte ' $77^{\prime}$ ) on the stack.

C@ ( adr -- n )
code\# 71
The byte at address adr is placed into the low 8 -bits of $n$ (the upper bits are padded with zeroes).
/C ( -- n )
code\# 5a
n is the size in bytes of a byte, which is 1 . See /w, /l, and /n.
/C* ( n1 -- n2 ) code\# 66
n 2 is the result of multiplying n 1 by the length in bytes of a byte. This is useful for converting an index into a byte offset.

```
Cat ( adr1 index -- adr2 )
code\# 5e
```

adr2 is the address of the index'th character after adr1. ca+ should be used in preference to + when calculating addresses because it more clearly expresses the intent of the operation and is more portable.

```
ca1t ( adr1 -- adr2 )
code# 62
```

adr2 is the address of the next byte after adr1. ca1+ should be used in preference to $1+$ because it more clearly expresses the intent of the operation and is more portable.

```
$call-method ( [...] adr len ihandle -- [...] )
                                    code# 2 0e
```

    version 2
    Executes the device interface method adr len within the open package instance ihandle. The ellipses (...) indicate that the contents of the stack before and after the method is called depend upon the particular method being called.

For example:

```
: dma-alloc ( #bytes -- vadr ) " dma-alloc" my-parent $call-method ;
```

See open-package.
call-package ( [...] acf ihandle -- [...] ) code\# 208
version 2
Executes the device interface method acf within the open package instance ihandle. See find-method and open-package. The ellipses (...) indicate that the contents of the stack before and after the method is called depend upon the particular method being called.

For example:

```
O value label-ihandle \ place to save the ihandle of other package
O value offset-method \ place to save the acf of found method
: init ( -- )
    my-args " disk-label" $open-package ( ihandle )
    is label-ihandle
    " offset" label-ihandle
    ihandle>phandle ( name-adr name-len phandle )
    find-method if
        is offset-method
    else
        ." Can't find offset method "
    then
;
init
: add-offset ( d.byte# -- d.bytes# )
    offset-method label-ihandle call-package
;
```

\$call-parent ( [...] adr len -- [...]) code\# 209 version 2

Calls the method named by adr len within the parent instance. If the called package has no such method, an error is signaled with throw. Equivalent to:

```
my-parent $call-method
```

The ellipses (...) indicate that the contents of the stack before and after the method is called depend upon the particular method being called.

For example:
: my-dma-alloc ( -- vadr ) h\# 2000 " dma-alloc" \$call-parent ;

```
carret ( -- n )
```

n is the ASCII code for the carriage return character; decimal 13, hex 0 d .

```
Case ( selector -- selector ) code# c4
    generates: b(case)
```

A case statement is started that selects its action based on the value of selector. Example of use:

```
: foo ( selector -- )
    case
        0 of ." It was 0" endof
        5 of ." It was 5" endof
        -2 of ." It was -2" endof
        ( selector ) ." It was " dup u. \ default clause
    endcase
;
```

The default clause is optional. When an of clause is executed, the selector is not on the stack. When a default clause is executed, the selector is on the stack. The default clause may use the selector, but must not remove it from the stack (it will be automatically removed just before the encase). of tests the top of the stack against the selector at run time. If they are the same, the selector is dropped and the following Forth code is executed. If they are not the same, execution continues at the point just following the matching endof.
case statements can only be used within colon definitions.

Catch ( [...] acf -- [...] error-code )
version 2
Creates a new error handling context and executes acf in that context.
If a throw (see below) is called during the execution of acf,

1. the error handling context is removed
2. the stack depth is restored to the depth that existed prior to the execution of acf (not counting the acf stack item)
3. the error code that was passed to throw is pushed onto the stack
4. catch returns

If throw is not called during the execution of acf, the error handling context is removed and catch returns a false. The stack effect is otherwise the same as if acf were executed using execute.

For example:

```
: add-n-check-limit ( n1 n2 n3 -- n )
    + + dup h# 30 > if true throw then
;
: add-me ( n1 n2 n3 -- a b c | n1+n2+n3 )
    ['] add-n-check-limit catch if
        ." Sum exceeds limit " .s
    else
        ." Sum is within limit. Sum = " .s
    then cr
;
```

Note that, given this definition:

```
12 3 add-me
```

shows

```
Sum is within limit. Sum = 6
```

while

$$
102030 \text { add-me }
$$

may show something like:

$$
\text { Sum exceeds limit } 50912
$$

An important thing to note is that upon a non-zero throw, only the stack depth is guaranteed to be the same as before catch, not the data stack contents.

## char-height

( -- n )
code\# 1 6c
A value, containing the standard height (in pixels) for all characters to be drawn. This number, when multiplied by \#lines, determines the total height (in pixels) of the active text area.

This word must be set to the appropriate value if you wish to use any fb1- or fb8- utility routines or >font. This may be done with is, but is normally done by calling set-font.
char-width ( -- n ) code\# 1 6d

A value, containing the standard width (in pixels) for all characters to be drawn. This number, when multiplied by \#columns, determines the total width (in pixels) of the active text area.

This word must be set to an appropriate value if you want to use any fb1- or fb 8 - utility routines. This may be done with is, but is normally done by calling set-font.

The fb1 and fb8 character painting support routines in current PROMs do not support widths larger than 16 (decimal). However, it is possible to display wider characters by splitting each character bitmap into 2 halves and calling fbx-draw-character twice.
child ( parent-phandle -- child-phandle )
code\# 2 3b version 2.3

Returns the phandle of the package that is the first child of the package parent-phandle.
child returns zero if the package parent-phandle has no children,.
You will generally use child, together with peer, to enumerate (possibly recursively) the children of a particular device. One common use could be for bus adapter device drivers to use the phrase my-self ihandle>phandle to develop the parent-phandle argument.

## For example:

```
: my-children ( -- ) \ shows phandles of all children
    my-self ihandle>phandle child ( first-child )
    begin ?dup while dup .h peer repeat
;
```

## close-package

( ihandle --)
code\# 206
version 2
Closes the instance identified by ihandle by calling that package's close method and then destroying the instance.

For example:

```
: tftp-load-avail? ( -- exist? )
    0 0 " obp-tftp" $open-package ( ihandle )
    dup ihandle>phandle " load" rot
    find-method if drop true else false then
    close-package
;
```

Cmove ( adr1 adr2 len -- )

Copy len bytes of an array starting at adr1 to adr2. This word calls move, which is "smart" and correctly handles overlapping arrays in either direction.
cmove and cmove> are older standard Forth words that explicitly command in which order to copy the bytes (back-to-front, or front-to-back). In most cases, the distinction is not important. This distinction is important if the arrays overlap, else the source array may be overwritten prematurely, with unexpected results.
move will also perform 16-bit, 32-bit or possibly even 64-bit operations (for better performance) if the alignment of the operands permit. If your hardware requires explicit 8 -bit or 16 -bit accesses, you will probably wish to use an explicitly-coded do... loop instead.

```
Cmove> ( adr1 adr2 len -- )
code# 78
generates: move
```

Copy len bytes of an array starting at adr1 to adr2. This word simply calls move. See cmove for more information.

## column\# ( -- n )

code\# 153
A value, set and controlled by the terminal emulator, that contains the current horizontal position of the text cursor. A value of 0 represents the leftmost cursor position (this is not the leftmost pixel of the framebuffer - see windowleft).

This word can (and should) be looked at as needed if your FCode program is implementing its own set of framebuffer primitives.

For example:

```
: set-column ( column# -- )
    0 max #columns 1-min is column#
;
```

\#columns ( -- n )
code\# 151
This is a value that returns the number of columns of text, i.e. the number of characters in a line, to be displayed using the boot PROM's terminal emulator. It must be set to a proper value in order for the terminal emulator to function correctly.
\#columns is defined in the boot PROM with an initial value of 80 (decimal), but it should always be actively set by the FCode program. This may be done with is, or it may be handled automatically as one of the functions performed by fbl-install or fb8-install. The value set by fbx-install or is the smaller of the passed \#cols parameter and the screen-\#columns NVRAM parameter.

For example:

```
: set-column ( column# -- )
    0 max #columns 1- min is column#
;
```

Compare two byte arrays starting at addresses adr1 and adr2 and continuing for len bytes. n is 0 if the arrays are the same. n is 1 if the first differing character in the array at adr1 is numerically greater than the corresponding character in the array at adr2. $n$ is -1 if the first differing character in the array at adr1 is numerically less than the corresponding character in the array at adr2.

For example:
" this" drop " that" comp .h
shows 1
" thisismy" drop " this" comp .h
shows 0
" thin" drop " this" comp .h
shows ffffffff .

Constant name ( $\mathrm{n} 1--$ ) at creation code\# (header) ba
( -- n1 ) at execution
generates: new header, $b(t y p e)=b$ (constant)
Creates a named constant. The name is initially created with:

```
456 constant purple
```

where the number before constant is the desired value for purple. Later occurrences of purple will leave the correct value on the stack. constant values should never be changed by the program. If you wish to change the value of a constant by the program, you should declare it to be a value instead.

```
control x ( -- n ) code# 10 00 00 00 xx
generates: b(lit) value
```

Interpret the next letter as a control-code. For example:

```
control c ( equals 03 )
```

Count ( pstr -- adr len )

Convert a packed string into a byte-array format. pstr is the address of a packed string, where the byte at address pstr is the length of the string and the string itself starts at address pstr+1.

Packed strings are generally not used in FCode. Virtually all string operations are in the "adr len" format.

For example:

```
h# 100 alloc-mem constant my-buff
" This is a string" my-buff pack ( pstr ) count type
```

Cpeek ( adr -- false | byte true ) code\# 20
version 2

Tries to read the 8 -bit byte at address adr. Returns the data and true if the access was successful. A false return indicates that a read access error occurred.

Cpoke ( byte adr -- ok? )
code\# 223
version 2
Attempts to write the 8 -bit byte at address adr. Returns true if the access was successful. A false return indicates that a write access error occurred.

Note - cpoke may be unreliable on bus adapters that buffer write accesses.

A defer word used to terminate the line on the display and go to the next line. The default implementation transmits a carriage return and line feed to the display, clears \#out, and adds 1 to \#line.

Use cr whenever you want to start a new line of output, or to force the display of any previously buffered output text. This forcing is valuable for outputting error messages, to ensure that the error message is sent before any system crash.

For example:

```
: show-info ( -- )
    ." This is the first line of output " cr
    ." This is the second line of output " cr
;
```

(Cr ( -- )
Output only the carriage return character (carret, hex 0d). This word is not commonly used; see cr.

```
Create name ( -- ) at creation code# (header) bb
    ( -- adr ) at execution
generates: new header, b(type) = b(create)
```

Create a name. It returns the address of memory at run time, immediately following the name in the dictionary. You can use this word to create an arraytype structure, as:

```
create green 77 c, 23 c, ff c, ff c, 47 c, 22 c, ...
```

Later execution of green leaves the address of the first byte of the array (here, the address of the byte '77') on the stack. The returned address will be twobyte aligned.

In the current implementation, create may not be used within definitions in an FCode program. The common Forth construct create...does> is not supported.

```
.d ( n -- ) code# a0 6d 49 10 00 00 00 0a a0 72 9d a0 72
    generates: base @ swap d# 10 base ! . base !
```

n is displayed in decimal (using . ). The value of base is not permanently affected.

```
d# number ( -- n ) code# 10 value
    generates: b(lit) value
```

Interpret the next number in decimal (base 10), regardless of any previous settings of hex, decimal, binary, or octal. Only the immediately following number is affected, the default numeric base setting is unchanged. For example:

```
hex
d# 100 ( equals decimal 100 )
100 ( equals decimal 256 )
```

See also b\#, h\#, and o\#.

## decimal

( -- )
code\# none
generates: 10 base ! code\# $10 \quad 00 \quad 0000$ aa a0 72
If outside of a definition, commands the tokenizer program to interpret subsequent numbers in decimal (base 10). If within a definition, change the value in base affecting later numeric output when the FCode program is executed. See base.

```
decode-2int ( adr len -- phys space )
code# 1 1b
version 2
```

Converts a string into a physical address and space.
For example:

```
" 4,ff001200" decode-2int .s
will show: ff001200 4
" 4" decode-2int .s
will show: 0 4
```

default-font ( -- fontbase charwidth charheight fontbytes \#firstchar \#chars
This function returns all necessary information about the character font that is built into the boot PROM. This font defines the appearance of every character to be displayed. To load this font, simply pass these parameters to set-font, with:

> default-font set-font

The actual parameters returned by default-font are:
fontbase - The address of the beginning of the built-in font table
charwidth - The width of each character in pixels
charheight - The height of each character in pixels
fontbytes - The separation (in bytes) between each scan line entry
\#firstchar - The ASCII value for the first character actually stored in the font table.
\#chars - The total number of characters stored in the font table.

```
defer name ( -- ) at creation code# (header) bc
    ( ??? -- ? ) at execution
generates: new header, b(type) = b(defer)
```

Create a defer'd executable. This is a word that has a variable behavior, depending on the function that is later loaded into it. The name is initially created with:

```
defer blob
```

Later, after some other word foobar has been created, this behavior can then be loaded in, with:

[^5]defer'd words are useful for generating recursive routines. Here's an example:

```
defer hold2 \ Will execute action2
: action1
    hold2 ( really action2 )
    ... ;
: action2
    ...
    action1
    ... ;
    v action2 is hold2
```

defer'd words can also be used for creating words with different behaviors depending on your needs. For example:

```
defer .special ( n -- ) \ Print a value, using special techniques
: print-em-all ( -- )
    ... .special
    ... .special
    ... .special
;
    ( .d prints in decimal
    ( .h prints in hexadecimal )
    ( .sp prints in a custom format )
    : print-all-styles
        [`] .d is .special print-em-all
        [`] .h is .special print-em-all
        [`] .sp is .special print-em-all
    ;
```

If a defer word is executed before being loaded with some behavior, an error message will be printed.

```
delete-attribute ( adr len -- ) code# 2 le
version 2
```

Deletes the property named by adr len in the active package, if such a property exists.

For example:

```
: unmap-me ( -- )
    my-reg my-size " map-out" $call-parent
    " address" delete-attribute
```

;

## delete-characters ( n -- )

code\# 1 5e
A defer word, called by the terminal emulator when needed to delete n characters to the right of the cursor. The cursor position is unchanged, the cursor character and the first $\mathrm{n}-1$ characters to the right of the cursor are deleted. All remaining characters to the right of the cursor, including the highlighted character, are moved left by n places. The end of the line is filled with blanks.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-delete-characters or fb8-delete-characters, respectively).
delete-lines ( n -- )
code\# 160
A defer word, called by the terminal emulator to delete $n$ lines starting with the cursor line (and deletes $\mathrm{n}-1$ lines below the cursor). Lines above the cursor are unchanged. The cursor position is unchanged. All lines below the deleted lines are scrolled upwards by $n$ lines, and $n$ blank lines are placed at the bottom of the active text area.

Use this word for scrolling, by temporarily moving the cursor to the top of the screen and then calling delete-lines.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fbl-install or fb8-install (which loads fb1-delete-lines or fb8-delete-lines, respectively).

## depth

$\qquad$
+n is the number of entries contained in the data stack, not counting itself. Note that when an FCode program is called, there could be other items on the stack from the calling program.
depth is especially useful for before/after stack depth checking, to determine if the stack was corrupted by a particular operation.

```
device-name
( adr len -- )
code# 2 01
version 2
```

Creates a name attribute with the given string value, for example:

```
" SUNW,zebra" device-name
```

This is equivalent to using the name macro or

```
xdrstring " name" attribute
```

except that device-name performs the same function with only 2 bytes of FCode, instead of 10 bytes. This could be useful for devices with extremely limited FCode space.

See "name" in Chapter 5, "Properties" for more information.
device-type ( adr len -- )
This is a shorthand word for creating a "device_type" property. This property is essential for any plug-in SBus device that will be used during booting, as it tells the boot PROM which type of boot device it is. An example usage would be:

```
" display" device-type
```

This is exactly equivalent to the following:

```
" display" xdrstring " device_type" attribute
```

Note the spelling difference between the FCode command device-type (hyphen) and the device_type property (underscore).

The device_type property is looked at and used by the boot PROM as well. See also: "device_type" in Chapter 5, "Properties".

Returns a true flag if the diag-switch? NVRAM parameter is set to true. This word enables an FCode program to optionally perform some extended selftests, based on the diag-switch? . For example:

```
diagnostic-mode?
if do-extended-tests
else do-normal-tests
then
```

FCode should not generate character output during probing unless diagnostic-mode? is true, or unless an error is encountered. Error output during probing typically goes to the system serial port.
digit ( char base -- digit true | char false ) code\# a3
If the character char is a digit in the specified base, returns the numeric value of that digit under true, else returns the character under false. Appropriate characters are hex 30-39 (for digits 0-9) and hex 61-66 (for digits a-f), depending on base.

## For example:

```
: probe-slot ( slot# -- ) ... ;
: probe-slots ( adr cnt -- )
    bounds ?do
            i c@ d# 16 digit if probe-slot else drop then
    loop
;
```

## display-status ( n -- ) <br> code\# 121

Display the results of some test. The method of display is system-dependent. This FCode is obsolete and should not be used.

```
do ( limit start -- ) code# 17 +offset
```

generates: b(do) +offset

Begin a counted loop in the form do . . . loop or do . . . +loop. The loop index begins at start, and terminates based on limit. See loop and +loop for details on how the loop is terminated. The loop is always executed at least once. For example:

```
8 3 do i . loop \ would print 3 4 5 6 7
```

93 do i . 2 +loop \would print 357
?do ( limit start -- ) code\# 18 +offset
generates: b(?do) +offset

Begin a counted loop in the form ? do . . . loop or ? do . . . +loop. The loop index begins at start, and terminates based on limit. See loop and +loop for details on how the loop is terminated. Unlike do, if start is equal to limit the loop is executed zero times. For example:

| 8 | 1 | ?do i | loop | \would print | 1 | 2 | 3 | 4 | 5 | 6 | 7 |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 2 | 1 | ?do i |  |  |  |  |  |  |  |  |  |  |
| 1 | 1 | ?do i loop | loop | \would print | 1 |  |  |  |  |  |  |  |
| 1 | 1 | do i . loop | \would print nothing |  |  |  |  |  |  |  |  |  |
| $\ldots$ |  |  |  | would print | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |

?do may be used in place of do in nearly all circumstances.
dma-alloc ( \#bytes -- virtual )
code\# 101
Used to allocate memory for DMA usae. The allocated memory may be returned to the system with free-virtual.

This FCode is obsolete on OpenBoot 2 PROMs. For use under OpenBoot 1, see Appendix D, "Changes in OpenBoot 1 FCode Usage". Also see Appendix C, "FCode Memory Allocation" for more information.

For version 2 OpenBoot systems, use " dma-alloc" method of parent:

```
" dma-alloc" $call-parent
" dma-map-in" $call-parent
```

For example:

```
: my-dma-alloc ( -- )
    my-size " dma-alloc" \$call-parent ( vaddr )
    is my-reg
;
```

draw-character ( char -- )
code\# 157
A defer word, called by the boot PROM's terminal emulator in order to display a single character on the screen at the current cursor location.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fbl-install or fb8-install (which loads fb1-draw-character or fb8-draw-character, respectively).

## draw-logo

line\# laddr lwidth lheight -- )
code\# 161
A defer word, called by the system to display the power-on logo (the graphic displayed on the left side during power-up, or by the banner Toolkit command).

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-draw-logo or fb8-draw-logo, respectively).

It is possible to pack a custom logo into the FCode PROM and then reinitialize draw-logo to output the custom logo instead.
draw-logo is called by the system using the following parameters:
line\# - The text line number at which to draw the logo.
laddr - The address of the logo template to be drawn. In practice, this will always be either the address of the oem-logo field in NVRAM, the address of a custom logo in the FCode PROM, or the address of a built-in Sun logo. In either case, the logo is a bit array of $64 \times 64$ (decimal) pixels ( 512 bytes). The most significant bit (msb) of the first byte represents the upper-left pixel; msb-1 represents the next pixel to the right, and so on. A bit value of 1 means that pixel will be painted.
lwidth - The width of the passed-in logo (in pixels).
lheight- The height of the passed-in logo (in pixels).

```
driver ( adr len -- )
```

code\# 18

This is an obsolete word for creating a name property.
driver is no longer supported and should not be used in FCode programs.

```
drop ( n -- ) code# 46
```

Removes one item from the stack.

```
2drop ( n1 n2 -- ) code# 52
```

Removes two items from the stack.

```
3drop ( n1 n2 n3 -- )
                                    code# 46 52
    generates: drop 2drop
```

Removes three items from the stack.

```
dup (n1 -- n1 n1 ) code# 47
```

Duplicates the top stack item.
?dup $(\mathrm{n} 1-0 \quad$ code\# 50
Duplicate the top stack item unless it is zero.

## 2dup ( n1 n2 -- n1 n2 n1 n2 ) <br> code\# 53

Duplicates the top two stack items.

3dup ( n1 n2 n3 -- n1 n2 n3 n1 n2 n3 ) code\# a7 4e a7 4e a7 4e generates: 2 pick 2 pick 2 pick

Duplicates the top three stack items.
else ( -- ) bode\# 13 +offset b2
Begin the else clause of an if ... else ... then statement. See if for more details.
emit ( char -- )
code\# 8f
A defer word that outputs the indicated ASCII character. For example, (hex) 41 emit outputs an " $A$ ", 62 emit outputs $a$ " $b$ ", 34 emit outputs a " 4 ".
emit-byte
( $n$-- )
code\# n
generates: $n$
A tokenizer command used to manually output a desired byte of FCode. Use it together with tokenizer [ as follows:

```
tokenizer[
    44 emit-byte 20 emit-byte
]tokenizer
```

emit-byte would be useful, for example, if you wished to generate a new FCode command that the tokenizer did not understand. This command should be used with caution or else an invalid FCode program will result.

## end0 ( -- )

code\# 00
A word that marks the end of an FCode program. This word must be present at the end of your program, or erroneous results may occur.

If you want to use endo inside a colon definition, for example in a conditional clause, use something like:

An alternate word for endo, to mark the end of an FCode program. endo is recommended.

```
endcase ( selector|<null> -- ) code# c5
    generates: b(endcase)
```

Marks the end of a case statement. See case for more details.

```
endof ( -- ) code# c6 +offset
    generates: b(endof) +offset
```

Marks the end of an of clause within a case statement. See case for more details.

```
erase ( adr len -- )
code# a5 79
```

    generates: 0 fill
    Sets len bytes of memory beginning at adr to zero. No action is taken if len is zero.
erase-screen ( -- )
code\# 1 5a
A defer word, called once during the terminal emulator initialization sequence in order to completely clear all pixels on the display. This word is called just before reset-screen, so that the user doesn't actually see the framebuffer data until it has been properly scrubbed.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-erase-screen or fb8-erase-screen, respectively).

```
eval ( ??? adr len -- ? )
code# cd
```

version 2

Executes Forth commands within a string. The overall stack effect depends on the commands being executed. For example:

```
" 4000 20 dump" eval
```

You can use eval like \$find, to find and execute Forth commands that are not FCodes.

The same cautions apply to eval as for \$find, in that programs executing Forth commands are likely to encounter portability problems when moved to other systems.

```
execute ( acf -- )
```

code\# 1d

Executes the word definition whose compilation address is acf. An error condition exists if acf is not a compilation address.

For example:

```
: my-word ( adr len -- )
    ." Given string is: " type cr
;
great" ['] my-word execute
```

exit ( -- )
code\# 33
Compiled within a colon definition. When encountered, execution leaves the current word and returns control to the calling word. May not be used within a do loop.

For example:

```
: probe-loop ( adr -- )
    \ generate a tight probe loop until any key is pressed.
    begin dup l@ drop key? if drop exit then again
;
```

## 三11

expect ( adr len -- )
code\# 8a
A defer word that receives a line of characters from the keyboard and stores them into memory, performing line editing as the characters are typed. Displays all characters actually received and stored into memory. The number of received characters is stored in span.

The transfer begins at adr proceeding towards higher addresses one byte per character until either a return is received or until len characters have been transferred. No more than len characters will be stored. The return is not stored into memory. No characters are received or transferred if len is zero.

For example:

```
h# 10 buffer: my-name-buff
: hello ( -- )
    ." Enter Your First name " my-name-buff h# 10 expect
    ." Sun Microsystems Welcomes " my-name-buff span @ type cr
;
```

external ( -- ) code\# none
version 2

After issuing external, all subsequent definitions are created so that names are later compiled into RAM, regardless of the value of the NVRAM variable fcode-debug?. external is used to define the package methods that may be called from other software external to the package, and whose names must therefore be present.
external stays in effect until headers or headerless is encountered.
For example:

```
external
: open ( -- ok? ) ... ;
```

## external-token

( -- )
code\# ca
version 2
A token-type, used to indicate that this word should always be compiled with the name header present. Activated by external, all subsequent words are created with external-token until deactivated with either headers or headerless. See named-token for more details. This word should never be used in source code.

```
false ( -- 0 ) code# a5
    generates: 0
```

Leave the value for the false flag (which is zero) on the stack.
fb1-blink-screen ( -- )
code\# 174
The built-in default routine to blink or flash the screen momentarily on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word blink-screen by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and has initialized frame-buffer-adr to a valid virtual address.

This word is implemented simply by calling fb1-invert-screen twice. In practice, this can be quite slow (around one full second). It is quite common for a framebuffer FCode program to replace fb1-blink-screen with a custom routine that simply disables the video for 20 milliseconds or so, i.e.

```
: my-blink-screen ( -- ) video-off 20 ms video-on ;
...
fb1-install
['] my-blink-screen is blink-screen
```

The built-in default routine to delete n characters at and to the right of the cursor, on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word delete-characters by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position is unchanged, the cursor character and the next $n-1$ characters to the right of the cursor are deleted, and the remaining characters to the right are moved left by n places. The end of the line is filled with blanks.

## fb1-delete-lines

( $n-2$
code\# 179
The built-in default routine to delete $n$ lines, starting with the cursor line, on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word delete-lines by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor line and $n-1$ lines below it are deleted. All lines above the cursor line are unchanged. The cursor position is unchanged. All lines below the deleted lines are scrolled upwards by $n$ lines, and $n$ blank lines are placed at the bottom of the active text area.

```
fb1-draw-character ( char -- )
code# 1 70
```

The built-in default routine for drawing a character on a generic 1-bit-per-pixel framebuffer, at the current cursor location. This routine is loaded into the defer word draw-character by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

If inverse? is true, then characters are drawn inverted (white-on-black). Otherwise (the normal case) they are drawn black-on-white.
fb1-draw-logo ( line\# logoadr lwidth lheight -- ) code\# 1 7a
The built-in default routine to draw the logo on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word draw-logo by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

See draw-logo for more information on the parameters passed.

## $11 \equiv$

## fb1-erase-screen

( -- )
code\# 173
The built-in default routine to clear (erase) every pixel in a generic 1-bit-perpixel framebuffer. This routine is loaded into the defer word erase-screen by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and has initialized frame-buffer-adr to a valid virtual address.

All pixels are erased (not just the ones in the active text area). If inversescreen? is true, then all pixels are set to 1 , resulting in a black screen. Otherwise (the normal case) all pixels are set to 0 , resulting in a white screen.

## fb1-insert- <br> characters ( n --

The built-in default routine to insert n blank characters to the right of the cursor, on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word insert-characters by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position is unchanged, but the cursor character and all characters to the right of the cursor are moved right by n places. An error condition exists if an attempt is made to create a line longer than the maximum line size (the value in \#columns ).
fb1-insert-lines ( n -- )
code\# 178
The built-in default routine to insert n blank lines below the cursor on a generic 1-bit-per-pixel framebuffer. This routine is loaded into the defer word insert-lines by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position on the screen is unchanged. The cursor line is pushed down, but all lines above it are unchanged. Any lines pushed off of the bottom of the active text area are lost.
( screen-width screen-height code\# 17 b
\#cols \#lines -- )

This built-in routine installs all of the built-in default routines for driving a generic 1-bit-per-pixel framebuffer. It also initializes most necessary values needed for using these default routines.
set-font must be called, and frame-buffer-adr initialized, before fb1install is called, because the char-width and char-height values set by set-font are needed when fb1-install is executed.
fb1-install loads the following defer routines with their corresponding fb1-(whatever) equivalents: reset-screen, toggle-cursor, erasescreen, blink-screen, invert-screen, insert-characters, delete-characters, insert-lines, delete-lines, draw-character, draw-logo.

The following values are also initialized:
screen-width - set to the value of the passed-in parameter screenwidth (screen width in pixels)
screen-height - set to the value of the passed-in parameter screenheight (screen height in pixels)
\#columns - set to the smaller of the following two: the passed-in parameter \#cols, and the NVRAM parameter screen-\#columns
\#lines - set to the smaller of the following two: the passed-in parameter \#lines, and the NVRAM parameter screen-\#rows
window-top - set to half of the difference between the total screen height (screen-height) and the height of the active text area (\#lines times char-height)
window-left - set to half of the difference between the total screen width (screen-width) and the width of the active text area (\#columns times charwidth), then rounded down to the nearest multiple of 32 (for performance reasons)

Several internal values used by various fb1- routine are also set.
fb1-invert-screen ( -- )
code\# 175
The built-in default routine to invert every visible pixel on a generic 1-bit-perpixel framebuffer. This routine is loaded into the defer word invertscreen by calling fb1-install.

This routine is invalid unless the FCode program has called fb1-install and has initialized frame-buffer-adr to a valid virtual address.

All pixels are inverted (not just the ones in the active text area).
fb1-reset-screen
( -- )
code\# 171
The built-in default routine to enable a generic 1-bit-per-pixel framebuffer to display data. This routine is loaded into the defer word reset-screen by calling fb1-install. (reset-screen is called just after erase-screen during the terminal emulator initialization sequence.)

This word is initially a NOP. Typically, an FCode program will define a hardware-dependent routine to enable video, and then replace this generic function with:

```
: my-video-enable ( -- ) ... :
fb1-install
...
['] my-video-enable is reset-screen
```

fb1-slide-up ( n -- )
code\# 1 7c

This is a utility routine. It behaves exactly like fb1-delete-lines, except that it doesn't clear the lines at the bottom of the active text area. Its only purpose is to scroll the enable plane for framebuffers that have 1-bit overlay and enable planes.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.
fb1-toggle-cursor ( -- )
code\# 172
The built-in default routine to toggle the cursor location in a generic 1-bit-perpixel framebuffer. This routine is loaded into the defer word togglecursor by calling fb1-install. The behavior is to invert every pixel in the one-character-size space for the current position of the text cursor.

This routine is invalid unless the FCode program has called fb1-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

## fb8-blink-screen ( -- )

code\# 184
The built-in default routine to blink or flash the screen momentarily on a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word blink-screen by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and has initialized frame-buffer-adr to a valid virtual address.

This word is implemented simply by calling fb8-invert-screen twice. In practice, this can be very slow (several seconds). It is quite common for a framebuffer FCode program to replace fb8-blink-screen with a custom routine that simply disables the video for 20 milliseconds or so, i.e.

```
: my-blink-screen ( -- ) video-off 20 ms video-on ;
...
fb8-install
...
['] my-blink-screen is blink-screen
```

fb8-delete-
characters ( n -- ) code\# 187

The built-in default routine to delete n characters to the right of the cursor, on a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word delete-characters by calling fb8-install.
This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position is unchanged. The cursor character and the next $n-1$ characters to the right of the cursor are deleted, and the remaining characters to the right are moved left by n places. The end of the line is filled with blanks.

## fb8-delete-lines ( n -- ) <br> code\# 189

The built-in default routine to delete $n$ lines, starting with the cursor line, on a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word delete-lines by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor line and $\mathrm{n}-1$ lines below it are deleted. All lines above the cursor line are unchanged. The cursor position is unchanged. All lines below the deleted lines are scrolled upwards by $n$ lines, and $n$ blank lines are placed at the bottom of the active text area.
fb8-draw-character ( char -- )
code\# 180
The built-in default routine for drawing a character on a generic 8 -bit-per-pixel framebuffer, at the current cursor location. This routine is loaded into the defer word draw-character by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

If inverse? is true, then characters are drawn inverted (white-on-black). Otherwise (the normal case) they are drawn black-on-white.

```
fb8-draw-logo ( line# logoadr lwidth lheight -- ) code# 1 8a
```

The built-in default routine to draw the logo on a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word draw-logo by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The logo is drawn by painting every desired pixel with the value 01 (normal characters are painted with the value FF). Typically, color\# 0xff is set to black (for normal black characters), whereas color\#01 is set to Sun-blue so that the Sun logo is painted the proper color.

See draw-logo for more information on the parameters passed.

## fb8-erase-screen <br> fb8-insert-

( -- )
code\# 183
The built-in default routine to clear (erase) every pixel in a generic 8-bit-per-pixel framebuffer. This routine is loaded into the defer word erase-screen by calling fb8-install.

This routine is invalid unless the FCode program has called $f b 8$-install and has initialized frame-buffer-adr to a valid virtual address.

All pixels are erased (not just the ones in the active text area). If inversescreen? is true, then all pixels are set to 0xff, resulting in a black screen. Otherwise (the normal case) all pixels are set to 0 , resulting in a white screen.
characters ( n -- ) code\# 186
The built-in default routine to insert n blank characters to the right of the cursor, on a generic 8-bit-per-pixel framebuffer. This routine is loaded into the defer word insert-characters by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position is unchanged, but the cursor character and all characters to the right of the cursor are moved right by n places. An error condition exists if an attempt is made to create a line longer than the maximum line size (the value in \#columns).

## fb8-insert-lines ( n -- )

code\# 188
The built-in default routine to insert $n$ blank lines below the cursor on a generic 8-bit-per-pixel framebuffer. This routine is loaded into the defer word insertlines by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.

The cursor position is unchanged. The cursor line is pushed down, but all lines above it are unchanged. Any lines pushed off of the bottom of the active text area are lost.

## fb8-install ( screen-width screen-height \#cols \#lines -- )

This built-in routine installs all of the built-in default routines for driving a generic 8 -bit-per-pixel framebuffer. It also initializes most necessary values needed for using these default routines.
set-font must be called, and frame-buffer-addr initialized, before fb8install is called, because the char-width and char-height values set by set-font are needed when fb8-install is executed.
fb8-install loads the following defer routines with their corresponding fb8(whatever) equivalents: reset-screen, toggle-cursor, erase-screen, blink-screen, invert-screen, insert-characters, deletecharacters, insert-lines, delete-lines, draw-character, draw-logo

The following values are also initialized:
screen-width - set to the value of the passed-in parameter screen-width (screen width in pixels)
screen-height - set to the value of the passed-in parameter screenheight (screen height in pixels)
\#columns - set to the smaller of the following two: the passed-in parameter \#cols, and the NVRAM parameter screen-\#columns

> \#lines - set to the smaller of the following two: the passed-in parameter \#lines, and the NVRAM parameter screen-\#rows
> window-top - set to half of the difference between the total screen height ( screen-height ) and the height of the active text area ( \#lines times char-height)
> window-left - set to half of the difference between the total screen width ( screen-width ) and the width of the active text area (\#columns times char-width ), then rounded down to the nearest multiple of 32 (for performance reasons)

Several internal values are also set that are used by various fb 8 - routines.

## fb8-invert-screen ( -- ) <br> code\# 185

The built-in default routine to XOR (with hex 0xff) every visible pixel on a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word invertscreen by calling fb8-install.

This routine is invalid unless the FCode program has called fb8-install and has initialized frame-buffer-adr to a valid virtual address.

All pixels are inverted (not just the ones in the active text area).
fb8-reset-screen
( --
code\# 181
The built-in default routine to enable a generic 8 -bit-per-pixel framebuffer to display data. This routine is loaded into the defer word reset-screen by calling fb8-install. ( reset-screen is called just after erase-screen during the terminal emulator initialization sequence.)

This word is initially a NOP. Typically, an FCode program will define a hardwaredependent routine to enable video, and then replace this generic function with:

```
: my-video-enable ( -- ) ... :
fb8-install
['] my-video-enable is reset-screen
...
```

## fb8-toggle-cursor ( -- )

code\# 182
The built-in default routine to toggle the cursor location in a generic 8 -bit-per-pixel framebuffer. This routine is loaded into the defer word toggle-cursor by calling fb8-install. The behavior is to XOR every pixel with 0xff in the one-character-size space for the current position of the text cursor.

This routine is invalid unless the FCode program has called fb8-install and set-font and has initialized frame-buffer-adr to a valid virtual address.
fcode-version

```
vers
```

This FCode is obsolete, use version instead.

This word, or fcode-version2, must be the first command in your FCode program (except for tokenizer directives such as hex or $\backslash$ that do not generate any FCode bytes). The command fcode-version1 creates an 8-byte header, as:

| (fd) version1 | $(1$ byte ) |
| :--- | :--- |
| (00) null byte | $(1$ byte ) |
| (xxyy) reserved | $(2$ bytes ) |
| (aabbccdd) length | $(4$ bytes ) |

The length field specifies the total usable length of FCode data, from version1 to end0 inclusive. Additional endo bytes are appended to the end of the data, if needed, to leave a total length which is evenly divisible by 4 . The "null byte" position may be used in the future to carry a version number or other information, but it is currently not used.

See Appendix D, "Changes in OpenBoot 1 FCode Usage".

```
fcode-version2 ( -- ) code# f1 00 xx yy aa bb cc dd
    generates: start1 (null) (reserved) (length)
    version 2
Starts a version2 FCode program, generating an 8-byte header similar to fcode-version1, except that the starting byte is start1 (f1) instead of version1 (fd).
```

For example:

```
fcode-version2
" SUNW,nvsimm" xdrstring " name" attribute
end0
```

Caution - FCode programs created with fcode-version2 will only run on OpenBoot 2 or later systems. They will not work on OpenBoot 1.0 systems.

Caution - In most cases, use fcode-version1, along with an escape routine to prevent any version 1.0 systems from trying to execute, as shown in the following example:

```
: ?quit ( -- ) version h# 2.0000 < if ['] end0 execute then ;
?quit
```

See Appendix D, "Changes in OpenBoot 1 FCode Usage".
ferror $\square$ version 2.3

Displays an "Unimplemented FCode" error message and stops FCode interpretation. All unimplemented FCode numbers resolve to ferror in all existing OpenBoot implementations.

The intended use of ferror is to determine whether or not a particular FCode is implemented, without checking the FCode version number.

For example:

```
: implemented? ( acf -- flag) [`] ferror <> ;
: my-peer ( prev -- next )
    [`] peer implemented? if
        peer
    else
        ." peer is not implemented" cr
    then
:
```

field ( offset size -- offset+size ) at creation code\# (header) be ( base -- base+offset ) at execution generates: new header, b(type) $=$ b(field)
struct and field are used to create named offset pointers into some array structure. For each field in the array structure, a name is assigned to the location of that field (as an offset from the beginning of the array). Here's a code example. (The numbers in parentheses show the stack after each word is created.) The structure being described is:

Typical usage of these defined words would be:

```
/record buffer: myrecord \ Create the "myrecord" buffer
myrecord flags l@ \ get flags data
myrecord key c@ \ get key data
myrecord size w@ \ get size data
/record \ get total size of the array
```

Note that struct is merely a cross-compiler equivalent that puts the number 0 on the stack.
fill ( adr u byte -- )
code\# 79
Set $u$ bytes of memory beginning at adr to byte. No action taken if $u=0$.
\$find ( adr len -- adr len false | acf +/-1 ) code\# cb
Takes a string from the stack, and tries to find that word in the OpenBoot PROM. This is an escape hatch, allowing an FCode program to perform any function that is available in the OpenBoot Forth Monitor but that is not defined as part of the standard FCode interface.

If the word is not found, the original string is left on the stack, with a false on top of the stack. If the word is found, the code field address of that word is left on the stack, and either a +1 or -1 is left on top. +1 is left if the found word is an immediate word, -1 is left otherwise.

Use \$find with caution! Different CPUs or even different versions of the boot PROM may change or delete certain words in the Toolkit. If your FCode program depends on one of these words, you may suddenly find that your SBus card doesn't work properly with future releases.

Caution - If you find yourself tempted to use \$find, please contact the Sun SBus Support Group and tell them what function you need to use this way. This will help Sun to plan for future FCode features, and will let you know the likelihood of the needed Toolkit word being changed in the future.

Example of use:

```
" root-info" $find ( adr len false | acf +/-1 )
if execute \ if found, then do the function
    \ in this example, we don't care about
    \ immediate vs. non-immediate
else ( adr len ) type ." was not found!" cr
then
```

find-method ( adr len phandle -- false | acf true ) code\# 207 version 2

Locates the method named by adr len within the package phandle. Returns false if the package has no such method, or acf and true if the operation succeeds. Subsequently, acf may be used with call-package.

For example:

```
: tftp-load-avail? ( -- exist? )
    " obp-tftp" find-package if ( phandle )
        " load" rot find-method if ( acf )
            drop true exit
        then
    then
    false
;
```

find-package ( adr len -- false | phandle true )
version 2

Locates a package whose name is given by the string adr len. If the package can be located, returns its phandle and true. Otherwise returns false. The name is interpreted relative to the / packages device node. For example, if adr len represents the string "disk-label", the package in the device tree at "/packages/disk-label" will be located. If there are multiple packages with the same name (within the /packages node), the phandle for the most recently created one is returned.

For example:

```
: tftp-load-avail? ( -- exist? )
    " obp-tftp" find-package if ( phandle )
        " load" rot find-method if ( acf )
                drop true exit
        then
    then
    false
;
```

The two words finish-device and new-device let a single FCode program declare more than one entry into the device tree. This capability is useful when a single SBus card contains two or more essentially independent devices, to be controlled by two or more separate SunOS device drivers. Typical usage:

```
fcode-version1
...driver#1...
finish-device \ terminate device tree entry#1
new-device \ begin a new device tree entry
...driver#2
finish-device \ terminate device tree entry#2
new-device \ begin a new device tree entry
...driver#3...
end0
```

There is an implicit new-device call at the beginning of an FCode program (at fcode-version1 or fcode-version2), and an implicit finish-device call at the end of an FCode program (at endo). Thus, FCode programs that only define a single device and driver will never need to call finish-device or new-device.

```
firmware-version
( -- n )
code# 2 11
version 2
```

Returns a 32-bit number identifying the version of the CPU firmware. The high 16 bits is the major version number and the low 16 bits is the minor version number.

This is the major/minor release number that is accessed by the ROMvec entry op_mon_id. For example, in version 2.1, firmware-version returns $0 \times 00020001$. This is also the same number displayed by banner or .version.

For example:

```
: show-version ( -- )
    ." CPU bootprom version is " base @ d# 16 base ! ( old-base )
    firmware-version ( old-base version )
    lwsplit (.) type ascii . emit .h cr base ! ( )
;
```

flip ( n1 -- n2 ) code\# 80
n 2 is the result of exchanging the two low-order bytes of the number n 1 . The two upper bytes of n 1 must be zero, or erroneous results will occur.

```
fload filename ( -- )
code# none
```

Tokenizer command that begins tokenizing text in the named file. When the named file is done, tokenizing continues on the file that called filename with fload.

For example:
fload my-disk-package.fth
fload commands may be nested; an floaded file may include fload commands.
fload is useful for creating large FCode programs, making it easier to break them up into function blocks for better clarity and portability.

Note - fload commands won't work when downloading text in source-code form. You can either manually merge your text into one big file, download and execute the various file separately, or tokenize it first and then download and execute the FCode in binary form.

## >font ( char -- adr )

code\# 1 6e
This routine converts a character value (ASCII 0-0xff) into the address of the font table entry for that character. For the normal, built-in font, only ASCII values 0x21$0 x 7 \mathrm{e}$ result in a printable character, other values will be mapped to a font entry for "blank".

This word is only of interest if you are implementing your own character-drawing routines. Note that $>$ font will generate invalid results unless set-font has been called to initialize the font table to be used.

## fontbytes ( -- n )

code\# 1 6f
A value, containing the interval between successive entries in the font table. Each entry contains the next scan line bits for the desired character. Each scan line is normally 12 pixels wide, and is stored as one bit per pixel, thus taking $11 / 2$ bytes per scan line. The standard value for fontbytes is 2 , meaning that the next scan line entry is 2 bytes after the previous one (the last $1 / 2$ byte is wasted space).
This word must be set to the appropriate value if you wish to use any $\mathrm{fb} 1-\mathrm{or} \mathrm{fb} 8-$ utility routines or >font. This may be done with is, but is normally done by calling set-font.
The standard value for fontbytes is one of the parameters returned by default-font .
frame-buffer-adr ( -- virt )
code\# 162
This is a value that returns the address of the beginning of framebuffer memory. It must be set to an appropriate virtual address (using is) in order to use any of the fb1- or fb8-utility routines. It is suggested that this same value variable be used in any of your custom routines that require a frame
buffer address, although of course you are free to create and use your own variable if you wish.

Generally, you should only map in the framebuffer memory just before you are ready to use it, and unmap it if it is no longer needed. Typically, this means you should do your mapping in your "install" routine, and unmap it in your "remove" routine (see is-install and is-remove ). Here's some sample code:

```
h# 2.0000 constant /frame \ # of bytes in frame buffer
h# 40.0000 constant foffset \ Location of frame buffer
: video-map ( -- )
    my-address foffset + /frame map-sbus is frame-buffer-adr
;
: video-unmap ( -- )
    frame-buffer-adr /frame free-virtual
    -1 is frame-buffer-adr \ Flag accidental accesses to a
                        \ now-illegal address
;
: power-on-selftest ( -- )
    video-map
        ( test video memory )
    video-unmap
;
power-on-selftest
: my-install ( -- )
    video-map
    ...
;
: my-remove ( -- )
    video-unmap
;
['] my-install is-install
['] my-remove is-remove
```

```
free-mem ( virtual #bytes -- )

Frees up memory allocated by alloc-mem.
For example:
```

O value my-string \ Holds address of temporary
: .upc-string ( adr len -- ) \ convert to uppercase and print.
dup alloc-mem is my-string ( adr len )
tuck my-string swap cmove ( len )
my-string over bounds ?do i c@ upc i c! loop ( len )
my-string over type ( len )
my-string swap free-mem
;

```
free-virtual ( virtual size -- )
Undoes the MMU page map entries generated by obsolete FCodes memmap, dma-alloc, or map-sbus.

This FCode is obsolete for OpenBoot 2. (For use under OpenBoot 1, see Appendix D, "Changes in OpenBoot 1 FCode Usage".) To undo maps created with " map-in" \$call-parent use:

> " map-out" \$call-parent
and to undo maps created with " dma-map-in" \$call-parent use:
" dma-map-out" \$call-parent
to undo maps created with " dma-alloc" \$call-parent" use::

\footnotetext{
" dma-free" \$call-parent
}
```

get-inherited-
attribute ( name-adr name-len -- true | xdr-adr xdr-len false )
version 2 code\# 2 1d
Locates, within the package associated with the current instance or any of its parents, the property whose name is name-adr name-len. If the property exists, returns the property value array $x d r-a d r x d r-l e n$ and false. Otherwise returns true.
The order in which packages is searched is the current instance first, followed by its immediate parent, followed by its parent's parent, and so on. This is useful for properties with default values established by a parent node, with the possibility of a particular child node "overriding" the default value.

```

For example:
```

: clock-frequency ( -- val.adr len false | true )
" clock-frequency" get-inherited-attribute
;

```
```

    get-msecs ( -- ms )
        code# 1 25
    ```

Returns the current value in a free-running system counter. The number returned is a running total, expressed in milliseconds. You can use this for measuring time intervals (by comparing the starting value with the ending value). No assumptions should be made regarding the absolute number returned; only relative interval comparisons are valid.

No assumptions should be made regarding the precision of the number returned. In many systems (including the SPARCstation 1), the value is derived from the system clock, which typically ticks once per second. Thus, the value returned by get-msecs on the SPARCstation 1 and \(1+\) will be seen to increase in jumps of 1000 (decimal), once per second. For a delay timer of millisecond accuracy, see ms.
get-my-attribute ( name-adr name-len -- true | val-adr val-len false )code\# 2 la version 2

Locates, within the package associated with the current instance, the property named by name-adr name-len. If the property exists, returns the property value array val-adr val-len and false. Otherwise returns true.

For example:
```

: show-model-name ( -- )
" model" get-my-attribute 0= if ( val.adr len )
." model name is " type cr
else ( )
." model attribute is missing " cr
then ( )
;

```

\section*{get-package-}
    attribute ( name-adr name-len phandle -- true | xdr-adr xdr-len false )
                version 2 code\# 2 1f

Locates, within the package phandle, the property named by name-adr name-len. If the property exists, returns the property value array xdr-adr xdr-len and false. Otherwise returns true.

For example:
```

: show-model-name ( -- )
my-self ihandle>phandle ( phandle )
" model" rot get-package-attribute 0= if ( val.adr len )
." model name is " type cr
else ( )
." model attribute is missing " cr
then ( )
;

```
group-code
( -- adr )
code\# 123
This FCode is obsolete and should not be used.
```

.h ( n -- ) code\# a0 6d 49 10 00 00 00 10 a0 72 9d a0 72
generates: base @ swap d\# 16 base ! . base !

```

Displays \(n\) in hex (using . ) The value of base is not permanently affected.
```

h\# number ( -- )
code\# 10 xx xx xx xx
generates: b(lit) value

```

Interpret the next number in hex (base 16), regardless of any previous settings of hex, decimal, binary, or octal. Only the immediately following number is affected, the default numeric base setting is unchanged. For example:
```

decimal
h\# 100 ( equals decimal 256 )
100 ( equals decimal 100 )

```

See also b\#, d\#, and o\#.
```

headerless ( -- )
code\# none

```

Causes all subsequent definitions to be created in FCode without the name field (the "head"). (See named-token and new-token.) This is sometimes done to save space in the final FCode PROM, or possibly to make it more difficult to reverse-engineer an FCode program.

All such headerless words may be used normally within the FCode program, but cannot be called interactively from the Toolkit for testing and development purposes.

Unless PROM space and/or dictionary space is a major consideration, Sun recommends not using headerless words, because they make debugging more difficult.
headerless remains in effect until headers or external is encountered.
For example:
```

headerless
h\# 3 constant reset-scsi

```
headers ( -- )
code\# none
Causes all subsequent definitions to be saved with the name field (the "head") intact. This is the initial default behavior.

Note that even normal FCode words (with heads) cannot be called interactively from the Toolkit unless the NVRAM parameter fcode-debug? has been set to true before a system reset.
headers remains in effect until headerless or external is encountered.
For example:
```

headers
: cnt@ ( -- w )
transfer-count-lo rb@
transfer-count-hi rb@
bwjoin
;

```
```

here ( -- adr ) code\# ad

``` adr is the address of the next available dictionary location.
```

hex ( -- ) code\# none
-or-
generates: b(lit) 16 base ! code\# 10 00 00 00 10 a0 72

```

If outside of a definition, commands the tokenizer program to interpret subsequent numbers in hex (base 16). If within a definition, change the value in base affecting later numeric output when the FCode program is executed.
See base .
hold ( char -- )
Inserts char into a pictured numeric output string. Typically used between <\# and \#> .

For example:
```

:. . 32 ( n -- )
base @ >r hex
<\# \# \# \# \# ascii . hold \# \# \# \# \#> type
r> base !
space
;

```
```

i ( -- n )
code\# 19

```
n is a copy of the loop index. May only be used inside of a do or ?do loop.
For example:
```

: simple-loop ( start len -- )
bounds ?do i .h cr loop
;

```
```

if ( flag -- )
code\# 14 +offset

```
generates: b?branch +offset

Execute the following code if flag is true. Used in the form:
```

flag if ... else ... then

```
or
```

flag if ... then

```

If flag is true, the words following if are executed and the words following else are skipped. The else part is optional. If flag is false, words from if through else, or from if through then (when no else is used), are skipped.

\section*{ihandle>phandle}
( ihandle -- phandle )
code\# 2 0b
version 2
Returns the phandle of the package from which the instance ihandle was created. This is often used with get-package-attribute to read the properties of the package corresponding to a given ihandle.

For example:
```

: show-parent ( -- )
my-parent ihandle>phandle " name" rot
get-package-attribute 0= if
." my-parent is " type cr
then
;

```
insert-characters ( n -- )
code\# 1 5d
A defer word, called by the terminal emulator when needed to insert n blank characters to the right of the cursor. The cursor position is unchanged, but the cursor character and all characters to the right of the cursor are moved right by \(n\) places. (This command is used during command-line editing.) An error condition exists if an attempt is made to create a line longer that the maximum line size (the value in \#columns ).
This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fbl-install or fb8-install (which loads fb1-insert-characters or fb8-insert-characters, respectively).
insert-lines ( n -- )
code\# 1 5f
A defer word, called by the terminal emulator when needed to insert n blank lines just above the cursor. This could be used by a screen editor, for example.

The cursor's position on the screen is unchanged. The cursor line is pushed down, but all lines above it are unchanged. Any lines "pushed" off of the bottom of the active text area are lost.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-insert-lines or fb8-insert-lines, respectively).
```

instance ( -- )
code\# c0
version 2.1

```

Used to declare that new versions of data should be created for each new instance of a package (as opposed to global data). Valid for FCode version 2.1 or later.
instance should be called just before the data-creation defining word. Valid uses are with value, variable, defer and buffer:. For example:
```

: instance ( -- ) \ verify if "instance" is implemented.
['] instance ['] ferror <> if
instance
then
;
-1 instance value my-chip-reg

```
```

intr ( sbus-intr-level vector -- ) code\# 1 17

```

This is a shorthand word for declaring the "intr" and "interrupts" properties.

See "intr" and "interrupts" in Chapter 5, "Properties".
See also attribute.

\section*{inverse-screen? ( -- flag )}

A value, set and controlled by the terminal emulator, that tells you how to paint the unused portions of each line, i.e. white or black? A value of \(t\) rue means paint the unused portion black.

This word can (and should) be looked at as needed if your FCode program is implementing its own set of framebuffer primitives.
inverse? ( -- flag )
code\# 154
A value, set and controlled by the terminal emulator, that tells you whether to paint characters as white-on-black or black-on-white. A value of true means white-on-black. Unused characters on each line are not affected (see inversescreen? ).

This word can (and should) be looked at as needed if your FCode program is implementing its own set of framebuffer primitives.

A defer word, called by the terminal emulator when needed to invert the entire screen. This routine should XOR every visible pixel.

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-invert-screen or fb8-invert-screen, respectively).
```

is name ( n -- )
generates: b(is) FCode
code\# c3 FCode

```

Changes the contents of a value or a defer word:
```

number is name ( for a value )
acf is name ( for a defer word )

```
is-install ( acf -- )
Creates open, write, and draw-logo methods for display devices.
For any SBus framebuffer that is to be used by the boot PROM before or during booting, is-install declares the FCode procedure that should be used to install (i.e. initialize) that framebuffer. Note that this is distinct from any onceonly power-on initialization, that should be performed during the probing process itself.

The is-install routine and is-remove routine should comprise a matched pair, that may be performed alternately as many times as needed. Typically, the is-install routine performs mapping functions and some initialization, and the is-remove performs any cleanup functions and then does a complementary unmapping.

A partial, typical code example follows:
```

fcode-version1
: power-on ( -- ) \ Once-only, power-on initialization
map-register
init-register
unmap-register
;
...
: map-devices ( -- ) \ Map register and buffer
map-register

```

\begin{tabular}{|c|c|c|}
\hline power-on & & \ Power-on initialization \\
\hline ['] install-me & is-install & \ Declare "install" routine \\
\hline ['] remove-me & is-remove & \ Declare "remove" routine \\
\hline ['] test-me & is-selftest & \ Declare "selftest" routine \\
\hline ; & & \ End of the definition \\
\hline my-probe & & \ Now, execute this routine \\
\hline endo & & \\
\hline
\end{tabular}

The routine loaded with is-remove should form a matched pair with the routine loaded with is-install. See is-install for more details.

\section*{is-selftest}
( acf -- )
code\# 1 1e
Creates a selftest method for display devices.
Declares the routine that will perform a self test of the framebuffer. For example:
```

FCode-version1
: test-me ( -- fail? ) \ self test method
...
;
...
\ This routine executed during the "probe" of this FCode
: my-probe ( -- ) \ First, define the routine
power-on \ Power-on initialization
['] install-me is-install \ Declare "install" routine
['] remove-me is-remove \ Declare "remove" routine
['] test-me is-selftest \ Declare "selftest" routine
;
\ End of the definition
my-probe \ Now, execute this routine
end0

```

This declaration is typically performed in the same place in the code as isinstall and is-remove.

\section*{11 ㅡ}

The self test routine should return a status parameter on the stack indicating the results of the test. A zero value indicates that the test passed. Any nonzero value indicates that the self test failed, but the actual meaning for any nonzero value is not specified. (memory-test-suite returns a flag meeting these specifications.)
selftest is not automatically executed.
For automatic testing, devices should perform a quick sanity check as part of the install routine. See "selftest" on page 40.

\section*{(is-user-word)}
```

(adracr--)
code\# 2 14
version 2

```

Creates a Forth word (not a package method) whose name is given by adr len, and whose behavior is given by the compilation address acf (as returned by [' ], for example). This allows an FCode program to define new user interface commands.

For example:
```

" xyz-abort" ' my-abort (is-user-word)

```
j
( -- n ) code\# 1a
\(n\) is a copy of the index of the next outer loop. May only be used within a nested do or ?do loop. For example:
```

do

```

```

        do ... j ... loop
    loop

```

Usually, do loops should not be nested this deeply inside a single definition. Forth programs are generally more readable if inner loops are defined inside a separate word.
key ( -- char )
code\# 8e
A defer word that reads the next ASCII character from the keyboard. If no character has been typed since key was last executed, key waits until a new character is typed. All valid ASCII characters can be received. Control characters are not processed by the system for any editing purpose. Characters received by key are not displayed.

For example:
```

: continue? ( -- continue? )
." Want to Continue? Enter Y/N" key dup emit
dup ascii Y = ascii y rot = or
;

```
key? ( -- flag )
code\# 8d
A defer word returning true if a character has been typed on the keyboard since the last time that key or expect was executed. The keyboard character is not consumed.

Use key? to make simple, interruptable infinite loops:
begin ... key? until

The contents of the loop will repeat indefinitely until any key is pressed.

1! ( \(n\) adr -- ) code\# 73

The 32 -bit value n is stored at location adr (through adr +3 ). The highest byte is stored at adr ; the lowest byte is stored at adr +3 . adr must be on a 32 -bit boundary; it must be evenly divisible by 4 .

1, ( n -- )
code\# d2
Compile 4-bytes into the dictionary, starting with the highest byte. See c, for limitations. The dictionary pointer must be 2-byte-aligned.

For example:
```

\ to create an array containing integers 40004000 23 45 6734
create my-array 40004000 l, 23 l, 45 l, 6734 l,

```

1@ ( adr -- n )
code\# 6e
Fetch the 32-bit number stored at adr (through adr+3). The highest byte is stored at adr ; the lowest byte is stored at adr +3 . adr must be on a 32 -bit boundary; it must be evenly divisible by 4 .
/l ( -- n )
code\# 5c
n is the size in bytes of a 32-bit word: 4 .
/l* ( n1 -- n2 )
code\# 68
n 2 is the result of multiplying n1 by the length in bytes of a (32-bit) long word. This is useful for converting an index into a byte offset. /l* is equivalent to 4 *, but should be used in preference to the less portable 4 *.
lat ( adr1 index -- adr2 ) code\# 60
adr2 is the address of the index'th 32-bit longword after adr1. For byteaddressed machines (such as this one), this is equivalent to \(4 *+\).

Use la+ in preference to the less portable and less clear 4 * +
la1t ( adr1 -- adr2 ) code\# 64
adr2 is the address of the next 32-bit word after adr1. For byte-addressed machines (such as this one), this is equivalent to \(4+\). la1 + should be used in preference to the less portable and clear \(4+\).
lbsplit ( n -- byte.lo byte byte byte.hi )
code\# 7e
Splits a 32-bit value into four bytes. The upper bits of each byte are all zeroes.
```

lCC ( char1 -- char2 )
code\# 82

```
char2 is the lower case version of char1. If char1 is not an upper case letter, it is unchanged. See upc .

For example:
```

ascii M lcc emit

```
shows m .
leave

generates: b(leave)
Transfers execution to just past the next loop or +loop. The loop is terminated and loop control parameters are discarded. May only be used within a do or ?do loop.
leave may appear within other control structures that are nested within the do loop structure. More than one leave may appear within a do loop.

For example:
```

: search-pat ( pat adr len -- found? )
rot false swap 2swap ( false pat adr len )
bounds ?do ( flag pat )
i @ over = if drop true swap leave then
loop
drop
;

```
?leave ( flag -- )
code\# 14 +offset 1 b b2
generates: if leave then
generates: b?branch +offset leave b(>resume)
If flag is true (nonzero), ? leave transfers control to just beyond the next loop or loop. The loop is terminated and loop control parameters are discarded. If flag is zero, no action is taken. May only be used within a do or ? do loop.
?leave may appear within other control structures that are nested within the do loop structure. More than one ?leave may appear within a do loop.

For example:
```

: show-mem ( vadr -- ) \ display h\# 10 bytes
dup h\# 9 u.r 5 spaces h\# 10 bounds do i c@ 3 u.r loop
;
: .mem ( vaddr size -- )
bounds ?do i show-mem key? ?leave h\# 10 +loop
;

```
left-parse-string ( adr len char -- adrR lenR adrL lenL ) code\# 240 version 2

A tool for separating fields within a string. For example:
" test;in;g" ascii ; left-parse-string
would leave the address and length of two strings on the stack:
"in;g" and "test".
The delimiter character may be any ASCII character. Note that if the delimiter is not found within the string, the effect is as if the delimiter was found at the very end. For example:
```

" testing" ascii q left-parse-string

```
would leave on the stack" " and "testing".
lflips ( adr len -- )
code\# 237
version 2
Swaps the order of the 16-bit words within each 32-bit longword in the memory buffer adr len. adr must be four-byte-aligned. len must be a multiple of four.

For example:
```

h\# 12345678 8000 1!
8000 4 lflips
8000 l@ .h

```
shows 56781234 .
\#line ( -- adr )
code\# 94
A variable that increments whenever cr executes. \#line @ returns the current value of this variable. The value in this variable is used to determine when to pause during long display output, such as dump. Its value is reset each time the ok prompt displays.

\section*{line\# ( -- n )}
code\# 152
A value, set and controlled by the terminal emulator, that contains the current vertical position of the text cursor. A value of 0 represents the topmost line of available text space (this is not the topmost pixel of the framebuffer - see windowtop).

This word can (and should) be looked at as needed if your FCode program is implementing its own set of framebuffer primitives.

For example:
\[
\text { : set-line ( line -- ) } 0 \text { max \#lines } 1 \text { - min is line\# ; }
\]
linefeed ( -- n )
code\# 10000000 0a
generates: b(lit) 10
n is the ASCII code for the linefeed character; decimal 10, hex 0 a .
\#lines ( -- n )
code\# 150
This is a value that returns the number of lines of text to be displayed using the boot PROM's terminal emulator. It must be set to a proper value in order for the terminal emulator to function correctly.
\#lines is defined in the boot PROM with an initial value of 34 (decimal), but it should always be actively set by the FCode program. This may be done with is, or it may be handled automatically as one of the functions performed by fb1install or fb8-install. The value set by fbx-install is the smaller of the passed \#lines parameter and the screen-\#rows NVRAM parameter.

For example:
: set-line ( line -- ) 0 max \#lines 1 - min is line\# ;
```

loop ( -- )
code\# 15 -offset
generates: b(loop) -offset

```

Terminates a do or ?do loop. Increments the loop index by one. If the index was incremented across the boundary between limit-1 and limit, the loop is terminated and loop control parameters are discarded. When the loop is not terminated, execution continues to just after the corresponding do or ? do .

For example, the following do loop:
```

8 0 do ... loop

```
terminates when the loop index changes from 7 to 8 . Thus, the loop will iterate with loop index values from 0 to 7 , inclusive.
+loop ( n -- )
code\# 16 -offset
generates: b(+loop) -offset
Terminates a do or ?do loop. Increments the loop index by n (or decrements the index if \(n\) is negative). If the index was incremented (or decremented) across the boundary between limit-1 and limit the loop is terminated and loop control parameters are discarded. When the loop is not terminated, execution continues to just after the corresponding do or ?do.

The following do loop:
```

8 0 do ... 2 +loop

```
terminates when the loop index crosses the boundary between 7 and 8 . Thus, the loop will iterate with loop index values of \(0,2,4,6\).

By contrast, a do loop created as follows:
08 do ... -2 +loop
terminates when the loop index crosses the boundary between -1 and 0 . Thus, the loop will iterate with loop index values of \(8,6,4,2,0\).
```

lpeek ( adr -- false | data true ) code\# 2 22

```
version 2

Tries to read the 32-bit longword at address adr. Returns the data and true if the access was successful. A false return indicates that a read access error occurred. adr must be 32-bit aligned.
```

lpoke ( data adr -- ok? )
code\# 2 25
version 2

```

Tries to write the 32-bit longword at address adr. Returns the data and true if the access was successful. A false return indicates a read access error. adr must be 32-bit aligned.

Note - lpoke may be unreliable on bus adapters that "buffer" write accesses.
lu>x ( ul -- ux ) code\# a5
generates: 0
Tokenizer instruction that zero-extends a 32 -bit number to 64 -bit.
lwsplit ( \(n\)-- word.lo word.hi )
Splits the 32 -bit value n into two 16 -bit words. The upper bits of the two generated words are zeroes.
```

mac-address ( -- adr len )

Usually used only by the network device-type, this FCode returns the value for the Media Access Control, or MAC address, that this SBus card should use for its own address. The data is encoded as a byte array, generally 6 bytes long.

The value returned by mac-address can either be supplied by the system, or by the card itself. If the card's FCode creates a property named local-macaddress, and the NVRAM parameter local-mac-address? (for typical systems) is set to true, then the value contained in the property local-macaddress will be returned by mac-address. Otherwise, the system will assign a value.

See also "mac-address", "local-mac-address", and "network" in Chapter 5, "Properties" and Chapter 9, "Network Devices".
map-sbus ( physoffset size -- virt )
code\# 130
This FCode is obsolete in version 2. For version 1 usage, see Appendix D, "Changes in OpenBoot 1 FCode Usage".

For version 2, use:

```
" map-in" $call-parent
```

Creates a memory mapping for some SBus locations, usually within the address space of this SBus card. The MMU page maps are updated, and the generated virtual address is returned.

The memory mapping can (and should) be later undone with free-virtual. Used as:

```
( -1 value vregs )
my-address 10.0000 + 100
map-sbus ( virt )
is vregs
```

mask ( -- adr )
code\# 124
This variable controls which bits out of every 32-bit longword which will be tested with memory-test-suite. To test all 32-bits, set mask to all ones with::

```
ffff.ffff mask !
```

To test only the low-order byte out of each longword, set just the lower bits of mask with:
0000.00ff mask!

Any arbitrary combination of bits may be tested or masked.

```
max ( n1 n2 -- n3 )
code# 2f
```

n 3 is the greater of n 1 and n 2 .
memmap ( physoffset space size -- virtual )
code\# 104
Creates a memory mapping for some locations. It updates MMU page maps and returns the generated virtual address. The actual physical address is specified by ( physoffset space ), that indicates the device space and the physical offset within that space.

This fcode is obsolete in OpenBoot 2. For OpenBoot 1 usage, refer to Appendix D, "Changes in OpenBoot 1 FCode Usage". For version 2, use:

```
" map-in" $call-parent
```

The memory mapping can (and should) be later undone with free-virtual.

## memory-test-suite ( adr len -- failed? )

Performs a series of tests on some memory, to verify its proper functioning. A true flag is returned if any of the tests failed.

If diagnostic-mode? is true ( diag-switch? NVRAM parameter is true), then a message is sent out to the current output device (to ttya if during probe time) giving the name of each test. If any test fails, a "Failed" message will also then be displayed.

For every one of the following tests, the value stored in the variable mask controls whether only some or all data lines are tested.

For example, to only test data bits 0-23 (skipping bits 24-31), mask would be set with: 00 ffffff mask !

The actual tests performed may vary from system to system. On current systems, the tests performed are:

- Data lines test. This test performs a walking ones and zeroes on each data line to test for stuck at zero or stuck at one.
- Address quick test. This tests each address line for being stuck at one, stuck at zero, shorted to another address line, or shorted to a data line.
- Data size test. Writes a constant 32-bit value to the starting location of the memory, both byte-at-a-time and shortword-at-a-time, then reads the data back with a 32-bit access and verifies the value. This test verifies proper 8bit, 16-bit and 32-bit access.

The above tests are very fast. If the diag-switch? NVRAM parameter is set to true, then the following (slower) additional tests are also performed:

- Data bits test. Tests every bit in memory, by testing a write/read of 0 and a write/read of ffffffff at every location.
- Address=data test. Writes each longword location with its own address, then verifies. This checks for the uniqueness of individual locations with RAM chips.
For example:

```
: test-result ( -- )
    frame-buffer-adr my-frame-size memory-test-suite ( failed? )
    xdrint " test-result" attribute
;
```

$\min (\mathrm{n} 1 \mathrm{n} 2--\mathrm{n} 3)$
code\# 2e
n 3 is the lesser of n 1 and n 2 .
mod ( n1 n2 -- rem )
rem is the remainder after dividing n 1 by the divisor n 2 . rem has the same sign as n 2 or is zero. An error condition results if the divisor is zero.

```
*/mod ( n1 n2 n3 -- rem quot )
code# 30 20 31 2a
    generates: >r * r> /mod
Calculates n1 * n2 / n3, returns the remainder and quotient. The inputs, outputs, and intermediate products are all 32-bit. rem has the same sign as n3 or is zero. An error condition results if the divisor is zero.
```

## $/$ mod ( n1 n2 -- rem quot )

code\# 2a
rem is the remainder and quot is the quotient of $n 1$ divided by the divisor $n 2$. rem has the same sign as $n 2$ or is zero. An error condition results if the divisor is zero.

## model

( adr len -_ )
code\# 119
This is a shorthand word for creating a model property. By convention, model identifies the model name/number for an SBus card, for manufacturing and field-service purposes. A sample usage would be:

```
" SUNW,501-1415" model
```

This is equivalent to:

```
" SUNW,501-1415" xdrstring " model" attribute
```

The model property is useful to identify the specific piece of hardware (the SBus card), as opposed to the name property (since several different but functionally-equivalent cards would have the same name property, thus calling the same SunOS device driver).

See also attribute, "model" in Chapter 5, "Properties".
move ( adr1 adr2 len -- )
len bytes starting at adr1 (through adr1+len-1 inclusive) are moved to address adr2 (through adr2+len-1 inclusive). If len is zero then nothing is moved.

The data are moved such that the len bytes left starting at address adr2 are the same data as was originally starting at address adr1. If adr1 > adr2 then the first byte of adr1 is moved first, otherwise the last byte (len'th) of adr1 is moved first. Thus, moves between overlapping fields are properly handled.
move will perform 16-bit, 32-bit or possibly even 64-bit operations (for better performance) if the alignment of the operands permits.
ms ( ms -- )
code\# 126
Delays all execution for the specified number of milliseconds, by executing an empty delay loop for an appropriate number of iterations. The maximum allowable delay will vary from system to system, but is guaranteed to be valid for all values up to at least $1,000,000$ (decimal). No other CPU activity takes place during delays invoked with ms , although generally this is not a problem for FCode drivers since there is nothing else to do in the meantime anyway. If this word is used excessively, noticeable delays could result.

For example:

```
: probe-loop-wait ( adr -- )
    \ wait h# 10 ms before doing another probe at the location
    begin dup l@ drop h# 10 ms key? until drop
;
```

my-address ( -- physoffset )
code\# 102
Returns a magic number, suitable for use with the map-in method, and with reg, xdrphys, map-sbus and memmap. The returned number, along with myspace, encodes the address of location 0 of this SBus device. The OpenBoot PROM automatically sets my-address to the correct value before each SBus slot is probed.

For example:

```
fcode-version1
    " audio" xdrstring " name" attribute
    my-address h# 130.0000 + my-space h# 8 reg
end0
```

```
    my-args ( -- adr len )
                                    code# 2 02
    version 2
```

Returns the argument string adr len that was passed to the current instance when it was created, if the argument string exists. Otherwise returns with a length of 0 .

For example:

```
" /obio:TEST-ARGS" select-dev
my-args type
```

The above will display arguments passed to /obio at open time as TESTARGS
my-params ( -- adr len ) code\# $10 f$
This fcode is obsolescent and should not be used.
my-params returns a string that contains arbitrary customization information for this device. The string comments are the contents of the params property if present, otherwise returns a null string (adr, len equals 0,0 ).
my-args may be used in some situations to perform the same function.
my-parent ( -- ihandle ) code\# 2 0a
version 2
Returns the ihandle of the instance that opened the current instance. For device driver packages, the relationships of parent/child instances mimic the parent/child relationships in the device tree.

For example:

```
: show-parent ( -- )
    my-parent ihandle>phandle " name" rot
    get-package-attribute 0= if
        ." my-parent is " type cr
    then
;
```

my-self ( -- ihandle )
code\# 203
version 2
Returns the current instance ihandle.
For example:

```
: show-model-name ( -- )
    my-self ihandle>phandle ( phandle )
    " model" rot get-package-attribute 0= if ( val.adr,len )
        ." model name is " type cr
    else ( )
        ." model attribute is missing " cr
    then ( )
```

;
my-space ( -- space ) code\# 103

Returns a "magic" number, representing the device space that this SBus card is plugged into.

For example:

```
fcode-version1
    " audio" xdrstring " name" attribute
    my-address h# 130.0000 + my-space h# 8 reg
    ...
end0
```

See my-address for more details.

```
my-unit ( -- low high )
code# 2 0d
version 2
```

Returns the unit address low high of the current instance. The unit address is set when the instance is created, as follows:

- If the node-name used to locate the instance's package contained an explicit unit-address, that is the instance's unit address. This would be used for a "wildcard" node with no associated "reg" property.
- Otherwise, if the device node associated with the package from which the instance was created contains a "reg" property, the first component of its property value is the instance's unit address.
- Otherwise, the instance's unit address is 00 .

For example. on SPARCclassic systems:
" /iommu/sbus/ledma@4,840010" select-dev my-unit .s
displays

8400104
/n ( -- n )
code\# 5d
The number of bytes in a normal stack item; 4 in this implementation.

```
/n* ( n1 -- n2 )
n 2 is the result of multiplying n 1 by the length in bytes of a normal stack item. This is useful for converting an index into a byte offset. This word is equivalent to 4 *.
nat ( adr1 index -- adr2 )
adr2 is the address of the index'th "normal" sized word after adr1. For this implementation, this is equivalent to \(4 *+\).
na+ should be used in preference to wa+ or la+ when the intent is to address items that are the same size as items on the stack.
na1+ ( adr1 -- adr2 )
code\# 65
adr2 is the address of the next "normal" sized word after adr1. For this implementation, this is equivalent to \(4+\) or la1+.
na1+ should be used in preference to wa1+ or la1+ when the intent is to address items that are the same size as items on the stack.
```

name ( adr len -- ) code\# 1 14 12 04 6e 61 6d 65 1 10
generates: xdrstring " name" attribute

```

A shorthand word for creating a "name" property, used to match a device node with the appropriate SunOS driver. The "name" declaration is required for booting with SunOS, and should be present in every FCode program. For example:
```

" SUNW,bison" name

```
is equivalent to:
" SUNW,bison" xdrstring " name" attribute

See also attribute, device-name.
See "name" in Chapter 5, "Properties".

\section*{named-token}
```

( -- ) code\# b6 len xx xx xx ... 08 xx b (type)

```
named-token, external-token or new-token are called to create a new dictionary entry. If headers are active, use named-token.

The new header for a word created with named-token has the following format:
```

named-token, string, new FCode\#, type

```

The first byte is b6, indicating a named-token format.
- Next is a string containing the name of the new created entry. The string is a length byte and then length bytes of text.
- Next is a new FCode\# assigned by the tokenizer, starting at 08,00 then 08,01 and working upwards. If \(08, \mathrm{ff}\) is exceeded then 09,00 and so on is used, up to a maximum of \(0 \mathrm{~b}, \mathrm{ff}\).
- Finally, the b(type) byte indicates the type of word being created, such as b(:) for colon definition, b(value) for values, etc.
named-token should never be used directly in source code.
```

    negate ( n1 -- n2 )
    code# 2c
    n2 is the opposite sign of n1. This is equivalent to -1 **
    new-device ( -- )
code\# 1 1f
Start a new entry in the device tree. This word is used for creating multiple devices in a single FCode program. See finish-device.

```
```

new-token ( -- )

```
new-token ( -- )
code# b5 xx xx b(type)
code# b5 xx xx b(type)
    generates: new-token FCode# b(type)
    generates: new-token FCode# b(type)
    named-token, external-token or new-token are called whenever a new
    dictionary entry is to be created. If headerless is active, then use new-
    token.
```

The format for new-token is identical to that for named-token, except that the string field is missing (and the first byte is b 5 instead of b 6 ). See named-token for more details.
new-token should never be used directly in source code.

```
newline ( -- n )
code# 10 00 00 00 0a
```

generates: b(lit) 10
n is the ASCII code for the character that terminates a line; decimal 10, hex 0 a. In this system this is the linefeed character.
newline is system-dependent, so its use is discouraged. Usually, it doesn't increment the line count, that results in problems with correct screen scrolling. Use of cr instead of newline is usually appropriate.
nip ( n1 n2 -- n2 )
code\# 4d
Remove the second item on the stack.
noop ( -- )
code\# 7b
Do nothing. This can be used to waste time or as a placeholder for something that will be patched in later.

```
not ( n1 -- n2 )
```

    code\# 26
    n 2 is the one's complement of n 1 , i.e. all the one bits in n 1 are changed to zero, and all the zero bits are changed to one.

For example:

```
: clear-lastbit ( -- )
    my-reg rl@ 1 not and my-reg rl!
;
```

See also $0=$.

```
$number ( adr len -- true | n false ) code# a2
```

version 2

A numeric conversion primitive that converts a string to a number, according to the current base value (usually hexadecimal). An error flag is returned if an inconvertible character is encountered. For example," 123 f " \$number returns 123 f 0 on the stack, while " $123 x$ " returns -1 , indicating that the conversion failed.

For example:

```
: number-or-0 ( adr len -- true | number false )
    dup if $number else 2drop 0 false then
;
```

```
O# number ( -- n )
code# 10 xx xx xx xx
generates: b(lit) value
```

Interpret the next number in octal (base 8), regardless of any previous settings of hex, decimal, binary, or octal. Only the immediately following number is affected, the default numeric base setting is unchanged. For example:

```
hex
o# 100 ( equals decimal 64 )
100 ( equals decimal 256 )
```

See also b\#, d\#, and h\# .

```
octal
```

```
generates: b(lit) 8 base !
```

If outside a definition, commands the tokenizer program to interpret subsequent numbers in octal (base 8). If within a definition, changes the value in base, affecting later numeric output when the FCode program is executed. See base.

```
Of ( selector testval -- selector | null ) code# 1c +offset
    generates: b(of) +offset
```

Begin the next test clause in a case statement. See case for more details.

```
Off( adr -- )
code# 6b
```

Set the 32-bit contents at adr to zero ( false).
offset16 ( -- ) code\# cc

Instructs the tokenizer program, and the boot PROM, to expect all further branch offsets to be 16 -bit values. This word is automatically generated by some current tokenizers.

On ( adr -- )
code\# 6a
Set the 32 -bit contents at adr to -1 or ffff.ffff (true ).
open-package ( arg-adr arg-len phandle -- ihandle | 0 ) code\# 2 ) 05 version 2

Creates an instance of the package identified by phandle, saves in that instance an argument string specified by arg-adr arg-len, and invokes the package's open method. The parent instance of the new instance is the instance that invoked open-package.

Returns the instance handle ihandle of the new instance if it can be opened. It returns 0 if the package could not be opened, either because that package has no open method or because its open method returned false indicating an error. In this case, the current instance is not changed.

For example:

```
: test-tftp-open ( -- ok? )
    " obp-tftp" find-package if ( phandle )
        0 0 rot open-package if true else false then
    else
        false
    then
;
```

\$open-package ( arg-adr arg-len name-adr name-len -- ihandle| 0 ) code\# 2 0f version 2

Similar to using find-package open-package, except that if findpackage fails, 0 is returned immediately, without calling open-package .

For example:
00 " obp-tftp" \$open-package ( ihandle )

```
Or ( n1 n2 -- n3 )
code# 24
```

n 3 is the bit-by-bit inclusive-or of n 1 with n 2 .
\#out ( adr -- )
code\# 93
A variable containing the current column number on the output device. This is updated by emit and some other words that modify the cursor position. It is used for display formatting.

For example:
: to-column ( column -- ) \#out @ - 1 max spaces ;
over ( n1 n2 -- n1 n2 n1 )
The second stack item is copied to the top of the stack.

2over (n1 n2 n3 n4 -- n1 n2 n3 n4 n1 n2 )
code\# 54
Copies the third and fourth stack items to the stack top.

```
pack ( adr len pstr -- pstr ) code# 83
```

Convert a byte array (indicated by " adr len ") into a packed string, and store it at the location pstr. The byte at address pstr is the length of the string and the string itself starts at address pstr+1.

Packed strings are generally not used in FCode. Virtually all string operations are in the "adr len "format.

For example:

```
h# 20 buffer: my-packed-string
" This is test string " my-packed-string pack
```

```
peer ( phandle -- next-phandle )
code# 2 3c
```

version 2.3
peer returns the phandle next-phandle of the package that is the next child of the parent of the package phandle.

If phandle is the last child of its parent, peer returns zero.
If phandle is zero, peer returns phandle of the root node.
Together with child, peer lets you enumerate (possibly recursively) the children of a particular device. A common application would be for a device driver to use child to determine the phandle of a node's first child, and use peer multiple times to determine the phandles of the node's other children. For example:

```
: my-children ( -- )
    my-self ihandle>phandle child (first-child )
    begin ?dup while dup . peer repeat
;
```

>physical ( virtual -- physoffset space )
code\# 106
Given a virtual address, return the mapped physical address as a ( physoffset space ) pair, specifying the device space (as a "magic number") and the physical offset within that space.

This word has inconsistent behavior in current boot PROMs, and you should avoid using it in FCode programs.

For example:

```
: in-ram? ( vadr -- phys flag )
    >physical ( padr space )
    \ code-to-verify if space and address refer to on-board memory
;
```

```
pick ( +n -- n2 )
code# 4e
```

n 2 is a copy of the +n 'th stack value, not counting +n itself. +n must be between 0 and the number of elements on the stack- 1 inclusive.

```
0 pick is equivalent to dup ( n1 -- n1 n1 )
1 pick is equivalent to over ( n1 n2 -- n1 n2 n1 )
2 ~ p i c k ~ i s ~ e q u i v a l e n t ~ t o ~ ( ~ n 1 ~ n 2 ~ n 3 ~ - - ~ n 1 ~ n 2 ~ n 3 ~ n 1 ~ ) ,
```

For readability's sake, the use of pick should be minimized.
probe ( arg-adr arg-len reg-adr reg-len fcode-adr fcode-len -- ) version 2.2 code\# 238

This FCode is obsolete, and should not be used. Use probe-self method of a hierarchical device node.

```
probe-virtual ( arg-adr arg-len reg-adr reg-len fcode-adr -- ) code# 2 39
version 2.2
This FCode is obsolete, and should not be used. Use " set-args" and "byte-load" as shown below. In case you have downloaded the FCode PROM image of a SBus device at virtual address 4000, and the device is in SBus slot \#1 use:
```

```
" /sbus" select-dev
```

" /sbus" select-dev
new-device
new-device
0 0 " 1,0" " set-args" \$find if ( arg-str reg-str acf )
0 0 " 1,0" " set-args" \$find if ( arg-str reg-str acf )
execute 4000 1 " byte-load" \$find if ( adr offset acf )
execute 4000 1 " byte-load" \$find if ( adr offset acf )
execute
execute
else
else
." byte-load missing " cr 2drop 2drop
." byte-load missing " cr 2drop 2drop
then
then
else
else
." set-args missing " cr 2drop 2drop 2drop
." set-args missing " cr 2drop 2drop 2drop
then
then
finish-device
finish-device
unselect-dev

```
unselect-dev
```

processor-type
( -- processor-type )
code\# 210
version 2

Returns the type of processor (instruction set architecture). Obsolete.

```
. }\boldsymbol{r}(\textrm{n}1+\textrm{n}--
n 1 is converted using the value of base and then displayed right aligned in a field +n characters wide. A leading minus sign is displayed if n is negative. A trailing space is not displayed.

If the number of characters required to display \(n 1\) is greater than +n , an error condition exists. In this implementation, all the characters required will be displayed, making the resulting field larger than +n .

For example:
```

: formatted-output ( -- )
my-length h\# 8 .r ." length" cr
my-width h\# 8 .r ." width" cr
my-depth h\# 8 .r ." depth" cr
;

```
\(\boldsymbol{r >}(--\mathrm{n})\)
code\# 31
Removes n from the return stack and places it on the (regular) stack. See \(>\mathrm{r}\) for restrictions on the use of this word.

For example:
: copyout ( buf adr len -- len ) >r swap r@ move r> ;
r@ ( -- n )
code\# 32
n is a copy of the top of the return stack.
For example:
: copyout ( buf adr len -- len ) >r swap r@ move r> ;
See \(>\mathrm{r}\) for more details.
\(\boldsymbol{> r}(\mathrm{n}-\mathrm{r})\)
Removes n from the stack and places it on the top of the return stack.
The return stack is a second stack, occasionally useful as a place to temporarily place numeric parameters, i.e. to "get them out of the way" for a little while. However, since the return stack is also used by the system for transferring control from word to word (and by do loops), improper use of \(>\mathrm{r}\) or \(\mathrm{r}>\) is guaranteed to crash your program.

For example:
```

: xdrintr ( int-level vector -- )
>r sbus-intr>cpu xdrint r> xdrint xdr+
;

```

Some restrictions that must be observed are:
- All values placed on the return stack within a colon definition must be removed before the colon definition is exited by normal termination, exit or throw, or else the program will crash.
- No values from the return stack should be removed from within a colon definition unless they were placed there within that definition.
- Entering a do loop automatically places values onto the return stack.

Therefore,
- Values placed on the return stack before the loop was started will not be accessible from within the loop.
- Values placed on the return stack within the loop must be removed before loop, +loop, or leave is encountered.
- The loop indices \(i\) or \(j\) will no longer be valid when additional values have been placed on the return stack within the loop.
```

rb! ( n adr -- )
code\# 2 31
version 2

```

Stores an 8 -bit byte, preserving bit order.
For example:
: my-stat! ( byte -- ) my-stat rb! ;
```

rb@ ( adr -- n )
code\# 2 30

```
    version 2

Fetches an 8-bit byte, preserving the bit order.
For example:
```

: my-stat@ ( -- byte ) my-stat rb@ ;

```
```

reg ( physoffset space size -- )
code\# 1 16

```

This is a shorthand word for declaring a property named "reg" (by convention, reg is used for declaring the location and size of device registers). Typical usage:
my-address \(40.0000+\) my-space 20 reg

This declares that the device registers are located at offset 40.0000 through 40.001 f in this slot. The following code would accomplish the same thing::
```

my-address 40.0000 + my-space xdrphys
20 xdrint xdr+
" reg" attribute

```

Note that if you need to declare more than one block of register addresses, you must use the longer, more explicit method in order to build the structure to be passed into the reg property.

For example, to declare two register fields at 10.0000-10.00ff and 20.000020.037f, use the following:
\begin{tabular}{|c|c|c|c|c|c|}
\hline my-address & 10.0000 & my-space & xdrphys & & \ Offset\#1 \\
\hline 100 xdrint & & & & \(x d r+\) & \ Merge size\#1 \\
\hline my-address & 20.0000 & my-space & xdrphys & xdr+ & \ Merge offset\#2 \\
\hline 380 xdrint & & & & xdr+ & \ Merge size\#2 \\
\hline " reg" att & bute & & & & \\
\hline
\end{tabular}

See also attribute. See also "reg" in Chapter 5, "Properties".
```

repeat ( -- ) code\# 13 -offset b2
generates: bbranch, -offset, b(>resolve)
Terminates a begin ... while ... repeat conditional loop. See while for more details.

A defer word, called by the boot PROM's terminal emulator (just after erasescreen ). This word is called only once, during the terminal emulator
initialization sequence, in order to enable the framebuffer to display information. A typical use for this function is to "enable video".

This word is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fb1-install or fb8-install (which loads fb1-reset-screen or fb8-reset-screen, respectively). These words are NOPs, so it is very common to first call $f b x$-install and then to override the default setting for reset-screen with:
['] my-video-on is reset-screen

```
rl! ( n adr -- )
code# 2 35
version 2
```

Stores a 32-bit longword, preserving bit order. adr must be 32-bit aligned.
For example:

```
: my-reg! ( n -- ) my-reg rl! ;
```

```
rl@ ( adr -- n )
code# 2 34
```

version 2

Fetches a 32-bit longword, preserving bit order. adr must be 32-bit aligned.
For example:

```
: my-reg@ ( -- n ) my-reg rl@ ;
```

roll ( +n -- )
The +n 'th stack value, not counting +n itself, is first removed and then transferred to the top of the stack, moving the remaining values into the vacated position. $+n$ must be between 0 and the number of elements on the stack-1, inclusive.

```
O roll is a null operation
1 roll is equivalent to swap ( n1 n2 -- n2 n1 )
2 roll is equivalent to rot ( n1 n2 n3 -- n2 n3 n1 )
3 roll is equivalent to ( n1 n2 n3 n4 -- n2 n3 n4 n1 )
```

For readability's sake, minimize your use of roll. It is also relatively slow.

```
rot ( n1 n2 n3 -- n2 n3 n1 )
```

code\# 4a

Rotates the top three stack entries, bringing the deepest to the top.
-rot (n1 n2 n3 -- n3 n1 n2 )
code\# 4b
Rotates the top three stack entries in the direction opposite from rot, putting the top number underneath the other two.

2rot (n1 n2 n3 n4 n5 n6 -- n3 n4 n5 n6 n1 n2 )
code\# 56
Rotates the top three pairs of numbers, bringing the third pair to the top of the stack.
$\mathbf{r w ! ~ ( ~} \mathrm{n}$ adr -- )
code\# 233
version 2
Stores a 16-bit word, preserving bit order. adr must be 16-bit aligned.
For example:
: my-count! ( w -- ) my-count rw! ;
rw@
$\qquad$
( adr -- $n$ )
code\# 232
version 2
Fetches a 16-bit word, preserving bit order. adr must be 16-bit aligned.
For example:
: my-count@ ( -- w ) my-count rw@ ;

Displays the absolute value of n in a free-field format with a leading minus sign if $n$ is negative. A trailing space is also displayed. Even if the base is hexadecimal, the number will be printed in signed format (see . ).
+1 is converted, appending each resultant character into the pictured numeric output string until the quotient is zero (see: \# ). A single zero is added to the output string if the number was initially zero. Typically used between <\# and \#> . See (.) and (u.) for typical usages.

This word is equivalent to calling \# repeatedly until the number remaining is zero.
(s text) ( -- )
code\# none
Ignore subsequent text after the (s up to a delimiting ). The same behavior occurs for (.

Although either ( or \works equally well for documentation, by common convention we use ( . . . ) or (s . . . ) for stack comments and \ . . for all other text comments and documentation.

Use ( $s$ to distinguish a definition's "interface" stack comment from stack comments within a definition (which clarify the current stack state). (This distinction could be of use for implementing automatic stack-checkers.) For example:

```
\ map in registers
: map-regs (s size -- virt )
    reg-addr swap ( addr size )
    map-sbus ( virt )
;
```

.S ( -- )
code\# 9f
Displays the contents of the data stack (using. ) in the current base. The top of the stack appears on the right. The contents of the stack are unchanged.

For example:

```
: debug-abtest ( ??? -- ??? )
    debug-on? if ." input params: " .s cr then
```

Convert the SBus interrupt level (1-7) to the CPU interrupt level. The mapping performed will be system-dependent.

This word is called by the intr command.
For example:

```
3 \text { sbus-intr>cpu xdrint 0 xdrint xdr+ " intr" attribute}
```

See "intr" in Chapter 5, "Properties".

A value, containing the height of the display (in pixels). It may also be interpreted as the number of "lines" of memory.

This word is initially set to 900 (decimal), but should always be set explicitly to the appropriate value if you wish to use the $£ \mathrm{fb} 1-$ or $\mathrm{fb} 8-$ utility routines. This may be done with is, or it may be loaded as one of the parameters to fb1-install or fb8-install.

In particular, this value is used in $£ b x$-invert, $f b x$-erase-screen, $£ b x-$ blink-screen and in calculating window-top.

Typical code might create a constant called vres. This would be used as the height parameter for fbx-install, and might also be passed as an attribute to SunOS if needed.

A value, containing the width of the display (in pixels). It may also be interpreted as the number of pixels (in memory) between one screen location and the next location immediately below it. The latter definition takes precedence if there is a conflict (e.g. there are unused/invisible memory locations at the end of each line).

Typical code might create a constant called hres. This would be used as the width parameter for $f b x$-install, and might also be passed as an attribute to SunOS if needed.
set-font ( fontbase charwidth charheight fontbytes \#firstchar \#chars --) $\begin{array}{r}\text { code\# } 1 \text { 6b }\end{array}$
This routine declares the font table to be used for printing characters on the screen. This routine must be called if you wish to use any of the $f$ b1- or fb 8 - utility routines or >font.

Note - These routines require the installed font to use the default value of two bytes per character.

Normally, set-font is called just after default-font . default-font leaves on the stack the exact set of parameters needed by set-font. This approach allows your FCode program to inspect and/or alter the default parameters if desired. See default-font for more information on these parameters.

```
sign ( n -- ) code# 98
```

If n is negative, appends an ASCII "-" (minus sign) to the pictured numeric output string. Typically used between <\# and \#>. See (.) for a typical usage.
space ( -- )
code\# a9 8f
generates: bl emit
Display a single space character.
spaces ( +n -- ) code\# a5 2 f a5 18 +offset a9 8f 15 -offset generates: 0 max 0 ?do space loop generates: $0 \max 0 \mathrm{~b}(? \mathrm{do})$ toffset bl emit $\mathrm{b}(\mathrm{loop})$-offset

Display +n space characters. Nothing is displayed if +n is zero.
span ( -- adr )
code\# 88
A variable containing the count of characters actually received and stored by the last execution of expect.

For example:

```
h# 10 buffer: my-name-buff
: hello ( -- )
    ." Enter Your First name " my-name-buff h# 10 expect
    ." Sun Microsystems Welcomes " my-name-buff span @ type cr
;
```

startn ( -- code\# f0 (start0) f1 (start1) f2 (start2) f3 (start4)
version 2

Four version 2.0 FCodes whose function is similar to version1, but for use with version 2.0 FCode programs. Their use is as follows:

- start0. Like version1, but for version 2 FCodes. Uses 16-bit branches. Fetches successive tokens from same address.
- start1. Like version1, but for version 2 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive addresses. Compiled by fcodeversion2.
- start2. Like version1, but for version 2 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive 16-bit addresses.
- start4. Like version1, but for version 2 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive 32-bit addresses.

```
struct ( -- 0 ) code# a5
    generates: 0
```

Initializes a struct . . . field structure. See field for details.
version 2
Tells the FCode interpreter that the device identification properties for the active package have been declared, and that the interpreter may postpone interpreting the remainder of the package if it so chooses.

If the FCode interpreter postpones (suspends) interpretation, it saves the state of the interpretation process so that interpretation may continue later.
Attempts to open a suspended package cause the FCode interpreter to resume and complete the interpretation of that package before executing the package's open method.

For example:

```
fcode-version1
    " SUNW,my-name" name
    " SUNW,my-model" xdrstring " model" attribute
    suspend-fcode
end0
```

This feature is intended to save memory space and reduce the system startup time by preventing the compilation of FCode drivers that are not actually used.
swap ( $\mathrm{n} 1 \mathrm{n} 2--\mathrm{n} 2 \mathrm{n} 1)$
code\# 49
Exchanges the top two stack items.

2swap (n1 n2 n3 n4 -- n3 n4 n1 n2 ) code\# 55
Exchanges the top two pairs of stack items.

| then $(--)$ |  |
| ---: | :--- |
| generates: b (>resolve) | code\# b 2 |

Terminate an if ... then or an if ... else ... then conditional structure. See if for more details.

```
throw ( error-code -- )
code# 2 18
version 2
```

Transfers control to the most recent dynamically enclosing error handling context, passing the indicated error code to that handler. Error code must be nonzero. If the value of error-code is zero, the zero is removed from the stack, but no other action is taken.

See catch for an example of use.

A defer word, called by the boot PROM's terminal emulator before and after any character or string is printed. (It is also called once during the terminal emulator initialization sequence.) The normal behavior of this word is to XOR the pixels at
the current cursor position to leave a colored rectangle marking the next character to be output.
toggle-cursor is initially empty, but must be loaded with an appropriate routine in order for the terminal emulator to function correctly. This may be done with is, or it may be loaded automatically with fbl-install or fb8-install (which load fb1-toggle-cursor or fb8-toggle-cursor, respectively).

This is a good place to perform any necessary "cleanup" of display hardware state, such as resetting color maps or selecting the proper modes. For example, a window system may have set a color lookup table so that the color used for displaying text does not contrast with the background. If the PROM terminal emulator is then asked to display some system messages on the screen, the messages would be unreadable. Consequently, it would be a good idea to restore the text entries in the color lookup table in the toggle-cursor routine.

## tokenizer[

( -- )
code\# none
This is a tokenizer command, used to end FCode byte generation and interpret following text as tokenizer commands (up to the closing ]tokenizer). A tokenizer [ . . ] tokenizer sequence may be used anywhere in an FCode program, either within any definition or outside of definitions.

One plausible use for tokenizer [ would be to generate debugging text during the tokenizing process. (A cr flushes the text from the output buffer immediately, which is useful if the tokenizer crashes.) For example:

```
...
tokenizer[ .( step a) cr ]tokenizer
tokenizer[ .( step b) cr ]tokenizer
```

Another use for tokenizer [ is together with emit-byte, to manually output a desired byte of FCode. This would be useful, for example, if you wished to generate a new FCode command that the tokenizer did not understand. For example:

```
...
tokenizer[ 1 emit-byte 27 emit-byte ]tokenizer
\ manually output finish-device fcode
...
```

Ends a tokenizer-only command sequence. See tokenizer [ .

```
true ( -- flag ) code# a4
generates: -1
```

Leave the value for the true flag (which is -1 ) on the stack.

```
tuck (n1 n2 -- n2 n1 n2 )}\mathrm{ code# 4c
```

Copy the top stack item underneath the second item.

```
tyPe ( adr len -- ) code# 90
```

A defer word that transfers len characters to the output, beginning with the character at address adr, continuing through len consecutive addresses. No action is taken if len is zero.

For example:

```
h# 10 buffer: my-name-buff
: hello ( -- )
    ." Enter Your First name " my-name-buff h# 10 expect
    ." Sun Microsystems Welcomes " my-name-buff span @ type cr
;
```

The output may go either to a framebuffer or to a serial port, depending on which is enabled.
u. ( $n$-- )
code\# 9b
Display n as an unsigned number in a free-field format, using the current value for base. A trailing space is also displayed.

For example:
hex -1 u.
shows

```
ffff.ffff
```

(u.) ( n -- adr len )
generates: <\# \#s \#>
code\# 96 9a 97

This is a numeric conversion primitive, used to implement display words such as u. . It converts an unsigned number into a string.

For example:
hex
d\# -12 (u.) type
shows:

```
fffffff4
```

$\mathbf{u . r}(\mathrm{n} 1+\mathrm{n}-\mathrm{-})$
code\# 9c
n 1 is converted using the value of base and then displayed as an unsigned number right-aligned in a field +n characters wide. A trailing space is not displayed.

If the number of characters required to display $n 1$ is greater than $+n$, an error condition exists. In this implementation, all the characters required will be displayed, making the resulting field larger than +n .

For example:

```
: formatted-output ( -- )
    my-base h# 8 u.r ." base" cr
    my-offset h# 8 u.r ." offset" cr
;
```

u/mod ( n1 n2 -- rem quot )
rem is the remainder and quot is the quotient after dividing n1 by n2. All values and arithmetic are unsigned. All values are 32-bit.

For example:
-1 $5 \mathrm{u} / \mathrm{mod} . \mathrm{s}$
shows

```
0 3333.3333
```

```
u2/ ( n1 -- n2 )
code# 58
``` n 2 is the result of n 1 logically shifted right one bit. A zero is shifted into the vacated sign bit.

For example:
```

-2 u2/ .s

```
shows
```

7fff.ffff

```
\(\mathbf{u}<(\mathrm{n} 1 \mathrm{n} 2\)-- flag )
flag is true if \(n 1\) is less than \(n 2\) where \(n 1\) and \(n 2\) are treated as unsigned integers.
\(\mathbf{u}<=(\mathrm{n} 1 \mathrm{n} 2\)-- flag )
code\# 3f
flag is true if \(n 1\) is less than or equal to \(n 2\) where \(n 1\) and \(n 2\) are treated as unsigned integers.
u> ( n1 n2 -- flag )
code\# \(3 e\)
flag is true if n 1 is greater than n 2 where n 1 and n 2 are treated as unsigned integers.
\(\mathbf{u} \boldsymbol{>}=(\mathrm{n} 1 \mathrm{n} 2--\mathrm{flag})\)
code\# 41
flag is true if \(n 1\) is greater than or equal to \(n 2\) where \(n 1\) and \(n 2\) are treated as unsigned integers.
```

until ( flag -- )
code\# 14 -offset
generates: b?branch -offset

```

Marks the end of a begin ... ( flag ) until conditional loop. When until is encountered, a flag is removed and tested. If the flag is true, the loop is terminated and execution continues just after the until. If the flag is false, execution jumps back to just after the corresponding begin.

For example:
```

: probe-loop ( adr -- )
\ generate tight probe-loop until a key is pressed.
begin dup 1@ drop key? until drop
;

```
upc ( char1 -- char2 )
code\# 81
char2 is the upper case version of char1. If char1 is not a lower case letter, it is left unchanged. See lcc.

For example:
```

: continue? ( -- continue? )
." Want to Continue? Enter Y/N" key dup emit
upc ascii Y =
;

```
```

( -- )
version 2.1

```

Used within an alarm routine to signify that the user has typed an abort sequence. When alarm finishes, instead of returning to the program that was interrupted by the execution of alarm, it enters the OpenBoot command interpreter. Valid for FCode version 2.1 or later.

For example:
```

: test-dev-status ( -- error? ) ... ;
: my-checker ( -- ) test-dev-status if user-abort then ;
: install-abort ( -- ) ['] my-checker d\# 10 alarm ;

```
\(\mathbf{u * x}\) ( u1[32] u2[32] -- product[64] ) code\# d4
version 2
Multiplies two unsigned 32-bit numbers, yielding an unsigned 64-bit product.
For example:
```

hex
3 3 u*x .s

```
gives

\section*{90}
while
4 ffff.ffff \(u^{*} x\).s
gives
```

ffff.fffc 3

```
```

value name ( n1 -- ) at creation
code\# (header) b8
( -- n1 ) at execution
generates: new header, b(type) = b(value)

```

Creates a named, value-type variable. The name is initially created with:
```

4 5 6 ~ v a l u e ~ b l a c k

```
where the number before value is the initial value for black. Later occurrences of black will leave the correct value on the stack.

You can change the numeric contents of a value variable with is, as follows:
123 is black
value-type variables are widely used in this system. We encourage the use of values instead of variables. values act similarly to constants or colon definitions, in that execution of the word leaves the desired number on the stack. (With a variable, you always have to do a @ .)
```

variable name ( -- ) at creation code\# (header) b9
( -- adr ) at execution
generates: new header, b(type) = b(value)

```

Create a named, variable-type variable. The name is initially created with:
```

variable red

```

Later occurrences of red leave an address on the stack.
The alignment of the returned address is system-dependent.The address holds a 32-bit value. To retrieve the value in a variable and leave it on the stack for subsequent use, enter:
```

red @

```

To change the value in a variable, enter:
```

123 red !

```

Sun encourages the use of values instead of variables. values act like constants or colon definitions, in that execution of the word leaves the desired number on the stack. (With a variable, you always have to do a @ .) This similarity between values and other words makes the FCode easier to read, write and maintain.

Returns a 32-bit number identifying the version of the FCode interface supported by the CPU firmware. The high 16 bits is the major version number and the low 16 bits is the minor version number.

For example:
```

: exit-if-version1 ( -- )
version h\# 20000 < if ['] end0 execute then
;

```

This is not the same as the OpenBoot PROM version (see firmwareversion ). For example, the CPU PROM might be version 3.7, but the FCode version might still be 2.0 ( \(=0 \times 00020000\) ).

The value returned is less consistent on version 1 systems, but it is guaranteed to less than \(0 \times 0002.0000\).

\section*{version1}

code\# fd
This byte is automatically generated by the fcode-version 1 command.
Never use the word version1 in FCode source code.
versionx? ( -- flag )
code\# ??
A group of tokenizer macros to determine the FCode version of the system running the FCode interpreter. They include:
\begin{tabular}{|c|c|c|}
\hline Word & \multicolumn{2}{|r|}{Generates} \\
\hline version1? & version b(lit) & \(2000.0000<\) \\
\hline version2? & version b(lit) & \(2000.0000>=\) \\
\hline & version b(lit) & \(3000.0000<\) \\
\hline version2.0? & version b(lit) & \(2000.0000=\) \\
\hline version2.1? & version b(lit) & \(2000.0001=\) \\
\hline version2.2? & version b(lit) & \(2000.0002=\) \\
\hline version2.3? & version b(lit) & \(2000.0003=\) \\
\hline
\end{tabular}

Each returns true if the named version matches the system running the FCode interpreter.
\(\mathbf{w !}(\mathrm{n}\) adr \(--\quad)\)
The low-order 16-bits of n are stored at location adr (through adr+1). The higher byte is stored at adr ; the lower byte is stored at adr+1 . adr must be on a 16 -bit boundary; it must be evenly divisible by 2 .

W,

Compile two bytes into the dictionary. The dictionary pointer must be two-byte-aligned.

See c, for limitations.
```

w@ ( adr -- n )
code\# 6f

```

Fetch the 16-bit number stored at adr (through adr+1). The higher byte is at adr ; the lower byte is at adr +1 . The remaining high bytes of \(n\) are set to zero. adr must be on a 16-bit boundary; it must be evenly divisible by 2 .
/w (-- n )
code\# 5b
n is the size in bytes of a 16-bit word: 2 .
/w* ( n1 -- n2 ) code\# 67
n 2 is the result of multiplying n 1 by the length in bytes of a (16-bit) word. This is useful for converting an index into a byte offset. /w* is equivalent to \(2^{*}\), but should be used in preference to \(2 *\) as it is more portable.
<w@ ( adr -- n ) code\# 70
Fetches the 16-bit number stored at adr (through adr+1). The higher byte is stored at adr; the lower byte is stored at adr +1 . The remaining high bytes of n are set by sign-extending the upper bit in the higher byte. adr must be two-byte-aligned.

For example:
```

9123 8000 w!
8000 <w@ .h

```
shows: ffff9123, while
```

8000 w@ .h

```
shows: 9123 .
```

wa+ ( adr1 index -- adr2 )
code\# 5f

```
adr2 is the address of the index'th 16 -bit word after adr1. For byteaddressed machines (such as this one), this is equivalent to \(2 *+\).

Use wa+ in preference to 2 * + because it more clearly expresses the intent of the operation and is more portable.
```

    wa1t ( adr1 -- adr2 )
    code# 63
    ```
    adr2 is the address of the next 16-bit word after adr1. For byte-addressed
    machines (such as this one), this is equivalent to \(2+\). wa1+ should be used in
        preference to \(2+\) because it more clearly expresses the intent of the operation
        and is more portable.
wbsplit ( w -- byte.lo byte.next )
code\# af

Split the two lower bytes of winto two separate bytes (stored as the lower byte of each resulting item on the stack). The upper bytes of w must be zero.
```

wflip ( n1 -- n2 )
code\# 7c 49 7d
generates: lwsplit swap wljoin

```

Swap the two 16-bit halves of a 32 -bit number.
wflips ( adr len -- )
code\# 236
version 2
Swaps the order of the bytes within each 16-bit word in the memory buffer adr len.
adr must be two-byte-aligned. len must be a multiple of two.
while ( flag -- )
code\# 14 +offset
generates: b?branch +offset
Test the exit condition for a begin ... (flag) while ... repeat conditional loop. When the while is encountered, a flag is removed from the stack and tested. If the flag is true, execution continues from just after the while through to the repeat which then jumps back to just after the begin. If the flag is false, the loop is exited by causing execution to jump ahead to just after the repeat.

For example:
```

: probe-loop ( adr -- )
\ generate tight probe-loop until a key is pressed.
begin key? 0= while dup l@ drop repeat drop
;

```
window-left ( -- n )
code\# 166
A value, containing the offset (in pixels) of the left edge of the active text area from the left edge of the visible display. The "active text area" is where characters are actually printed. (There is generally a border of unused blank area surrounding it on all sides.) window-left contains the size of the left portion of the unused border.

The size of the right portion of the unused border is determined by the difference between screen-width and the sum of window-left plus the width of the active text area ( \#columns times char-width ).
This word is initially set to 0 , but should always be set explicitly to the appropriate value if you wish to use \(a n y \mathrm{fb} 1\) - or fb 8 - utility routines. This may be done with is, or it may be set automatically by calling fb1-install or fb8-install.
When set with fbx -install, a calculation is done to set window-left so that the available unused border area is evenly split between the left border and the right border. (The calculated value for window-left is rounded down to the nearest multiple of 32 , though. This allows all pixel-drawing to proceed more efficiently.) If you wish to use fbx -install but desire a different value for window-top, simply change it with is after calling fbx-install.
window-top ( -- \(n\) )
code\# 165
A value, containing the offset (in pixels) of the top of the active text area from the top of the visible display. The "active text area" is where characters are actually printed. (There is generally a border of unused blank area surrounding it on all sides.) window-top contains the size of the top portion of the unused border.
The size of the bottom portion of the unused border is determined by the difference between screen-height and the sum of window-top plus the height of the active text area (\#lines times char-height).
This word is initially set to 0 , but should always be set explicitly to the appropriate value if you wish to use any fb1-or fb8-utility routines. This may be done with is, or it may be set automatically by calling fb1-install or fb8-install.
When set with fbx-install, a calculation is done to set window-t op so that the available unused border area is evenly split between the top border and the bottom border. If you wish to use fbx-install but desire a different value for windowtop, simply change it with is after calling fbx-install.
```

within ( $n$ min max -- flag )
code\# 45
flag is true if $n$ is between min and max, inclusive of min and exclusive of
$\max .(\min <=n<\max$.) See between for another version.
wljoin ( word.lo word.hi -- n ) code\# 7d
Merge two 16-bit numbers into a 32-bit number. The high bits of each 16-bit number must be zero.

```
```

wpeek ( adr -- false | data true ) code\# 2 21

```
wpeek ( adr -- false | data true ) code# 2 21
    version 2
```

    version 2
    ```

Tries to read the 16-bit half-word at address adr. Returns the data and true if the access was successful. A false return indicates that a read access error occurred. adr must be 16-bit aligned.
wpoke ( data adr -- ok? ) code\# 24 version 2

Tries to write the 16-bit half-word at address adr. Returns true if the access was successful. A false return indicates that a write access error occurred. adr must be 16-bit aligned.

Note: wpoke may be unreliable on bus adapters that buffer write accesses.
```

x+ ( x1 x2 -- x3 ) code\# d8

```
    version 2

Adds two 64-bit numbers, leaving 64-bit sum.
For example:
1234.00000056 .7800 9abc \(3400.009 a \quad x+\quad . s\)
shows
```

1234.9abc 3456.789a

```
\(\mathbf{x}\) - ( x1 x2 -- x3 )
code\# d9
version 2
Subtracts two 64-bit numbers, leaving 64-bit result.
For example:
\(\begin{array}{llllll}0 & 6 & 1 & 0 & x- & . s\end{array}\)
shows
```

ffff.ffff 5

```
and
\[
4444.8888 \text { aaaa.bbbb } 2222.11115555 .2222 \quad \mathrm{x}-\mathrm{s}
\]
shows
```

xdr+ ( xdr-adr1 xdr-len1 xdr-adr2 xdr-len2 -- xdr-adr1 len1+2 )
code\# 1 12

```

Merge two xdr-format strings into a single xdr-format string. The two input strings must have been created sequentially with no intervening dictionary allocation or other xdr-format strings having been created. This can be called repeatedly, to create complex, multi-valued \(x d r\)-format strings for passing to attribute.

For example, suppose you wished to create a property named myprop with the following information packed sequentially:
```

"size" 2000 "vals" 3 128 40 22

```

This could be written in FCode as follows:
```

: xdrstring,num ( adr len number -- )
>r xdrstring
r> xdrint xdr+
;
" size" 2000 xdrstring,num
" vals" 3 xdrstring,num xdr+
128 xdrint xdr+
40 xdrint xdr+
22 xdrint xdr+
" myprop" attribute

```
xdrbytes ( adr len -- xdr-adr xdr-len ) code\# 115
version 2.1

Encodes a byte array into a property value array. The external representation of a byte array is the sequence of bytes itself, with no appended null byte.

For example:
```

my-idprom h\# 20 xdrbytes " idprom" attribute

```
xdrint ( n1 -- xdr-adr xdr-len )
code\# 111
Convert an integer into an xdr-format string, suitable for passing as a "value" to attribute . For example:
\[
1152 \text { xdrint " hres" attribute }
\]
xdrphys ( physoffset space -- xdr-adr xdr-len )
code\# 113
Convert a physical address (as a device space and a physical offset) into an xdr-format string suitable for attribute. For example:
```

my-address 20.0000 + my-space xdrphys
" resetloc" attribute

```
xdrstring ( adr len -- xdr-adr xdr-len )
code\# 114

Converts an ordinary string, such as created by ", into an xdr-format string suitable for attribute. For example:
```

" MJS,SEH" xdrstring " authors" attribute

```
xdrtoint ( xdr1-adr xdr1-len -- xdr2-adr xdr2-len \(n\) ) code\# 2 1b version 2

Decodes a number from the beginning of the property value array \(x d r 1-a d r\) \(x d r 1-l e n\), and returns the remainder of the property value array \(x d r 2-a d r\) \(x d r 2-l e n\) and the number \(n\).

For example:
```

: show-clock-frequency ( -- )
" clock-frequency" get-inherited-attribute 0= if
." Clock frequency: " xdrtoint .h cr 2drop
then
;

```
xdrtostring ( xdr1-adr xdr1-len -- xdr2-adr xdr2-len adr len ) code\# 2 1c version 2

Decodes a string from the beginning of the property value array xdr1-adr xdr1-len, and returns the remainder of the property value array xdr2-adr \(x d r 2-l e n\) and the string adr3 len3.

For example:
```

: show-model ( -- )
" model" get-my-attribute 0= if xdrtostring type 2drop then

```
;
```

XOI ( n1 n2 -- n3 ) code\# 25

```
n 3 is the bit-by-bit exclusive-or of n 1 with n 2 .
```

xu>l ( ux -- ul )
code\# 46
generates: drop

```

Tokenizer instruction that truncates a 64 -bit number to 32 -bit .
    version 2

Divides an unsigned 64 -bit number by an unsigned 32 -bit number, yields a 32bit remainder and quotient

ㅍ11

\section*{FCode Reference}
\(A \equiv\)

\section*{FCode Primitives}

This appendix contains four lists:
- FCodes sorted according to functional group
- FCodes sorted by byte value
- FCodes sorted alphabetically by name
- Version 2 FCodes listed alphabetically

\section*{FCodes by Function}

The following tables describe FCodes currently supported by the OpenBoot PROM. New 2.0 FCodes are indicated by V2. Both the FCode token values and Forth names are included. A token value entry of CR indicates a cross-compiler-generated sequence, while - indicates that no FCode is generated.

Table A-1 Stack Manipulation
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 51 & depth & ( -- +n ) & How many items on stack? \\
\hline 46 & drop & ( \(\mathrm{n}-\mathrm{-}\) ) & Removes n from the stack \\
\hline 52 & 2drop & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{-}\) ) & Removes 2 items from stack \\
\hline 47 & dup & ( \(\mathrm{n}-\mathrm{n} \mathrm{n}\) ) & Duplicates n \\
\hline 53 & 2dup & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 1 \mathrm{n} 2 \mathrm{n} 1 \mathrm{n} 2)\) & Duplicates 2 stack items \\
\hline 50 & ?dup & ( \(\mathrm{n}-\mathrm{n} \mathrm{n} \mid 0\) ) & Duplicates n if it is non-zero \\
\hline CR & 3dup & ( n1 n2 n3 -- n1 n2 n3 n1 n2 n3 ) & Copies top 3 stack items \\
\hline 4 d & nip & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 2\) ) & Discards the second stack item \\
\hline 48 & over & ( n1 n2 -- n1 n2 n1 ) & Copies second stack item to top of stack \\
\hline 54 & 2over & ( n1 n2 n3 n4-- n1 n2 n3 n4 n1 n2 ) & Copies 2 stack items \\
\hline 4 e & pick & ( +n -- n2 ) & Copies +n-th stack item \\
\hline 30 & >r & ( \(\mathrm{n}-\mathrm{-}\) ) ( rs: -- n ) & Moves a stack item to the return stack* \\
\hline 31 & r> & ( -- n ) ( rs: \(\mathrm{n}-\mathrm{-}\) ) & Moves item from return stack to data stack* \\
\hline 32 & r@ & ( -- n ) ( rs: -- ) & Copies the top of the return stack to the data stack \\
\hline 4f & roll & ( +n--) & Rotates +n stack items \\
\hline 4a & rot & ( \(\mathrm{n} 1 \mathrm{n} 2 \mathrm{n} 3-\mathrm{n} 2 \mathrm{n} 3 \mathrm{n} 1)\) & Rotates 3 stack items \\
\hline 4b & -rot & ( n1 n2 n3-- n3 n1 n2 ) & Shuffles top 3 stack items \\
\hline 56 & 2rot & ( n1 n2 n3 n4 n5 n6 -- n3 n4 n5 n6 n1 n2 ) & Rotates 3 pairs of stack items \\
\hline 49 & swap & ( n1 n2-- n2 n1 ) & Exchanges the top 2 stack items \\
\hline 55 & 2swap & ( \(\mathrm{n} 1 \mathrm{n} 2 \mathrm{n} 3 \mathrm{n} 4-\mathrm{n} 3 \mathrm{n} 4 \mathrm{n} 1 \mathrm{n} 2\) ) & Exchanges 2 pairs of stack items \\
\hline 4c & tuck & ( n1 n2 -- n2 n1 n2 ) & Copies the top stack item below the second item \\
\hline \multicolumn{4}{|l|}{* Use these FCodes cautiously.} \\
\hline
\end{tabular}

Table A-2 Arithmetic Operations
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 20 & * & ( n1 n2 -- n3 ) & Multiplies n1 times n2 \\
\hline 1 e & + & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 3\) ) & Adds n1+n2 \\
\hline 1f & - & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 3\) ) & Subtracts n1-n2 \\
\hline 21 & / & ( n 1 n 2 -- quot ) & Divides n1/n2 \\
\hline CR & 1+ & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Adds one \\
\hline CR & 1- & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Subtracts one \\
\hline 59 & \(2^{*}\) & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Multiplies by 2 \\
\hline 57 & 2/ & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Divides by 2 \\
\hline 27 & << & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2\) ) & Left shifts n 1 by +n places \\
\hline 28 & >> & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2\) ) & Right shifts n 1 by +n places \\
\hline CR & <<a & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2\) ) & Arithmetic left shifts (same as <<) \\
\hline 29 & >>a & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2)\) & Arithmetic right shifts n 1 by +n places \\
\hline 2d & abs & ( \(\mathrm{n}-\mathrm{l} \mathrm{u}\) ) & Absolute value \\
\hline ae & aligned & ( adr1 -- adr2 ) & Adjusts an address to a machine word boundary \\
\hline 23 & and & ( n1 n2-- n3 ) & Logical and \\
\hline ac & bounds & ( startadr len -- endadr startadr ) & Converts start,len to end,start for do loop \\
\hline 2 f & max & ( n1 n2 -- n3 ) & n 3 is maximum of n 1 and n 2 \\
\hline 2 e & min & ( n1 n2 -- n3 ) & n 3 is minimum of n 1 and n 2 \\
\hline 22 & mod & ( n1 n2 -- rem ) & Remainder of n1/n2 \\
\hline CR & */mod & ( n1 n2 n3 -- rem quot ) & Remainder, quotient of \(n 1 * n 2 / \mathrm{n} 3\) \\
\hline 2a & \(/\) mod & ( n1 n2 -- rem quot ) & Remainder, quotient of n1/n2 \\
\hline 2c & negate & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Changes the sign of n1 \\
\hline 26 & not & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & One's complement \\
\hline 24 & or & ( n1 n2 -- n3 ) & Logical or \\
\hline 2 b & \(\mathrm{u} / \mathrm{mod}\) & ( ul un -- un.rem un.quot ) & Unsigned 32-bit divide of ul/un \\
\hline 58 & u2/ & ( u1-- u2 ) & Logical right shifts 1 bit \\
\hline 25 & xor & ( n1 n2 -- n3 ) & Exclusive or \\
\hline d4 & \(u^{*} \mathrm{x}\) & ( u1[32] u2[32] -- product[64] ) & Multiplies two unsigned 32-bit numbers, yields an unsigned 64bit product. V2 \\
\hline d5 & \(x u / m o d\) & \[
\begin{aligned}
& (\text { u1[64] u2[32] -- remainder[32] } \\
& \text { quot[32] ) }
\end{aligned}
\] & Divides an unsigned 64-bit number by an unsigned 32-bit number, yields a 32-bit remainder and quotient V2 \\
\hline d8 & x+ & ( \(\mathrm{x} 1 \times 2 \mathrm{l}\)-- x 3 ) & Adds two 64-bit numbers V2 \\
\hline d9 & x- & ( x1 x2 -- x3 ) & Subtracts two 64-bit numbers V2 \\
\hline
\end{tabular}

Table A-3 Memory Operations
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 72 & ! & ( n adr -- ) & Stores a 32-bit number into the variable at adr \\
\hline 6c & +! & ( n adr -- ) & Adds n to the 32-bit number stored in the variable at adr \\
\hline 77 & \(2!\) & ( n1 n2 adr -- ) & Stores 2 numbers at adr; n2 at lower address \\
\hline 76 & 2@ & ( adr -- n1 n2 ) & Fetches 2 numbers from adr; n2 from lower address \\
\hline 6d & @ & ( adr -- n ) & Fetches a number from the variable at adr \\
\hline CR & ? & ( adr -- ) & Displays the 32-bit number at adr \\
\hline 75 & c! & ( n adr -- ) & Stores low byte of n at adr \\
\hline 71 & c@ & ( adr -- byte ) & Fetches a byte from adr \\
\hline CR & blank & ( adr len -- ) & Sets len bytes of memory to ASCII space, starting at adr \\
\hline CR & cmove & ( adr1 adr2 u -- ) & Same as move \\
\hline CR & cmove> & ( adr1 adr2 u -- ) & Same as move \\
\hline 7a & comp & ( adr1 adr2 len -- n ) & Compares two byte arrays including case. \(\mathrm{n}=0\) if same \\
\hline CR & erase & ( adr len -- ) & Sets len bytes of memory to zero, starting at adr \\
\hline 79 & fill & ( adr u byte -- ) & Sets u bytes of memory to byte \\
\hline 0237 & lflips & ( adr len -- ) & Exchanges 16-bit words within 32-bit longwords in adr len V2 \\
\hline 73 & \(1!\) & ( 1 adr -- ) & Stores the 32-bit number at adr, must be 32-bit aligned \\
\hline 6 e & 1 @ & ( adr -- 1 ) & Fetches the 32-bit longword at adr, must be 32-bit aligned \\
\hline 78 & move & ( adr1 adr2 u -- ) & Copies u bytes from adr1 to adr2, handles overlap correctly. \\
\hline 6b & off & ( adr -- ) & Stores false (32-bit 0) at adr \\
\hline 6a & on & ( adr -- ) & Stores true (32-bit -1) at adr \\
\hline 0236 & wflips & ( adr len -- ) & Exchanges bytes within 16-bit words in the specified region V2 \\
\hline 74 & w ! & ( w adr -- ) & Stores a 16-bit word at adr, must be 16-bit aligned \\
\hline 6 f & w@ & ( adr -- w ) & Fetches the unsigned 16-bit word at adr, must be 16-bit aligned \\
\hline 70 & <w@ & ( adr -- n ) & Fetches the signed 16-bit word at adr, must be 16-bit aligned \\
\hline
\end{tabular}

Table A-4 Atomic Access
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0230 & rb@ & ( adr -- byte ) & Reads the 8-bit value at the given address, atomically V2 \\
0231 & rb! & ( byte adr -- ) & Writes the 8-bit value at the given address, atomically V2 \\
\hline 0232 & rw@ & ( adr -- word ) & Reads the 16-bit value at the given address, atomically V2 \\
0233 & rw! & ( word adr -- ) & Writes the 16-bit value at the given address, atomically V2 \\
\hline 0234 & rl@ & ( adr -- long ) & Reads the 32-bit value at the given address, atomically V2 \\
0235 & rl! & ( long adr -- ) & Writes the 32-bit value at the given address, atomically V2 \\
\hline
\end{tabular}

Table A-5 Data Exception Tests
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0220 & cpeek & ( adr -- false | byte true ) & \begin{tabular}{l} 
Reads the 8-bit value at the given address, returns false if unsuccessful \\
V2
\end{tabular} \\
0221 & wpeek & ( adr -- false | word true ) & \begin{tabular}{l} 
Reads the 16-bit value at the given address, returns false if \\
unsuccessful V2
\end{tabular} \\
\hline 0222 & lpeek & ( adr -- false | long true ) & \begin{tabular}{l} 
Reads the 32-bit value at the given address, returns false if \\
unsuccessful V2
\end{tabular} \\
0223 & cpoke & (byte adr -- ok? ) & \begin{tabular}{l} 
Writes the 8-bit value at the given address, returns false if unsuccessful \\
V2
\end{tabular} \\
\hline 0224 & wpoke & ( word adr -- ok?) & \begin{tabular}{l} 
Writes the 16-bit value at the given address, returns false if \\
unsuccessful V2 \\
025
\end{tabular} \\
lpoke & (long adr -- ok?) & \begin{tabular}{l} 
Writes the 32-bit value at the given address, returns false if \\
unsuccessful V2
\end{tabular} \\
\hline
\end{tabular}

Table A-6 Comparison Operations
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 36 & \(0<\) & ( n -- flag ) & True if \(\mathrm{n}<0\) \\
\hline 37 & \(0<=\) & ( n -- flag ) & True if \(\mathrm{n}<=0\) \\
\hline 35 & 0<> & ( n -- flag ) & True if \(\mathrm{n}<>0\) \\
\hline 34 & \(0=\) & ( n -- flag ) & True if \(\mathrm{n}=0\), also inverts any flag \\
\hline 38 & 0> & ( n -- flag ) & True if \(\mathrm{n}>0\) \\
\hline 39 & \(0>=\) & ( n -- flag ) & True if \(\mathrm{n}>=0\) \\
\hline 3 a & < & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1<\mathrm{n} 2\) \\
\hline 43 & <= & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1<=\mathrm{n} 2\) \\
\hline 3d & <> & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1<>\mathrm{n} 2\) \\
\hline 3c & = & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1=\mathrm{n} 2\) \\
\hline 3 b & > & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1>\mathrm{n} 2\) \\
\hline 42 & >= & ( n1 n2 -- flag ) & True if \(\mathrm{n} 1>=\mathrm{n} 2\) \\
\hline 44 & between & ( n min max -- flag ) & True if \(\min <=\mathrm{n}<=\) max \\
\hline CR & false & (-- 0 ) & The value false \\
\hline CR & true & ( -- -1 ) & The value true \\
\hline 40 & \(\mathrm{u}<\) & ( u1 u2 -- flag ) & True if \(\mathrm{u} 1<\mathrm{u} 2\), unsigned \\
\hline 3 f & \(\mathrm{u}<=\) & ( u1 n2 -- flag ) & True if \(\mathrm{u} 1<=\mathrm{u} 2\), unsigned \\
\hline
\end{tabular}
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 3 e & \(\mathrm{u}>\) & \((\mathrm{u} 1 \mathrm{n} 2-\) - flag \()\) & True if \(\mathrm{u} 1>\mathrm{u} 2\), unsigned \\
\hline 41 & \(\mathrm{u}>=\) & \((\mathrm{u} 1 \mathrm{n} 2-\mathrm{flag})\) & True if \(\mathrm{u} 1>=\mathrm{u} 2\), unsigned \\
45 & within & ( n min max -- flag \()\) & True if \(\min <=\mathrm{n}<\max\) \\
\hline
\end{tabular}

Table A-7 Text Input
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline- & \((\) text & \((--)\) & Begins a comment (ignored) \\
- & \(\\
) & \((--)\) & Ignore rest of line (comment) \\
\hline CR & ascii \(\boldsymbol{x}\) & \((--\) char \()\) & ASCII value of next character \\
CR & control \(\boldsymbol{x}\) & \((-\) char \()\) & Interprets next character as ASCII control character \\
\hline 8 e & key & \((--\) char \()\) & Reads a character from the keyboard \\
8 d & key? & \((--\) flag \()\) & True if a key has been typed on the keyboard \\
\hline 8 a & expect & \((\) adr +n -- \()\) & Gets a line of edited input from the keyboard; store at adr \\
88 & span & \((--\) adr \()\) & Variable containing the number of characters read by expect \\
\hline- & \((\) s text & \((--)\) & Begins a comment (ignored) \\
\hline
\end{tabular}

\section*{Table A-8 ASCII Constants}
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline ab & bell & \((--\mathrm{n})\) & The ASCII code for the bell character; decimal 7 \\
a9 & bl & \((-\mathrm{n})\) & The ASCII code for the space character; decimal 32 \\
\hline aa & bs & \((--\mathrm{n})\) & The ASCII code for the backspace character; decimal 8 \\
CR & carret & \((--\mathrm{n})\) & The ASCII code for the carriage return character; decimal 13 \\
\hline CR & linefeed & \((--\mathrm{n})\) & The ASCII code for the linefeed character; decimal 10 \\
CR & newline & \((--\mathrm{n})\) & The ASCII code for the newline character; decimal 10 \\
\hline
\end{tabular}

Table A-9 Numeric Input
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline a4 & -1 & \((--1)\) & Constant -1 \\
a5 & 0 & \((-0)\) & Constant 0 \\
\hline a6 & 1 & \((-1)\) & Constant 1 \\
a7 & 2 & \((-2)\) & Constant 2 \\
\hline a8 & 3 & \((-3)\) & Constant 3 \\
CR & b\# number & \((--\) n \()\) & Interprets next number in binary \\
\hline
\end{tabular}
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline- & binary & \((--)\) & If outside definition, input text in binary \\
CR & d\# number & \((--\mathrm{n})\) & Interprets next number in decimal \\
\hline- & decimal & \((--)\) & If outside definition, input text in decimal \\
CR & h\# number & \((--\mathrm{n})\) & Interprets next number in hexadecimal \\
\hline- & hex & \((--)\) & If outside definition, input text in hexadecimal \\
CR & o\# number & \((--\mathrm{n})\) & Interprets next number in octal \\
\hline- & octal & \((--)\) & If outside definition, input text in octal \\
\hline
\end{tabular}

Table A-10 Numeric Primitives
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 99 & \(\#\) & \((+11--+12)\) & Converts a digit in pictured numeric output \\
97 & \(\#>\) & \((1--\) adr +n\()\) & Ends pictured numeric output \\
\hline 96 & \(<\#\) & \((--)\) & Initializes pictured numeric output \\
a0 & base & \((--\) adr \()\) & Variable containing number base \\
\hline a3 & digit & \((\) char base -- digit true \(\mid\) char false \()\) & Converts a character to a digit \\
95 & hold & \((\) char -- \()\) & Inserts the char in the pictured numeric output string \\
\hline 9 a & \#s & \((+\mathrm{l}--0)\) & Converts the rest of the digits in pictured numeric output \\
98 & sign & \((\mathrm{n} \mathrm{--})\) & Sets sign of pictured output \\
\hline a2 & \$number & \((\) adr len -- true \(\mid \mathrm{n}\) false \()\) & Converts a string to a number V2 \\
\hline
\end{tabular}

Table A-11 Numeric Output
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 9 d & \(\cdot\) & \((\mathrm{n}--)\) & Displays a number \\
CR &. d & \((\mathrm{n}--)\) & Displays number in decimal \\
\hline CR & binary & \((--)\) & If inside definition, output in binary \\
CR & decimal & \((--)\) & If inside definition, output in decimal \\
\hline CR &. h & \((\mathrm{n}--)\) & Displays number in hexadecimal \\
CR & hex & \((--)\) & If inside definition, output in hexadecimal \\
\hline CR & octal & \((--)\) & If inside definition, output in octal \\
9 e &.\(r\) & \((\mathrm{n}+\mathrm{n}--)\) & Displays a number in a fixed width field \\
\hline 9 f &. s & \((--)\) & Displays the contents of the data stack \\
CR & s. & \((\mathrm{n} \mathrm{--})\) & Displays n as a signed number \\
\hline 9 b & u. & \((\mathrm{u}--)\) & Displays an unsigned number \\
9 c & u.r & \((\mathrm{u}+\mathrm{n}--)\) & Prints an unsigned number in a fixed width field \\
\hline
\end{tabular}

Table A-12 General-purpose Output
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline CR &.\("\) text & \((--)\) & Compiles string for later output \\
CR &.\((\) text & \((--)\) & Displays a string now \\
\hline 91 & \((\) cr & \((--)\) & Outputs ASCII CR character; decimal 13 \\
92 & cr & \((--)\) & Starts a new line of display output \\
\hline 8 f & emit & \((\) char -- \()\) & Displays the character \\
CR & space & \((--)\) & Outputs a single space character \\
\hline CR & spaces & \((+\mathrm{n}--)\) & Outputs +n spaces \\
90 & type & \((\) adr \(+\mathrm{n}--)\) & Displays n characters \\
\hline
\end{tabular}

Table A-13 Formatted Output
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 94 & \#line & \((--\) adr \()\) & Variable holding the line number on the output device \\
93 & \#out & \((-\) adr \()\) & Variable holding the column number on the output device \\
\hline
\end{tabular}

Table A-14 begin Loops
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline\(C R\) & again & \((--)\) & Ends begin..again (infinite) loop \\
\(C R\) & begin & \((--)\) & Starts conditional loop \\
\hline\(C R\) & repeat & \((--)\) & Returns to loop start \\
\(C R\) & until & \((\) flag --\()\) & If true, exits begin..until loop \\
\hline\(C R\) & while & ( flag --\()\) & If true, continues begin..while..repeat loop, else exits loop \\
\hline
\end{tabular}

Table A-15 Conditionals
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline CR & if & ( flag -- ) & If true, executes next FCode(s) \\
CR & else & \((--)\) & (optional) Executes next FCode(s) if if failed \\
\hline CR & then & \((--)\) & Terminates if..else..then \\
\hline
\end{tabular}

Table A-16 do Loops
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline CR & do & ( end start -- ) & Loops, index startto end-1 inclusive \\
CR & ?do & ( end start -- ) & Like do, but skips loop if end \(=\) start \\
\hline 19 & i & \((--\mathrm{n})\) & Returns current loop index value \\
1 a & j & \((--\mathrm{n})\) & Returns value of next outer loop index \\
\hline CR & leave & \((--)\) & Exits do loop immediately \\
CR & ?leave & \((\) flag -- \()\) & If flag is true, exits do loop \\
\hline CR & loop & \((--)\) & Increments index, returns to do \\
CR & + loop & \((\mathrm{n} \mathrm{--} \mathrm{)}\) & Increments by n, returns to do. If \(\mathrm{n}<0\), index start to end \\
\hline
\end{tabular}

Table A-17 Control Words
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 1d & execute & \((\) acf -- ) & \begin{tabular}{l} 
Executes the word whose \\
compilation address is on the stack
\end{tabular} \\
33 & exit & \((--)\) & Returns from the current word
\end{tabular} \begin{tabular}{lll}
\hline 0238 & probe & ( arg-adr arg-len reg-adr reg-len fcode-adr fcode-len -- ) \\
0239 & probe-virtual & ( arg-adr arg-len reg-adr reg-len fcode-adr -- )
\end{tabular}

Table A-18 Strings
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline CR & " text" & ( -- adr len ) & Collects a string \\
84 & count & ( pstr -- adr +n ) & Unpacks a packed string \\
\hline 82 & lcc & ( char -- lower-case-char ) & Converts char to lower case \\
83 & pack & ( adr len pstr -- pstr ) & Makes a packed string from adr len, placing it at pstr \\
\hline 81 & upc & ( char -- upper-case-char ) & Converts char to upper case \\
0240 & left-parse- & ( adr len char -- adrR lenR adrL lenL ) & Splits a string at the given delimiter (which is discarded) \\
& string & & V2 \\
\hline 011 b & decode-2int & ( adr len -- phys space ) & Converts a string into a physical address and space V2 \\
\hline
\end{tabular}

Table A-19 Defining Words
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline CR & : (colon) name & ( -- ) & Begins colon definition \\
\hline CR & ; (semicolon) & ( -- ) & Ends colon definition \\
\hline - & alias newname oldname & ( -- ) & Creates newname with behavior of oldname \\
\hline CR & buffer: name & ( size -- ) & Creates data array of size bytes \\
\hline \(\overline{C R}\) & constant name & ( \(\mathrm{n}-\mathrm{-}\) ) & Creates a constant \\
\hline CR & create name & ( -- ) & Generic defining word \\
\hline \(\overline{C R}\) & defer name & ( -- ) & Execution vector (change with is) \\
\hline CR & field name & ( offset size -- offset+size ) & Creates a named offset pointer \\
\hline c0 & instance & ( -- ) & Declare a data type to be local V2.1 \\
\hline CR & struct & (-- 0 ) & Initializes for field creation \\
\hline CR & variable name & (-- ) & Creates a data variable \\
\hline CR & value name & ( \(\mathrm{n}-\mathrm{-}\) ) & Creates named value-type variable (change with is) \\
\hline
\end{tabular}

Table A-20 Dictionary Compilation
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline d3 &, & \((\mathrm{n}--)\) & Places a number in the dictionary \\
d0 & c, & \((\mathrm{n}--)\) & Places a byte in the dictionary \\
\hline ad & here & \((--\) adr \()\) & Address of top of dictionary \\
d2 & l, & \((\mathrm{l} \mathrm{--})\) & Places a 32-bit longword in the dictionary \\
\hline d1 & w, & \((\mathrm{w} \mathrm{--})\) & Places a 16-bit word in the dictionary \\
CR & is name & \((\mathrm{n}--)\) & Changes value in a defer word or a value \\
\hline
\end{tabular}

Table A-21 Dictionary Search
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline CR & ' name & \((--\) acf ) & Finds the word (while executing) \\
CR & ['] name & \((--\) acf ) & Finds word (while compiling) \\
\hline cb & \$find & ( adr len -- adr len false \(\mid\) acf +-1) & Finds a name in the OpenBoot PROM \\
cd & eval & ( ??? adr len -- ? ) & Executes Forth commands within a string V2 \\
\hline
\end{tabular}

Table A-22 Conversions Operators
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline \(\overline{7}\) & bljoin & ( b.low b2 b3 b.hi -- 1) & Joins four bytes to form a longword \\
\hline b0 & bwjoin & ( b.low b.hi -- w ) & Joins two bytes to form a 16-bit word \\
\hline 5a & /c & ( -- n ) & Address increment for a byte; 1 \\
\hline 66 & \(/ c^{*}\) & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Multiplies by /c \\
\hline 5 e & ca+ & ( adr1 index -- adr2 ) & Increments adr1 by index times /c \\
\hline 62 & ca1+ & ( adr1 -- adr2 ) & Increments adr1 by /c \\
\hline 80 & flip & ( w1 -- w2 ) & Swaps the bytes within a 16-bit word \\
\hline 5c & /1 & ( -- n ) & Address increment for a 32-bit longword; 4 \\
\hline 68 & /1* & ( n1-- n2 ) & Multiplies by /l \\
\hline 60 & la+ & ( adr1 index -- adr2 ) & Increments adr1 by index times /l \\
\hline 64 & la1+ & ( adr1 -- adr2 ) & Increments adr1 by /l \\
\hline 7 e & lbsplit & ( 1 -- b.low b2 b3 b.high ) & Splits a longword into four bytes \\
\hline 7c & lwsplit & ( 1 -- w.low w.high ) & Splits a longword into two words \\
\hline 5 d & /n & ( -- n ) & Address increment for a normal; 4 \\
\hline 69 & \(/ \mathrm{n}\) * & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Multiplies by /n \\
\hline 61 & na+ & ( adr1 index -- adr2 ) & Increments adr1 by index times /n \\
\hline 65 & na1+ & ( adr1 -- adr2 ) & Increments adr1 by /n \\
\hline 5 b & /w & ( -- n ) & Address increment for a 16-bit word; 2 \\
\hline 67 & /w* & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & Multiplies by /w \\
\hline 5 f & wa+ & ( adr1 index -- adr2 ) & Increments adr1 by index times /w \\
\hline 63 & wa1+ & ( adr1 -- adr2 ) & Increments adr1 by /w \\
\hline af & wbsplit & ( w -- b.low b.high ) & Splits a 16-bit word into two bytes \\
\hline CR & wflip & ( \(11-12\) ) & Swaps halves of 32-bit longword \\
\hline 7d & wljoin & ( w.low w.high -- 1 ) & Joins two words to form a longword \\
\hline
\end{tabular}

Table A-23 Memory Buffers Allocation
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 8 b & alloc-mem & ( nbytes -- adr ) & Allocates nbytes of memory and returns its address \\
8 c & free-mem & ( adr nbytes -- ) & Frees memory allocated by alloc-mem \\
\hline
\end{tabular}

Table A-24 Miscellaneous Operators
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 86 & \(>\) body & \((\) acf -- apf \()\) & Finds parameter field address from compilation address \\
85 & body \(>\) & \((\) apf -- acf \()\) & Finds compilation address from parameter field address \\
\hline CR & emit-byte & \((\mathrm{n}--)\) & Outputs FCode byte (use with tokenizer[) \\
00 & end0 & \((--)\) & Marks the end of FCode \\
\hline ff & end1 & \((--)\) & Alternates form for end0 (not recommended) \\
CR & fcode-version1 & \((--)\) & Begins FCode program \\
\hline- & fload filename & \((--)\) & Begins tokenizing filename \\
- & headerless & \((--)\) & Creates new names with new-token (no name fields) \\
\hline- & headers & \((--)\) & Creates new names with named-token (default) \\
7 b & noop & \((--)\) & Does nothing \\
\hline cc & offset16 & \((--)\) & All further branches use 16-bit offsets (instead of 8-bit) \\
- & tokenizer[ & \((--)\) & Begins tokenizer program commands \\
\hline- & ltokenizer & \((--)\) & Ends tokenizer program commands \\
CR & fcode-version2 & \((--)\) & Begins 2.0 FCode program, compiles start1 V2 \\
\hline- & external & \((--)\) & Creates new names with external-token V2 \\
\hline
\end{tabular}

Table A-25 Internal Operators, (invalid for program text)
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 1-f & \{ table\#1-15 \} & & Reserved byte codes, used for 2-byte entries \\
\hline 10 & b (lit) & ( -- n ) & Followed by 32-bit\#. Compiled by numeric data \\
\hline 11 & \(\mathrm{b}\left({ }^{\prime}\right)\) & ( -- acf ) & Followed by a token (1 or 2-byte code) . Compiled by ['] or ' \\
\hline 12 & b (") & ( -- adr len ) & Followed by count byte, text. Compiled by " or ." \\
\hline c3 & b (is) & ( \(\mathrm{n}-\mathrm{-}\) ) & Compiled by is \\
\hline fd & version1 & ( -- ) & Followed by reserved byte, checksum (2 bytes), length (4 bytes). Compiled by fcode-version1, as the first FCode bytes \\
\hline fe & 4-byte-id & ( -- ) & Followed by 3 identifier bytes. First FCode byte. Not supported. \\
\hline 13 & bbranch & ( -- ) & Followed by offset. Compiled by else or again \\
\hline 14 & b? branch & ( -- ) & Followed by offset. Compiled by if or until \\
\hline 15 & b(loop) & ( -- ) & Followed by offset. Compiled by loop \\
\hline 16 & b(+loop) & ( \(\mathrm{n}-\mathrm{-}\) ) & Followed by offset. Compiled by +loop \\
\hline 17 & b(do) & ( end start -- ) & Followed by offset. Compiled by do \\
\hline 18 & b(?do) & ( end start -- ) & Followed by offset. Compiled by ?do \\
\hline 1b & b(leave) & ( -- ) & Compiled by leave or ?leave \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline b1 & b (<mark) & ( -- ) & Compiled by begin \\
\hline b2 & b (>resolve) & ( -- ) & Compiled by else or then \\
\hline c4 & b (case) & ( -- ) & Compiled by case \\
\hline c5 & \(b\) (endcase) & ( -- ) & Compiled by endcase \\
\hline c6 & b(endof) & ( -- ) & Compiled by endof \\
\hline 1c & b(of) & ( sel testval -sel | none ) & Followed by offset. Compiled by of \\
\hline b5 & new-token & ( -- ) & Followed by table\#, code\#, token-type. Compiled by any defining word. Headerless, not used normally. \\
\hline b6 & named-token & ( -- ) & Followed by packed string (count,text), table\#, code\#, token-type. Compiled by any defining word (: value constant etc.) \\
\hline b7 & \(\mathrm{b}(:)\) & & Token-type compiled by : \\
\hline b8 & \(b\) (value) & & Token-type compiled by value \\
\hline b9 & b(variable) & & Token-type compiled by variable \\
\hline ba & b(constant) & & Token-type compiled by constant \\
\hline bb & b (create) & & Token-type compiled by create \\
\hline bc & \(b\) (defer) & & Token-type compiled by defer \\
\hline bd & b(buffer:) & & Token-type compiled by buffer: \\
\hline be & b (field) & & Token-type compiled by field \\
\hline c2 & b(;) & ( -- ) & End a colon definition. Compiled by ; \\
\hline ca & external-token & ( -- ) & Like named-token, but name header is always created at probe time V2 \\
\hline f0 & start0 & ( -- ) & Like version1, but for version 2.0 FCodes. Uses 16-bit branches. Fetches successive tokens from same address V2 \\
\hline f1 & start1 & ( -- ) & Like version1, but for version 2.0 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive addresses. Compiled by fcode-version2 V2 \\
\hline f2 & start2 & ( -- ) & Like version1, but for version 2.0 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive 16-bit addresses V2 \\
\hline f3 & start4 & ( -- ) & Like version1, but for version 2.0 FCodes. Uses 16-bit branches. Fetches successive tokens from consecutive 32-bit addresses V2 \\
\hline
\end{tabular}

Table A-26 Memory Allocation
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0101 & dma-alloc & ( nbytes -- virt ) & Maps in nbytes of DMA space, return virtual adr \\
0104 & memmap & ( phys space nbytes -- virt ) & Maps in a region, return virtual address \\
\hline 0105 & free-virtual & ( virt nbytes -- ) & Frees virtual memory from memmap, dma-alloc,or map-sbus \\
0106 & >physical & ( virt -- phys space ) & Returns physical adr and space for virtual adr \\
\hline
\end{tabular}

Table A-27 Non-volatile Parameters
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 010 f & my-params ( -- adr len ) & \begin{tabular}{l} 
Returns a data array for this plug-in device. The data format is defined \\
specifically for each plug-in device, in order to customize the device. Params for \\
each device, as needed, will be stored in the system NVRAM
\end{tabular} \\
\hline
\end{tabular}

Table A-28 Properties
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 0110 & attribute & ( xdr-adr xdr-len name-adr name-len -- ) & Declares a property with the given value structure, for the given name string. \\
\hline 0111 & xdrint & ( n -- xdr-adr xdr-len ) & Converts a number into an xdr-format string \\
\hline 0112 & xdr+ & ( xdr-adr1 xdr-len1 xdr-adr2 xdr-len2 -- xdr-adr xdr-len1+2 ) & Merges two xdr-format strings. They must have been created sequentially \\
\hline 0113 & xdrphys & ( phys space -- xdr-adr xdr-len ) & Converts physical address and space into an xdrformat string \\
\hline 0114 & xdrstring & ( adr len -- xdr-adr xdr-len ) & Converts a string into an xdr-format string \\
\hline 0115 & xdrbytes & ( adr len -- xdr-adr xdr-len ) & Converts a byte array into an xdr-format string V2.1 \\
\hline 021a & get-my-attribute & ```
( nam-adr nam-len -- true |
    xdr-adr xdr-len false )
``` & Returns the xdr-format string for the given property name V2 \\
\hline 021b & xdrtoint & \[
\begin{aligned}
& \text { ( xdr-adr xdr-len -- xdr2-adr } \\
& \text { xdr2-len } n \text { ) }
\end{aligned}
\] & Converts the beginning of an xdr-format string to an integer V2 \\
\hline 021c & xdrtostring & ```
( xdr-adr xdr-len -- xdr2-adr
    xdr2-len adr len )
``` & Converts the beginning of an xdr-format string to a normal string V2 \\
\hline 021d & get-inheritedattribute & ( nam-adr nam-len -- true | xdr-adr xdr-len false ) & Returns the value string for the given property, searches parents' properties if not found V2 \\
\hline 021e & delete-attribute & ( nam-adr nam-len -- ) & Deletes the property with the given name V2 \\
\hline 021f & get-packageattribute & ( adr len phandle -- true | xdr-adr xdr-len false ) & Returns the xdr-format string for the given property name in the package "phandle" V2 \\
\hline
\end{tabular}

Table A-29 Commmonly-used Properties
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0116 & reg & ( phys space size -- ) & Declares location and size of device registers \\
0117 & intr & ( intr-level vector -- ) & Declares interrupt level and vector for this device \\
\hline 0118 & driver & ( adr len -- ) & Not supported \\
0119 & model & ( adr len -- ) & Declares model\# for this device, such as " SUNW,501-1415-01" \\
\hline \(011 a\) & device-type & ( adr len -- ) & Declares type of device, e.g. " display", " block", " network", or " byte" \\
\(C R\) & name & ( adr len -- ) & Declares SunOS driver name, as in " SUNW,zebra" \\
\hline 0201 & device- & ( adr len -- ) & Creates the "name" attribute with the given value V2 \\
& name & & \\
\hline
\end{tabular}

Table A-30 System Version Information
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0210 & \begin{tabular}{l} 
processor- \\
type \\
firmware- \\
version
\end{tabular} & \begin{tabular}{l}
\((-\) processor- \\
type \()\) \\
\((--n)\)
\end{tabular} & Obsolete V2 \\
0211 & \begin{tabular}{l} 
Returns major/minor CPU firmware version V2
\end{tabular} \\
\hline 0212 & \begin{tabular}{l} 
fcode- \\
version
\end{tabular} & \((-\mathrm{n})\) & Obsolete V2 \\
87 & \begin{tabular}{l} 
version
\end{tabular} & \((-\mathrm{n})\) & Returns major/minor FCode interface version \\
\hline
\end{tabular}

Table A-31 Device Activation Vector Setup
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 011 c & is-install & \((\) acf -- ) & Identifies "install" routine to allocate a framebuffer \\
011 d & is-remove & \((\) acf -- \()\) & Identifies "remove" routine, to deallocate a framebuffer \\
\hline 011 e & is-selftest & \((\) acf -- \()\) & Identifies "selftest" routine for this framebuffer \\
011 f & new-device & \((--)\) & Opens an additional device, using this driver package \\
\hline 0127 & finish-device & \((--)\) & Closes out current device, ready for new-device \\
\hline
\end{tabular}

Table \(A\)-32 Self-test utility Routines
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0120 & diagnostic-mode? & \((--\) flag \()\) & Returns "true" if extended diagnostics are desired \\
0121 & display-status & \((\mathrm{n}--)\) & Obsolete \\
\hline
\end{tabular}
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0122 & memory-test-suite & ( adr len -- status ) & Calls memory tester for given region \\
0123 & group-code & \((--\) adr ) & Obsolete \\
\hline 0124 & mask & \((--\) adr ) & Variable, holds "mask" used by memory-test-suite \\
\hline
\end{tabular}

Table A-33 Time Utilities
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0125 & get-msecs & \((--\mathrm{ms})\) & Returns the current time, in milliseconds, approx. \\
0126 & ms & \((\mathrm{n}--)\) & Delays for n milliseconds. Resolution is 1 millisecond \\
\hline 0213 & alarm & \((\) acf \(\mathrm{n}--)\) & Periodically execute acf. If \(\mathrm{n}=0\), stop. V2 \\
\hline
\end{tabular}

Table A-34 Machine-specific Support
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0130 & map-sbus & ( phys size -- virt ) & Maps a region of memory in 'sbus' address space \\
0131 & sbus-intr>cpu & ( sbus-intr\# -- cpu-intr\# ) & Translates SBus interrupt\# into CPU interrupt\# \\
\hline
\end{tabular}

Note - Table A-35 through Table A-41 apply only to display device-types.

Table A-35 User-set Terminal Emulation Values
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0150 & \#lines & \((--\mathrm{n})\) & \begin{tabular}{l} 
Number of lines of text being used for display. This word must be initialized (using \\
is). fbx-install does this automatically, and also properly incorporates the NVRAM \\
parameter "screen-\#rows"
\end{tabular} \\
0151 & \#columns & \((--\mathrm{n})\) & \begin{tabular}{l} 
Number of columns (chars/line) used for display. This word must be initialized \\
(using is). fbx-install does this automatically, and also properly incorporates the \\
NVRAM parameter "screen-\#columns"
\end{tabular} \\
\hline
\end{tabular}

Table A-36 Terminal Emulator-set Terminal Emulation Values
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0152 & line\# & \((-\mathrm{n} \mathrm{)}\) & Current cursor position (line\#). 0 is top line \\
0153 & column\# & \((--\mathrm{n})\) & Current cursor position (column\#). 0 is left char. \\
\hline 0154 & inverse? & \((--\) flag \()\) & True if output is inverted (white-on-black) \\
0155 & inverse-screen? & \((--\) flag \()\) & True if screen has been inverted (black background) \\
\hline
\end{tabular}

Table A-37 Terminal Emulation Routines*
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0157 & draw-character & \((\) char -- ) & \begin{tabular}{l} 
Paints the given character and advance the \\
cursor
\end{tabular} \\
0158 & reset-screen & \((--)\) & Initializes the display device
\end{tabular} \begin{tabular}{lll}
\hline 0159 & toggle-cursor & \((--)\) \\
015 a & erase-screen & \((--)\)
\end{tabular}

Table A-38 Frame Buffer Parameter Values*
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 016 c & char-height & \((--\mathrm{n})\) & Height (in pixels) of a character (usually 22) \\
016 d & char-width & \((--\mathrm{n})\) & Width (in pixels) of a character (usually 12) \\
\hline 016 f & fontbytes & \((--\mathrm{n})\) & Number of bytes/scan line for font entries (usually 2) \\
0162 & frame-buffer-adr & \((--\mathrm{adr})\) & Address of frame buffer memory \\
\hline 0163 & screen-height & \((--\mathrm{n})\) & Total height of the display (in pixels) \\
0164 & screen-width & \((--\mathrm{n})\) & Total width of the display (in pixels) \\
\hline 0165 & window-top & \((--\mathrm{n})\) & Distance (in pixels) between display top and text window \\
0166 & window-left & \((-\mathrm{n})\) & Distance (in pixels) between display left edge and text window left edge \\
\hline
\end{tabular}
*These must all be initialized before using any fbx- routines.
Table A-39 Font Operators
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 016a & default-font & \begin{tabular}{c} 
( -- fontbase charwidth charheight \\
fontbytes \#firstchar \#chars )
\end{tabular} & \begin{tabular}{l} 
Returns default font values, plugs directly into \\
set-font
\end{tabular} \\
016b & set-font & \begin{tabular}{l} 
(fontbase charwidth charheight \\
fontbytes \#firstchar \#chars -- )
\end{tabular} & Sets the character font for text output \\
\hline 016e & \(>\) font & ( char -- adr ) & Returns font address for given ASCII character \\
\hline
\end{tabular}

Table A-40 One-bit Framebuffer Utilities
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 0170 & fb1-draw-character & ( char -- ) & Paints the character and advance the cursor \\
\hline 0171 & fb1-reset-screen & ( -- ) & Initializes the display device (noop) \\
\hline 0172 & fb1-toggle-cursor & (--) & Draws or erases the cursor \\
\hline 0173 & fb1-erase-screen & ( -- ) & Clears all pixels on the display \\
\hline 0174 & fb1-blink-screen & ( -- ) & Inverts the screen, twice (slow) \\
\hline 0175 & fb1-invert-screen & ( -- ) & Changes all pixels to the opposite color \\
\hline 0176 & fb1-insert-characters & ( \(\mathrm{n}-\mathrm{-}\) ) & Inserts n blanks just before the cursor \\
\hline 0177 & fb1-delete-characters & ( \(\mathrm{n}-\mathrm{-}\) ) & Deletes n characters, starting at with cursor character, rightward. Remaining chars slide left \\
\hline 0178 & fb1-insert-lines & ( \(\mathrm{n}-\mathrm{-}\) ) & Inserts \(n\) blank lines just before the current line, lower lines are scrolled downward \\
\hline 0179 & fb1-delete-lines & ( \(\mathrm{n}-\mathrm{-}\) ) & Deletes \(n\) lines starting with the current line,lower lines are scrolled upward \\
\hline
\end{tabular}
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 017 a & fb1-draw-logo & \begin{tabular}{l} 
( line\# logoaddr logowidth \\
logoheight -- )
\end{tabular} & Draws the logo \\
( width height \#columns \#lines -- ) & Installs the one-bit built-in routines \\
\hline 017 c & fb1-install & fb1-slide-up & \((\mathrm{n} \mathrm{--} \mathrm{)}\)
\end{tabular} \begin{tabular}{l} 
Like fb1-delete-lines, but doesn't clear lines at \\
bottom
\end{tabular}

Table A-41 Eight-bit Framebuffer Utilities
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 0180 & fb8-draw-character & ( char -- ) & Paints the character and advance the cursor \\
\hline 0181 & fb8-reset-screen & ( -- ) & Initializes the display device (noop) \\
\hline 0182 & fb8-toggle-cursor & (-- ) & Draws or erases the cursor \\
\hline 0183 & fb8-erase-screen & ( -- ) & Clears all pixels on the display \\
\hline 0184 & fb8-blink-screen & (--) & Inverts the screen, twice (slow) \\
\hline 0185 & fb8-invert-screen & ( -- ) & Changes all pixels to the opposite color \\
\hline 0186 & fb8-insert-characters & ( \(\mathrm{n}-\mathrm{-}\) ) & Inserts n blanks just before the cursor \\
\hline 0187 & fb8-delete-characters & ( \(\mathrm{n}-\mathrm{-}\) ) & Deletes n characters starting at with cursor character, rightward. Remaining chars slide left \\
\hline 0188 & fb8-insert-lines & ( \(\mathrm{n}-\mathrm{-}\) ) & Inserts n blank lines just before the current line, lower lines are scrolled downward \\
\hline 0189 & fb8-delete-lines & ( \(\mathrm{n}-\mathrm{-}\) ) & Deletes \(n\) lines starting with the current line, lower lines are scrolled upward \\
\hline 018a & fb8-draw-logo & ( line\# logoaddr logowidth logoheight -- ) & Draws the logo \\
\hline 018b & fb8-install & ( width height \#columns \#lines -- ) & Installs the eight-bit built-in routines \\
\hline
\end{tabular}

Table A-42 Package Support
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 023 c & peer & \begin{tabular}{l} 
( phandle -- \\
next-phandle ) \\
( parent-phandle -- \\
child-phandle )
\end{tabular} & \begin{tabular}{l} 
Returns phandle of package that is the next child of the the \\
parent of the package V2.3
\end{tabular} \\
023 l & child & \begin{tabular}{l} 
Returns phandle of the package that is the first child of the \\
package parent-phandle V2.3
\end{tabular} \\
\hline 0204 & find-package & \begin{tabular}{l} 
(adr len -- false \\
phandle true )
\end{tabular} & \begin{tabular}{l} 
Finds a package named "adr len" V2
\end{tabular} \\
0205 & open-package & \begin{tabular}{l} 
(adr len phandle -- \\
ihandle | 0)
\end{tabular} & \begin{tabular}{l} 
Opens an instance of the package "phandle," passes arguments \\
"adr len" V2
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Description \\
\hline 020f & \$open-package & ( arg-adr arg-len adr len -ihandle | 0 ) & Finds a package "adr len," then opens it with arguments "argadr arg-len" V2 \\
\hline 020a & my-parent & ( -- ihandle ) & Returns the ihandle of the parent of the current package instance V2 \\
\hline 0203 & my-self & ( -- ihandle ) & Returns the instance handle of currently-executing package instance V2 \\
\hline 020b & ihandle>phandle & ( ihandle -- phandle ) & Converts an ihandle to a phandle V2 \\
\hline 0206 & close-package & ( ihandle -- ) & Closes an instance of a package V2 \\
\hline 0207 & find-method & ( adr len phandle -- false | acf true ) & Finds the method (command) named "adr len" within the package "phandle" V2 \\
\hline 0208 & call-package & ( [...] acf ihandle -- [...]) & Executes the method "acf" within the instance "ihandle" V2 \\
\hline 020e & \$call-method & ( [...]adr len ihandle -[...]) & Executes the method named "adr len" within the instance "ihandle" V2 \\
\hline 0209 & \$call-parent & ( [...] adr len -- [...] ) & Executes the method "adr len" within the parent's package V2 \\
\hline 0202 & my-args & ( -- adr len ) & Returns the argument string "adr len" passed when this package was opened V2 \\
\hline 020d & my-unit & ( -- low high ) & Returns the physical unit number pair for this package V2 \\
\hline 0102 & my-address & ( -- phys ) & Returns the physical adr of this plug-in device. "phys" is a "magic" number, usable by other routines V2 \\
\hline 0103 & my-space & ( -- space ) & Returns address space of plug-in device. "space" is a "magic" number, usable by other routines V2 \\
\hline
\end{tabular}

Table A-43 Asynchronous Support
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0213 & alarm & \((\) acf \(\mathrm{n}--)\) & Executes the method (command) indicated by "acf" every "n" milliseconds V2 \\
0219 & user-abort & \((--)\) & Abort after alarm routine finishes execution \\
\hline
\end{tabular}

Table A-44 Miscellaneous Operations
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0214 & (is-user-word) & ( adr len acf -- ) & Creates a new word called "adr len" which executes "acf" V2 \\
01 a 4 & mac-address & \((-\) adr len ) & Returns the MAC address V2 \\
\hline
\end{tabular}

Table A-45 Interpretation
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0215 & suspend-fcode & \((--)\) & Suspends execution of FCode, resumes later if an undefined command is required \\
& & V2 \\
\hline
\end{tabular}

Table A-46 Error Handling
\begin{tabular}{llll}
\hline Value & Function & Stack & Description \\
\hline 0216 & abort & \((--)\) & Aborts FCode execution, returns to the "ok" prompt V2 \\
0217 & catch & \(([\ldots]\) acf -- [...] error-code ) & \begin{tabular}{l} 
Executes "acf," returns throw error code or 0 if throw not \\
encountered V2
\end{tabular} \\
\hline 0218 & throw & \((\) error-code -- \()\) & \begin{tabular}{l} 
Returns given error code to catch V2 \\
fc
\end{tabular} \\
ferror & \((--)\) & Displays "Unimplemented FCode" and stops FCode interpretation \\
\hline
\end{tabular}

\section*{FCodes by Byte Value}

The following table lists, in hexadecimal order, currently-assigned FCode byte values.

Table A-47 FCodes by Byte Value
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Version 2? \\
\hline 00 & end0 & ( -- ) & \\
\hline 10 & b(lit) & ( -- n ) & \\
\hline 11 & \(\mathrm{b}\left({ }^{\prime}\right)\) & ( -- acf ) & \\
\hline 12 & b (") & ( -- adr len ) & \\
\hline 13 & bbranch & ( -- ) & \\
\hline 14 & b?branch & ( -- ) & \\
\hline 15 & b(loop) & ( -- ) & \\
\hline 16 & b (+loop) & ( \(\mathrm{n}-\mathrm{-}\) ) & \\
\hline 17 & b(do) & ( end start -- ) & \\
\hline 18 & b (?do) & ( end start -- ) & \\
\hline 19 & i & ( -- n ) & \\
\hline 1a & j & ( -- n ) & \\
\hline 1b & b(leave) & ( -- ) & \\
\hline 1c & b(of) & ( sel testval -- sel | none ) & \\
\hline 1d & execute & ( acf -- ) & \\
\hline 1 e & + & ( n1 n2 -- n3 ) & \\
\hline 1f & - & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 3\) ) & \\
\hline 20 & * & ( n1 n2 -- n3 ) & \\
\hline 21 & / & ( n1 n2 -- quot ) & \\
\hline 22 & mod & ( n1 n2 -- rem ) & \\
\hline 23 & and & ( n1 n2 -- n3 ) & \\
\hline 24 & or & ( n1 n2 -- n3 ) & \\
\hline 25 & xor & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 3\) ) & \\
\hline 26 & not & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & \\
\hline 27 & << & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2\) ) & \\
\hline 28 & >> & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2)\) & \\
\hline 29 & >>a & ( \(\mathrm{n} 1+\mathrm{n}-\mathrm{n} 2\) ) & \\
\hline 2a & \(/ \bmod\) & ( n1 n2 -- rem quot ) & \\
\hline 2b & \(\mathrm{u} / \mathrm{mod}\) & ( ul un -- un.rem un.quot ) & \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Value & Function & Stack & Version 2? \\
\hline 2c & negate & ( \(\mathrm{n} 1-\mathrm{n} 2\) ) & \\
\hline 2d & abs & ( \(\mathrm{n}-\mathrm{l} \mathrm{u}\) ) & \\
\hline 2 e & min & ( \(\mathrm{n} 1 \mathrm{n} 2-\mathrm{n} 3\) ) & \\
\hline 2f & max & ( n1 n2--n3) & \\
\hline 30 & >r & ( \(\mathrm{n}-\mathrm{-}\) ) ( rs: -- n) & \\
\hline 31 & r> & ( -- n ) (rs: \(\mathrm{n}-\mathrm{l}\) ) & \\
\hline 32 & r@ & ( -- n ) ( rs: -- ) & \\
\hline 33 & exit & (-- ) & \\
\hline 34 & \(0=\) & ( n -- flag ) & \\
\hline 35 & 0<> & ( n -- flag ) & \\
\hline 36 & \(0<\) & ( n -- flag ) & \\
\hline 37 & \(0<=\) & ( n -- flag ) & \\
\hline 38 & 0> & ( n -- flag ) & \\
\hline 39 & \(0>=\) & ( n -- flag ) & \\
\hline 3a & < & ( n1 n2 -- flag ) & \\
\hline 3 b & > & ( n1 n2 -- flag ) & \\
\hline 3c & = & ( n1 n2 -- flag ) & \\
\hline 3d & <> & ( n1 n2 -- flag ) & \\
\hline 3 e & u> & ( u1 n2 -- flag ) & \\
\hline 3f & \(\mathrm{u}<=\) & ( u1 n2 -- flag ) & \\
\hline 40 & \(\mathrm{u}<\) & ( u1 u2 -- flag ) & \\
\hline 41 & \(\mathrm{u}>=\) & ( u1 n2 -- flag ) & \\
\hline 42 & \(>=\) & ( n1 n2 -- flag ) & \\
\hline 43 & <= & ( n1 n2 -- flag ) & \\

\section*{OpenBoot Interrupt Testing}

An important, and not always obvious, part of programming peripheral devices is dealing with interrupts. Table B-1 describes Open Boot 2.0 words for testing interrupts from the Forth Monitor. Note that these cannot be used in FCode programs because of their highly system-dependent nature.

Table B-1 Interrrupt-handling Words
\begin{tabular}{lll}
\hline Word & Stack Diagram & Descriptions \\
\hline catch-interrupt & \((\) level --\()\) & \begin{tabular}{l} 
Establishes a handler for interrupt "level" (1-15). If an interrupt occurs \\
on that level, the handler sets the value of the interrupt-occurred? \\
variable to -1 and sets the value of the vector-used variable to the \\
interrupt level.
\end{tabular} \\
\hline interrupt-occurred? & \((--\) adr \()\) & \begin{tabular}{l} 
Returns the address of a variable whose value will be set to "-1" when \\
an interrupt occurs.
\end{tabular} \\
\hline vector-used & \((--a d r)\) & \begin{tabular}{l} 
Returns the address of a variable whose value will be set to the \\
interrupt level when an interrupt occurs on a level guarded by catch- \\
interrupt.
\end{tabular} \\
\hline pil@ & \((\) level --\()\) & \begin{tabular}{l} 
Gets (pil@) and sets (pil!) the current processor interrupt level. \\
The system will only respond to interrupts above the current setting \\
of the PIL. After the first interrupt is handled, the PIL is automatically \\
raised to the level of the interrupt (thus disabling further interrupts at \\
the same level). Re-lower the PIL if you wish to process additional \\
interrupts.
\end{tabular} \\
\hline
\end{tabular}

Assume a device which interrupts on level 3. Here is a sample Forth program for testing the device's ability to interrupt.
```

: test-interrupt ( -- )
pil@ >r \ Remember old priority level
interrupt-occurred? off
3 catch-interrupt
2 pil! \ Allow level 3 interrupts
<do whatever is necessary to make the device interrupt>
1000 0 loop \ Wait awhile; may not be necessary
interrupt-occurred? @ if
<do whatever is necessary to turn off the device's interrupt request>
." Interrupt on level " vector-used @ . cr
else
." No interrupt." cr
then
r> pil!
;

```

Note - If you want to test interrupts on CPU levels 14,10 or 8 , you will also need to set the interrupt-enable register to the appropriate value as well. (SBus level 6 is equivalent to CPU level 8 on most current systems.) See comments at end for more details.

Caution - There is a bug in Open Boot PROMs 1.1 thru 2.1 in the interruptoccurred? flag, causing it to return a 0 even after an interrupt has occurred.

For example:
```

interrupt-occurred? off \ Clear flag
6 catch-interrupt \ Establish handler
5 pil! \ Lower CPU priority to allow level 6 interrupts
89 interrupt-enable! \ Cause a level 6 "software interrupt"
interrupt-occurred? ? \ Examine flag; it should be ffffffff but it's 0 (bug)

```

Here is a workaround patch for this bug.
```

ok see catch-interrupt
: catch-interrupt
10 + (ffeac10c) swap vector!
;

```

Note the number shown in parentheses (ffeac 10 c in this example). In the following step, substitute that number in place of the example number ffeac10c.
```

ok ramforth
8000.0000 ffeac10c execute 4 + !
ok

```

A way to determine this magic value from a program would be (for any Open Boot 2.0 -based system) as follows:
```

['] catch-interrupt (addr of catch-interrupt)
h\# 0a + w@ (offset pointer for ffxxxxxx routine)
4 * origin + (ffeac10c)

```

An interrupt can be generated just by writing the proper value to the interrupt register. Here is the format of this register:

Table B-2 Interrupt Register Format
\begin{tabular}{lll}
\hline Bit \# & Bit Name & Function \\
\hline 7 & A & Enable level 14 interrupts. \\
6 & B & None (always 0). \\
\hline 5 & C & Enable level 10 interrupts. \\
4 & D & Enable level 8 interrupts. \\
\hline 3 & E & Software interrupt level 6. \\
2 & F & Software interrupt level 4. \\
\hline 1 & G & Software interrupt level 1. \\
0 & H & Enable all interrupts. \\
\hline
\end{tabular}

Writing a zero to bits A, C, or D only masks that interrupt, it does not clear the source.

Writing a one to a software interrupt bit requests an interrupt on that level; the bit must be cleared to clear the request.

Merely writing a one to register bit H will not enable interrupts on levels 14, 10 and 8 , since these also have a separate mask.

To enable level 8, for example, You need to write a one to both bits D and H. After power-up or after any Forth traps, the Open Boot writes this interrupt register to "81".

Note - Writing a zero to bit H will clear the Asynchronous Memory (level 15) Interrupt, as well as masking all interrupts. Interrupts should be immediately re-enabled by writing a one to bit 0 .

On reset, all bits are cleared and all interrupts are reset.
Finally, here is a complete test example. All known bugs are accounted for.
```

\ Interrupt-testing program
hex
: patch-bugs ( -- )
ramforth
8000.0000
['] catch-interrupt 0a + w@ 2* ( 8000.0000 token )
\ If "firmware-version" found and >=2.0 (2.0000), then 2* again
\2.0 boot PROMS use a 4* multiplier, to expand the available dictionary
p" firmware-version" find ( acf n | pstr 0 )
if execute ( version ) 2.0000 >= if 2* then
else drop then ( 8000.0000 token' )
origin + ( 8000.0000 acf )
execute 4 + !
;
: catch-level ( level -- )
interrupt-occurred? off
dup d\# 8 = if 91 interrupt-enable! then
dup d\# 10 = if al interrupt-enable! then
\ Or, just always do "b1 interrupt-enable!" to enable all masks...
dup catch-interrupt ( level )
1- pil! \ Set priority level to allow this interrupt

```
```

    Interrupt-testing program
    ;
: check-interrupt ( -- )
<do whatever is necessary to make the device interrupt>
20 ms \ Wait awhile; may not be necessary
interrupt-occurred? @ ( flag )
if
<do whatever is necessary to turn off the device's interrupt request>
." Interrupt on level " vector-used @ . cr
else ." No interrupt." cr
then
;
7 value my-level \ My device's interrupt level
\ Alternatively...
\ 5 value my-sbus-level
\ : my-level ( -- int-level ) my-sbus-level sbus-intr>cpu ;
O value old-pil \ Holder for system interrupt level
: test-interrupt ( -- )
patch-bugs \ Overkill, only needs to be called once per session
pil@ is old-pil \ Save old interrupt level
my-level catch-level \ Setup handler
check-interrupt \ Do the test
old-pil pil! \ Restore old interrupt level
;

```
\(\equiv B\)

\section*{FCode Memory Allocation}

For OpenBoot 2
To get general-purpose memory, use buffer: or alloc-mem. Use free-mem to deallocate memory obtained with alloc-mem.

To map in portions of your device for ordinary access, use " map-in" \$call-parent ( adr space size -- virt ), as in:
my-address offset + my-space size " map-in" \$call-parent ( virt )

To later map out those portions of your device, use " map-out" \$callparent ( virt size -- ), as in:
( virt ) size " map-out" \$call-parent
To use a region of system memory for DMA (for example, for both direct CPU access and DMA access from a device), first define the following mapping and allocation routines, then follow the steps below to ensure data coherency.
```

: dma-alloc ( n -- virt ) " dma-alloc" \$call-parent ;
: dma-free ( virt n -- ) " dma-free" \$call-parent ;
: dma-map-in ( virt n cache? -- devaddr ) " dma-map-in" \$call-parent ;
: dma-map-out ( virt devaddr n -- ) " dma-map-out" \$call-parent ;
: dma-sync ( virt devaddr size -- ) \ Correct even if "dma-sync" missing
" dma-sync" ['] \$call-parent catch if

```
1. Allocate the DMA region with:
- dma-alloc
- dma-map-in
2. CPU accesses the region using virt from dma-alloc, then perform:
- dma-sync
3. Start DMA operation, using devaddr from dma-map-in.
- Wait for DMA complete status.
- Repeat DMA as needed, then perform dma-sync
4. Repeat steps 2 and 3 as needed

\section*{5. 5) Deallocate the region when completed, with:}
- dma-map-out
- dma-free

\section*{For OpenBoot 1}

To obtain general-purpose memory, use buffer: or alloc-mem for small amounts (less than several hundred bytes). Use dma-alloc for larger amounts.

Use free-mem to deallocate memory allocated with alloc-mem. Use freevirtual to deallocate memory allocated with dma-alloc.

To map in portions of your device for ordinary access, use map-sbus.
To map out portions of your device, use free-virtual.
To use a region of system memory for DMA (for example, both direct CPU access and DMA access from a device), map it in with dma-alloc. CPU accesses and DMA accesses may be performed interchangeably.

When the memory is no longer needed, unmap it with free-virtual.
When unmapping multiple regions using free-virtual, you must perform the unmapping in the reverse order that the memory was originally mapped in.

\title{
Changes in OpenBoot 1 FCode Usage
}

\section*{FCode For OpenBoot 1 Systems}

There are two groups of FCode functions - OpenBoot 1 and OpenBoot 2. You will need to keep the differences in mind while writing your FCode program (depending on your intended system market).

The first SBus systems shipped by Sun used only OpenBoot 1 FCodes. Such systems, including SPARCstation1, \(1+\), 1E, original IPC, have a Open Boot PROM with a version number of 1.x. All later SPARC systems from Sun have an Open Boot PROM with a version number of 2.x. These systems recognize both Open Boot 1 and OpenBoot 2 FCodes. (2.x upgrade PROMs are available for SPARCstation 1, \(1+\) and IPC.)

Most basic FCode functions are OpenBoot 1. Framebuffer support FCodes are also OpenBoot 1. OpenBoot 2 FCodes support package access, bootable devices, and several other miscellaneous functions. The individual FCode descriptions state whether that FCode is version 2 or not. (See Appendix A, "FCode Reference" for a list of all OpenBoot 2 FCodes.)

Any OpenBoot 2 FCode encountered by a OpenBoot 1 system will not be recognized, causing the FCode program to fail. To deal with this possibility, write your FCode to conform to one of the several styles shown here. The correct choice of style will depend on your FCode requirements, and the intended system targets.

\section*{FCode Programming Style 1}
```

fcode-version1
.
(version 1 FCodes only)
end0

```

This style will operate correctly on either OpenBoot 1 or OpenBoot 2 systems.
FCode Programming Style 2
```

fcode-version2
(version 1 plus version 2 FCodes)
...
end0

```

This style operates correctly only on OpenBoot 2 systems. Any such FCode will abort immediately if encountered on a OpenBoot 1 system, as the fcodeversion2 header will be rejected. This style is suitable for any device is not intended for operation on any OpenBoot 1 system.

\section*{FCode Programming Style 3}
```

fcode-version1
(version 1 FCodes only)
...
: v1-exit ( -- ) version h\# 2.0000 < if ['] end0 execute then ;
v1-exit
*
(version 1 plus version 2 FCodes)
end0

```

This style will operate correctly on either OpenBoot 1 or OpenBoot 2 systems. It is used when OpenBoot 2 functionality is needed, but where a limited OpenBoot 1 functionality is also acceptable on OpenBoot 1 systems. It works by initially restricting usage to OpenBoot 1 FCodes only, and then ending FCode execution on a OpenBoot 1 system. On a OpenBoot 2 system, execution continues with subsequent OpenBoot 1 plus OpenBoot 2 FCodes.

Style 1 is suitable for framebuffers, and for other devices with simple non-boot FCode requirements.

Style 2 or 3 is appropriate for bootable devices, depending on whether an abbreviated non-boot functionality on OpenBoot 1 systems is appropriate or desired.

\section*{Other OpenBoot 1 Restrictions}

FCode that will operate on OpenBoot 1 systems must also take into account the following restrictions and limitations:

\section*{Total FCode Program Size}

OpenBoot 1 systems only have about 13 K of dictionary space to accomodate all plug-in SBus cards. Combinations of cards each containing FCode exceeding 5 K or so in size may fail. (The actual size of the FCode binary can be
used as a first estimate of the consumed dictionary space in many instances. For a more precise measure, look at the value in here at the start and end of FCode compilation.)

OpenBoot 2 systems have substantially more available dictionary space.

\section*{Old-style Memory Mapping And Unmapping}

On OpenBoot 2 systems, the standard technique for device-dependent memory mapping/unmapping is with " xxxx" \$call-parent (where " xxxx"could be " map-in"," map-out"," dma-alloc"," dma-free", " dma-map-in"," dma-map-out").

Since \$call-parent is not defined on OpenBoot 1 systems, you must use the obsolescent FCode functions dma-alloc, map-sbus, memmap and freevirtual in FCode programs that will run on OpenBoot 1 systems.

\section*{Memory Mapping Size Limits}

On OpenBoot 1 systems, the total available mapping (for all devices) is hex 12.4000 , divided into two regions: 10.0000 and 2.4000 . The 10.0000 region is typically used up by the active framebuffer.

To ensure correct behavior with multiple devices, Sun recommends:
- limit large mappings to only 1.0000 ( 64 K )
- have only one such mapping active at any time
- return the mapping when done.

It is also best to perform a single larger mapping in preference to several smaller mappings, where possible.

\section*{Large General-purpose Mappings}

On OpenBoot 1 systems, memory allocated with alloc-mem or buffer: uses up limited dictionary space. For general-purpose memory allocations larger than several hundred bytes or so, dma-alloc should be used instead to avoid this limitation. (OpenBoot 2 systems do not have this limitation, so allocmem and buffer: may be freely used.)

\section*{Memory De-allocation}

Memory allocated with alloc-mem, memmap, dma-alloc or map-sbus must be deallocated in a specific sequence on OpenBoot 1 systems. When deallocating memory on OpenBoot 1 systems, you should de-allocate in the reverse order that the memory was allocated. (OpenBoot 2 systems do not have this restriction.)

\section*{Total Properties}

On OpenBoot 1 systems, each device is limited to 16 properties total. (OpenBoot 2 systems do not have this restriction.)

\section*{Interpretation of my-address and my-space}

The interpretation of these numbers differs between OpenBoot 1 and OpenBoot 2.

In OpenBoot 1, my-address is a slot offset (200.0000, 400.0000, etc.) and myspace is a magic number representing the SBus address space. In OpenBoot 2, my-address is typically 0 and my-space is typically the SBus slot number. Properly-written FCode programs will operate correctly in both versions.

To do this, make sure that my-address and my-space are not interpreted directly, but are only used as input parameters to mapping functions (mapsbus, memmap, " map-in" \$call-parent) or property declarations (reg, xdrphys).

\section*{my-address Volatility}

On OpenBoot 1 systems, my-address will change when other slots are probed, so later execution of your routines which use my-address could generate illegal results. The best workaround is to save my-address into a constant or value during the initial probe, and then always use that saved value instead. (This precaution is not necessary on OpenBoot 2 systems.)

\section*{free-virtual and Properties}

Execution of free-virtual on any OpenBoot 2 system will automatically delete an address property with the same virtual address contents.

\section*{Changes in new-device and finish-device Usage}

Nested new-device FCodes will create "children-of-children" on FCode 2.0 systems. This feature is not supported on OpenBoot 1 systems: they will create only sibling children (children of the parent of the nested new-device operations).
finish-device is not implemented on SPARCstation 1 PROM versions 1.0 and 1.1. It is implemented as a NOP in other OpenBoot 1 systems.

OpenBoot 1 systems are limited to a maximum of eight plug-in device nodes per system. Each plug-in device occupies a node, and each new-device call uses up an additional node.
