Preface

OVERVIEW

A man page is provided for both the naive user, and sophisticated user who is familiar with the SunOS operating system and is in need of on-line information. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

The following contains a brief description of each section in the man pages and the information it references:

• Section 1 describes, in alphabetical order, commands available with the operating system.

• Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.

• Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.

• Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume.

	• Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
	• Section 5 contains miscellaneous documentation such as character set tables, etc.
	• Section 6 contains available games and demos.
	• Section 7 describes various special files that refer to specific hardware peripherals, and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
	• Section 9 provides reference information needed to write device drivers in the kernel operating systems environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver–Kernel Interface (DKI).
	• Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer may include in a device driver.
	• Section 9F describes the kernel functions available for use by device drivers.
	• Section 9S describes the data structures used by drivers to share information between the driver and the kernel.
	Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man (1) for more information about man pages in general.
NAME	
	This section gives the names of the commands or functions documented, followed by a brief description of what they do.
SYNOPSIS	
	This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full pathname is shown. Literal characters (commands and options) are in bold font and variables (arguments, parameters and substitution characters) are in <i>italic</i> font. Options and

	arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.	
	The following special characters are used in this section:	
	[] The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument <i>must</i> be specified.	
	Ellipses. Several values may be provided for the previous argument, or the previous argument can be specified multiple times, for example, <i>'filename'</i> .	
	Separator. Only one of the arguments separated by this character can be specified at time.	
	{} Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.	
PROTOCOL		
	This section occurs only in subsection 3R to indicate the protocol description file. The protocol specification pathname is always listed in bold font.	
AVAILABILITY		
	This section briefly states any limitations on the availabilty of the command. These limitations could be hardware or software specific.	
	A specification of a class of hardware platform, such as x86 or SPARC , denotes that the command or interface is applicable for the hardware platform specified.	
	In Section 1 and Section 1M, AVAILABILITY indicates which package contains the command being described on the manual page. In order to use the command, the specified package must have been installed with the operating system. If the package was not installed, see pkgadd (1) for information on how to upgrade.	
MT-LEVEL		
	This section lists the MT-LEVEL of the library functions described in the Section 3 manual pages. The MT-LEVEL defines the libraries' ability to support threads. See Intro (3) for more information.	

Preface

iii

DESCRIPTION	
	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, functions and such, are described under USAGE.
IOCTL	
	This section appears on pages in Section 7 only. Only the device class which supplies appropriate parameters to the ioctl (2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtio (7).
OPTIONS	
	This lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	
	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	
	This section describes the output - standard output, standard error, or output files - generated by the command.
RETURN VALUES	
	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1 , these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared as void do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code. **USAGE** This section is provided as a guidance on use. This section lists special rules, features and commands that require in-depth explanations. The subsections listed below are used to explain built-in functionality: **Commands Modifiers** Variables **Expressions Input Grammar EXAMPLES** This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command line entry and machine response is shown. Whenever an example is given, the prompt is shown as example% or if the user must be super-user, example# Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, **OPTIONS and USAGE sections. ENVIRONMENT** This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

Preface

EXIT STATUS	
	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion and values greater than zero for various error conditions.
FILES	
	This section lists all filenames referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
SEE ALSO	
	This section lists references to other man pages, in-house documentation and outside publications.
DIAGNOSTICS	
	This section lists diagnostic messages with a brief explanation of the condition causing the error. Messages appear in bold font with the exception of variables, which are in <i>italic</i> font.
WARNINGS	
	This section lists warnings about special conditions which could seriously affect your working conditions — this is not a list of diagnostics.
NOTES	
	This section lists additional information that does not belong anywhere else on the page. It takes the form of an <i>aside</i> to the user, covering points of special interest. Critical information is never covered here.
BUGS	
	This section describes known bugs and wherever possible suggests workarounds.

NAME	Intro, intro – introduction to commands and application programs	
AVAILABILITY	This section indicates which package contains the commands being described on this page. To be able to use the command, the indicated package must have been installed with the operating system. For information on how to add a package see pkgadd (1).	
DESCRIPTION	This section describes, in alphabetical order, commands available with this operating sys- tem.	
	Pages of special interest are categorized as follows:	
	1B Commands found only in the <i>SunOS/BSD Compatibility Package</i> . Refer to the <i>Source Compatibility Guide</i> for more information.	
	1C Commands for communicating with other systems.	
	1F Commands associated with <i>Form and Menu Language Interpreter</i> (FMLI).	
	1S Commands specific to the SunOS system.	
OTHER SECTIONS	See these sections of the <i>man Pages(1M): System Administration Commands</i> for more information.	
	Section 1M in this manual for system maintenance commands.	
	• Section 4 of this manual for information on file formats.	
	• Section 5 of this manual for descriptions of publicly available files and miscellaneous information pages.	
	 Section 6 in this manual for computer demonstrations. For tutorial information about these commands and procedures, see: Solaris Advanced User's Guide 	
	Programming Utilities Guide	
Manual Page Command Syntax	Unless otherwise noted, commands described in the SYNOPSIS section of a manual pag- accept options and other arguments according to the following syntax and should be interpreted as explained below.	
	name [-option] [cmdarg] where:	
	[] Surround an <i>option</i> or <i>cmdarg</i> that is not required.	
	Indicates multiple occurrences of the <i>option</i> or <i>cmdarg</i> .	
	<i>name</i> The name of an executable file.	
	<pre>{} The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</pre>	
	option (Always preceded by a "–".) noargletter or, argletter optarg[,]	

	noargletter	A single letter representing an option without an option-argument. Note that more than one <i>noargletter</i> option can be grouped after one "–" (Rule 5, below).
	argletter	A single letter representing an option requiring an option-argument.
	optarg	An option-argument (character string) satisfying a preceding <i>argletter</i> . Note that groups of <i>optargs</i> following an <i>argletter</i> must be separated by commas, or separated by a tab or space character and quoted (Rule 8, below).
	cmdarg	Path name (or other command argument) <i>not</i> beginning with "–", or "–" by itself indicating the standard input.
Command Syntax Standard: Rules	mands will o tional param	and syntax rules are not followed by all current commands, but all new com- obey them. getopts (1) should be used by all shell procedures to parse posi- neters and to check for legal options. It supports Rules 3-10 below. The c of the other rules must be done by the command itself.
	1.	Command names (<i>name</i> above) must be between two and nine characters long.
	2.	Command names must include only lower-case letters and digits.
	3.	Option names (option above) must be one character long.
	4.	All options must be preceded by "–".
	5.	Options with no arguments may be grouped after a single "–".
	6.	The first option-argument (<i>optarg</i> above) following an option must be pre- ceded by a tab or space character.
	7.	Option-arguments cannot be optional.
	8.	Groups of option-arguments following an option must either be separated by commas or separated by tab or space character and quoted (–o xxx,z,yy or –o "xxx z yy ").
	9.	All options must precede operands (<i>cmdarg</i> above) on the command line.
	10.	"" may be used to indicate the end of the options.
	11.	The order of the options relative to one another should not matter.
	12.	The relative order of the operands (<i>cmdarg</i> above) may affect their significance in ways determined by the command with which they appear.
	13.	"–" preceded and followed by a space character should only be used to mean standard input.
SEE ALSO	getopts(1), v	vait(1), exit(2), getopt(3C), wait(3B)

DIAGNOSTICS	Upon termination, each command returns two bytes of status, one supplied by the sys- tem and giving the cause for termination, and (in the case of "normal" termination) one supplied by the program [see wait (3B) and exit (2)]. The former byte is 0 for normal ter- mination; the latter is customarily 0 for successful execution and non-zero to indicate troubles such as erroneous parameters, or bad or inaccessible data. It is called variously "exit code", "exit status", or "return code", and is described only where special conven- tions are involved. Some commands produce unexpected results when processing files containing null char- acters. These commands often treat text input lines as strings and therefore become con- fused upon encountering a null character (the string terminator) within a line.	
	Name	Description
	acctcom(1)	search and print process accounting files
	adb (1)	general-purpose debugger
	addbib(1)	create or extend a bibliographic database
	admin(1)	See sccs-admin (1)
	aedplot(1B)	See plot(1B)
	alias(1)	create or remove a pseudonym or shorthand for a command or series of commands
	apropos(1)	locate commands by keyword lookup
	ar (1)	maintain portable archive or library
	arch(1)	display the architecture of the current host
	as (1)	assembler
	asa(1)	convert FORTRAN carriage-control output to print- able form
	at(1)	execute commands at a later time
	atoplot(1B)	See plot(1B)
	atq(1)	display the jobs queued to run at specified times
	atrm(1)	remove jobs spooled by at or batch
	audioconvert(1)	convert audio file formats
	audioplay(1)	play audio files
	audiorecord(1)	record an audio file
	awk (1)	pattern scanning and processing language
	banner(1)	make posters
	basename(1)	deliver portions of path names
	basename(1B)	display portions of pathnames

batch(1)	See at(1)
bc (1)	arbitrary precision arithmetic language
bdiff(1)	big diff
bg (1)	See jobs(1)
bgplot(1B)	See plot (1B)
biff(1B)	give notice of incoming mail messages
break(1)	shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop
cal (1)	display a calendar
calendar(1)	reminder service
cancel(1)	See lp(1)
case(1)	shell built-in functions to choose from among a list of actions
cat (1)	concatenate and display files
cc (1B)	C compiler
cd (1)	change working directory
cdc (1)	See sccs-cdc(1)
chdir(1)	See cd (1)
checkeq(1)	See eqn(1)
checknr(1)	check nroff and troff input files; report possible errors
chgrp(1)	change file group ownership
chkey(1)	change user's secure RPC key pair
chmod(1)	change the permissions mode of a file
chown(1)	change file ownership
chown(1B)	change owner
ckdate(1)	prompts for and validates a date
ckgid(1)	prompts for and validates a group id
ckint(1)	display a prompt; verify and return an integer value
ckitem(1)	build a menu; prompt for and return a menu item
ckkeywd(1)	prompts for and validates a keyword
ckpath(1)	display a prompt; verify and return a pathname
ckrange(1)	prompts for and validates an integer
ckstr(1)	display a prompt; verify and return a string answer
cksum(1)	write file checksums and sizes
cktime(1)	display a prompt; verify and return a time of day
ckuid(1)	prompts for and validates a user ID

ckyorn(1)	prompts for and validates yes/no
clear(1)	clear the terminal screen
cmp (1)	compare two files
cocheck(1F)	See coproc(1F)
cocreate(1F)	See coproc(1F)
codestroy(1F)	See coproc(1F)
col (1)	reverse line-feeds filter
comb (1)	See sccs-comb(1)
comm (1)	select or reject lines common to two files
command(1)	execute a simple command
compress(1)	compress, uncompress files or display expanded files
continue(1)	See break(1)
coproc(1F)	communicate with a process
coreceive(1F)	See coproc(1F)
cosend(1F)	See coproc(1F)
cp (1)	copy files
cpio(1)	copy file archives in and out
cpp (1)	the C language preprocessor
crontab(1)	user crontab file
crtplot(1B)	See plot (1B)
crypt(1)	encode or decode a file
csh (1)	shell command interpreter with a C-like syntax
csplit(1)	split files based on context
ct (1C)	spawn login to a remote terminal
ctags(1)	create a tags file for use with ex and vi
cu (1C)	call another UNIX system
cut (1)	cut out selected fields of each line of a file
date(1)	write the date and time
dc (1)	desk calculator
delta(1)	See sccs-delta(1)
deroff(1)	remove nroff/troff, tbl, and eqn constructs
df (1B)	display status of disk space on file systems
diff(1)	display line-by-line differences between pairs of text files
diff3 (1)	3-way differential file comparison

diffmk(1)	mark differences between versions of a troff input file
dircmp(1)	directory comparison
dirname(1)	See basename(1)
dirs(1)	See cd (1)
dis (1)	object code disassembler
disable(1)	See enable(1)
dispgid(1)	displays a list of all valid group names
dispuid(1)	displays a list of all valid user names
dos2unix(1)	convert text file from DOS format to ISO format
download(1)	host resident PostScript font downloader
dpost(1)	troff postprocessor for PostScript printers
du (1B)	display the number of disk blocks used per directory or file
dumbplot(1B)	See plot(1B)
dump (1)	dump selected parts of an object file
dumpcs(1)	show codeset table for the current locale
dumpkeys(1)	See loadkeys(1)
echo(1)	echo arguments
echo(1B)	echo arguments to standard output
echo(1F)	put string on virtual output
ed (1)	text editor
edit(1)	text editor (variant of ex for casual users)
egrep(1)	search a file for a pattern using full regular expres- sions
eject(1)	eject media such as CD-ROM and floppy from drive
enable(1)	enable/disable LP printers
env (1)	obtain or alter environment variables for command execution
eqn (1)	typeset mathematics test
errange(1)	See ckrange(1)
errdate(1)	See ckdate(1)
errgid(1)	See ckgid(1)
errint(1)	See ckint(1)
erritem(1)	See ckitem (1)
error(1)	insert compiler error messages at right source lines
errpath(1)	See ckpath(1)

errstr(1)	See ckstr(1)
errtime(1)	See cktime(1)
erruid(1)	See ckuid(1)
erryorn(1)	See ckyorn(1)
eval(1)	See exec(1)
ex (1)	text editor
exec(1)	shell built-in functions to execute other commands
exit(1)	shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps
expand(1)	expand TAB characters to SPACE characters, and vice versa
export(1)	See set(1)
exportfs(1B)	translates exportfs options to share/unshare com- mands
expr(1)	evaluate arguments as an expression
expr(1B)	evaluate arguments as a logical, arithmetic, or string expression
exstr(1)	extract strings from source files
face(1)	executable for the Framed Access Command Environment Interface
factor(1)	obtain the prime factors of a number
false(1)	See true(1)
fastboot(1B)	reboot/halt the system without checking the disks
fasthalt(1B)	See fastboot (1B)
fc (1)	See history(1)
fdformat(1)	format floppy diskette or PCMCIA memory card
fg (1)	See jobs(1)
fgrep(1)	search a file for a character string
file (1)	determine file type
file(1B)	determine the type of a file by examining its contents
find (1)	find files
finger(1)	display information about local and remote users
fmlcut(1F)	cut out selected fields of each line of a file
fmlexpr(1F)	evaluate arguments as an expression
fmlgrep(1F)	search a file for a pattern
fmli (1)	invoke FMLI

fmt (1)	simple text formatters
fmtmsg(1)	display a message on stderr or system console
fnattr(1)	Update and examine attributes associated with an FNS named object
fnbind(1)	Bind a reference to an FNS name
fnlist(1)	Display the names and references bound in an FNS context
fnlookup(1)	Display the reference bound to an FNS name
fnrename(1)	Rename the binding of an FNS name
fnunbind(1)	Unbind the reference from an FNS name
fold(1)	filter for folding lines
for (1)	shell built-in functions to repeatedly execute action(s) for a selected number of times
foreach(1)	See for (1)
from(1B)	display the sender and date of newly-arrived mail messages
ftp(1)	file transfer program
function(1)	shell built-in command to define a function which is usable within this shell
gcore(1)	get core images of running processes
gencat(1)	generate a formatted message catalog
get(1)	See sccs-get(1)
getconf(1)	get configuration values
getfacl(1)	display discretionary information for a file or files
getfrm(1F)	returns the current frameID number
getitems(1F)	returns a list of currently marked menu items
getopt(1)	parse command options
getoptcvt(1)	convert to getopts to parse command options
getopts(1)	parse utility options
gettext(1)	retrieve text string from message database
gettxt(1)	retrieve a text string from a message database
gigiplot(1B)	See plot (1B)
glob (1)	shell built-in function to expand a word list
goto(1)	See exit(1)
gprof (1)	display call-graph profile data
graph(1)	draw a graph

	seensh a file for a nottorn
grep(1)	search a file for a pattern
groups(1)	print group membership of user
groups(1B)	display a user's group memberships
grpck(1B)	check group database entries
hash(1)	evaluate the internal hash table of the contents of directories
hashstat(1)	See hash(1)
head(1)	display first few lines of files
help(1)	See sccs-help(1)
helpdate(1)	See ckdate(1)
helpgid(1)	See ckgid (1)
helpint(1)	See ckint(1)
helpitem(1)	See ckitem(1)
helppath(1)	See ckpath(1)
helprange(1)	See ckrange(1)
helpstr(1)	See ckstr(1)
helptime(1)	See cktime(1)
helpuid(1)	See ckuid(1)
helpyorn(1)	See ckyorn(1)
history(1)	process command history list
hostid(1)	print the numeric identifier of the current host
hostname(1)	set or print name of current host system
hp7221plot(1B)	See plot (1B)
hpplot(1B)	See plot (1B)
i286 (1)	See machid(1)
i386 (1)	See machid(1)
i486 (1)	See machid(1)
i860 (1)	See machid(1)
iAPX286 (1)	See machid(1)
iconv(1)	code set conversion utility
if (1)	evaluate condition(s) or make execution of actions dependent upon the evaluation of condition(s)
implot(1B)	See plot(1B)
indicator(1F)	display application specific alarms and/or the "work- ing" indicator
indxbib(1)	create an inverted index to a bibliographic database

install(1B)	install files
ipcrm(1)	remove a message queue, semaphore set, or shared memory ID
ipcs (1)	report inter-process communication facilities status
jobs(1)	control process execution
join (1)	relational database operator
jsh (1)	See sh (1)
kbd (1)	manipulate the state of keyboard or display the type of keyboard
kdestroy(1)	destroy Kerberos tickets
kerberos(1)	introduction to the Kerberos system
keylogin(1)	decrypt and store secret key with keyserv
keylogout(1)	delete stored secret key with keyserv
kill(1)	terminate or signal processes
kinit(1)	Kerberos login utility
klist(1)	list currently held Kerberos tickets
ksh (1)	KornShell, a standard/restricted command and pro- gramming language
ksrvtgt(1)	fetch and store Kerberos ticket-granting ticket using a service key
last(1)	display login and logout information about users and terminals
lastcomm(1)	display the last commands executed, in reverse order
ld (1)	link editor for object files
ld (1B)	link editor, dynamic link editor
ldd (1)	list dynamic dependencies of executable files or shared objects
let (1)	shell built-in function to evaluate one or more arith- metic expressions
lex (1)	generate programs for lexical tasks
limit(1)	set or get limitations on the system resources avail- able to the current shell and its descendents
line (1)	read one line
lint(1B)	C program verifier
listusers(1)	list user login information
ln (1)	make hard or symbolic links to files
ln (1B)	make hard or symbolic links to files

User Commands

loadfont(1)	display or change font information in the RAM of the video card on an x86 system in text mode
loadkeys(1)	load and dump keyboard translation tables
locale(1)	get locale-specific information
localedef(1)	define locale environment
logger(1)	add entries to the system log
logger(1B)	add entries to the system log
login(1)	sign on to the system
logname(1)	return user's login name
logout(1)	shell built-in function to exit from a login session
longline(1F)	See readfile (1F)
look (1)	find words in the system dictionary or lines in a sorted list
lookbib(1)	find references in a bibliographic database
lorder(1)	find ordering relation for an object or library archive
lp (1)	send/cancel requests to an LP print service
lpc (1B)	line printer control program
lpq (1B)	display the queue of printer jobs
lpr (1B)	send a job to the printer
lprm(1B)	remove jobs from the printer queue
lpstat(1)	print information about the status of the LP print service
lptest(1B)	generate lineprinter ripple pattern
ls (1)	list contents of directory
ls (1B)	list the contents of a directory
m4 (1)	macro processor
mach (1)	display the processor type of the current host
machid(1)	get processor type truth value
mail(1)	read mail or send mail to users
Mail(1B)	See mailx(1)
mail (1B)	See mailx(1)
mailcompat(1)	provide SunOS compatibility for Solaris mailbox for- mat
mailstats(1)	print statistics collected by sendmail
mailx(1)	interactive message processing system
make(1S)	maintain, update, and regenerate related programs

modified 24 Feb 1993

	and files
man (1)	find and display reference manual pages
mconnect(1)	connect to SMTP mail server socket
mcs (1)	manipulate the comment section of an object file
mesg(1)	permit or deny messages
message(1F)	puts its arguments on FMLI message line
mkdir(1)	make directories
mkmsgs(1)	create message files for use by gettxt
mkstr(1B)	create an error message file by massaging C source files
more(1)	browse or page through a text file
msgfmt(1)	create a message object from a message file
mt (1)	magnetic tape control
mv (1)	move files
nawk(1)	pattern scanning and processing language
neqn(1)	See eqn(1)
newaliases(1)	rebuild the data base for the mail aliases file
newform(1)	change the format of a text file
newgrp(1)	log in to a new group
news(1)	print news items
nice(1)	run a command at a different priority
nis +(1)	a new version of the network information name service
NIS +(1)	See nis +(1)
nis (1)	See nis+(1)
niscat(1)	display NIS+ tables and objects
nischgrp(1)	change the group owner of a NIS+ object
nischmod(1)	change access rights on a NIS+ object
nischown(1)	change the owner of a NIS+ object
nischttl(1)	change the time to live value of a NIS+ object
nisdefaults(1)	display NIS+ default values
niserror(1)	display NIS+ error messages
nisgrep(1)	See nismatch(1)
nisgrpadm(1)	NIS+ group administration command
nisln(1)	symbolically link NIS+ objects
nisls(1)	list the contents of a NIS+ directory

nismatch(1)	utilities for searching NIS+ tables
nismkdir(1)	create NIS+ directories
nispasswd(1)	change NIS+ password information
nisrm(1)	remove NIS+ objects from the namespace
nisrmdir(1)	remove NIS+ directories
nistbladm(1)	NIS+ table administration command
nistest(1)	return the state of the NIS+ namespace using a condi- tional expression
nl (1)	line numbering filter
nm (1)	print name list of an object file
nohup(1)	run a command immune to hangups
notify(1)	See jobs(1)
nroff (1)	format documents for display or line-printer
od(1)	octal dump
on (1)	execute a command on a remote system, but with the local environment
onintr(1)	See trap(1)
pack(1)	compress and expand files
page(1)	See more(1)
pagesize(1)	display the size of a page of memory
passwd(1)	change login password and password attributes
paste(1)	merge corresponding or subsequent lines of files
patch(1)	apply changes to files
pathchk(1)	check path names
pathconv(1F)	search FMLI criteria for filename
pax (1)	portable archive interchange
pcat(1)	See pack(1)
pcmapkeys(1)	set keyboard extended map and scancode translation for the PC console in text mode
pcred(1)	See proc(1)
pdp11(1)	See machid(1)
pfiles(1)	See proc(1)
pflags(1)	See proc(1)
pg (1)	files perusal filter for CRTs
pkginfo(1)	display software package information
pkgmk(1)	produce an installable package

displays package parameter values
generate prototype file entries for input to pkgmk command
translate package format
See proc(1)
graphics filters for various plotters
See plot(1B)
See proc(1)
See cd (1)
PostScript translator for Diablo 630 daisy-wheel files
PostScript translator for DMD bitmap files
serial interface for PostScript printers
matrix display program for PostScript printers
PostScript translator for plot(4) graphics files
PostScript translator for text files
reverse the page order in a PostScript file
PostScript translator for Tektronix 4014 files
print files
probe external control
shell built-in function to output characters to the screen or window
display environment variables currently set
write formatted output
display or set scheduling parameters of specified process(es)
proc tools
display profile data
See sccs-prs(1)
See sccs-prt(1)
See proc (1)
report process status
display the status of current processes
See proc (1)
See proc(1)
See proc(1)
See proc(1)

ptree(1)	See proc(1)
pushd(1)	See cd (1)
pvs (1)	display the internal version information of dynamic objects
pwait(1)	See proc(1)
pwd (1)	return working directory name
pwdx (1)	See proc(1)
ranlib(1)	convert archives to random libraries
rcp (1)	remote file copy
rdist(1)	remote file distribution program
read (1)	read a line from standard input
readfile(1F)	reads file, gets longest line
readonly(1)	shell built-in function to protect the value of the given variable from reassignment
red (1)	See ed (1)
refer(1)	expand and insert references from a bibliographic database
regcmp(1)	regular expression compile
regex(1F)	match patterns against a string
rehash(1)	See hash(1)
reinit(1F)	runs an initialization file
<pre>remote_shell(1)</pre>	See rsh (1)
remsh(1)	See rsh (1)
renice(1)	alter priority of running processes
repeat(1)	See for (1)
reset(1B)	See tset(1B)
reset(1F)	reset the current form field to its default values
return(1)	See exit(1)
rksh (1)	See ksh (1)
rlogin(1)	remote login
rm (1)	remove directory entries
rmail(1)	See mail(1)
rmdel(1)	See sccs-rmdel(1)
rmdir(1)	See rm (1)
roffbib(1)	format and print a bibliographic database
rpcgen(1)	an RPC protocol compiler

rsh (1)	remote shell
run(1F)	run an executable
rup (1)	show host status of remote machines (RPC version)
rup (1C)	show host status of remote machines (RPC version)
ruptime(1)	show host status of local machines
rusage(1B)	print resource usage for a command
rusers(1)	who's logged in on remote machines
rwho (1)	who's logged in on local machines
sact(1)	See sccs-sact(1)
sag(1)	system activity graph
sar(1)	system activity reporter
sccs(1)	front end for the Source Code Control System (SCCS)
sccs-admin(1)	create and administer SCCS history files
sccs-cdc(1)	change the delta commentary of an SCCS delta
sccs-comb(1)	combine SCCS deltas
sccs-delta(1)	make a delta to an SCCS file
sccsdiff(1)	See sccs-sccsdiff(1)
sccs-get(1)	retrieve a version of an SCCS file
sccs-help(1)	ask for help regarding SCCS error or warning mes- sages
sccs-prs(1)	display selected portions of an SCCS history
sccs-prt(1)	display delta table information from an SCCS file
sccs-rmdel(1)	remove a delta from an SCCS file
sccs-sact(1)	show editing activity status of an SCCS file
<pre>sccs-sccsdiff(1)</pre>	compare two versions of an SCCS file
sccs-unget(1)	undo a previous get of an SCCS file
sccs-val(1)	validate an SCCS file
script(1)	make record of a terminal session
sdiff(1)	print differences between two files side-by-side
sed (1)	stream editor
sed (1B)	stream editor
select(1)	See case(1)
set(1)	shell built-in functions to determine the characteris- tics for environmental variables of the current shell and its descendents
set(1F)	set and unset local or global environment variables

setcolor(1F)	redefine or create a color
setenv(1)	See set(1)
setfacl(1)	modify the Access Control List (ACL) for a file or files
sh (1)	shell: the standard shell, and job control shell com- mand interpreters
shell(1F)	run a command using shell
<pre>shell_builtins(1)</pre>	shell command interpreter built-in functions
shift(1)	shell built-in function to traverse either a shell's argument list or a list of field-separated words
shutdown(1B)	close down the system at a given time
size(1)	print section sizes in bytes of object files
sleep(1)	suspend execution for an interval
soelim(1)	resolve and eliminate .so requests from nroff or troff input
sort(1)	sort, merge, or sequence check text files
sortbib(1)	sort a bibliographic database
source(1)	See exec(1)
sparc(1)	See machid(1)
spell(1)	find spelling errors
spline(1)	interpolate smooth curve
split(1)	split a file into pieces
srchtxt(1)	display contents of, or search for a text string in, mes- sage data bases
stop(1)	See jobs(1)
strchg(1)	change or query stream configuration
strconf(1)	See strchg(1)
strings(1)	find printable strings in an object or binary file
strip(1)	strip symbol table, debugging and line number infor- mation from an object file
stty(1)	set the options for a terminal
stty(1B)	set the options for a terminal
sum (1)	print checksum and block count for a file
sum (1B)	calculate a checksum for a file
sun (1)	See machid(1)
suspend(1)	shell built-in function to halt the current shell
switch(1)	See case(1)

symorder(1)	rearrange a list of symbols
sysV-make(1)	maintain, update, and regenerate groups of programs
t300 (1)	See tplot(1)
t300 (1B)	See plot(1B)
t300s (1)	See tplot(1)
t300s (1B)	See plot(1B)
t4013 (1B)	See plot (1B)
t 4014 (1)	See tplot(1)
t450 (1)	See tplot(1)
t450 (1B)	See plot (1B)
tabs(1)	set tabs on a terminal
tail(1)	deliver the last part of a file
talk(1)	talk to another user
tar(1)	create tape archives, and add or extract files
tbl (1)	format tables for nroff or troff
tcopy(1)	copy a magnetic tape
tee (1)	replicate the standard output
tek (1)	See tplot(1)
tek (1B)	See plot (1B)
telnet(1)	user interface to a remote system using the TELNET protocol
test(1)	See if(1)
test(1B)	condition evaluation command
test(1F)	condition evaluation command
tftp(1)	trivial file transfer program
time(1)	time a simple command
times(1)	shell built-in function to report time usages of the current shell
timex(1)	time a command; report process data and system activity
tip (1)	connect to remote system
tnfdump(1)	converts binary TNF file to ASCII
tnfxtract(1)	extract kernel probes output into a trace file
touch(1)	change file access and modification times
touch(1B)	update the access and modification times of a file
tplot(1)	graphics filters for various plotters

tput(1)	initialize a terminal or query terminfo database
tr (1)	translate characters
tr (1B)	translate characters
trap (1)	shell built-in functions to respond to (hardware) sig- nals
troff(1)	typeset or format documents
true(1)	provide truth values
truss(1)	trace system calls and signals
tset(1B)	establish or restore terminal characteristics
tsort(1)	topological sort
tty(1)	return user's terminal name
type (1)	write a description of command type
typeset(1)	shell built-in functions to set/get attributes and values for shell variables and functions
u370 (1)	See machid(1)
u3b (1)	See machid(1)
u3b15 (1)	See machid(1)
u3b2 (1)	See machid(1)
u3b5 (1)	See machid(1)
ucblinks(1B)	adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices
ul (1)	do underlining
ulimit(1)	See limit (1)
umask(1)	get or set the file mode creation mask
unalias(1)	See alias(1)
uname(1)	print name of current system
uncompress(1)	See compress(1)
unexpand(1)	See expand(1)
unget(1)	See sccs-unget(1)
unhash(1)	See hash(1)
unifdef(1)	resolve and remove ifdef'ed lines from C program source
uniq(1)	report or filter out repeated lines in a file
units(1)	converts quantities expressed in standard scales to other scales
unix2dos(1)	convert text file from ISO format to DOS format

unlimit(1)	See limit(1)
unpack(1)	See pack(1)
unset(1)	See set(1)
unset(1F)	See set(1F)
unsetenv(1)	See set(1)
until(1)	See while(1)
uptime(1)	show how long the system has been up
users(1B)	display a compact list of users logged in
uucp(1C)	UNIX-to-UNIX system copy
uudecode(1C)	See uuencode(1C)
uuencode(1C)	encode a binary file, or decode its encoded represen- tation
uuglist(1C)	print the list of service grades that are available on this UNIX system
uulog(1C)	See uucp(1C)
uuname(1C)	See uucp(1C)
uupick(1C)	See uuto(1C)
uustat(1C)	uucp status inquiry and job control
uuto(1C)	public UNIX-to-UNIX system file copy
uux (1C)	UNIX-to-UNIX system command execution
vacation(1)	reply to mail automatically
val (1)	See sccs-val(1)
valdate(1)	See ckdate(1)
valgid(1)	See ckgid(1)
valint(1)	See ckint(1)
valpath(1)	See ckpath(1)
valrange(1)	See ckrange(1)
valstr(1)	See ckstr(1)
valtime(1)	See cktime(1)
valuid(1)	See ckuid(1)
valyorn(1)	See ckyorn(1)
vax (1)	See machid(1)
vc (1)	version control
vedit(1)	See vi(1)
ver (1)	See tplot(1)
vgrind(1)	grind nice program listings

1-24

vi (1)	screen-oriented (visual) display editor based on ex
view(1)	See vi(1)
vipw (1B)	edit the password file
volcancel(1)	cancel user's request for removable media that is not currently in drive
volcheck(1)	checks for media in a drive and by default checks all floppy media
volmissing(1)	notify user that volume requested is not in the CD- ROM or floppy drive
vplot(1B)	See plot(1B)
vsig(1F)	synchronize a co-process with the controlling FMLI application
w (1)	who is logged in, and what are they doing
wait(1)	await process completion
wc (1)	display a count of lines, words and characters in a file
what(1)	extract SCCS version information from a file
whatis(1)	display a one-line summary about a keyword
whence(1)	See typeset(1)
whereis(1B)	locate the binary, source, and manual page files for a command
which(1)	locate a command; display its pathname or alias
while(1)	shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE
who (1)	who is on the system
whoami(1B)	display the effective current username
whois(1)	Internet user name directory service
write(1)	write to another user
xargs(1)	construct argument lists and invoke utility
xgettext(1)	extract gettext call strings from C programs
xstr(1)	extract strings from C programs to implement shared strings
yacc(1)	yet another compiler-compiler
ypcat(1)	print values in a NIS database
ypmatch(1)	print the value of one or more keys from a NIS map
yppasswd(1)	change your network password in the NIS database
ypwhich(1)	return name of NIS server or map master
zcat(1)	See compress(1)

NAME	acctcom – search and print process accounting files		
SYNOPSIS	acctcom [-abfhikmqrtv] [-C sec] [-e time] [-E time] [-g group] [-H factor] [-I chars] [-l line] [-n pattern] [-o output-file] [-O sec] [-s time] [-S time] [-u user] [filename]		
AVAILABILITY	SUNWaccu		
DESCRIPTION	acctcom reads <i>filenames</i> , the standard input, or /var/adm/pacct, in the form described acct(4) and writes selected records to standard output. Each record represents the ex- tion of one process. The output shows the COMMAND NAME, USER, TTYNAME, STA TIME, END TIME, REAL (SEC), CPU (SEC), MEAN SIZE (K), and optionally, F (the fork()/exec() flag: 1 for fork() without exec()), STAT (the system exit status), HOG F. TOR, KCORE MIN, CPU FACTOR, CHARS TRNSFD, and BLOCKS READ (total blocks r and written).		
	A '#' is prepended to the command name if the command was executed with super-user privileges. If a process is not associated with a known terminal, a '?' is printed in the TTYNAME field.		
	If no <i>filename</i> is specified, and if the standard input is associated with a terminal or /dev/null (as is the case when using ' & ' in the shell), /var/adm/pacct is read; otherwise, the standard input is read.		
	If any <i>filename</i> arguments are given, they are read in their respective order. Each file is normally read forward, that is, in chronological order by process completion time. The file / var/adm/pacct is usually the current file to be examined; a busy system may need several such files of which all but the current file are found in / var/adm/pacct incr.		
OPTIONS	- a	Show some average statistics about the processes selected. The statistics will be printed after the output records.	
	-b	Read backwards, showing latest commands first. This option has no effect when standard input is read.	
	-f	Print the fork() / exec() flag and system exit status columns in the output. The numeric output for this option will be in octal.	
	-h	Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This "hog factor" is computed as (total CPU time)/(elapsed time).	
	- i	Print columns containing the I/O counts in the output.	
	$-\mathbf{k}$	Instead of memory size, show total kcore-minutes.	
	-m	Show mean core size (the default).	
	- q	Do not print any output records, just print the average statistics as with the $-a$ option.	
	-r	Show CPU factor (user-time/(system-time + user-time)).	

modified 20 Jan 1995

	-t	Show separate system and user CPU times.
	$-\mathbf{v}$	Exclude column headings from the output.
	-C sec	Show only processes with total CPU time (system-time + user-time) exceeding <i>sec</i> seconds.
	−e time	Select processes existing at or before time.
	-E time	Select processes ending at or before <i>time</i> . Using the same <i>time</i> for both –S and –E shows the processes that existed at <i>time</i> .
	– g group	Show only processes belonging to <i>group</i> . The <i>group</i> may be designated by either the group ID or group name.
	–H factor	Show only processes that exceed <i>factor</i> , where factor is the "hog factor" as explained in option $-h$ above.
	–I chars	Show only processes transferring more characters than the cutoff number given by <i>chars</i> .
	–l line	Show only processes belonging to terminal /dev/term/line.
	– n pattern	Show only commands matching <i>pattern</i> that may be a regular expression as in regcmp (3G), except + means one or more occurrences.
	-o output-file	Copy selected process records in the input data format to <i>output-file</i> ; suppress printing to standard output.
	–O sec	Show only processes with CPU system time exceeding sec seconds.
	–s time	Select processes existing at or after <i>time,</i> given in the format <i>hr</i> [: <i>min</i> [: <i>sec</i>]].
	–S time	Select processes starting at or after time.
	-u user	Show only processes belonging to <i>user</i> . The user may be specified by a user ID, a login name that is then converted to a user ID, '#' (which designates only those processes executed with superuser privileges), or '?' (which designates only those processes associated with unknown user IDs).
FILES	/etc/group	system group file
-	/etc/passwd	system password file
	/var/adm/pacct	<i>incr</i> active processes accounting file
SEE ALSO	ps(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), fwtmp(1M), runacct(1M), su(1M), acct(2), regcmp(3G), acct(4), utmp(4)	
	System Administr	ration Guide, Volume II
NOTES	acctcom reports	s only on processes that have terminated; use $\mathbf{ps}(1)$ for active processes.

modified 20 Jan 1995

NAME	adb – general-purpose debugger		
SYNOPSIS	adb [–w] [–k] [–I dir] [–P prompt] [–V mode] [objectfile [corefile [swapfile]]]	
AVAILABILITY	SUNWcsu		
DESCRIPTION	 adb is an interactive, general-purpose debugger. It can be used to examine files and provides a controlled environment for the execution of programs. <i>objectfile</i> is normally an executable program file, preferably containing a symbol table. If the file does not contain a symbol table, it can still be examined, but the symbolic features of adb cannot be used. The default for <i>objectfile</i> is a.out. <i>corefile</i> is assumed to be a core image file produced after executing <i>objectfile</i>. The default for <i>corefile</i> is core. <i>swapfile</i> is the image of the swap device used. It is valid only when used with the –k option. 		
OPTIONS	$-\mathbf{w}$	Create both <i>objectfile</i> and <i>corefile</i> , if necessary, and open them for reading and writing so that they can be modified using adb .	
	- k	Perform kernel memory mapping; use when <i>corefile</i> is a system crash dump or / dev/mem , or when using a <i>swapfile</i> .	
	−I dir	Specify a colon-separated list of directories where files to be read with \$< or \$<< (see below) will be sought; the default is /usr/platform/plat- name/lib/adb:/usr/lib/adb, where <i>plat-name</i> is the name of the platform implementation. <i>plat-name</i> can be found using the –i option of uname(1).	
	–P prompt	Specify the adb prompt string.	
	-V mode	(SPARC only) Specify the disassembly and register display mode. Options are: 0 (v8), 1 (generic V9), and 2 (v9 plus Sun Ultra-SPARC specific instructions). The default mode is determined by the type of corefile being examined.	
USAGE	 adb reads commands from the standard input and displays responses on the standard output. It does not supply a prompt by default. It ignores the QUIT signal. INTERRUPT invokes the next adb command. adb generally recognizes command input of the form: [address] [, count] [command] [;] address and count (if supplied) are expressions that result, respectively, in a new current address, and a repetition count. command is composed of a verb followed by a modifier or list of modifiers. The symbol '.' represents the current location. It is initially zero. The default count is '1'. 		
Expressions	+ ^ &	The value of <i>dot</i> . The value of <i>dot</i> incremented by the current increment. The value of <i>dot</i> decremented by the current increment. The last <i>address</i> typed. (In older versions of adb , '''' was used.)	
l	integer	A number. The prefixes 00 and 00 indicate octal; 0t and 0T , decimal; 0x	

1-28

		and 0X , hexadecimal (the default).
	int.frac	A floating-point number.
	'cccc'	ASCII value of up to 4 characters.
	<name< th=""><th>The value of <i>name</i>, which is either a variable name or a register name.</th></name<>	The value of <i>name</i> , which is either a variable name or a register name.
	symbol	A symbol in the symbol table.
	(exp)	The value of <i>exp</i> .
	(onp)	
Unary Operators	*exp	The contents of location <i>exp</i> in <i>corefile</i> .
	%exp	The contents of location <i>exp</i> in <i>objectfile</i> (In older versions of adb , '@' was used).
	-exp	Integer negation.
	~exp	Bitwise complement.
	#exp	Logical negation.
Binary Operators	Binary operate	ors are left associative and have lower precedence than unary operators.
	+	Integer addition.
	-	Integer subtraction.
	*	Integer multiplication.
	%	Integer division.
	&	Bitwise conjunction ("AND").
		Bitwise disjunction ("OR").
	#	<i>lhs</i> rounded up to the next multiple of <i>rhs</i> .
Variables	Named variab	les are set initially by adb but are not used subsequently.
	0	The last value printed.
	1	The last offset part of an instruction source.
	2	The previous value of variable 1.
	9	The count on the last \$< or \$<< command.
	On entry the f	ollowing are set from the system header in the <i>corefile</i> or <i>objectfile</i> as
	appropriate.	
	b	The base address of the data segment.
	d	The data segment size.
	e	The entry point.
	m	The 'magic' number
	t	The text segment size.
Commands	Commands to	adb consist of a <i>verb</i> followed by a <i>modifier</i> or list of modifiers.
Verbs	?	Print locations starting at <i>address</i> in <i>objectfile</i> .
	1	Print locations starting at address in corefile.
	=	Print the value of <i>address</i> itself.
	:	Manage a subprocess.
	>	Assign a value to a variable or register.
	RETURN	Repeat the previous command with a <i>count</i> of 1. Increment '.'.
	!	Shell escape.

?, /, and = Modifiers	The following format modifiers apply to the commands ? , /, and =. To specify a format, follow the command with an optional repeat count, and the desired format letter or		
	letters:		
	$\{?,/,=\} [[r] f]]$		
	where <i>r</i> is a repeat count, and <i>f</i> is one of the format letters listed below:		
	o ('.' increment: 2) Print 2 bytes in octal.		
	0	(4) Print 4 bytes in octal.	
	q	(2) Print in signed octal.	
	$\mathbf{\hat{Q}}$	(4) Print long signed octal.	
	d	(2) Print in decimal.	
	D	(4) Print long decimal.	
	x	(2) Print 2 bytes in hexadecimal.	
	X	(4) Print 4 bytes in hexadecimal.	
	u	(2) Print as an unsigned decimal number.	
	U	(4) Print long unsigned decimal.	
	f	(4) Print a single-precision floating-point number.	
	F	(8) Print a double-precision floating-point number.	
	b	(1) Print the addressed byte in octal.	
	С	(1) Print the addressed character.	
	С	(1) Print the addressed character using ^ escape convention.	
	S	(<i>n</i>) Print the addressed string.	
	S	(n) Print a string using the escape convention.	
	Y	(4) Print 4 bytes in date format.	
	i	(4 on SPARC; <i>n</i> on x86) Print as machine instructions.	
	а	(0) Print the value of '.' in symbolic form.	
	р	(4) Print the addressed value in symbolic form.	
	t	(0) Tab to the next appropriate TAB stop.	
	r	(0) Print a SPACE.	
	n	(0) Print a NEWLINE.	
	""	(0) Print the enclosed string.	
	^	(0) Decrement '.'.	
	+	(0) Increment '.'.	
	-	(0) Decrement '.' by 1.	
? and / Modifiers	l value mask	Apply <i>mask</i> and compare for <i>value</i> ; move '.' to matching location.	
	L value mask	Apply <i>mask</i> and compare for 4-byte <i>value</i> ; move '.' to matching location.	
	w value	Write the 2-byte value to address.	
	W value	Write the 4-byte value to address.	
	m b1 e1 f1[?]	Map new values for <i>b1, e1, f1</i> . If the ? or / is followed by * then the	
		second segment (<i>b2</i> , <i>e2</i> , <i>f2</i>) of the address mapping is changed.	
	v	Like w , but writes only bytes at a time.	

: Modifiers	b commands	Set breakpoint, execute <i>commands</i> when reached.
	r	Run <i>objectfile</i> as a subprocess.
	d	Delete breakpoint at <i>address</i> .
	Z	Delete all breakpoints.
	CS CS	x86: The subprocess is continued with signal <i>s</i> .
	SS	Single-step the subprocess with signal <i>s</i> .
	i	Add the signal specified by <i>address</i> to the list of signals passed directly to
		the subprocess.
	t	Remove the signal specified by <i>address</i> from the list implicitly passed to
		the subprocess.
	k	Terminate (kill) the current subprocess, if any.
	Α	Attach adb to an existing process id. (For example, 0t1234:A would attach adb to decimal process number 1234 .)
	R	Release the previously attached process.
\$ Modifiers	<filename< td=""><td>Read commands from the file <i>filename</i>.</td></filename<>	Read commands from the file <i>filename</i> .
	< <filename< td=""><td>Similar to <, but can be used in a file of commands without closing the file.</td></filename<>	Similar to <, but can be used in a file of commands without closing the file.
	>filename	Append output to <i>filename</i> , which is created if it does not exist.
	l	x86: Show the current lightweight process (lwp) ID.
	L	x86: Show all the lwp IDs.
	P	Specify the adb prompt string.
	?	Print process ID, the signal which stopped the subprocess, and the
	•	registers.
	r	Print the names and contents of the general CPU registers, and the
		instruction addressed by pc .
	x or X	x86: Print the contents of floating point registers. \$x and \$X accept a "count" which determines the precision in which the floating point regis-
		ters will be printed; the default is 25 . Using \$X will produce more verbose output than using \$x .
	x	SPARC: Print the names and contents of floating-point registers 0
		through 15.
	X	SPARC: Print the names and contents of floating-point registers 16
		through 31.
	b	Print all breakpoints and their associated counts and commands.
	C	C stack backtrace. On SPARC systems, it is impossible for adb to deter-
		mine how many parameters were passed to a function. The default that
		adb chooses in a \$c command is to show the six parameter registers.
		This can be overridden by appending a hexadecimal number to the \$c
		command, specifying how many parameters to display. For example,
		the \$cf command will print 15 parameters for each function in the stack
	0	trace.
	C	x86: Same as \$c , but in addition it displays the frame pointer values.
	d	Set the default radix to <i>address</i> and report the new value. Note: <i>address</i> is interpreted in the (old) current radix. Thus ' 10\$d ' never changes the
		default radix.

		nt the names and values of external variables.
		the page width for output to <i>address</i> (default 80).
		the limit for symbol matches to <i>address</i> (default 255).
	— •	integers input are regarded as octal.
	1	t from adb . It all non zero variables in octal.
		it the address map.
		a list of known source filenames.
		<i>rnel debugging</i>) Change the current kernel memory mapping to map
		designated user structure to the address given by <i>u</i> ; this is the
		ress of the user's proc structure.
		w which signals are passed to the subprocess with the minimum of
		o interference.
	V SPA	ARC: Change the current disassembly and register display mode.
		tions are: 0 (v8), 1 (generic V9), and 2 (v9 plus Sun Ultra-SPARC
		cific instructions). Omitting the numeric parameter prints informa-
		on the current disassembly mode.
		ppen <i>objectfile</i> and <i>corefile</i> for writing, as though the – w command-line
	aig	ument had been given.
EXAMPLES	To start adb on the running kernel, use (as root):	
	example# ac	lb -k /dev/ksyms /dev/mem
	can be used to exami	ial driver that provides an image of the kernel's symbol table. This ine kernel state and debug device drivers. Refer to the Debugging <i>vice Drivers</i> for more information.

		default directories in which files are to be read with \$< and \$<<.
		<i>platform-name</i> is the name of the platform implementation and can
		be found using uname – i .
	a.out	default name for <i>objectfile</i> operand.
	core	default name for <i>corefile</i> operand.
	/dev/ksyms	special driver to provide an image of the kernel's symbolic table.
SEE ALSO	umama(1) $mtmaa(2)$	$a \operatorname{out}(A) \operatorname{opp}(A) \operatorname{pros}(A) \operatorname{Lourms}(7D)$
SEE ALSO	-	a.out(4), core(4), proc(4), ksyms(7D)
	Writing Device Driver	S
DIAGNOSTICS	adb when there is n	o current command or format, comments about inaccessible files,
2101001100		nal termination of commands, etc.
	, abitoin	

NOTES	adb should be changed to use the new format symbolic information generated by $-g$. adb is platform and release dependent. Kernel core dumps should be examined on the same platform they were created on.
BUGS	Since no shell is invoked to interpret the arguments of the :r command, the customary wild-card and variable expansions cannot occur. Since there is little type-checking on addresses, using a sourcefile address in an inappropriate context may lead to unexpected results. The S <i>cparameter-count</i> command is a workaround.

1					
NAME	addbib – create or extend a bibliographic database				
SYNOPSIS	addbib [–a] [addbib [–a] [–p promptfile] database			
AVAILABILITY	SUNWdoc				
DESCRIPTION	When addbib starts up, answering y to the initial Instructions ? prompt yields directions; typing n or RETURN skips them. addbib then prompts for various bibliographic fields, reads responses from the terminal, and sends output records to <i>database</i> . A null response (just RETURN) means to leave out that field. A '–' (minus sign) means to go back to the previous field. A trailing backslash allows a field to be continued on the next line. The repeating Continue ? prompt allows the user either to resume by typing y or RETURN, to quit the current session by typing n or q , or to edit <i>database</i> with any system editor (see vi (1), ex (1), ed (1)).				
OPTIONS	-a	Suppress prompting for an abstract; asking for an abstract is the default. Abstracts are ended with a CTRL–D.			
	- p promptfile	Use a new prompting skeleton, defined in <i>promptfile</i> . This file should contain prompt strings, a TAB, and the key-letters to be written to the <i>database</i> .			
USAGE Bibliography Key Letters	The most common key-letters and their meanings are given below. addbib insulates you from these key-letters, since it gives you prompts in English, but if you edit the bibliography file later on, you will need to know this information.				
	%A	Author's name			
	% B	Book containing article referenced			
	% C	City (place of publication)			
	%D	Date of publication			
	%E	Editor of book containing article referenced			
	% F	Footnote number or label (supplied by refer)			
	% G	Government order number			
	%H	Header commentary, printed before reference			
	%I	Issuer (publisher)			
	% J	Journal containing article			
	%K	Keywords to use in locating reference			
	%L	Label field used by – k option of refer			
	% M	Bell Labs Memorandum (undefined)			
	%N	Number within volume			
	% O	Other commentary, printed at end of reference			

modified 14 Sep 1992

	% P	Page number(s)
	% Q	Corporate or Foreign Author (unreversed)
	% R	Report, paper, or thesis (unpublished)
	%S	Series title
	%Т	Title of article or book
	%V	Volume number
	%X	Abstract — used by roffbib , not by refer
	%Y,Z	Ignored by refer
EXAMPLES	Except for A, eaplied.	ach field should be given just once. Only relevant fields should be sup-
	%A	Mark Twain
	%Т	Life on the Mississippi

modified 14 Sep 1992

NAME	alias, unalias – create or remove a pseudonym or shorthand for a command or series of commands
SYNOPSIS	/usr/bin/alias [alias-name[=string]]
	/usr/bin/unalias alias-name /usr/bin/unalias -a
csh	alias [name [def]]
	unalias pattern
ksh	alias [-tx] [name[=value]]
	unalias name
DESCRIPTION	
/usr/bin/alias	The alias utility creates or redefines alias definitions or writes the values of existing alias definitions to standard output. An alias definition provides a string value that replaces a command name when it is encountered.
	An alias definition affects the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this docu- ment, the alias definition will not affect the parent process of the current shell nor any utility environment invoked by the shell.
/usr/bin/unalias	The unalias utility removes the definition for each alias name specified. The aliases are removed from the current shell execution environment.
csh	alias assigns <i>def</i> to the alias <i>name</i> . <i>def</i> is a list of words that may contain escaped history- substitution metasyntax. <i>name</i> is not allowed to be alias or unalias . If <i>def</i> is omitted, the alias <i>name</i> is displayed along with its current definition. If both <i>name</i> and <i>def</i> are omitted, all aliases are displayed.
	Because of implementation restrictions, an alias definition must have been entered on a previous command line before it can be used.
	unalias discards aliases that match (filename substitution) <i>pattern</i> . All aliases may be removed by ' unalias *'.
ksh	alias with no arguments prints the list of aliases in the form <i>name=value</i> on standard output. An <i>alias</i> is defined for each name whose <i>value</i> is given. A trailing space in <i>value</i> causes the next word to be checked for alias substitution. The –t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given <i>name</i> . The value becomes undefined when the value of PATH is reset but the aliases remained tracked. Without the –t flag, for each <i>name</i> in the argument list for which no <i>value</i> is given, the name and value of the alias is printed. The – x flag is used to set or print <i>exported aliases</i> . An <i>exported alias</i> is defined for scripts invoked by name. The exit status is non-zero if a <i>name</i> is given, but no value, and no alias has been defined for

	the <i>name</i> .
	The <i>alias</i> es given by the list of <i>names</i> may be removed from the <i>alias</i> list with unalias .
OPTIONS	The following option is supported by unalias :
	-a Remove all alias definitions from the current shell execution environment.
OPERANDS alias unalias	The following operands are supported:alias-nameWrite the alias definition to standard output.alias-nameThe name of an alias to be removed.
	<i>alias-name=string</i> Assign the value of <i>string</i> to the alias <i>alias-name</i> .
	If no operands are given, all alias definitions will be written to standard output.
OUTPUT	The format for displaying aliases (when no operands or only <i>name</i> operands are specified) is:
	"%s=%s∖n" name, value
	The <i>value</i> string will be written with appropriate quoting so that it is suitable for reinput to the shell.
EXAMPLES	 Change ls to give a columnated, more annotated output: alias ls="ls –CF"
	2. Create a simple "redo" command to repeat previous entries in the command history file:
	alias r='fc -s'
	3. Use 1K units for du : alias du=du∖ −k
	 Set up nohup so that it can deal with an argument that is itself an alias name: alias nohup="nohup "
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of alias and unalias : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
alias	 0 Successful completion. >0 One of the <i>alias-name</i> operands specified did not have an alias definition, or an error occurred.
unalias	 One of the <i>alias-name</i> operands specified did not represent a valid alias definition, or an error occurred.
SEE ALSO	csh(1), ksh(1), shell_builtins(1), environ(5)

NAME	apropos – locate commands by keyword lookup
SYNOPSIS	apropos keyword
AVAILABILITY	SUNWdoc
DESCRIPTION	apropos displays the man page name, section number, and a short description for each man page whose NAME line contains <i>keyword</i> . This information is contained in the / usr/share/man/windex database created by catman (1M). If catman (1M) was not run, or was run with the – n option, apropos fails. Each word is considered separately and the case of letters is ignored. Words which are part of other words are considered; for example, when looking for 'compile', apropos finds all instances of 'compiler' also.
	apropos is actually just the $-\mathbf{k}$ option to the man (1) command.
	Try
	example% apropos password
	and
	example% apropos editor If the line starts ' <i>filename(section)</i> ' you can do ' man – s <i>section filename</i> ' to display the man page for <i>filename</i> . Try
	example% apropos format
	and then
	example% man –s 3s printf
	to get the manual page on the subroutine printf() .
FILES	/usr/share/man/windex table of contents and keyword database
SEE ALSO	man(1), whatis(1), catman(1M)
DIAGNOSTICS	/usr/share/man/windex: No such file or directory This database does not exist. catman(1M) must be run to create it.

modified 14 Sep 1992

NAME	ar – maintain portable archive or library
SYNOPSIS	<pre>/usr/bin/ar -d [-Vv] archive file /usr/bin/ar -m [-abiVv] [posname] archive file /usr/bin/ar -p [-sVv] archive [file] /usr/bin/ar -q [-cVv] archive file /usr/bin/ar -r [-abciuVv] [posname] archive file /usr/bin/ar -t [-sVv] archive [file] /usr/spg4/bin/ar -d [-Vv] archive file /usr/xpg4/bin/ar -m [-abiVv] [posname] archive file /usr/xpg4/bin/ar -m [-abiVv] [posname] archive file /usr/xpg4/bin/ar -q [-cVv] archive [file] /usr/xpg4/bin/ar -q [-cVv] archive file /usr/xpg4/bin/ar -q [-cVv] archive file /usr/xpg4/bin/ar -q [-cVv] archive file /usr/xpg4/bin/ar -r [-abciuVv] [posname] archive file /usr/xpg4/bin/ar -r [-abciuVv] [posname] archive file</pre>
AVAILABILITY /usr/bin/ar	SUNWbtool
/usr/xpg4/bin/ar	SUNWxcu4
DESCRIPTION	The ar command maintains groups of files combined into a single archive file. Its main use is to create and update library files. However, it can be used for any similar purpose. The magic string and the file headers used by ar consist of printable ASCII characters. If an archive is composed of printable files, the entire archive is printable.
	When ar creates an archive, it creates headers in a format that is portable across all machines. The portable archive format and structure are described in detail in ar (4). The archive symbol table (described in ar (4)) is used by the link editor ld to effect multiple passes over libraries of object files in an efficient manner. An archive symbol table is only created and maintained by ar when there is at least one object file in the archive. The archive symbol table is in a specially named file that is always the first file in the archive. This file is never mentioned or accessible to the user. Whenever the ar command is used to create or update the contents of such an archive, the symbol table is rebuilt. The s option described below will force the symbol table to be rebuilt.
OPTIONS	The following options are supported:
	- a Position new <i>files</i> in <i>archive</i> after the file named by the <i>posname</i> operand.
	- b Position new <i>files</i> in <i>archive</i> before the file named by the <i>posname</i> operand.
	 -c Suppress the diagnostic message that is written to standard error by default when <i>archive</i> is created.
	−C Prevent extracted files from replacing like-named files in the file system. This option is useful when − T is also used to prevent truncated file names from

replacing files with the same prefix.

- -d Delete one or more *files* from *archive*.
- -i Position new *files* in *archive* before the file named by the *posname* operand (equivalent to -b).
- -**m** Move *files*. If **-a**, **-b**, or **-i** with the *posname* operand are specified, move *files* to the new position; otherwise, move *files* to the end of *archive*.
- -p Print the contents of *files* in *archive* to standard output. If no *files* are specified, the contents of all files in *archive* will be written in the order of the archive.
- -q Quickly append *files* to the end of *archive*. Positioning options -a, -b, and -i are invalid. The command does not check whether the added *files* are already in *archive*. This option is useful to avoid quadratic behavior when creating a large archive piece-by-piece.
- -r Replace or add *files* in *archive*. If *archive* does not exist, a new archive file will be created and a diagnostic message will be written to standard error (unless the -c option is specified). If no *files* are specified and the *archive* exists, the results are undefined. Files that replace existing files will not change the order of the archive. If the -u option is used with the -r, option, then only those files with dates of modification later than the archive files are replaced. If the -a, -b, or -i option is used, then the *posname* argument must be present and specifies that new files are to be placed after (-a) or before (-b or -i) *posname*; otherwise the new *files* are placed at the end.
- -**s** Force the regeneration of the archive symbol table even if **ar** is not invoked with a option which will modify the archive contents. This command is useful to restore the archive symbol table after the **strip**(1) command has been used on the archive.
- Print a table of contents of *archive*. The files specified by the *file* operands will be included in the written list. If no *file* operands are specified, all files in *archive* will be included in the order of the archive.
- -T Allow file name truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long is an error; a diagnostic message will be written and the file will not be extracted.
- -u Update older files. When used with the -r option, files within *archive* will be replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file within *archive*.
- -V prints its version number on standard error.
- /usr/bin/ar –v Give verbose output. When used with the option characters –d, –r, or –x, write a detailed file-by-file description of the archive creation and the constituent *files*, and maintenance activity.

When used with $-\mathbf{p}$, write the name of the file to the standard output before writing the file itself to the standard output.

modified 28 Mar 1995

1-40

	When used with –t, include a long listing of information about the files within th archive.		
	When used with $-\mathbf{x}$, print the filename preceding each extraction.		
	When writing to an archive, a message is written to the standard error.		
/usr/xpg4/bin/ar	-v Same as /usr/bin/ar version, except when writing to an archive, no message is written to the standrad error.		
	 -x Extract the files named by the <i>file</i> operands from <i>archive</i>. The contents of <i>archive</i> will not be changed. If no <i>file</i> operands are given, all files in <i>archive</i> will be extracted. If the file name of a file extracted from <i>archive</i> is longer than that supported in the directory to which it is being extracted, the results are undefined. The modification time of each <i>file</i> extracted will be set to the time <i>file</i> is extracted from <i>archive</i>. 		
OPERANDS	The following operands are supported:		
	<i>archive</i> A path name of the archive file.		
	<i>file</i> A path name. Only the last component will be used when comparing against the names of files in the archive. If two or more <i>file</i> operands have the same last path name component (basename (1)), the results are unspecified. The implementation's archive format will not truncate valid file names of files added to or replaced in the archive.		
	<i>posname</i> The name of a file in the archive file, used for relative positioning; see options $-\mathbf{m}$ and $-\mathbf{r}$.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of ar : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	>0 An error occurred.

NAME	arch – display the architecture of the current host		
SYNOPSIS	/usr/bin/a /usr/bin/a /usr/bin/a		
DESCRIPTION	arch displ	ays the application architecture of the current host system.	
	Systems can be broadly classified by their <i>architectures</i> , which define what executables will run on which machines. A distinction can be made between <i>kernel architecture</i> and <i>application architecture</i> (or, commonly, just "architecture"). Machines that run different kernels due to underlying hardware differences may be able to run the same application programs.		
OPTIONS	-k	Display the kernel architecture, such as sun4 , sun4c , etc. This defines which specific SunOS kernel will run on the machine, and has implications only for programs that depend on the kernel explicitly (for example, ps (1)).	
	archname	Return "true" (exit status 0) if <i>application</i> binaries for <i>archname</i> can run on the current host system, otherwise, return "false" (exit status 1). This is the pre-ferred method for installation scripts to determine the environment of the host machine; that is, which architecture of a multi-architecture release to install on this machine. <i>archname</i> must be a valid application architecture.

NAME	as – assembler		
SPARC SYNOPSIS	as $[-b] [-K PIC] [-L] [-m] [-n] [-o outfile] [-P] [-Dname] [-Dname=def] [-Ipath] [-Uname] [-q] [-Qy / n] [-s] [-S[a/C]] [-T] [-V] [-xarch=v7] [-xarch=v8] [-xarch=v8a] [-xarch=v8plus] [-xarch=v8plusa] [-xF] filename$		
x86 SYNOPSIS	as $[-m][-n][-o \text{ outfile }][-P][-Dname][-Dname=def][-Ipath][-Uname][-Qy / n][-s][-V] filename$		
AVAILABILITY	SUNWsprot		
DESCRIPTION	The as comman	nd creates object files from assembly language source files.	
OPTIONS	NS The following flags may be specified in any order:		
	–Dname –Dname=def	When the $-\mathbf{P}$ option is in effect, these options are passed to the cpp (1) preprocessor without interpretation by the as command; otherwise, they are ignored.	
	-Ipath	When the $-\mathbf{P}$ option is in effect, this option is passed to the cpp (1) preprocessor without interpretation by the as command; otherwise, it is ignored.	
	- m	Run the m4 (1) macro processor on the input to the assembler.	
	-n	Suppress all the warnings while assembling.	
	–o outfile	Put the output of the assembly in <i>outfile</i> . By default, the output file name is formed by removing the .s suffix, if there is one, from the input file name and appending a .o suffix.	
	- P	Run cpp (1), the C preprocessor, on the files being assembled. The preprocessor is run separately on each input file, not on their concatenation. The preprocessor output is passed to the assembler.	
	$-\mathbf{Q}\mathbf{y}\mid\mathbf{n}$	Produce the "assembler version" information in the comment section of the output object file if the <i>y</i> option is specified; if the <i>n</i> option is specified, the information is suppressed.	
	- s	Place all stabs in the .stabs section. By default, stabs ares placed in stabs.excl sections, which are stripped out by the static linker, ld (1), during final execution. When the -s option is used, stabs remain in the final executable because .stab sections are not stripped by the static linker.	
	3f4–Uname	When the $-\mathbf{P}$ option is in effect, this option is passed to the cpp (1) preprocessor without interpretation by the as command; otherwise, it is ignored.	
	$-\mathbf{V}$	Write the version number of the assembler being run on the standard	

modified 10 Apr 1995

1-43

		error output.
SPARC Options	- b	Generate extra symbol table information for the Sun SourceBrowser.
	-K PIC	Generate position-independent code.
	–L	Save all symbols, including temporary labels that are normally dis- carded to save space, in the ELF symbol table.
	-q	Perform a quick assembly. When the $-\mathbf{q}$ option is used, many error checks are not performed. Note: This option disables many error checks. It is recommended that you do not use this option to assemble handwritten assembly language.
	$-\mathbf{S}[a/C]$	 Produce a disassembly of the emitted code to the standard output. Adding the character <i>a</i> to the option appends a comment line to each assembly code which indicates its relative address in its own section. Adding the character <i>C</i> to the option prevents comment lines from appearing in the output.
	- T	This is a migration option for 4.x assembly files to be assembled on 5.x systems. With this option, the symbol names in 4.x assembly files will be interpreted as 5.x symbol names.
	-xarch=v7	This option instructs the assembler to accept instructions defined in the SPARC version 7 (V7) architecture. The resulting object code is in ELF format.
	-xarch=v8	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format.
	-xarch=v8a	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions and less the <i>fsmuld</i> instruction. The resulting object code is in ELF format. This is the default choice of the -xarch= options.
	-xarch=v8plus	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instruc- tions. The resulting object code is in ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system.
	-xarch=v8plusa	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions, plus the instructions in the Visual Instruction Set (VIS). The resulting object code is in V8+ ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system
	-xF	Generates additional information for performance analysis of the exe- cutable using SPARCworks analyzer. If the input file does not contain any stabs (debugging directives), then the assembler will generate some

modified 10 Apr 1995

SunOS 5.5	User Commands as	s(1)
	default stabs which are needed by the SPARCworks analyzer. Also s the manual page dbx .	see
ENVIRONMENT	TMPDIR as normally creates temporary files in the directory / tmp . You may specify another directory by setting the environment variable TMPDIR to your chosen directory. (If TMPDIR isn't a valid directory, then as will use / tmp).	
FILES	By default, as creates its temporary files in / tmp .	
SEE ALSO	cc(1B), cpp(1), ld(1), m4(1), nm(1), strip(1), tmpnam(3S), a.out(4)	
NOTES	 If the -m (invoke the m4(1) macro processor) option is used, keywords for m4(1) cannot be used as symbols (variables, functions, labels) in the input file since m4(1) cannot de mine which keywords are assembler symbols and which keywords are real m4(1) macros. Whenever possible, you should access the assembler through a compilation system in face program such as cc(1B). All undefined symbols are treated as global. 	eter- c-

modified 10 Apr 1995

NAME	asa – convert FORTRAN carriage-control output to printable form					
SYNOPSIS	asa [-f] [file]					
AVAILABILITY	SUNWcsu					
DESCRIPTION	The asa utility will write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences.					
	The first character of every line will be removed from the input, and the following actions will be performed.					
	If the character removed is:					
	SPACE The rest of the line will be output without change.					
	0 It is replaced by a newline control sequence followed by the rest of the input line.					
	1 It is replaced by a newpage control sequence followed by the rest of the input line.					
	+ It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.					
	For any other character in the first column of an input line, asa skips the character and prints the rest of the line unchanged.					
	If asa is called without providing a <i>filename</i> , the standard input is used.					
OPTIONS	-f Start each file on a new page.					
OPERANDS	<i>file</i> A pathname of a text file used for input. If no <i>file</i> operands are specified, or '-' is specified, then the standard input will be used.					
EXAMPLES	The command					
	a.out asa lp					
	converts output from a.out to conform with conventional printers and directs it through a pipe to the printer.					
	The command					
	asa output					
	shows the contents of file <i>output</i> on a terminal as it would appear on a printer.					
	The following program is used in the next two examples:					
	write(*,'(" Blank")') write(*,'("0Zero ")') write(*,'("+ Plus ")')					
	write(*,'("10ne ")') end					

modified 18 Apr 1995

	Example 1. With actual files: a.out > MyOutputFile asa < MyOutputFile lp Example 2. With only pipes: a.out asa lp
	Both of the above examples produce two pages of output. Page 1: Blank
	ZeroPlus Page 2: One
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of asa : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:0All input files were output successfully.>0An error occurred.
SEE ALSO	lp(1), environ(5)

NAME	at, batch – execute commands at a later time
SYNOPSIS	at $[-c -k -s] [-m] [-f file] [-q queuename] -t timeat [-c -k -s] [-m] [-f file] [-q queuename] timespecat -1 [-q queuename] [at_job_id]at -r at_job_id$
	batch
AVAILABILITY at	SUNWcsu
batch	SUNWesu
DESCRIPTION at	The at utility reads commands from standard input and groups them together as an <i>atjob</i> , to be executed at a later time.
	The at-job will be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask (see umask (1)), and system resource limits (for sh and ksh only, see ulimit (1)) in effect when the at utility is executed will be retained and used when the at-job is executed.
	When the at-job is submitted, the <i>at_job_id</i> and scheduled time are written to standard error. The <i>at_job_id</i> is an identifier that will be a string consisting solely of alphanumeric characters and the period character. The <i>at_job_id</i> is assigned by the system when the job is scheduled such that it uniquely identifies a particular job.
	User notification and the processing of the job's standard output and standard error are described under the $-\mathbf{m}$ option.
	Users are permitted to use at and batch (see below) if their name appears in the file /usr/lib/cron/at.allow. If that file does not exist, the file /usr/lib/cron/at.deny is checked to determine if the user should be denied access to at . If neither file exists, only a process with the super-user privileges is allowed to submit a job. If only at.deny exists and is empty, global usage is permitted. The at.allow and at.deny files consist of one user name per line.
batch	The batch utility reads commands to be executed at a later time. It is the equivalent of the command: at -q b -m now where queue b is a special at queue, specifically for batch jobs. Batch jobs will be submit-
	ted to the batch queue for immediate execution.
OPTIONS	The following options are supported. If the $-c$, $-k$, or $-s$ options are not specified, the SHELL environment variable by default determines which shell to use.
	-c C shell. $csh(1)$ is used to execute the at-job.

	- k	Korn shell. ksh (1) is used to execute the at-job.			
	- s	Bourne shell. $\mathbf{sh}(1)$ is used to execute the at-job.			
	-f file	Specify the path of a file to be used as the source of the at-job, instead of standard input.			
	-1	(The letter ell.) Report all jobs scheduled for the invoking user if no <i>at_job_id</i> operands are specified. If <i>at_job_id</i> s are specified, report only information for these jobs.			
	- m	Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job will be mailed to the user as well, unless redirected elsewhere. Mail will be sent even if the job produces no output.			
		If $-\mathbf{m}$ is not used, the job's standard output and standard error will be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the user is not notified of the job's completion.			
	-q queuename	Specify in which queue to schedule a job for submission. When used with the $-l$ option, limit the search to that particular queue. Values for <i>queuename</i> are limited to the lower case letters a through z . By default, at-jobs will be scheduled in queue a . In contrast, queue b is reserved for batch jobs. Since queue c is reserved for cron jobs, it can not be used with the $-\mathbf{q}$ option.			
	–r at_job_id	Remove the jobs with the specified <i>at_job_id</i> operands that were previously scheduled by the at utility.			
	-t time	Submit the job to be run at the time specified by the <i>time</i> option- argument, which must have the format as specified by the touch (1) util- ity.			
OPERANDS	The following operands are supported:				
	at_job_id	The name reported by a previous invocation of the at utility at the time the job was scheduled.			
	timespec	Submit the job to be run at the date and time specified. All of the <i>timespec</i> operands are interpreted as if they were separated by space characters and concatenated. The date and time are interpreted as being in the timezone of the user (as determined by the TZ variable), unless a timezone name appears as part of <i>time</i> , below.			
		In the "C" locale, the following describes the three parts of the time specification string. All of the values from the LC_TIME categories in the "C" locale are recognized in a case-insensitive manner.			
		<i>time</i> The <i>time</i> can be specified as one, two or four digits. One- and two-digit numbers are taken to be hours, four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning			

		the am_pm h follow the tin stood. A tim time; see TZ	An AM/PM indication (one of the values from keywords in the LC_TIME locale category) can me; otherwise, a 24-hour clock time is under- nezone name can follow to further qualify the on the environ (5) manual page. The <i>time</i> field ne of the following tokens in the "C" locale:
		midnight	Indicates the time 12:00 am (00:00).
		noon	Indicates the time 12:00 pm.
		now	Indicate the current day and time. Invoking at now will submit an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).
	date	(one of the v LC_TIME loc possibly yea week (one of	<i>date</i> can be specified as either a month name alues from the mon or abmon keywords in the ale category) followed by a day number (and r number preceded by a comma) or a day of the T the values from the day or abday keywords in c locale category). Two special days are recog- "C" locale:
		today	Indicates the current day.
		tomorrow	Indicates the day following the current day.
		greater than is less. If the	given, today is assumed if the given time is the current time, and tomorrow is assumed if it given month is less than the current month (and ven), next year is assumed.
	increment	<i>increment</i> is a number preceded by a plus sign xed by one of the following: minutes , hours , , months , or years . (The singular forms will be d.) The keyword next is equivalent to an incre- r of + 1. For example, the following are ommands: + 1 week next week	
USAGE	Other locales are not suppo	rted for mid	n here is guaranteed only for the "C" locale. ight, noon, now, mon, abmon, day, abday, weeks, months, years, and next.
		erminal, open	ell invocation, running in a separate process file descriptors, traps and priority inherited

EXAMPLES	
at	 This sequence can be used at a terminal: \$ at -m 0730 tomorrow sort < file >outfile <eot></eot>
	2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant): S at now + 1 hour < </p diff file1 file2 2>&1 >outfile mailx mygroup !
	3. To have a job reschedule itself, at can be invoked from within the at-job. For example, this "daily-processing" script named my.daily will run every day (although crontab is a more appropriate vehicle for such work): # my.daily runs every day at now tomorrow < my.daily daily-processing
	 4. The spacing of the three portions of the "C" locale <i>timespec</i> is quite flexible as long as there are no ambiguities. Examples of various times and operand presentations include: at 0815am Jan 24 at 8:15amjan24 at now "+ 1day" at 5 pm FRIday at '17 utc+ 30minutes'
batch	1. This sequence can be used at a terminal: \$ batch sort <file>outfile <eot></eot></file>
	 2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant): \$ batch <<!--</li--> diff file1 file2 2>&1 >outfile mailx mygroup !
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of at and batch : LC_CTYPE, LC_MESSAGES, NLSPATH, and LC_TIME.
	SHELL Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or NULL , sh will be used. If it is set to a value other than sh , the implementation will use that shell; a warning

t(1)		SunOS 5.5			
		diagnosti	c will be printed telling which	shell will be used.	
	TZ	time spec the TZ va <i>timespec</i> d	ine the timezone. The job will be submitted for execution at the ecified by <i>timespec</i> or -t <i>time</i> relative to the timezone specified by variable. If <i>timespec</i> specifies a timezone, it will override TZ . If c does not specify a timezone and TZ is unset or NULL , an ified default timezone will be used.		
	DATEMSK	full path i consist of richer set ate setting allowable The forma argument	name of a template file contain format specifiers and text cha of allowable date formats in c gs of the environment variable format specifiers is located in ats described in the OPERAN ts, the special names noon , mi	is set, at will use its value as the ning format strings. NAME	atq – display the jobs queued to run at specified times			
SYNOPSIS	atq [-c] [-n] [username]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	atq displays the at jobs queued up for the current user. at (1) is a utility that allows users to execute commands at a later date. If invoked by the privileged user, atq will display all jobs in the queue.			
	If no options are given, the jobs are displayed in chronological order of execution.			
	When a privileged user invokes atq without specifying <i>username</i> , the entire queue is displayed; when a <i>username</i> is specified, only those jobs belonging to the named user are displayed.			
OPTIONS	- c Display the queued jobs in the order they were created (that is, the time that the at command was given).			
	- n Display only the total number of jobs currently in the queue.			
FILES	/ var/spool/cron/atjobs spool area for at jobs.

modified 1 Mar 1994

1-53

NAME	atrm – remove jobs spooled by at or batch			
SYNOPSIS	atrm [–afi] [[job #] [user]]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	atrm removes delayed-execution jobs that were created with the at (1) command, but have not yet executed. The list of these jobs and associated job numbers can be displayed by using atq (1).			
	atrm removes each job-number you specify, and/or all jobs belonging to the user you specify, provided that you own the indicated jobs.			
	You can only remove jobs belonging to other users if you have super-user privileges.			
OPTIONS	 -a All. Remove all unexecuted jobs that were created by the current user. If invoked by the privileged user, the entire queue will be flushed. 			
	 -f Force. All information regarding the removal of the specified jobs is suppressed. 			
	 -i Interactive. atrm asks if a job should be removed. If you respond with a y, the job will be removed. 			
FILES	/var/spool/cron/atjobs spool area for at jobs

NAME	audioconvert – convert audio file formats					
SYNOPSIS	audioconvert [$[-\mathbf{pF}] [-\mathbf{f} \text{ outfint}] [-\mathbf{o} \text{ outfile}] [[-\mathbf{i} \text{ infint}] [file]]$				
DESCRIPTION	audioconvert converts audio data between a set of supported audio encodings and file formats. It can be used to compress and decompress audio data, to add audio file headers to raw audio data files, and to convert between standard data encodings, such as μ -law and linear PCM.					
	If no filenames are present, audioconvert reads the data from the standard input streat and writes an audio file to the standard output. Otherwise, input files are processed is order, concatenated, and written to the output file.					
	Input files are expected to contain audio file headers that identify the audio data forma If the audio data does not contain a recognizable header, the format must be specified with the –i option, using the <i>rate</i> , <i>encoding</i> , and <i>channels</i> keywords to identify the input data format.					
	 The output file format is derived by updating the format of the first input file with the format options in the -f specification. If -p is not specified, all subsequent input files ar converted to this resulting format and concatenated together. The output file will conta an audio file header, unless <i>format=raw</i> is specified in the output format options. Input files may be converted in place by using the -p option. When -p is in effect, the format of each input file is modified according to the -f option to determine the output format. The existing files are then overwritten with the converted data. 					
	The file (1) com	mand decodes and prints the audio data format of Sun audio files.				
OPTIONS	-р	<i>In Place</i> : The input files are individually converted to the format specified by the $-\mathbf{f}$ option and rewritten. If a target file is a symbolic link, the underlying file will be rewritten. The $-\mathbf{o}$ option may not be specified with $-\mathbf{p}$.				
	- F	<i>Force</i> : This option forces audioconvert to ignore any file header for input files whose format is specified by the –i option. If –F is not specified, audioconvert ignores the –i option for input files that contain valid audio file headers.				
	-f outfmt	<i>Output Format</i> : This option is used to specify the file format and data encoding of the output file. Defaults for unspecified fields are derived from the input file format. Valid keywords and values are listed in the next section.				
	–o outfile	<i>Output File</i> : All input files are concatenated, converted to the output for- mat, and written to the named output file. If $-\mathbf{o}$ and $-\mathbf{p}$ are not specified, the concatenated output is written to the standard output. The $-\mathbf{p}$ option may not be specified with $-\mathbf{o}$.				

modified 10 Dec 1992

	−i infmt	i 1 1 1 1	<i>Input Format</i> : This option is used to specify the data encoding of raw input files. Ordinarily, the input data format is derived from the audio file header. This option is required when converting audio data that is not preceded by a valid audio file header. If $-\mathbf{i}$ is specified for an input file that contains an audio file header, the input format string will be ignored, unless $-\mathbf{F}$ is present. The format specification syntax is the same as the $-\mathbf{f}$ output file format.	
		i	Multiple input formats may be specified. An input format describes all input files following that specification, until a new input format is specified.	
	file	1	File Specification: The named audio files are concatenated, converted to the output format, and written out. If no filename is present, or if the special filename '–' is specified, audio data is read from the standard input.	
	-?		Help: Print a command line usage message.	
FORMAT SPECIFICATION	The syntax for the input and output format specification is: keyword=value[,keyword=value] with no intervening whitespace. Unambiguous values may be used without the preced- ing keyword=.			
	rate	lowed	adio sampling rate is specified in samples per second. If a number is fol- by the letter \mathbf{k} , it is multiplied by 1000 (for example, 44.1k = 44100). ard of the commonly used sample rates are: 8k, 16k, 32k, 44.1k, and 48k.	
	channels	mono	umber of interleaved channels is specified as an integer. The words and stereo may also be used to specify one and two channel data, ctively.	
	encoding	mine j	ption specifies the digital audio data representation. Encodings deter- precision implicitly (ulaw implies 8-bit precision) or explicitly as part of me (for example, linear16). Valid encoding values are:	
		ulaw	CCITT G.711 μ -law encoding. This is an 8-bit format primarily used for telephone quality speech.	
		alaw	CCITT G.711 A-law encoding. This is an 8-bit format primarily used for telephone quality speech in Europe.	
		linear	8, linear16, linear32 Linear Pulse Code Modulation (PCM) encoding. The name identifies the number of bits of precision. linear16 is typically used for high quality audio data.	
		рст	Same as linear16 .	

modified 10 Dec 1992

		g721	CCITT G.721 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 4-bit precision. It is primarily used for compressing μ -law voice data (achieving a 2:1 compression ratio).
		g723	CCITT G.723 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 3-bit precision. It is primarily used for compressing μ -law voice data (achieving an 8:3 compression ratio). The audio quality is similar to G.721, but may result in lower quality when used for non-speech data.
			ving encoding values are also accepted as shorthand to set the sam- hannels, and encoding:
		voice	Equivalent to encoding=ulaw,rate=8k,channels=mono .
		cd	Equivalent to encoding=linear16,rate=44.1k,channels=stereo .
		dat	Equivalent to encoding=linear16,rate=48k,channels=stereo .
	format	This optio	n specifies the audio file format. Valid formats are:
		sun	Sun compatible file format (the default).
		raw	Use this format when reading or writing raw audio data (with no audio header), or in conjunction with an offset to import a foreign audio file format.
	offset		pecify a byte offset to locate the start of the audio data. This option ed to import audio data that contains an unrecognized file header.
EXAMPLES	Record vo	oice data and	d compress it before storing it to a file:
	exar	nple% audi	orecord audioconvert –f g721 > mydata.au
		ate two Sun 16 kHz, mo	format audio files, regardless of their data format, and output an 8- no file:
	exar	nple% audi	oconvert –f ulaw,rate=16k,mono –o outfile.au infile1 infile2
	Convert a header to		ontaining raw voice data files, in place, to Sun format (adds a file
	exar	nple% audi	oconvert –p –i voice –f sun *.au
SEE ALSO	audioplay	y(1), audior	ecord(1), file(1)
NOTES	summing case if a m	the channel	or converting multi-channel data to mono is implemented by simply is together. If the input data is perfectly in phase (as would be the converted to stereo and back to mono), the resulting data may con-

modified 10 Dec 1992

NAME	audioplay	y – play audio files
SYNOPSIS	audioplay [–iV] [–v vol] [–b bal] [–p speaker headphone line] [–d dev] [file]	
AVAILABILITY	SUNWau	Idio
DESCRIPTION	audioplay copies the named audio files (or the standard input if no filenames are present) to the audio device. If no input file is specified and standard input is a tty, the port, volume, and balance settings specified on the command line will be applied and the program will exit.	
	The input files must contain a valid audio file header. The encoding information in this header is matched against the capabilities of the audio device and, if the data formats are incompatible, an error message is printed and the file is skipped. Compressed ADPCM (G.721) monaural audio data is automatically uncompressed before playing.	
	This allow only supp	viations in sampling frequency (that is, less than 1%) are ordinarily ignored. ws, for instance, data sampled at 8012 Hz to be played on an audio device that ports 8000 Hz. If the $-V$ option is present, such deviations are flagged with messages.
OPTIONS	-i	<i>Immediate</i> : If the audio device is unavailable (that is, another process currently has write access), audioplay ordinarily waits until it can obtain access to the device. When the – i option is present, audioplay prints an error message and exits immediately if the device is busy.
	- V	<i>Verbose</i> : Print messages on the standard error when waiting for access to the audio device or when sample rate deviations are detected.
	–v vol	<i>Volume</i> : The output volume is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The <i>vol</i> argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the output volume remains at the level most recently set by any process.
	-b bal	<i>Balance</i> : The output balance is set to the specified value before playing begins, and is reset to its previous level when audioplay exits. The <i>bal</i> argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the output balance remains at the level most recently set by any process.
	–p speak	er headphone line <i>Output Port</i> : Select the built-in speaker , (the default), headphone jack, or line out as the destination of the audio output signal. If this argument is not specified, the output port will remain unchanged. <i>Not all audio adapters sup-</i> <i>port all of the output ports. If the named port does not exist, an appropriate substi-</i> <i>tute will be used.</i>
	-d dev	<i>Device</i> : The <i>dev</i> argument specifies an alternate audio device to which output should be directed. If the $-\mathbf{d}$ option is not specified, the AUDIODEV

NAME	audiorec	ord – record an audio file	
SYNOPSIS	audiorecord [-af] [-v vol] [-b bal] [-m monvol] [-p mic line internal-cd] [-c channels] [-s rate] [-e encoding] [-t time] [-i info] [-d dev] [file]		
AVAILABILITY	SUNWau	ıdio	
DESCRIPTION	dard out is a tty, tl	cord copies audio data from the audio device to a named audio file (or the stan- put if no filename is present). If no output file is specified and standard output he volume, balance, monitor volume, port, and audio format settings specified ommand line will be applied and the program will exit.	
	By default, monaural audio data is recorded at 8 kHz and encoded in μ -law format. If the audio device supports additional configurations, the $-c$, $-s$, and $-e$ options may be used to specify the data format. The output file is prefixed by an audio file header that identifies the format of the data encoded in the file.		
	is receive	ng begins immediately and continues until a SIGINT signal (for example, CTRL-C) ed. If the –t option is specified, audiorecord stops when the specified quantity of been recorded.	
		dio device is unavailable (that is, another process currently has read access), c ord prints an error message and exits immediately.	
OPTIONS	-a	<i>Append</i> : Append the data on the end of the named audio file. The audio device must support the audio data format of the existing file.	
	-f	<i>Force</i> : When the $-a$ flag is specified, the sample rate of the audio device must match the sample rate at which the original file was recorded. If the $-f$ flag is also specified, sample rate differences are ignored, with a warning message printed on the standard error.	
	–v vol	<i>Volume</i> : The recording gain is set to the specified value before recording begins, and is reset to its previous level when audiorecord exits. The <i>vol</i> argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the input volume will remain at the level most recently set by any process.	
	-b bal	<i>Balance</i> : The recording balance is set to the specified value before recording begins, and is reset to its previous level when audiorecord exits. The <i>bal</i> argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the input balance will remain at the level most recently set by any process.	

modified 25 Jan 1994

	- m monvo.	<i>l Monitor Volume</i> : The input monitor volume is set to the specified value before recording begins, and is reset to its previous level when audiorecord exits. The <i>monval</i> argument is an integer value between 0 and 100, inclusive. A non-zero value allows a directly connected input source to be heard on the output speaker while recording is in-progress. If this argument is not specified, the monitor volume will remain at the level most recently set by any process.
	−p mic l	 ine internal-cd Input Port: Select the mic, line, or internal-cd input as the source of the audio output signal. If this argument is not specified, the input port will remain unchanged. Some systems will not support all possible input ports. If the named port does not exist, this option is ignored.
	–c channel	<i>s</i> <i>Channels</i> : Specify the number of audio channels (1 or 2). The value may be specified as an integer or as the string mono or stereo . The default value is mono .
	–s rate	Sample Rate: Specify the sample rate, in samples per second. If a number is followed by the letter \mathbf{k} , it is multiplied by 1000 (for example, 44.1k = 44100). The default sample rate is 8 kHz.
	–e encodin	g <i>Encoding</i> : Specify the audio data encoding. This value may be one of ulaw , alaw , or linear . The default encoding is ulaw .
	-t time	<i>Time</i> : The <i>time</i> argument specifies the maximum length of time to record. Time can be specified as a floating-point value, indicating the number of seconds, or in the form: <i>hh:mm:ss.dd</i> , where the hour and minute specifications are optional.
	−i info	<i>Information</i> : The 'information' field of the output file header is set to the string specified by the <i>info</i> argument. This option cannot be specified in conjunction with the $-a$ argument.
	− d dev	<i>Device</i> : The <i>dev</i> argument specifies an alternate audio device from which input should be taken. If the – d option is not specified, the AUDIODEV environment variable is consulted (see below). Otherwise, / dev / audio is used as the default audio device.
	file	<i>File Specification</i> : The named audio file is rewritten (or appended). If no filename is present (and standard output is not a tty), or if the special filename '-' is specified, output is directed to the the standard output.
	-\?	Help: Print a command line usage message.
ENVIRONMENT	AUDIODE	The full path name of the audio device to record from, if no –d argument is supplied. If the AUDIODEV variable is not set, /dev/audio is used.

NAME	awk – pattern scanning and processing language		
SYNOPSIS	/usr/bin/awk [–f progfile] [–Fc] ['prog'] [parameters] [filename]		
	/usr/xpg4/bin/awk [–F ERE] [–v assignn [argument]	nent] 'program' -f progfile	
AVAILABILITY	SUNWesu		
DESCRIPTION	the shell. For each pattern in <i>prog</i> there m line of a <i>filename</i> matches the pattern. The literally as <i>prog</i> or in a file specified with t		
OPTIONS	- f progfile awk uses the set of	patterns it reads from <i>progfile</i> .	
	-FcUse the character of discussion of FS be	as the field separator (FS) character. See the clow.	
USAGE Input Lines	the associated action is performed for eac <i>var=value</i> is treated as an assignment, not have been opened if it were a filename. <i>V</i> able inside a BEGIN rule, and are assigned read.	tern portion of every pattern-action statement; h matched pattern. Any <i>filename</i> of the form a filename, and is executed at the time it would <i>ariables</i> assigned in this manner are not avail- d after previously specified files have been ds separated by white spaces. (This default can	
	be changed by using the FS built-in varial leading blanks and to separate fields by b	ble or the $-Fc$ option.) The default is to ignore lanks and/or tab characters. However, if FS is y of the white spaces, then leading blanks are	
Pattern-action Statements	A pattern-action statement has the form: <i>pattern</i> { <i>action</i> } Either pattern or action may be omitted.	If there is no action, the matching line is printed.	
		ned on every input line. Pattern-action state-	
		ns (!, , &&, and parentheses) of relational elational expression is one of the following:	

	expression relop		
	expression matchop regular_expression where a <i>relop</i> is any of the six relational operators in C, and a <i>matchop</i> is either ~ (contains) or !~ (does not contain). An <i>expression</i> is an arithmetic expression, a relational expression, the special expression		
	var in array		
	or a Boolean combination of these.		
		e as in egrep (1). In patterns they must be surrounded by slashes.	
	Isolated regular expres may also occur in relat by a comma; in this cas	sions in a pattern apply to the entire line. Regular expressions ional expressions. A pattern may consist of two patterns separated se, the action is performed for all lines between the occurrence of occurrence of the second pattern.	
	line has been read and	GIN and END may be used to capture control before the first input after the last input line has been read respectively. These key- with any other patterns.	
Built-in Variables	Built-in variables inclu	de:	
	FILENAME	name of the current input file	
	FS	input field separator regular expression (default blank and tab)	
	NF	number of fields in the current record	
	NR	ordinal number of the current record	
	OFMT	output format for numbers (default % .6g)	
	OFS	output field separator (default blank)	
	ORS	output record separator (default new-line)	
	RS	input record separator (default new-line)	
	An action is a sequence	e of statements. A statement may be one of the following:	
	if (expression) statement [else statement] while (expression) statement do statement while (expression) for (expression; expression) statement		
	for (var in array) statement		
	break		
	continue { [statement]	}	
	expression	# commonly variable = expression	
		ion-list] [>expression]	
	print f format [next	, <i>expression-list</i>] [> <i>expression</i>] # skip remaining patterns on this input line	
	exit [expr]	# skip the rest of the input; exit status is expr	

	Statements are terminated by semicolons, newlines, or right braces. An empty expression-list stands for the whole input line. Expressions take on string or numeric values as appropriate, and are built using the operators $+, -, *, /, \%$, and concatenation (indicated by a blank). The operators $++ += -= *= /= \% = ^{=} >> = < <= = != ?:$ are also available in expressions. Variables may be scalars, array elements (denoted x[i]), or fields. Variables are initialized to the null string or zero. Array subscripts may be any string, not necessarily numeric; this allows for a form of associative memory. String constants are quoted (""), with the usual C escapes recognized within.		
	is present, or on a pipe if ' <i>cmd</i> ' is present. The output resulted from the print statement is terminated by the output record separator with each argument separated by the current output field separator. The printf statement formats its expression list according to the format (see printf (3S)).		
	The mathemat	ical functions: exp , log , sqrt , are built-in.	
	Other built-in	functions include:	
	index(s, t)	returns the position in string <i>s</i> where string <i>t</i> first occurs, or 0 if it does not occur at all.	
	int(s)	truncates <i>s</i> to an integer value. If <i>s</i> is not specified, \$0 is used.	
	length(s)	returns the length of its argument taken as a string, or of the whole line if there is no argument.	
	match(s, re)	returns the position in string s where the regular expression re occurs, or 0 if it does not occur at all.	
	split(s, a, fs)	splits the string <i>s</i> into array elements $a[1]$, $a[2]$, $a[n]$, and returns <i>n</i> . The separation is done with the regular expression <i>fs</i> or with the field separator FS if <i>fs</i> is not given.	
	<pre>sprintf(fmt, expr, expr,)</pre>		
		formats the expressions according to the printf (3S) format given by <i>fmt</i> and returns the resulting string.	
	substr(s, m, n)	returns the <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> .	
	The input/output built-in function is:		
	getline	sets \$0 to the next input record from the current input file. getline returns 1 for successful input, 0 for end of file, and –1 for an error.	
EXAMPLES	Print lines long	ger than 72 characters:	
	length	-	
	Print first two fields in opposite order:		
		\$2, \$1 }	
	-	out fields separated by comma and/or blanks and tabs:	

	BEGIN { FS = ",[\t]* [\t]+" } { print \$2, \$1 }
	Add up first column, print sum and average:
	$\{s = \$1\}$
	END { print "sum is", s, " average is", s/NR }
	Print fields in reverse order:
	{ for (i = NF; i > 0;i) print \$i }
	Print all lines between start/stop pairs:
	/start/, /stop/
	Print all lines whose first field is different from previous one:
	\$1 != prev { print; prev = \$1 }
	Print a file, filling in page numbers starting at 5:
	/Page/ { \$2 = n++; } { print }
	Assuming this program is in a file named prog , the following command line prints the file input numbering its pages starting at 5: awk – f prog n=5 input .
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of awk for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S style) locale determines how awk behaves.
	LC_CTYPE determines how awk handles characters. When LC_CTYPE is set to a valid value, awk can display and handle text and filenames containing valid characters for that locale. awk can display and handle Extended Unix Code (EUC) characters where any character can be 1, 2, or 3 bytes wide. awk can also handle EUC char- acters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.
	LC_MESSAGES determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S/English).
SEE ALSO	<pre>egrep(1), grep(1), nawk(1), sed(1), printf(3S), environ(5)</pre>
NOTES	Input white space is not preserved on output if fields are involved.
	There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string ("") to it.

1	
NAME	banner – make posters
SYNOPSIS	banner strings
AVAILABILITY	SUNWesu
DESCRIPTION	banner prints its arguments (each up to 10 characters long) in large letters on the stan- dard output.
SEE ALSO	echo(1)

modified 14 Sep 1992

NAME	basename, dirname – deliver portions of path names
SYNOPSIS	/usr/bin/basename string [suffix] /usr/xpg4/bin/basename string [suffix]
	dirname string
AVAILABILITY /usr/bin/basename /usr/bin/dirname	SUNWcsu
/usr/xpg4/bin/basename	SUNWxcu4
DESCRIPTION	basename deletes any prefix ending in / and the <i>suffix</i> (if present in <i>string</i>) from <i>string</i> , and prints the result on the standard output. It is normally used inside substitution marks (\cdot, \cdot) within shell procedures.
/usr/bin/basename /usr/xpg4/bin/basename	The <i>suffix</i> is a pattern defined on the expr (1) manual page. The <i>suffix</i> is a string with no special significance attached to any of the characters it con- tains.
	dirname delivers all but the last level of the path name in <i>string</i> .
EXAMPLES	The following example, invoked with the argument / home/sms/personal/mail sets the environment variable NAME to the file named mail and the environment variable MYMAILPATH to the string / home/sms/personal :
	example% NAME=`basename \$HOME/personal/mail` example% MYMAILPATH=`dirname \$HOME/personal/mail`
	This shell procedure, invoked with the argument / usr/src/bin/cat.c , compiles the named file and moves the output to cat in the current directory:
	example% cc \$1 example% mv a.out `basename \$1 .c`
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of basename and dirname: LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 Successful completion.
	>0 An error occurred.
SEE ALSO	expr(1), environ(5)

basename – display portions of pathnames
/usr/ucb/basename string [suffix]
SUNWscpu
basename deletes any prefix ending in '/' and the <i>suffix</i> , if present in <i>string</i> . It directs the result to the standard output, and is normally used inside substitution marks (``) within shell procedures. The <i>suffix</i> is a string with no special significance attached to any of the characters it contains.
This shell procedure invoked with the argument / usr/src/bin/cat.c compiles the named file and moves the output to cat in the current directory: example% cc \$1 example% mv a.out `basename \$1 .c`
sh(1)

NAME	bc – arbitrary precision arithmetic language	
SYNOPSIS	bc [- c] [- l] [file]	
AVAILABILITY	SUNWesu	
DESCRIPTION	given, then reads from the stand bc are attached to a terminal, the straints described in the followir and is a preprocessor for the des	bitrary precision calculator. It takes input from any files and input. If the standard input and standard output to invocation of bc is <i>interactive</i> , causing behavioural con- ag sections. bc processes a language that resembles C k calculator program dc , which it invokes automatically In this case the dc input is sent to the standard output
USAGE		follows: (mathematical or logical) value, an operand that takes a of operands and operators that evaluates to a value,
Comments	Enclosed in /* and */.	
Names (Operands)		p to BC_DIM_MAX dimensions). imited to BC_BASE_MAX), and scale (limited to
Other Operands	Arbitrarily long numbers with optional sign and decimal point. Strings of fewer than BC_STRING_MAX characters, between double quotes ('(E)	
	sqrt (E)	Square root
	length (E)	Number of significant decimal digits.
	scale (E)	Number of digits right of decimal point.
	L(E,,E)	
Operators	+ - * / % ^	(% is remainder; ^ is power)
-	++	(prefix and postfix; apply to names)
	== <= >= != < >	
	= =+ =- =* =/ =% =	_^

Statements	E { S;; S } if (E) S while (E) S for (E; E; E) S null statement break quit
Function Definitions	define L (L , L) { auto L , L S ; S return (E) }
Functions in –l Math Library	s(x)sine $c(x)$ cosine $e(x)$ exponential $l(x)$ log $a(x)$ arctangent $j(n,x)$ Bessel functionAll function arguments are passed by value.The value of a statement that is an expression is printed unless the main operator is an assignment. Either semicolons or new-lines may separate statements. Assignment to scale influences the number of digits to be retained on arithmetic operations in the manner of dc. Assignments to ibase or obase set the input and output number radix respectively.The same letter may be used as an array, a function, and a simple variable simultane- ously. All variables are global to the program. auto variables are stacked during func- tion calls. When using arrays as function arguments or defining them as automatic vari- ables, empty square brackets must follow the array name.
OPTIONS	 -c Compile only. The output is dc commands that are sent to the standard output. -l Define the math functions and initialize scale to 20, instead of the default zero.
OPERANDS	 The following operands are supported: <i>file</i> A pathname of a text file containing bc program statements. After all cases of <i>file</i> have been read, bc will read the standard input.
EXAMPLES	In the shell, the following assigns an approximation of the first ten digits of π to the variable x : x=\$(printf "%s n" 'scale = 10; 104348/33215' bc)

1-71

	Defines a function to compute an approximate value of the exponential function:
	scale = 20
	define e(x){
	auto a, b, c, i, s
	a = 1
	b = 1 s = 1
	for(i=1; 1==1; i++){
	$\mathbf{a} = \mathbf{a} * \mathbf{x}$
	$\mathbf{b} = \mathbf{b} * \mathbf{i}$
	$\mathbf{c} = \mathbf{a}/\mathbf{b}$
	if(c == 0) return(s)
	$\mathbf{s} = \mathbf{s} + \mathbf{c}$
	}
	Prints approximate values of the exponential function of the first ten integers:
	for(i=1; i<=10; i++) e(i)
	or for $(i = 1; i \le 10; ++i)$ {
	$e(i) \}$
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of bc : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following wit values are returned.
EATT STATUS	The following exit values are returned: 0 All input files were processed successfully.
	unspecified An error occurred.
FILES	/usr/lib/lib.b mathematical library
	/usr/include/limits.h to define BC_ parameters
SEE ALSO	dc(1), awk(1)
NOTES	The bc command does not recognize the logical operators && and $ $.
	The for statement must have all three expressions (<i>E</i> 's).
	The for statement must have an ance expressions (E s).

NAME	bdiff – big diff
SYNOPSIS	bdiff filename1 filename2 [n] [- s]
AVAILABILITY	SUNWesu
DESCRIPTION	bdiff is used in a manner analogous to diff to find which lines in <i>filename1</i> and <i>filename2</i> must be changed to bring the files into agreement. Its purpose is to allow processing of files too large for diff . If <i>filename1</i> (<i>filename2</i>) is –, the standard input is read.
	bdiff ignores lines common to the beginning of both files, splits the remainder of each file into <i>n</i> -line segments, and invokes diff on corresponding segments. If both optional arguments are specified, they must appear in the order indicated above.
	The output of bdiff is exactly that of diff , with line numbers adjusted to account for the segmenting of the files (that is, to make it look as if the files had been processed whole). Note: Because of the segmenting of the files, bdiff does not necessarily find a smallest sufficient set of file differences.
OPTIONS	<i>n</i> The number of line segments. The value of <i>n</i> is 3500 by default. If the optional third argument is given and it is numeric, it is used as the value for <i>n</i> . This is useful in those cases in which 3500-line segments are too large for diff , causing it to fail.
	 -s Specifies that no diagnostics are to be printed by bdiff (silent option). Note: However, this does not suppress possible diagnostic messages from diff, which bdiff calls.
FILES	/tmp/bd?????
SEE ALSO	diff (1)
DIAGNOSTICS	Use help for explanations.

biff(1B)	SunOS/BSD Compatibility Package Commands SunOS 5.5	
NAME	biff – give notice of incoming mail messages	
SYNOPSIS	/usr/ucb/biff [y n]	
AVAILABILITY	SUNWscpu	
DESCRIPTION	 biff turns mail notification on or off for the terminal session. With no arguments, biff displays the current notification status for the terminal. If notification is allowed, the terminal rings the bell and displays the header and the first 	
	few lines of each arriving mail message. biff operates asynchronously. For synchronized notices, use the MAIL variable of $sh(1)$ or the mail variable of $csh(1)$.	
	A ' biff y ' command can be included in your ~ / .login or ~ / .profile file for execution when you log in.	
OPTIONS	y Allow mail notification for the terminal.	
	n Disable notification for the terminal.	
FILES	~/.login ~/.profile	
SEE ALSO	csh(1), mail(1), sh(1)	

NAME	break, continue – shell built-in functions to escape from or advance within a controlling
	while, for, foreach, or until loop
SYNOPSIS sh	break [n] continue [n]
csh	break continue
ksh	† break [<i>n</i>] † continue [<i>n</i>]
DESCRIPTION sh	break exits from the enclosing for or while loop, if any. If <i>n</i> is specified, break <i>n</i> levels. continue resumes the next iteration of the enclosing for or while loop. If <i>n</i> is specified, resume at the <i>n</i> -th enclosing loop.
csh	 break resumes execution after the end of the nearest enclosing foreach or while loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of break commands, all on one line. continue continues execution of the next iteration of the nearest enclosing while or foreach loop.
ksh	break exits from the enclosed for, while, until, or select loop, if any. If <i>n</i> is specified then break <i>n</i> levels.continue resumes the next iteration of the enclosed for, while, until, or select loop. If <i>n</i> is specified then resume at the <i>n</i>-th enclosed loop.
	 On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort. 4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
SEE ALSO	csh(1), exit(1), for(1), foreach(1), ksh(1), select(1), sh(1), until(1), while(1)

modified 15 Apr 1994

NAME	cal – display a calendar
SYNOPSIS	cal [[month] year]
AVAILABILITY	SUNWesu
DESCRIPTION	The cal utility writes a Gregorian calendar to standard output. If the <i>year</i> operand is specified, a calendar for that year is written. If no operands are specified, a calendar for the current month is written.
OPERANDS	The following operands are supported:
	<i>month</i> Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default is the current month.
	<i>year</i> Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999 . The default is the current year.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cal : LC_TIME , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.
SEE ALSO	calendar(1), environ(5)
NOTES	An unusual calendar is printed for September 1752. That is the month 11 days were skipped to make up for lack of leap year adjustments. To see this calendar, type: cal 9 1752
	The command cal 83 refers to the year 83, not 1983.
	The year is always considered to start in January.

NAME	calendar – reminder service
SYNOPSIS	calendar [–]
AVAILABILITY	SUNWesu
DESCRIPTION	The calendar utility consults the file calendar in the current directory and writes lines that contain today's or tomorrow's date anywhere in the line to standard output. Most reasonable month-day dates such as Aug. 24 , august 24 , 8/24 , and so forth, are recognized, but not 24 August or 24/8 . On Fridays and weekends "tomorrow" extends through Monday. calendar can be invoked regularly by using the crontab (1) or at (1) commands.
	When the optional argument – is present, calendar does its job for every user who has a file calendar in his or her login directory and sends them any positive results by mail (1). Normally this is done daily by facilities in the UNIX operating system (see cron (1M)).
	If the environment variable DATEMSK is set, calendar will use its value as the full path name of a template file containing format strings. The strings consist of conversion specifications and text characters and are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable LANG or LC_TIME ; see environ (5). See strftime (3C) for the list of allowable conversion specifications.
EXAMPLES	The following example shows the possible contents of a template: %B %eth of the year %Y
	% B represents the full month name, % e the day of month and % Y the year (4 digits).
	If DATEMSK is set to this template, the following calendar file would be valid:
	March 7th of the year 1989 < Reminder>
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of calendar : LC_CTYPE , LC_TIME , LC_MESSAGES , NLSPATH , and TZ .
EXIT STATUS	0 Successful completion.
	>0 An error occurred.
FILES	/etc/passwdsystem password file/tmp/cal*temporary files used by calendar/usr/lib/calprogprogram used to determine dates for today and tomorrow
SEE ALSO	at(1), crontab(1), mail(1), cron(1M), ypbind(1M), strftime(3C), environ(5)
NOTES	Appropriate lines beginning with white space will not be printed.

Your calendar must be public information for you to get reminder service.

calendar's extended idea of "tomorrow" does not account for holidays.

The – argument works only on calendar files that are local to the machine; **calendar** is intended not to work on calendar files that are mounted remotely with **NFS**. Thus, '**calendar** –' should be run only on diskful machines where home directories exist; running it on a diskless client has no effect.

calendar is no longer in the default root crontab. Because of the network burden '**calendar** –' can induce, it is inadvisable in an environment running **ypbind**(1M) with a large passwd.byname map. If, however, the usefulness of **calendar** outweighs the network impact, the super-user may run '**crontab** –**e**' to edit the root crontab. Otherwise, individual users may wish to use '**crontab** –**e**' to edit their own crontabs to have **cron** invoke **calendar** without the – argument, piping output to mail addressed to themselves.

NAME	case, switch, select – shell built-in functions to choose from among a list of actions
SYNOPSIS sh	case word in [pattern [pattern]) actions ;;] esac
csh	switch (expression) case comparison1: actions breaksw case comparison2: actions breaksw default: endsw
ksh	case word in [pattern [pattern]) actions ;;] esac select identifier [in word] ; do list ; done
DESCRIPTION sh	A case command executes the <i>actions</i> associated with the first <i>pattern</i> that matches <i>word</i> . The form of the patterns is the same as that used for file-name generation except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.
csh	The c-shell uses the switch statement, in which each <i>comparison</i> is successively matched, against the specified <i>expression</i> , which is first command and filename expanded. The file metacharacters *, ? and [] may be used in the case comparison, which are variable expanded. If none of the comparisons match before a "default" comparison is found, execution begins after the default comparison. Each case statement and the default statement must appear at the beginning of a line. The command breaksw continues execution after the endsw . Otherwise control falls through subsequent case and default statements as with C. If no comparison matches and there is no default, execution continues after the endsw .
	case comparison: A compared-expression in a switch statement.
	default: If none of the preceeding <i>comparisons</i> match <i>expression</i> , then this is the default case in a switch statement. The default should come after all case comparisons. Any remaining commands on the command line are first executed.
	breaksw exits from a switch, resuming after the endsw.
ksh	A case command executes the <i>actions</i> associated with the first <i>pattern</i> that matches <i>word</i> . The form of the patterns is the same as that used for file-name generation (see File Name Generation in ksh (1)).

modified 15 Apr 1994

	A select command prints to standard error (file descriptor 2), the set of <i>words</i> , each pre- ceded by a number. If in <i>word</i> is omitted, then the positional parameters are used instead. The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed <i>words</i> , then the value of the variable <i>identifier</i> is set to the <i>word</i> corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable <i>identifier</i> is set to NULL . The contents of the line read from standard input is saved in the shell variable REPLY . The <i>list</i> is exe- cuted for each selection until a break or <i>end-of-file</i> is encountered. If the REPLY variable is set to NULL by the execution of <i>list</i> , then the selection list is printed before displaying the PS3 prompt for the next selection.
EXAMPLES	STODI ICHT-groop
sh	STOPLIGHT=green case \$STOPLIGHT in
	red) echo "STOP" ;;
	orange) echo "Go with caution; prepare to stop" ;;
	green) echo "you may GO" ;;
	blue brown) echo "invalid stoplight colors" ;;
	esac
csh	In the C-shell, you must add NEWLINE characters as below. set STOPLIGHT = green switch (\$STOPLIGHT) case red:
	echo "STOP"
	breaksw
	case orange:
	echo "Go with caution; prepare to stop" breaksw
	case green:
	echo "you may GO"
	endsw
	endsw
ksh	STOPLIGHT=green case \$STOPLIGHT in

modified 15 Apr 1994

NAME	cat – concatenate and display files
SYNOPSIS	cat [-nbsuvet] [file]
AVAILABILITY	SUNWcsu
DESCRIPTION	<pre>cat reads each file in sequence and writes it on the standard output. Thus: example% cat file prints file on your terminal, and: example% cat file1 file2 >file3 concatenates file1 and file2, and writes the results in file3. If no input file is given, cat reads from the standard input file.</pre>
OPTIONS	 -n Precede each line output with its line number. -b Number the lines, as -n, but omit the line numbers from blank lines. -u The output is not buffered. (The default is buffered output.) -s cat is silent about non-existent files. -v Non-printing characters (with the exception of tabs, new-lines and form-feeds) are printed visibly. ASCII control characters (octal 000 – 037) are printed as ^n, where n is the corresponding ASCII character in the range octal 100 – 137 (@, A, B, C,, X, Y, Z, [,], ^, and _); the DEL character (octal 0177) is printed [?]. Other non-printable characters are printed as M-x, where x is the ASCII character specified by the low-order seven bits. When used with the -v option, the following options may be used: -e A \$ character will be printed at the end of each line (prior to the new-line). -t Tabs will be printed as T's and formfeeds to be printed as ^L's.
OPERANDS	 The following operand is supported: <i>file</i> A path name of an input file. If no <i>file</i> is specified, the standard input is used. If <i>file</i> is '-', cat will read from the standard input at that point in the sequence. cat will not close and reopen standard input when it is referenced in this way, but will accept multiple occurrences of '-' as <i>file</i>.
EXAMPLES	 The following command: example% cat myfile writes the contents of the file myfile to standard output.

	2. The following command:				
	example% cat doc1 doc2 > doc.all				
	concatenates the files doc1 and doc2 and writes the result to doc.all .				
	3. The command:				
	example% cat start - middle - end > file				
	when standard input is a terminal, gets two arbitrary pieces of input from the termi- nal with a single invocation of cat . Note, however, that if standard input is a regular file, this would be equivalent to the command:				
	cat start - middle /dev/null end > file				
	because the entire contents of the file would be consumed by cat the first time ' $-$ ' was used as a <i>file</i> operand and an end-of-file condition would be detected immediately when ' $-$ ' was referenced the second time.				
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cat : LC_CTYPE , LC_MESSAGES , and NLSPATH .				
EXIT STATUS	The following exit values are returned:				
	0 All input files were output successfully.				
	>0 An error occurred.				
SEE ALSO	touch(1), environ(5)				
NOTES	Redirecting the output of cat onto one of the files being read will cause the loss of the data originally in the file being read. For example,				
	example% cat filename1 filename2 >filename1				
	causes the original data in filename1 to be lost.				

NAME	cc – C compiler	
SYNOPSIS	/usr/ucb/cc [opti	ions]
AVAILABILITY	SUNWscpu	
DESCRIPTION	that looks for the able only with th / usr/ucb/cc is ide libraries are linke	e interface to the BSD Compatibility Package C compiler. It is a script e link / usr/ccs/bin/ucbcc to the C compiler. / usr/ccs/bin/ucbcc is avail- te SPROcc package, whose default location is / opt/SUNWspro . entical to / usr/ccs/bin/ucbcc , except that BSD headers are used and BSD ed <i>before</i> base libraries. The / opt/SUNWspro/man/man1/acc.1 man page with the SPROcc package.
OPTIONS	/usr/ucb/cc accep	ots the same options as / usr/ccs/bin/ucbcc , with the following exceptions:
	Idir	Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple –I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing <i>sourcefile</i> , and then in directories named with –I options (if any), then /usr/ucbinclude, and finally, in /usr/include.
	–Ldir	Add <i>dir</i> to the list of directories searched for libraries by /usr/ccs/bin/ucbcc. This option is passed to /usr/ccs/bin/ld and /usr/ccs/lib. Directories specified with this option are searched before /usr/ucblib and /usr/lib.
	–YP, dir	Change the default directory used for finding libraries.
EXIT STATUS	The following ex	it values are returned:
	0 Succe	essful compilation or link edit.
	> 0 An er	ror occurred.
FILES	/usr/ccs/bin/ld /usr/lib/libc /usr/ucbinclude /usr/ucblib /usr/ucblib/libu /usr/lib/libsocke /usr/lib/libnsl /usr/lib/libelf /usr/lib/libaio	BSD Compatibility directory for libraries BSD Compatibility C library
SEE ALSO	ld(1), a.out(4)	

NOTES The –**Y P**, *dir* option may have unexpected results, and should not be used.

NAME	cd, chdir, pushd, popd, dirs – change working directory
SYNOPSIS	/usr/bin/cd [directory]
sh	cd [argument] chdir [argument]
csh	cd [<i>dir</i>] chdir [<i>dir</i>] pushd [+n <i>dir</i>] popd [+n] dirs [-l]
ksh	cd [arg] cd old new
DESCRIPTION /usr/bin/cd	The cd utility will change the working directory of the current shell execution environ- ment. When invoked with no operands, and the HOME environment variable is set to a non-empty value, the directory named in the HOME environment variable will become the new working directory.
sh	The Bourne shell built-in cd changes the current directory to <i>argument</i> . The shell parameter HOME is the default <i>argument</i> . The shell parameter CDPATH defines the search path for the directory containing <i>argument</i> . Alternative directory names are separated by a colon (:). The default path is < null > (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If <i>argument</i> begins with '/', ' . ', or ' ', the search path is not used. Otherwise, each directory in the path is searched for <i>argument</i> . cd must have execute (search) permission in <i>argument</i> . Because a new process is created to execute each command, cd would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the shell. (See pwd (1), sh (1), and chdir (2)).
csh	chdir is just another way to call cd. If <i>dir</i> is not specified, the C shell built-in cd uses the value of shell parameter HOME as the new working directory. If <i>dir</i> specifies a complete path starting with '/', '.', or '', <i>dir</i> becomes the new working directory. If neither case applies, cd tries to find the designated directory relative to one of the paths specified by the CDPATH shell variable. CDPATH has the same syntax as, and similar semantics to, the PATH shell variable. cd must have execute (search) permission in <i>dir</i> . Because a new process is created to execute each command, cd would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the C-shell. (See pwd(1), sh(1), and chdir(2)).

modified 28 Mar 1995

cd(1)	User Commands	SunOS 5.5
	chdir changes the shell's working directory to directory <i>dir</i> . If no ar change to the home directory of the user. If <i>dir</i> is a relative pathnam current directory, check for it in those directories listed in the cdpat name of a shell variable whose value starts with a /, change to the director that value.	ne not found in the h variable. If <i>dir</i> is the
	pushd will push a directory onto the directory stack. With no argun top two elements.	ments, exchange the
	+ <i>n</i> Rotate the <i>n</i> 'th entry to the top of the stack and cd to it.	
	<i>dir</i> Push the current working directory onto the stack and chan	ge to <i>dir</i> .
	popd pops the directory stack and cd to the new top directory. The tory stack are numbered from 0 starting at the top.	elements of the direc-
	+ n Discard the n 'th entry in the stack.	
	dirs will print the directory stack, most recent to the left; the first directory directory. With the –l argument, produce an unabbreviated notation is suppressed.	č
ksh	The Korn shell built-in cd command can be in either of two forms. If changes the current directory to <i>arg</i> . If <i>arg</i> is – the directory is change directory. The shell variable HOME is the default <i>arg</i> . The variable current directory. The shell variable CDPATH defines the search part containing <i>arg</i> . Alternative directory names are separated by a colo path is < null > (specifying the current directory). Note that the current specified by a null path name, which can appear immediately after the between the colon delimiters anywhere else in the path list. If <i>arg</i> be or '', then the search path is not used. Otherwise, each directory if for <i>arg</i> .	ged to the previous PWD is set to the th for the directory n (:). The default ent directory is the equal sign or egins with a '/', '.',
	The second form of cd substitutes the string <i>new</i> for the string <i>old</i> in name, PWD and tries to change to this new directory.	the current directory
	The cd command may not be executed by rksh . Because a new proc cute each command, cd would be ineffective if it were written as a r therefore, it is recognized by and is internal to the Korn shell. (See p chdir (2)).	normal command;
OPERANDS	The following operands are supported:	
	<i>directory</i> An absolute or relative pathname of the directory that be ing directory. The interpretation of a relative pathname CDPATH environment variable.	
OUTPUT	If a non-empty directory name from CDPATH is used, an absolute p working directory will be written to the standard output as follows: "% s\n ", < <i>new directory</i> >	

1-86

	Otherwise, th	here will be no output.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cd : LC_CTYPE, LC_MESSAGES, and NLSPATH.			
	CDPATH	A colon-separated list of pathnames that refer to directories. If the <i>directory</i> operand does not begin with a slash (/) character, and the first component is not dot or dot-dot, cd will search for <i>directory</i> relative to each directory named in the CDPATH variable, in the order listed. The new working directory will be set to the first matching directory found. An empty string in place of a directory pathname represents the current directory. If CDPATH is not set, it will be treated as if it were an empty string.		
	HOME	The name of the home directory, used when no <i>directory</i> operand is specified.		
	PWD	A pathname of the current working directory, set by cd after it has changed to that directory.		
EXIT STATUS	0 T.	g exit values are returned by cd : he directory was successfully changed. In error occurred.		
SEE ALSO	csh(1), ksh(1), pwd(1), sh(1), chdir(2), environ(5)			

User Commands

NAME	checknr – check nroff and troff input files; report possible errors			
SYNOPSIS	checknr [- fs] [- a . <i>x</i> 1 . <i>y</i> 1 . <i>x</i> 2 . <i>y</i> 2 <i>xn</i> . <i>yn</i>] [- c . <i>x</i> 1 . <i>x</i> 2 . <i>x</i> 3 <i>xn</i>] [filename]			
AVAILABILITY	SUNWdoc			
DESCRIPTION	checknr checks a list of nroff (1) or troff (1) input files for certain kinds of errors involving mismatched opening and closing delimiters and unknown commands. If no files are specified, checknr checks the standard input. Delimiters checked are:			
	• Font changes using $fx \dots fP$.			
	• Size changes using $sx \dots s0$.			
	• Macros that come in open close forms, for example, the .TS and .TE macros which must always come in pairs.			
	checknr knows about the ms (5) and me (5) macro packages.			
	checknr is intended to be used on documents that are prepared with checknr in mind. It expects a certain document writing style for \ f and \ s commands, in that each \ f x must be terminated with \ fP and each \ s x must be terminated with \ s0 . While it will work to directly go into the next font or explicitly specify the original font or point size, and many existing documents actually do this, such a practice will produce complaints from checknr . Since it is probably better to use the \ fP and \ s0 forms anyway, you should think of this as a contribution to your document preparation style.			
OPTIONS	$-\mathbf{f}$ Ignore \f font changes.			
	$-s$ Ignore \s size changes.			
	 -a .x1 .y1 Add pairs of macros to the list. The pairs of macros are assumed to be those 			
	(such as .DS and .DE) that should be checked for balance. The –a option must be followed by groups of six characters, each group defining a pair of macros. The six characters are a period, the first macro name, another period, and the second macro name. For example, to define a pair .BS and .ES, use '–a.BS.ES'			
	-c .x1 Define commands which checknr would otherwise complain about as undefined.			
SEE ALSO	eqn (1), nroff (1), troff (1), me (5), ms (5)			
BUGS	There is no way to define a one-character macro name using the $-\mathbf{a}$ option.			

NAME	chgrp – change file group ownership				
SYNOPSIS	chgrp [-fhR] group file				
AVAILABILITY	SUNWcsu				
DESCRIPTION	The chgrp utility will set the group ID of the file named by each <i>file</i> operand to the group ID specified by the <i>group</i> operand.				
	For each <i>file</i> operand, it will perform actions equivalent to the chown (2) function, called with the following arguments:				
	• The <i>file</i> operand will be used as the <i>path</i> argument.				
	• The user ID of the file will be used as the <i>owner</i> argument.				
	• The specified group ID will be used as the <i>group</i> argument.				
	Unless chgrp is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file will be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.				
	The operating system has a configuration option {_POSIX_CHOWN_RESTRICTED} , to restrict ownership changes. When this option is in effect, the owner of the file may change the group of the file only to a group to which the owner belongs. Only the super-user can arbitrarily change owner IDs, whether or not this option is in effect.				
OPTIONS	-f Force. Do not report errors.				
	- h If the file is a symbolic link, change the group of the symbolic link. Without this option, the group of the file referenced by the symbolic link is changed.				
	 -R Recursive. chgrp descends through the directory, and any subdirectories, setting the specified group ID as it proceeds. When a symbolic link is encountered, the group of the target file is changed (unless the -h option is specified), but no recursion takes place. 				
OPERANDS	The following operands are supported:				
	<i>group</i> A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the <i>file</i> operands. If a numeric <i>group</i> operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.				
	file A path name of a file whose group ID is to be modified.				
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of chgrp : LC_CTYPE , LC_MESSAGES , and NLSPATH .				
EXIT STATUS	The following exit values are returned:				
	0 The utility executed successfully and all requested changes were made.				
	> 0 An error occurred.

NAME	chkey – change user's secure RPC key pair				
SYNOPSIS	chkey [–p]	[-s nisplus nis files]			
AVAILABILITY	SUNWcsu				
DESCRIPTION	chkey is used to change a user's secure RPC public key and secret key pair. chkey prompts for the old secure-rpc password and verifies that it is correct by decrypting the secret key. If the user has not already keylogged in, chkey registers the secret key with the local keyserv (1M) daemon. If the secure-rpc password does not match the login password, chkey prompts for the login password. chkey uses the login password to encrypt the user's secret Diffie-Hellman (192 bit) cryptographic key.				
	•	res that the login password and the secure-rpc password are kept the same, g password shadowing, (see shadow (4)).			
	The key pair can be stored in the / etc/publickey file, (see publickey (4)), NIS publickey map or NIS+ cred.org_dir table. If a new secret key is generated, it will be registered with the local keyserv (1M) daemon.				
	If the source of the publickey is not specified with the – s option, chkey consults the publickey entry in the name service switch configuration file (see nsswitch.conf (4)). If the publickey entry specifies one and only one source, then chkey will change the key in the specified name service. However, if multiple name services are listed, chkey can not decide which source to update and will display an error message. The user should specify the source explicitly with the – s option.				
	Non root us	ers are not allowed to change their key pair in the files database.			
OPTIONS	- p	Re-encrypt the existing secret key with the user's login password.			
	–s nisplus	Update the NIS + database.			
	–s nis	Update the NIS database.			
	-s files	Update the files database.			
FILES	/etc/nsswitc /etc/publick				
SEE ALSO		, keylogout(1), keyserv(1M), newkey(1M), nisaddcred(1M), nf(4), publickey(4), shadow(4)			

modified 22 Feb 1993

NAME	chmod – change	e the permis	sions mode of a file
SYNOPSIS	chmod [–fR] < chmod [–fR] <		
AVAILABILITY	SUNWcsu		
DESCRIPTION	•	0	he mode of a file. The mode of a file specifies its permissions ode may be absolute or symbolic.
Absolute mode	An absolute mod	de is specifie	d using octal numbers:
		nnnn file	0
	where:		
	n		er from 0 to 7 . An absolute mode is constructed from the OR f the following modes:
			Set user ID on execution. Set group ID on execution if $\#$ is 7, 5, 3, or 1. Enable mandatory locking if $\#$ is 6, 4, 2, or 0. For directories, files are created with BSD semantics for propagation of the group ID. With this option, files and subdirectories created in the directory inherit the group ID of the directory, rather than of the current process. It may be cleared only by using symbolic mode. Turn on sticky bit. See chmod (2). Allow read by owner. Allow write by owner. Allow write, and execute (search) by owner. Allow read, write, and execute (search) by owner. Allow read by group. Allow read by group. Allow write by group. Allow read, write, and execute (search) by group. Allow read by others. Allow read by others. Allow read by others. Allow read by others. Allow write by others. Allow read, write, and execute (search) by group. Allow read by others. Allow read, write, and execute (search) by others. Allow read, write, and execute (search) by others. Allow read by others. Allow read, write, and execute (search) by others.

Symbolic mode	A symbolic <i>mode</i>	specification	has the following format:		
	chmod <s< th=""><th colspan="4">chmod <<i>symbolic-mode-list</i> > <i>file</i></th></s<>	chmod < <i>symbolic-mode-list</i> > <i>file</i>			
	symbolic mode ex	where: < <i>symbolic-mode-list</i> > is a comma-separated list (with no intervening whitespace) of symbolic mode expressions of the form: [<i>who</i>] operator [<i>permissions</i>]			
			the order given. Multiple <i>permissions</i> letters following a sin- oonding operations to be performed simultaneously.		
	who		ore of the characters u , g , o , and a specifying whose permis- o be changed or assigned:		
		u g o a	user's permissions group's permissions others' permissions all permissions (user, group, and other)		
		tion mask into accou	mitted, it defaults to a , but the setting of the file mode crea- (see umask in $\mathbf{sh}(1)$ or $\mathbf{csh}(1)$ for more information) is taken int. When <i>who</i> is omitted, chmod will not override the res- f your user mask.		
	operator	either +, –,	, or =, signifying how permissions are to be changed:		
		+	Add permissions.		
			If <i>permissions</i> is omitted, nothing is added.		
			If <i>who</i> is omitted, add the file mode bits represented by <i>permissions, except</i> for the those with corresponding bits in the file mode creation mask.		
			If <i>who</i> is present, add the file mode bits represented by the <i>permissions</i> .		
		-	Take away permissions.		
			If <i>permissions</i> is omitted, do nothing.		
			If <i>who</i> is omitted, clear the file mode bits represented by <i>permissions, except</i> for those with corresponding bits in the file mode creation mask.		
			If <i>who</i> is present, clear the file mode bits represented by <i>permissions</i> .		
		=	Assign permissions absolutely.		
			If <i>who</i> is omitted, clear all file mode bits; if <i>who</i> is present, clear the file mode bits represented by <i>who</i> .		
			If <i>permissions</i> is omitted, do nothing else.		
			If <i>who</i> is omitted, add the file mode bits represented by <i>permissions, except</i> for the those with corresponding bits in the file mode creation mask.		

1-93

If *who* is present, add the file mode bits represented by *permissions*.

Unlike other symbolic operations, = has an absolute effect in that it resets all other bits represented by *who*. Omitting *permissions* is useful only with = to take away all permissions.

permission any compatible combination of the following letters:

r	read permission
W	write permission
Х	execute permission
1	mandatory locking
S	user or group set-ID
t	sticky bit
u,g,o	indicate that <i>permission</i> is to be taken from the current
-	user, group or other mode respectively.

Permissions to a file may vary depending on your user identification number (UID) or group identification number (GID). Permissions are described in three sequences each having three characters:

User Group Other rwx rwx rwx

This example (user, group, and others all have permission to read, write, and execute a given file) demonstrates two categories for granting permissions: the access class and the permissions themselves.

The letter **s** is only meaningful with **u** or **g**, and **t** only works with **u**.

Mandatory file and record locking (l) refers to a file's ability to have its reading or writing permissions locked while a program is accessing that file.

It is not possible to permit group execution and enable a file to be locked on execution at the same time. In addition, it is not possible to turn on the set-group-ID bit and enable a file to be locked on execution at the same time. The following examples, therefore, are invalid and elicit error messages:

```
chmod g+x,+l file
chmod g+s,+l file
```

Only the owner of a file or directory (or the super-user) may change that file's or directory's mode. Only the super-user may set the sticky bit on a non-directory file. If you are not super-user, **chmod** will mask the sticky-bit but will not return an error. In order to turn on a

	file's set-group-ID bit, your own group ID must correspond to the file's and group execution must be set.		
OPTIONS	The following options are supported:		
	-f Force. chmod will not complain if it fails to change the mode of a file.		
	 -R Recursively descend through directory arguments, setting the mode for each file as described above. When symbolic links are encountered, the mode of the target file is changed, but no recursion takes place. 		
OPERANDS	The following operands are supported:		
	<i>mode</i> Represents the change to be made to the file mode bits of each file named by one of the <i>file</i> operands; see DESCRIPTION .		
	<i>file</i> A path name of a file whose file mode bits are to be modified.		
EXAMPLES	Deny execute permission to everyone:		
	example% chmod a-x file		
	Allow only read permission to everyone:		
	example% chmod 444 file		
	Make a file readable and writable by the group and others:		
	example% chmod go+rw <i>file</i> example% chmod 066 <i>file</i>		
	Cause a file to be locked during access:		
	example% chmod +1 file		
	Allow everyone to read, write, and execute the file and turn on the set group-ID.		
	example% chmod a=rwx,g+s file example% chmod 2777 file		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of chmod : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
SEE ALSO	ls(1), chmod(2), environ(5)		
NOTES	Absolute changes don't work for the set-group-ID bit of a directory. You must use g+s or g-s . chmod permits you to produce useless modes so long as they are not illegal (for instance, making a text file executable). chmod does not check the file type to see if mandatory locking is meaningful.		
	1		

1-95

If the filesystem is mounted with the *nosuid* option, *setuid* execution is not allowed.

NAME	chown – change file ownership		
SYNOPSIS	chown [-fhR] owner[:group] file		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The chown utility will set the user ID of the file named by each <i>file</i> to the user ID specified by <i>owner</i> , and, optionally, will set the group ID to that specified by <i>group</i> .		
	If chown is invoked by other than the super-user, the set-user-ID bit is cleared.		
	Only the owner of a file (or the super-user) may change the owner of that file.		
	The operating system has a configuration option {_POSIX_CHOWN_RESTRICTED}, to retrict ownership changes. When this option is in effect the owner of the file is prevented from changing the owner ID of the file. Only the super-user can arbitrarily change own IDs whether or not this option is in effect.		
OPTIONS	The following options are supported:		
	-f Do not report errors.		
	-h If the file is a symbolic link, change the owner of the symbolic link. Without this option, the owner of the file referenced by the symbolic link is changed.		
	-R Recursive. chown descends through the directory, and any subdirectories, setting the ownership ID as it proceeds. When a symbolic link is encountered, the owner of the target file is changed (unless the -h option is specified), but no recursion takes place.		
OPERANDS	The following operands are supported:		
	owner[: group]A user ID and optional group ID to be assigned to file. The owner portion of this operand must be a user name from the user database or a numeric user ID. Either specifies a user ID to be given to each file named by file. If a numeric owner exists in the user database as a user name, the user ID number associated with that user name will be used as the user ID. Similarly, if the group portion of this operand is present, it must be a group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name will be used as the group ID.		
	file A path name of a file whose user ID is to be modified.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of chown : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 The utility executed successfully and all requested changes were made.		

	> 0 An error occurred.	
FILES	/etc/passwd system password file	
SEE ALSO	<pre>chgrp(1), chmod(1), chown(2), passwd(4), environ(5)</pre>	

SunOS 5.5	SunOS/BSD Compatibility Package Commands chown (1B)		
NAME	chown – change owner		
SYNOPSIS	/usr/ucb/chown [–fR] owner[.group] filename		
AVAILABILITY	SUNWscpu		
DESCRIPTION	chown changes the owner of the <i>filenames</i> to <i>owner</i> . The owner may be either a decimal user ID (UID) or a login name found in the password file. An optional <i>group</i> may also be specified. The group may be either a decimal group ID (GID) or a group name found in the GID file.		
	Only the super-user can change owner, in order to simplify accounting procedures.		
OPTIONS	- f Do not report errors.		
	 -R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed. 		
FILES	/etc/passwd password file		
SEE ALSO	chgrp(1), chown(2), group(4), passwd(4)		

NAME	ckdate, errdate, helpdate, valdate – prompts for and validates a date		
SYNOPSIS	ckdate [–Q] [–W width] [–f format] [–d default] [–h help] [–e error] [–p prompt] [–k pid [–s signal]]		
	/usr/sadm/bin/errdate [–W width] [–e error] [–f format]		
	/usr/sadm/bin/helpdate [–Wwidth] [–h help] [–f format]		
	/usr/sadm/bin/valdate [–f format] input		
AVAILABILITY	SUNWcsu		
DESCRIPTION	ckdate prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a date, text for help and error messages, and a default value (which will be returned if the user responds with a RETURN). The user response must match the defined format for a date.		
	All messages are limited in length to 70 characters and are formatted automatically. An white space used in the definition (including newline) is stripped. The – W option cance the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.		
	Three visual tool modules are linked to the ckdate command. They are errdate (which formats and displays an error message), helpdate (which formats and displays a help message), and valdate (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <i>format</i> is defined in the errdate and helpdate modules, the messages will describe the expected format.		
OPTIONS	$-\mathbf{Q}$ Specifies that quit will not be allowed as a valid response. $-\mathbf{W}$ widthSpecifies that prompt, help and error messages will be formatted to a line length of width. $-\mathbf{f}$ formatSpecifies the format against which the input will be verified. Possible formats and their definitions are: $\% \mathbf{b}$ = abbreviated month name (jan, feb, mar) $\% \mathbf{B}$ = full month name %d = day of month (01 - 31) $\% \mathbf{D}$ = date as $\% \mathbf{m}/\% \mathbf{d}/\%$ y (the default format) 		

	- d default	Defines the default value as <i>default</i> . The default does not have to meet	
		the format criteria.	
	–h help	Defines the help messages as <i>help</i> .	
	-e error	Defines the error message as <i>error</i> .	
	- p prompt	Defines the prompt message as <i>prompt</i> .	
	− k pid	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.	
	–s signal	Specifies that the process ID <i>pid</i> defined with the –k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.	
	input	Input to be verified against format criteria.	
EXIT CODES	0	Successful execution	
	1	EOF on input	
		or negative width on –W option,	
		or usage error	
	3	User termination (quit)	
	4	Garbled format argument	
NOTES	The default pro	ompt for ckdate is:	
	Enter the date [?,q]:		
	The default error message is:		
	 ERROR - Please enter a date. Format is <format>.</format> The default help message is: Please enter a date. Format is <format>.</format> When the quit option is chosen (and allowed), q is returned along with the return code 3. The valdate module will not produce any output. It returns zero for success and non-zero for failure. 		

NAME	ckgid, errgid, helpgid, valgid – prompts for and validates a group id		
SYNOPSIS	ckgid [–Q] [–W width] [–m] [–d default] [–h help] [–e error] [–p prompt] [–k pid [–s signal]]		
		errgid [–W width] [–e error] helpgid [–W width] [–m] [–h help] valgid input	
AVAILABILITY	SUNWcsu		
DESCRIPTION	ckgid prompts a user and validates the response. It defines, among other things, a prompt message whose response should be an existing group ID, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).		
	All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The $-W$ option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.		
	mats and displa sage), and valg	ol modules are linked to the ckgid command. They are errgid (which for- ays an error message), helpgid (which formats and displays a help mes- id (which validates a response). These modules should be used in con- ML objects. In this instance, the FML object defines the prompt.	
OPTIONS	–Q –W width –m	Specifies that quit will not be allowed as a valid response. Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> . Displays a list of all groups when help is requested or when the user	
	- d default	makes an error. Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	
	–h help	Defines the help messages as <i>help</i> .	
	-e error	Defines the error message as <i>error</i> .	
	– p prompt – k pid	Defines the prompt message as <i>prompt</i> . Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.	
	–s signal	Specifies that the process ID <i>pid</i> defined with the $-\mathbf{k}$ option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is	
	input	used. Input to be verified against / etc/group .	

EXIT CODES	0 1 3	Successful execution EOF on input or negative width on – W option, or usage error User termination (quit)
NOTES	Enter t The default err ERROF If the –m optio The default hel ERROF If the –m optio When the quit	ompt for ckgid is: he name of an existing group [?,q]: or message is: 3: Please enter one of the following group names: [<i>List</i>] n of ckgid is used, a list of valid groups is displayed here.

NAME	ckint, errint, helpint, valint – display a prompt; verify and return an integer value		
SYNOPSIS		W width] [–b base] [–d default] [–h help] [–e error] [–p prompt] –s signal]]	
	/usr/sadm/bin/	errint [–W width] [–b base] [–e error] helpint [–W width] [–b base] [–h help] valint [–b base] input	
AVAILABILITY	SUNWcsu		
DESCRIPTION	prompt messag	a user, then validates the response. It defines, among other things, a ge whose response should be an integer, text for help and error messages, alue (which will be returned if the user responds with a carriage return).	
	All messages are limited in length to 70 characters and are formatted automatical white space used in the definition (including newline) is stripped. The –W option the automatic formatting. When a tilde is placed at the beginning or end of a mes definition, the default text will be inserted at that point, allowing both custom tex the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.		
	Three visual tool modules are linked to the ckint command. They are errint (which for- mats and displays an error message), helpint (which formats and displays a help mes- sage), and valint (which validates a response). These modules should be used in con- junction with FML objects. In this instance, the FML object defines the prompt. When <i>base</i> is defined in the errint and helpint modules, the messages will include the expected base of the input.		
OPTIONS	$-\mathbf{Q}$	Specifies that quit will not be allowed as a valid response.	
	- W width	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .	
	- b base	Defines the base for input. Must be 2 to 36 , default is 10 .	
	-d default	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	
	– h help	Defines the help messages as <i>help</i> .	
	-e error	Defines the error message as <i>error</i> .	
	– p prompt	Defines the prompt message as <i>prompt</i> .	
	– k pid	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.	

	–s signal input	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used. Input to be verified against <i>base</i> criterion.	
EXIT CODES	0	Successful execution	
	1	EOF on input, or negative width on $-\mathbf{W}$ option, or usage error	
	3	User termination (quit)	
NOTES	The default base 10 prompt for ckint is:		
	Enter an integer [?,q]:		
	The default bas	e 10 error message is:	
	ERROR - Pl	ease enter an integer.	
	The default bas	e 10 help message is:	
	Please enter an integer.		
	The messages are changed from "integer" to "base <i>base</i> integer" if the base is set to a number other than 10.		
		option is chosen (and allowed), \mathbf{q} is returned along with the return code 3. ule will not produce any output. It returns 0 for success and non-zero for	

NAME	ckitem, erritem, helpitem – build a menu; prompt for and return a menu item		
SYNOPSIS	<pre>ckitem [-Q] [-W width] [-uno] [-f filename] [-l label] [[-i invis] [,]] [-m max] [-d default] [-h help] [-e error] [-p prompt] [-k pid [-s signal]] [choice []] /usr/sadm/bin/erritem [-W width] [-e error] [choice []] /usr/sadm/bin/helpitem [-W width] [-h help] [choice []]</pre>		
AVAILABILITY	SUNWcsu		
DESCRIPTION	ckitem builds a menu and prompts the user to choose one item from a menu of items. It then verifies the response. Options for this command define, among other things, a prompt message whose response will be a menu item, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).		
	By default, the menu is formatted so that each item is prepended by a number and is printed in columns across the terminal. Column length is determined by the longest choice. Items are alphabetized.		
	All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The – W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.		
	Two visual tool modules are linked to the ckitem command. They are erritem (which formats and displays an error message) and helpitem (which formats and displays a help message). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <i>choice</i> is defined in these modules, the messages will describe the available menu choice (or choices).		
OPTIONS	-Q Specify that quit will not be allowed as a valid response.		
	 -W width Specify that prompt, help and error messages will be formatted to a line length of width. 		
	-u Specify that menu items should be displayed as an unnumbered list.		
	- n Specify that menu items should not be displayed in alphabetical order.		
	-o Specify that only one menu token will be returned.		
	 <i>-f filename</i> Define a file, <i>filename</i>, which contains a list of menu items to be displayed. (The format of this file is: token<tab>description. Lines beginning with a pound sign (#) are designated as comments and ignored.)</tab> 		
	-l <i>label</i> Define a label, <i>label</i> , to print above the menu.		

	− i invis	Define invisible menu choices (those which will not be printed in the menu). (For example, "all" used as an invisible choice would mean it is a legal option but does not appear in the menu. Any number of invisible choices may be defined.) Invisible choices should be made known to a user either in the prompt or in a help message.
	- m max	Define the maximum number of menu choices that the user can choose. The default is 1.
	- d default	Define the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.
	– h help	Define the help messages as <i>help</i> .
	-e error	Define the error message as <i>error</i> .
	– p prompt	Define the prompt message as <i>prompt</i> .
	– k pid	Specify that the process ID <i>pid</i> is to be sent a signal if the user chooses to abort.
	– s signal	Specify that process ID <i>pid</i> defined with the – k option is to be sent signal sig-nal when quit is chosen. If no signal is specified, SIGTERM is used.
	choice	Define menu items. Items should be separated by white space or newline.
EXIT CODES	0	Successful execution
	1	EOF on input, or negative width on –W option, or inability to open file on –f option, or usage error
	3	User termination (quit)
	4	No choices from which to choose
NOTES		nay input the number of the menu item if choices are numbered or as much of required for a unique identification of the item. Long menus are paged with 10 page.
	command used to su	nu entries are defined both in a file (by using the $-\mathbf{f}$ option) and also on the line, they are usually combined alphabetically. However, if the $-\mathbf{n}$ option is ppress alphabetical ordering, then the entries defined in the file are shown first, by the options defined on the command line.
	The defaul	lt prompt for ckitem is:
	Enter	selection [?,??,q]:
		ion mark will give a help message and then redisplay the prompt. Two ques- s will give a help message and then redisplay the menu label, the menu and the
	The defaul	lt error message if you typed a number is:
	ER	ROR: Bad numeric choice specification

The default error message if you typed a string is:

ERROR: Entry does not match available menu selection. Enter the number of the menu item you wish to select, the token which is associated with the menu item, or a partial string which uniquely identifies the token for the menu item. Enter ?? to reprint the menu.

The default help message is:

Enter the number of the menu item you wish to select, the token which is associated with the menu item, or a partial string which uniquely identifies the token for the menu item. Enter ?? to reprint the menu.

When the quit option is chosen (and allowed), **q** is returned along with the return code **3**.

NAME	ckkeywd – pro	mpts for and validates a keyword	
SYNOPSIS	ckkeywd [–Q] [–W width] [–d default] [–h help] [–e error] [–p prompt] [–k pid [–s signal]] keyword []		
AVAILABILITY	SUNWcsu		
DESCRIPTION	ckkeywd prompts a user and validates the response. It defines, among other things, a prompt message whose response should be one of a list of keywords, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return). The answer returned from this command must match one of the defined list of keywords.		
	All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The –W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, h NOTES) will be	help or error message is not defined, the default message (as defined under e displayed.

User Commands

NAME	ckpath, errpatł	n, helppath, valpath – display a prompt; verify and return a pathname	
SYNOPSIS	ckpath [-Q] [-W width] [-a l] [-b c f y] [-n [o z]] [-rtwx] [-d default] [-h help] [-e error] [-p prompt] [-k pid [-s signal]]		
		'errpath [−W width] [−a l] [−b c f y] [−n [o z]] [−e error]	
		helppath [–W <i>width</i>] [–a l] [–b c f y] [–n [o z]] [–h <i>help</i>]	
	/usr/sadm/bin/	valpath [–a l] [–b c f y] [–n [o z]] [–rtwx] input	
AVAILABILITY	SUNWcsu		
DESCRIPTION	prompt messag	ts a user and validates the response. It defines, among other things, a ge whose response should be a pathname, text for help and error messages, alue (which is returned if the user responds with a RETURN).	
	is defined, the	must obey the criteria specified by the first group of options. If no criteria pathname must be for a normal file that does not yet exist. If neither $-\mathbf{a}$ (relative) is given, then either is assumed to be valid.	
	and newlines a but spaces are	re limited in length to 79 characters and are formatted automatically. Tabs re removed after a single white space character in a message definition, not removed. When a tilde is placed at the beginning or end of a message default text is inserted at that point, allowing both custom text and the be displayed.	
	If the prompt, EXAMPLES) is	help or error message is not defined, the default message (as defined under s displayed.	
	formats and di and displays a response). The	ol modules are linked to the ckpath command. They are errpath (which splays an error message on the standard output), helppath (which formats help message on the standard output), and valpath (which validates a see modules should be used in conjunction with Framed Access Command FACE) objects. In this instance, the FACE object defines the prompt.	
OPTIONS	$-\mathbf{Q}$	Specify that quit is not allowed as a valid response.	
	-W width	Specify that prompt, help and error messages be formatted to a line length of <i>width</i> .	
	-a	Pathname must be an absolute path.	
	- l	Pathname must be a relative path.	
	-b	Pathname must be a block special file.	
	- c	Pathname must be a character special file.	
	$-\mathbf{f}$	Pathname must be a regular file.	
	- y	Pathname must be a directory.	

modified 14 Sep 1992

	n	Pathname must not exist (must be new).	
	- o	Pathname must exist (must be old).	
	-z	Pathname must have a file having a size greater than 0 bytes.	
		Pathname must be readable.	
	-r -t	Pathname must be creatable (touchable). Pathname will be created if it	
	-1	does not already exist.	
	$-\mathbf{w}$	Pathname must be writable.	
	- x	Pathname must be executable.	
	− d default	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	
	–h help	Defines the help message as <i>help</i> .	
	-e error	Defines the error message as error.	
	– p prompt	Defines the prompt message as <i>prompt</i> .	
	− k pid	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.	
	–s signal	Specifies that the process ID <i>pid</i> defined with the –k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.	
	input	Input to be verified against validation options.	
EXIT CODES	0	Successful execution	
	1	EOF on input, or negative width on $-\mathbf{W}$ option, or usage error	
	2	Mutually exclusive options	
	3	User termination (quit)	
	4	Mutually exclusive options	
EXAMPLES	PLES The text of the default messages for ckpath depends upon the criteria op been used. An example default prompt for ckpath (using the – a option)		
	example% ckpath –a Enter an absolute pathname [?,q]		
	An example de	fault error message (using the $-\mathbf{a}$ option) is:	
	example% /usr/sadm/bin/errpath –a ERROR: A pathname is a filename, optionally preceded by parent directories. The pathname you enter: - must begin with a slash (/)		
	-	fault help message (using the $-\mathbf{a}$ option) is:	
	-	le% /usr/sadm/bin/helppath –a	
	A path	name is a filename, optionally preceded by parent directories. thname you enter: - must begin with a slash (/)	
	I		

When the quit option is chosen (and allowed), \bf{q} is returned along with the return code $\bf{3}$. Quit input gets a trailing newline.

The **valpath** module will produce a usage message on stderr. It returns **0** for success and non-zero for failure.

example% /usr/sadm/bin/valpath usage: valpath [–[a | l][b | c | f | y][n | [o | z]]rtwx] input

NAME	ckrange, errang	e, helprange, valrange – prompts for and validates an integer	
SYNOPSIS	ckrange [– Q] [– W width] [– l lower] [– u upper] [– b base] [– d default] [– h help] [– e error] [– p prompt] [– k pid [– s signal]]		
	/usr/sadm/bin/	errange [–W width] [–e error] [–l lower] [–u upper] [–b base]	
	/usr/sadm/bin/l	helprange [–W width] [–h help] [–l lower] [–u upper] [–b base]	
	/usr/sadm/bin/v	valrange [–l lower] [–u upper] [–b base] input	
AVAILABILITY	SUNWcsu		
DESCRIPTION	this response is should be an in	ts a user for an integer between a specified range and determines whether valid. It defines, among other things, a prompt message whose response teger in the range specified, text for help and error messages, and a vhich is returned if the user responds with a RETURN).	
		also defines a range for valid input. If either the lower or upper limit is then the range is bounded on only one end.	
	All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single whitespace character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under EXAMPLES) is displayed.		
	formats and dis mats and displa dates a respons	ol modules are linked to the ckrange command. They are errange (which splays an error message on the standard output), helprange (which for- ays a help message on the standard output), and valrange (which vali- e). These modules should be used in conjunction with Framed Access ironment (FACE) objects. In this instance, the FACE object defines the	
	the argument, g	e "input" arguments confuse getopt in valrange . By inserting a "" before getopt processing will stop. See getopt (1) and intro (1) about getopt lling. getopt is used to parse positional parameters and to check for legal	
OPTIONS	$-\mathbf{Q}$	Specifies that quit will not be allowed as a valid response.	
	–W width	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .	
	-l lower	Defines the lower limit of the range as <i>lower</i> . Default is the machine's largest negative long.	

	– u upper	Defines the upper limit of the range as <i>upper</i> . Default is the machine's largest positive long.	
	- b base	Defines the base for input. Must be 2 to 36, default is 10. Base conversion uses strtol (3C). Output is always base 10.	
	– d default	Defines the default value as <i>default</i> . <i>default</i> is converted using strtol (3C) in the desired base. Any characters invalid in the specified base will terminate the strtol conversion without error.	
	–h help	Defines the help message as <i>help</i> .	
	-e error	Defines the error message as <i>error</i> .	
	- p prompt	Defines the prompt message as <i>prompt</i> .	
	− k pid	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.	
	–s signal	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.	
	input	Input to be verified against upper and lower limits and base.	
EXIT CODES	0	Successful execution	
	1	EOF on input, or negative width on $-\mathbf{W}$ option, or usage error	
	2	Usage error	
	3	User termination (quit)	
EXAMPLES	The default bas	e 10 prompt for ckrange is:	
	example% ckrange Enter an integer between lower_bound and upper_bound [lower_bound–upper_bound,?,q]:		
	The default base 10 error message is:		
	example% /usr/sadm/bin/errange ERROR: Please enter an integer between lower_bound and upper_bound.		
	The default base 10 help message is:		
	example% /usr/sadm/bin/helprange Please enter an integer between <i>lower_bound</i> and <i>upper_bound</i> .		
	The messages are changed from "integer" to "base <i>base</i> integer" if the base is set to a number other than 10, for example, example % / usr/sadm/bin/helprange – b 36.		
		option is chosen (and allowed), q is returned along with the return code 3 . a trailing newline.

NAME	ckstr, errstr, he	lpstr, valstr – display a prompt; verify and return a string answer	
SYNOPSIS	ckstr [– Q] [– W width] [[– r regexp] []] [– l length] [– d default] [– h help] [– e error] [– p prompt] [– k pid [– s signal]]		
	/usr/sadm/bin/	errstr [–W width] [–e error] [–l length] [[–r regexp] []]	
	/usr/sadm/bin/	'helpstr [–W width] [–h help] [–l length] [[–r regexp] []]	
	/usr/sadm/bin/	valstr [–l length] [[–r regexp] []] input	
AVAILABILITY	SUNWcsu		
DESCRIPTION	prompt messag	a user and validates the response. It defines, among other things, a ge whose response should be a string, text for help and error messages, alue (which are returned if the user responds with a RETURN).	
	The answer returned from this command must match the defined regular expression and be no longer than the length specified. If no regular expression is given, valid input must be a string with a length less than or equal to the length defined with no internal, leading or trailing white space. If no length is defined, the length is not checked.		
	All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single white space character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under EXAMPLES) is displayed.		
	mats and displ displays a help These modules	ol modules are linked to the ckstr command. They are errstr (which for- ays an error message on the standard output), helpstr (which formats and message on the standard output), and valstr (which validates a response). should be used in conjunction with Framed Access Command Environ- ojects. In this instance, the FACE object defines the prompt.	
OPTIONS	$-\mathbf{Q}$	Specifies that quit will not be allowed as a valid response.	
	-W width	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .	
	–r regexp	Specifies a regular expression, regexp , against which the input should be validated. May include white space. If multiple expressions are defined, the answer need match only one of them.	
	–l length	Specifies the maximum length of the input.	
	- d default	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	
	– h help	Defines the help message as <i>help</i> .	
	-e error	Defines the error message as <i>error</i> .	

	– p prompt	Defines the prompt message as <i>prompt</i> .	
	– k pid	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.	
	–s signal	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.	
	input	Input to be verified against format length and/or regular expression criteria.	
EXIT CODES	0	Successful execution	
	1	EOF on input, or negative width on $-\mathbf{W}$ option, or usage error	
	2	Invalid regular expression	
	3	User termination (quit)	
EXAMPLES	The default pro	ompt for ckstr is:	
	example% ckstr Enter an appropriate value [?,q]:		
	The default error message is dependent upon the type of validation involved. The will be told either that the length or the pattern matching failed. The default error sage is:		
	example% /usr/sadm/bin/errstr ERROR: Please enter a string which contains no embedded, leading or trailing spaces or tabs.		
	The default help message is also dependent upon the type of validation involved. If a regular expression has been defined, the message is:		
	example% /usr/sadm/bin/helpstr –r regexp Please enter a string which matches the following pattern: regexp Other messages define the length requirement and the definition of a string. When the quit option is chosen (and allowed), q is returned along with the return co- Quit input gets a trailing newline.		
	The valstr mod non-zero for fa	ule will produce a usage message on stderr. It returns 0 for success and ilure.

SEE ALSO	face(1), signal(5)	

NAME	cksum – write file checksums and sizes		
SYNOPSIS	cksum [file]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The cksum command calculates and writes to standard output a cyclic redundancy checl (CRC) for each input file, and also writes to standard output the number of octets in each file.		
	For each file processed successfully, cksum will write in the following format:		
	"%u %d %s\n" <checksum>, <# of octets>, <path name=""></path></checksum>		
	If no <i>file</i> operand was specified, the path name and its leading space will be omitted.		
	The CRC used is based on the polynomial used for CRC error checking in the referenced Ethernet standard.		
	The encoding for the CRC checksum is defined by the generating polynomial: $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$		
	Mathematically, the CRC value corresponding to a given file is defined by the following procedure:		
	1. The <i>n</i> bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These <i>n</i> bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer is used.		
	2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31 .		
	3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.		
	4. The bit sequence is complemented and the result is the CRC.		
OPERANDS	The following operand is supported:		
	<i>file</i> A path name of a file to be checked. If no <i>file</i> operands are specified, the stan- dard input is used.		
USAGE	The cksum command is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are astronomically small; deliberate deception is difficult, but probably not impossible.		

cksum	(1)	
-------	---	---	---	--

	Although input files to cksum can be any type, the results need not be what would be expected on character special device files. Since this document does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.
	The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as moving 8-bit characters into 9-bit bytes or changing "Little Endian" byte ordering to "Big Endian"), identical CRC values cannot be expected. Implementations performing such transformations may extend cksum to handle such situations.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cksum : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 All files were processed successfully.
	>0 An error occurred.
SEE ALSO	sum(1), environ(5)

NAME	cktime, errtime, helptime, valtime – display a prompt; verify and return a time of day		
SYNOPSIS	cktime [–Q] [–W width] [–f format] [–d default] [–h help] [–e error] [–p prompt] [–k pid [–s signal]]		
	/usr/sadm/bin/errtime [–W width] [–e error] [–f format]		
	/usr/sadm/bin/helptime [–W width] [–h help] [–f format]		
	/usr/sadm/bin/valtime [–f format] input		
AVAILABILITY	SUNWcsu		
DESCRIPTION	cktime prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a time, text for help and error messages, and a default value (which is returned if the user responds with a RETURN). The user response must match the defined format for the time of day.		
	All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including NEWLINE) is stripped. The – W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.		
	If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.		
	Three visual tool modules are linked to the cktime command. They are errtime (which formats and displays an error message), helptime (which formats and displays a help message), and valtime (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <i>format</i> is defined in the errtime and helptime modules, the messages will describe the expected format.		
OPTIONS	-QSpecifies that quit will not be allowed as a valid responseW widthSpecifies that prompt, help and error messages will be formatted to a line length of widthf formatSpecifies the format against which the input will be verified. Possible formats and their definitions are:		
	%H = hour (00 - 23) %I = hour (00 - 12) %M = minute (00 - 59) %p = ante meridian or post meridian %r = time as %I:%M:%S %p %R = time as %H:%M (the default format) %S = seconds (00 - 59) %T = time as %H:%M:%S		

	-d default -h help -e error -p prompt -k pid -s signal input	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria. Defines the help messages as <i>help</i> . Defines the error message as <i>error</i> . Defines the prompt message as <i>prompt</i> . Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort. Specifies that the process ID <i>pid</i> defined with the – k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used. Input to be verified against format criteria.
EXIT CODES	0	Successful execution
	1	EOF on input, or negative width on – W option, or usage error
	3	User termination (quit)
	4	Garbled format argument
NOTES	The default pro	ompt for cktime is:
	Enter a	time of day [?,q]:
	The default err	or message is:
		: Please enter the time of day. Format is <i><format></format></i> .
	The default hel	p message is:
	Please	enter the time of day. Format is <format>.</format>
		option is chosen (and allowed), q is returned along with the return code 3 . odule will not produce any output. It returns 0 for success and non-zero

NAME	ckuid, erruid, h	elpuid, valuid – prompts for and validates a user ID
SYNOPSIS	–k <i>pid</i> – /usr/sadm/bin/e	erruid [–W width] [–e error] nelpuid [–W width] [–m] [–h help]

	–s signal	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal signal when quit is chosen. If no signal is specified, SIGTERM is used.
	input	Input to be verified as y , yes , or n , no (in any combination of upper- and lower-case letters).

EXIT CODES	0 Successful execution
	1 EOF on input, or negative width on –W option, or usage error
	2 Usage error
	3 User termination (quit)
NOTES	The default prompt for ckyorn is:
	Yes or No [y,n,?,q]:
	The default error message is:
	ERROR - Please enter yes or no.
	The default help message is:
	To respond in the affirmative, enter y, yes, Y, or YES. To respond in the negative, enter n, no, N, or NO.
	When the quit option is chosen (and allowed), q is returned along with the return code 3 . The valyorn module will not produce any output. It returns 0 for success and non-zero for failure.

NAME	clear – clear the terminal screen
SYNOPSIS	clear
AVAILABILITY	SUNWcsu
DESCRIPTION	clear clears your screen if this is possible. It looks in the environment for the terminal type and then in the terminfo database to figure out how to clear the screen.

NAME	cmp – compare two files
SYNOPSIS	cmp [– l] [– s] file1 file2 [skip1] [skip2]
AVAILABILITY	SUNWcsu
DESCRIPTION	The cmp utility compares two files. cmp will write no output if the files are the same. Under default options, if they differ, it writes to standard output the byte and line numbers at which the first difference occurred. Bytes and lines are numbered beginning with 1. If one file is an initial subsequence of the other, that fact is noted. <i>skip1</i> and <i>skip2</i> are initial byte offsets into <i>file1</i> and <i>file2</i> respectively, and may be either octal or decimal; a leading 0 denotes octal.
OPTIONS	-I Write the byte number (decimal) and the differing bytes (octal) for each difference.
	- s Write nothing for differing files; return exit statuses only.
OPERANDS	The following operands are supported:
	<i>file1</i> A path name of the first file to be compared. If <i>file1</i> is –, the standard input will be used.
	<i>file2</i> A path name of the second file to be compared. If <i>file2</i> is –, the standard input will be used.
	If both <i>file1</i> and <i>file2</i> refer to standard input or refer to the same FIFO special, block special or character special file, an error results.
EXAMPLES	The following example: example% cmp file1 file2 0 1024
	does a byte for byte comparison of file1 and file2 . It skips the first 1024 bytes in file2 before starting the comparison.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cmp : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following error values are returned:
	0 The files are identical.
	1 The files are different; this includes the case where one file is identical to the first part of the other.
	>1 An error occurred.
SEE ALSO	<pre>comm(1), diff(1), environ(5)</pre>

1-128

NAME	col – reverse line-feeds filter		
SYNOPSIS	col [-bfpx]		
AVAILABILITY	SUNWesu		
DESCRIPTION	The col utility reads from the standard input and writes to the standard output. It performs the line overlays implied by reverse line-feeds, and by forward and reverse half-line-feeds. Unless $-\mathbf{x}$ is used, all blank characters in the input will be converted to tab characters wherever possible. col is particularly useful for filtering multi-column output made with the .rt command of nroff (1) and output resulting from use of the tbl (1) preprocessor.		
	The ASCII control characters SO and SI are assumed by col to start and end text in an alternative character set. The character set to which each input character belongs is remembered, and on output SI and SO characters are generated as appropriate to ensure that each character is written in the correct character set.		
	On input, the only control characters accepted are space, backspace, tab, carriage-return and newline characters, SI, SO, VT, reverse line-feed, forward half-line-feed and reverse half-line-feed. The VT character is an alternative form of full reverse line-feed, included for compatibility with some earlier programs of this type. The only other characters to be copied to the output are those that are printable.		
	The ASCII codes for the control functions and line-motion sequences mentioned above are as given in the table below. ESC stands for the ASCII escape character, with the octal code 033; ESC- means a sequence of two characters, ESC followed by the character x. reverse line-feedESC-7 reverse half-line-feedreverse half-line-feedESC-7 reverse half-line-feedESC-9 vertical-tab (VT)otal table below.013 start-of-text (SO)016 end-of-text (SI)		
OPTIONS	-b Assume that the output device in use is not capable of backspacing. In this case, if two or more characters are to appear in the same place, only the last one read will be output.		
	 -f Although col accepts half-line motions in its input, it normally does not emit them on output. Instead, text that would appear between lines is moved to the next lower full-line boundary. This treatment can be suppressed by the -f (fine) option; in this case, the output from col may contain forward half-line-feeds (ESC-9), but will still never contain either kind of reverse line motion. 		
	 -p Normally, col will ignore any escape sequences unknown to it that are found in its input; the -p option may be used to cause col to output these sequences as regular characters, subject to overprinting from reverse line motions. The 		

col(1)	User Commands SunOS 5.5
	use of this option is highly discouraged unless the user is fully aware of the textual position of the escape sequences.
	- x Prevent col from converting blank characters to tab characters on output wherever possible. Tab stops are considered to be at each column position <i>n</i> such that <i>n</i> modulo 8 equals 1.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of col : LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	The following error values are returned:
	0 Successful completion.
	>0 An error occurred.
SEE ALSO	nroff (1), tbl (1), ascii (5), environ (5)
NOTES	The input format accepted by col matches the output produced by nroff with either the –T37 or –Tlp options. Use –T37 (and the –f option of col) if the ultimate disposition of the output of col will be a device that can interpret half-line motions, and –Tlp otherwise.
	col cannot back up more than 128 lines or handle more than 800 characters per line.
	Local vertical motions that would result in backing up over the first line of the document are ignored. As a result, the first line must not have any superscripts.

NAME	comm – select or reject lines common to two files		
SYNOPSIS	comm [–123] file1 file2		
AVAILABILITY	SUNWesu		
DESCRIPTION	The comm utility will read <i>file1</i> and <i>file2</i> , which should be ordered in the current collating sequence, and produce three text columns as output: lines only in <i>file1</i> ; lines only in <i>file2</i> ; and lines in both files. If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.		
OPTIONS	The following options are supported:		
	-1 Suppress the output column of lines unique to <i>file1</i> .		
	-2 Suppress the output column of lines unique to <i>file2</i> .		
	-3 Suppress the output column of lines duplicated in <i>file1</i> and <i>file2</i> .		
OPERANDS	The following operands are supported:		
	<i>file1</i> A path name of the first file to be compared. If <i>file1</i> is –, the standard input is used.		
	<i>file2</i> A path name of the second file to be compared. If <i>file2</i> is –, the standard input is used.		
EXAMPLES	If <i>file1</i> , <i>file2</i> , and <i>file3</i> each contained a sorted list of utilities: example% comm -23 <i>file1 file2</i> comm -23 - <i>file3</i> would print a list of utilities in <i>file1</i> not specified by either of the other files; example% comm -12 <i>file1 file2</i> comm -12 - <i>file3</i> would print a list of utilities specified by all three files; and example% comm -12 <i>file2 file3</i> comm -23 - <i>file1</i> would print a list of utilities specified by both <i>file2</i> and <i>file3</i> , but not specified in <i>file1</i> .		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of comm : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 All input files were successfully output as specified.		
	>0 An error occurred.		
SEE ALSO	cmp(1), diff(1), sort(1), uniq(1)		

NAME	command – execute a simple command		
SYNOPSIS	command [-p] command_name [argument] command [-v -V] command_name		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The command utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup.		
	If the <i>command_name</i> is the same as the name of one of the special built-in utilities, the special properties will not occur. In every other respect, if <i>command_name</i> is not the nation of a function, the effect of command will be the same as omitting command .		
	The command utility also provides information concerning how a command name will be interpreted by the shell; see $-\mathbf{v}$ and $-\mathbf{V}$.		
OPTIONS	The following options are supported:		
	- p Perform the command search using a default value for PATH that is guaranteed to find all of the standard utilities.		
	 -v Write a string to standard output that indicates the path or command that will be used by the shell, in the current shell execution environment to invoke <i>command_name</i>. 		
	 Utilities, regular built-in utilities, <i>command_names</i> including a slash character, and any implementation-provided functions that are found using the PATH variable will be written as absolute path names. 		
	• Shell functions, special built-in utilities, regular built-in utilities not associ- ated with a PATH search, and shell reserved words will be written as just their names.		
	• An alias will be written as a command line that represents its alias definition.		
	• Otherwise, no output will be written and the exit status will reflect that the name was not found.		
	-V Write a string to standard output that indicates how the name given in the <i>command_name</i> operand will be interpreted by the shell, in the current shell execution environment. Although the format of this string is unspecified, it will indicate in which of the following categories <i>command_name</i> falls and include the information stated:		
	• Utilities, regular built-in utilities, and any implementation-provided func- tions that are found using the PATH variable will be identified as such and include the absolute path name in the string.		
	• Other shell functions will be identified as functions.		
	• Aliases will be identified as aliases and their definitions will be included in		

	 the string. Special built-in utilities will be identified as special built-in utilities. Regular built-in utilities not associated with a PATH search will be identified as regular built-in utilities. Shell reserved words will be identified as reserved words. 		
OPERANDS	The following operands are supported:		
	<i>argument</i> One of the strings treated as an argument to <i>command_name</i> .		
	<i>command_name</i> The name of a utility or a special built-in utility.		
EXAMPLES	1. Make a version of cd that always prints out the new working directory exactly once cd() {		
	 Start off a ''secure shell script'' in which the script avoids being spoofed by its parent: IFS=' 		
	 # The preceding value should be <space><tab><newline>.</newline></tab></space> # Set IFS to its default value. 		
	 \unalias -a # Unset all possible aliases. # Note that unalias is escaped to prevent an alias # being used for unalias. 		
	unset -f command # Ensure command is not a user function.		
	PATH="\$(command -p getconf _CS_PATH):\$PATH" # Put on a reliable PATH prefix.		
	#		
	At this point, given correct permissions on the directories called by PATH , the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this document, but it is not prohibited as an extension. For example, the ENV variable precedes the invocation of the script with a user startup script. Such a script could define functions to spoof the application.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of command: LC_CTYPE , LC_MESSAGES , and NLSPATH .		
	PATHDetermine the search path used during the command search, except as described under the $-\mathbf{p}$ option.		

EXIT STATUS	When the $-\mathbf{v}$ or $-\mathbf{V}$ options are specified, the following exit values are returned:		
	0	0 Successful completion.	
	>0 The <i>command_name</i> could not be found or an error occurred.		
	Otherwise, the following exit values are returned:		
	126	126 The utility specified by <i>command_name</i> was found but could not be invoked.	
	127 An error occurred in the command utility or the utility specified by <i>command_name</i> could not be found.		
	Otherwise, the exit status of command will be that of the simple command specified by the arguments to command .

	>2 An error occurred.		
SEE ALSO	ln (1), pack (1)		
DIAGNOSTICS	Usage: compress [-fvc] [-b maxbits] [<i>file</i>] Invalid options were specified on the command line.		
	Missing maxbits Maxbits must follow – b , or invalid maxbits, not a nu	meric value.	
	<i>file</i> : not in compressed format The file specified to uncompress has not been compre	essed.	
	<i>file</i> : compressed with <i>xx</i> bits , can only handle <i>yy</i> bits <i>file</i> was compressed by a program that could deal wit compress code on this machine. Recompress the file		
	<i>file</i> : already has . Z suffix no change The file is assumed to be already compressed. Renam	ne the file and try again.	
	<i>file</i> : already exists; do you wish to overwrite (y or n)? Respond y if you want the output file to be replaced;	n if not.	
	uncompress: corrupt input A SIGSEGV violation was detected, which usually m corrupted.	neans that the input file is	

	Compression: $xx.xx\%$ Percentage of the input saved by compression. (Relevant only for $-v$.)
	– not a regular file: unchanged When the input file is not a regular file, (such as a directory), it is left unal- tered.
	– has xx other links: unchanged The input file has links; it is left unchanged. See ln(1) for more information.
	– – file unchanged No savings are achieved by compression. The input remains uncompressed.
	filename too long to tack on .Z The path name is too long to append the .Z suffix.
NOTES	Although compressed files are compatible between machines with large memory, – b 12 should be used for file transfer to architectures with a small process data space (64KB or less).
	compress should be more flexible about the existence of the . Z suffix.

NAME	coproc, cocreate, cosend, cocheck, coreceive, codestroy – communicate with a process
SYNOPSIS	cocreate [–r rpath] [–w wpath] [–i id] [–R refname] [–s send_string] [–e expect_string] command
	cosend [–n] proc_id string
	cocheck proc_id
	coreceive proc_id
	codestroy [-R refname] proc_id [string]
DESCRIPTION	These co-processing functions provide a flexible means of interaction between FMLI and an independent process; especially, they enable FMLI to be responsive to asynchronous activity.
	The cocreate function starts <i>command</i> as a co-process and initializes communications by setting up pipes between FMLI and the standard input and standard output of <i>command</i> . The argument <i>command</i> must be an executable and its arguments (if any). This means that <i>command</i> expects strings on its input (supplied by cosend) and sends information on its output that can be handled in various ways by FMLI.
	The cosend function sends <i>string</i> to the co-process identified by <i>proc_id</i> via the pipe set up by cocreate (optionally <i>wpath</i>), where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in cocreate . By default, cosend blocks, waiting for a response from the co-process. Also by default, FMLI does not send a <i>send_string</i> and does not expect an <i>expect_string</i> (except a newline). That is, it reads only one line of output from the co-process. If <i>-e expect_string</i> was not defined when the pipe was created, then the output of the co-process is any sin- gle string followed by a newline: any other lines of output remain on the pipe. If the <i>-e</i> option was specified when the pipe was created, cosend reads lines from the pipe until it reads a line starting with <i>expect_string</i> . All lines except the line starting with <i>expect_string</i> become the output of cosend .
	The cocheck function determines if input is available from the process identified by <i>proc_id</i> , where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in cocreate . It returns a Boolean value, which makes cocheck useful in if statements and in other backquoted expressions in Boolean descriptors. cocheck receives no input from the co-process; it simply indicates if input is available from the co-process. You must use coreceive to actually accept the input. The cocheck function can be called from a reread descriptor to force a frame to update when new data is available. This is useful when the default value of a field in a form includes coreceive .
	The coreceive function is used to read input from the co-process identified by <i>proc_id</i> , where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in cocreate . It should only be used when it has been determined, using cocheck , that input is actually available. If the –e option was used when the co-process was created, coreceive will continue to return lines of input until <i>expect_string</i> is read. At this point, coreceive will terminate. The output of coreceive is all the lines that were read excluding the line starting with <i>expect_string</i> . If the –e option was not used in the cocreate , each invocation of coreceive

modified 5 Jul 1990

will return exactly one line from the co-process. If no input is available when **coreceive** is invoked, it will simply terminate without producing output.

The **codestroy** function terminates the read/write pipes to *proc-id*, where *proc_id* can be either the *command* or *id* specified in **cocreate**. It generates a **SIGPIPE** signal to the (child) co-process. This kills the co-process, unless the co-process ignores the **SIGPIPE** signal. If the co-process ignores the **SIGPIPE**, it will not die, even after the FMLI process terminates (the parent process id of the co-process will be **1**).

The optional argument *string* is sent to the co-process before the co-process dies. If *string* is not supplied, a NULL string is passed, followed by the normal *send_string* (newline by default). That is, **codestroy** will call **cosend** *proc_id string*: this implies that **codestroy** will write any output generated by the co-process to *stdout*. For example, if an interactive co-process is written to expect a "quit" string when the communication is over, the **close** descriptor could be defined;

```
close=`codestroy ID 'quit' | message`
```

and any output generated by the co-process when the string **quit** is sent to it via **codestroy** (using **cosend**) would be redirected to the message line.

The **codestroy** function should usually be given the $-\mathbf{R}$ option, since you may have more than one process with the same name, and you do not want to kill the wrong one. **codestroy** keeps track of the number of *refnames* you have assigned to a process with **cocreate**, and when the last instance is killed, it kills the process (*id*) for you. **codestroy** is typically called as part of a **close** descriptor because **close** is evaluated when a frame is closed. This is important because the co-process will continue to run if **codestroy** is not issued.

When writing programs to use as co-processes, the following tips may be useful. If the co-process program is written in C language, be sure to flush output after writing to the pipe. (Currently, **awk**(1) and **sed**(1) cannot be used in a co-process program because they do not flush after lines of output.) Shell scripts are well-mannered, but slow. C language is recommended. If possible, use the default *send_string, rpath* and *wpath*. In most cases, *expect_string* will have to be specified. This, of course, depends on the co-process.

In the case where asynchronous communication from a co-process is desired, a coprocess program should use **vsig** to force strings into the pipe and then signal FMLI that output from the co-process is available. This causes the **reread** descriptor of all frames to be evaluated immediately.

1F-139

OPTIONS	cocreate options are:		
	–r rpath	If -r is specified, <i>rpath</i> is the pathname from which FMLI reads informa- tion. This option is usually used to set up communication with processes that naturally write to a certain path. If -r is not specified, cocreate will choose a unique path in /var/tmp .	
	-w wpath	If – w is specified, <i>wpath</i> is the pathname to which cosend writes infor- mation. This option is usually used so that one process can talk to many different FMLI processes through the same pipe. If – w is not specified, cocreate will choose a unique path in / var/tmp .	
	−i id	If -i is specified, <i>id</i> is an alternative name for the co-processinitialized by this cocreate . If -i is not specified, <i>id</i> defaults to <i>command</i> . The argument <i>id</i> can later be used with the other co-processing functions rather than <i>command</i> . This option is typically used, since it facilitates the creation of two or more co-processes generated from the same <i>command</i> . (For example, cocreate -i ID1 program args and cocreate -i ID2 program different_args).	
	- R refname	If $-\mathbf{R}$ is specified, <i>refname</i> is a local name for the co-process. Since the cocreate function can be issued more than once, a <i>refname</i> is useful when the same co-process is referenced a second or subsequent time. With the $-\mathbf{R}$ option, if the co-process already exists a new one will not be created: the same pipes will be shared. Then, <i>refname</i> can be used as an argument to the $-\mathbf{R}$ option to codestroy when you want to end a particular connection to a co-process and leave other connections undisturbed. (The co-process is only killed after codestroy $-\mathbf{R}$ has been called as many times as cocreate $-\mathbf{R}$ was called.)	
	–s send_string	The -s option specifies <i>send_string</i> as a string that will be appended to all output sent to the co-process using cosend . This option allows a co-process to know when input from FMLI has completed. The default <i>send_string</i> is a newline if -s is not specified.	
	-e expect_string	The – e option specifies <i>expect_string</i> as a string that identifies the end of all output returned by the co-process. (Note: <i>expect_string</i> need only be the initial part of a line, and there must be a newline at the end of the co-process output.) This option allows FMLI to know when output from the co-process has completed. The default <i>expect_string</i> is a newline if – e is not specified.	
	cosend options are:		
	-n	If the $-\mathbf{n}$ option is specified, cosend will not wait for a response from the co-process. It simply returns, providing no output. If the $-\mathbf{n}$ option is not used, a co-process that does not answer will cause FMLI to permanently hang, waiting for input from the co-process.	

modified 5 Jul 1990

EXAMPLES							
	init=`cocreate –i BIGPROCESS initialize` close=`codestroy BIGPROCESS`						
	reread=`cocheck BIGPROCESS`						
	name=`cosend –n BIGPROCESS field1`						
	name="Receive field"						
	inactive=TRUE						
	value=`coreceive BIGPROCESS`						
SEE ALSO	awk(1), cat(1), sed(1), vsig(1F)						
NOTES	If cosend is used without the –n option, a co-process that does not answer will cause FMLI to permanently hang.						
	The use of non-alphabetic characters in input and output strings to a co-process should be avoided because they may not get transferred correctly.

NAME	cp – copy files					
SYNOPSIS	/usr/bin/cp [-fip] source_file target_file /usr/bin/cp [-fip] source_file target /usr/bin/cp -r -R [-fip] source_dir target					
	/usr/xpg4/bin/cp [-fip] source_file target_file /usr/xpg4/bin/cp [-fip] source_file target /usr/xpg4/bin/cp -r -R [-fip] source_dir target					
AVAILABILITY /usr/bin/cp	SUNWcsu					
/usr/xpg4/bin/cp	SUNWxcu4					
DESCRIPTION	In the first synopsis form, neither <i>source_file</i> nor <i>target_file</i> are directory files, nor can they have the same name. The cp utility will copy the contents of <i>source_file</i> to the destination path named by <i>target_file</i> . If <i>target_file</i> exists, cp will overwrite its contents, but the mode (and ACL if applicable), owner, and group associated with it are not changed. The last modification time of <i>target_file</i> and the last access time of <i>source_file</i> are set to the time the copy was made. If <i>target_file</i> does not exist, cp creates a new file named <i>target_file</i> that has the same mode as <i>source_file</i> except that the sticky bit is not set unless the user is super-user; the owner and group of <i>target_file</i> are those of the owner. If <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file. In the second synopsis form, one or more <i>source_files</i> are copied to the directory specified by <i>target</i> . For each <i>source_file</i> specified, a new file with the same mode (and ACL if applicable), is created in <i>target</i> ; the owner and group are those of the user making the copy. It					
	is an error if any <i>source_file</i> is a file of type directory, if <i>target</i> either does not exist or is not a directory.					
	In the third synopsis form, one or more directories specified by <i>source_dir</i> are copied to the directory specified by <i>target</i> . Either $-\mathbf{r}$ or $-\mathbf{R}$ must be specified. For each <i>source_dir</i> , cp will copy all files and subdirectories.					
OPTIONS	The following options are supported:					
	-f Unlink. If a file descriptor for a destination file cannot be obtained, attempt to unlink the destination file and proceed.					
	 -i Interactive. cp will prompt for confirmation whenever the copy would overwrite an existing <i>target</i>. A y answer means that the copy should proceed. Any other answer prevents cp from overwriting <i>target</i>. 					
/usr/bin/cp	-p Preserve. cp duplicates not only the contents of <i>source_file</i> , but also preserves the owner and group id, permissions modes, modification and access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. The command will not fail if unable to preserve modification and access time or permission modes. If unable to					

modified 27 Jun 1995

	preserve owner and group id, cp will not fail, and it will clear S_ISUID and S_ISGID bits in the target. cp will print a diagnostic message to stderr and return a non-zero exit status if unable to clear these bits.
/usr/xpg4/bin/cp	-p Preserve. cp duplicates not only the contents of <i>source_file</i> , but also preserves the owner and group id, permission modes, modification and access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. If unable to duplicate the modification and access time or the permission modes, cp will print a diagnostic message to stderr and return a non-zero exit status. If unable to preserve owner and group id, cp will not fail, and it will clear S_ISUID and S_ISGID bits in the target. cp will print a diagnostic message to stderr and return a non-zero exit status.
	 -r Recursive. cp will copy the directory and all its files, including any subdirectories and their files to <i>target</i>.
	- R Same as - r , except pipes are replicated, not read from.
OPERANDS	The following operands are supported:
	<i>source_file</i> A path name of a regular file to be copied.
	<i>source_dir</i> A path name of a directory to be copied.
	<i>target_file</i> A pathname of an existing or non-existing file, used for the output when a single file is copied.
	<i>target</i> A pathname of a directory to contain the copied files.
EXAMPLES	1. To copy a file:
	example% cp goodies goodies.old example% ls goodies* goodies goodies.old
	2. To copy a list of files to a destination directory:
	example% cp ~/src/* /tmp
	3. To copy a directory, first to a new, and then to an existing destination directory:
	example% ls ~/bkup /usr/example/fred/bkup not found example% cp -r ~/src ~/bkup example% ls -R ~/bkup x.c y.c z.sh example% cp -r ~/src ~/bkup example% ls -R ~/bkup src x.c y.c z.sh
	src: x.c y.c z.sh

modified 27 Jun 1995

cp(1)	User Commands SunOS 5.5	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of cp : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	 The following exit values are returned: 0 All files were copied successfully. >0 An error occurred. 	
SEE ALSO	<pre>chmod(1), setfacl(1), environ(5)</pre>	
NOTES	The permission modes of the source file are preserved in the copy. A permits the user to mark the end of any command line options explicitly, thus allowing cp to recognize filename arguments that begin with a If a and a - both appear on the same command line, the second will be interpreted as a filename.	

NAME	cpio – copy file archives in and out
SYNOPSIS	 cpio −i [bBcdfkmrsStuvV6] [−C bufsize] [−E file] [−H header] [−I file [−M message]] [−R id] [pattern] cpio −o [aABcLvV] [−C bufsize] [−H header] [−O file [−M message]] cpio −p [adlLmuvV] [−R id] directory
AVAILABILITY	SUNWcsu
DESCRIPTION	The cpio command copies files in to and out from a cpio archive. The cpio achive may span multiple volumes. The $-i$, $-o$, and $-p$ options select the action to be performed. The following list describes each of the actions (which are mutually exclusive).
Copy In Mode	cpio – i (copy in) extracts files from the standard input, which is assumed to be the product of a previous cpio – o . Only files with names that match <i>patterns</i> are selected. See sh (1) and OPERANDS for more information about <i>pattern</i> . Extracted files are conditionally created and copied into the current directory tree based on the options described below. The permissions of the files will be those of the previous cpio – o . Owner and group will be the same as the current user unless the current user is super-user. If this is true, owner and group will be the same as those resulting from the previous cpio – o . Note that if cpio – i tries to create a file that already exists and the existing file is the same age or younger (newer), cpio will output a warning message and not replace the file. (The – u option can be used to overwrite, unconditionally, the existing file.)
Copy Out Mode	cpio – o (copy out) reads the standard input to obtain a list of path names and copies those files onto the standard output together with path name and status information. Output is padded to a 512-byte boundary by default or to the user specified block size (with the – B or – C options) or to some device-dependent block size where necessary (as with the CTC tape).
Pass Mode	cpio $-\mathbf{p}$ (pass) reads the standard input to obtain a list of path names of files that are conditionally created and copied into the destination <i>directory</i> tree based on the options described below.
	Note: cpio assumes four-byte words.
	If, when writing to a character device (-o) or reading from a character device (-i), cpio reaches the end of a medium (such as the end of a diskette), and the -O and -I options are not used, cpio prints the following message:
	To continue, type device/file name when ready.
	To continue, you must replace the medium and type the character special device name (/dev/rdiskette for example) and press RETURN. You may want to continue by directing cpio to use a different device. For example, if you have two floppy drives you may want to switch between them so cpio can proceed while you are changing the floppies. (Simply pressing RETURN causes the cpio process to exit.)

OPTIONS	The following options are supported:		
	- i	(copy in) cpio – i extracts files from the standard input.	
	-0	(copy out) cpio – o reads the standard input to obtain a list of path names and copies those files onto the standard output.	
	- p	(pass) cpio $-\mathbf{p}$ reads the standard input to obtain a list of path names of files.	
	The following o	options can be appended in any sequence to the $-\mathbf{o}$, $-\mathbf{i}$, or $-\mathbf{p}$ options:	
	- a	Reset access times of input files after they have been copied. Access times are not reset for linked files when cpio $-$ pla is specified (mutually exclusive with $-$ m).	
	- A	Append files to an archive. The $-\mathbf{A}$ option requires the $-\mathbf{O}$ option. Valid only with archives that are files, or that are on floppy diskettes or hard disk partitions.	
	-b	Reverse the order of the bytes within each word. (Use only with the $-{\bf i}$ option.)	
	- B	Block input/output 5120 bytes to the record. The default buffer size is 512 bytes when this and the – C options are not used. – B does not apply to the <i>pass</i> option; – B is meaningful only with data directed to or from a character special device, for example, / dev/rmt/0m .	
	- c	Read or write header information in ASCII character form for portability. Use this option between SVR4-based machines, or the –H odc option between unknown machines. The –c option implies the use of expanded device numbers, which are only supported on SVR4-based systems. When transferring files between Solaris 1.x or Interactive UNIX and Solaris 2.x use –H odc .	
	-C bufsize	Block input/output <i>bufsize</i> bytes to the record, where <i>bufsize</i> is replaced by a positive integer. The default buffer size is 512 bytes when this and – B options are not used. (– C does not apply to the <i>pass</i> option; – C is meaningful only with data directed to or from a character special device, for example, / dev/rmt/0m .)	
	- d	Create directories as needed.	
	-E file	Specify an input file (<i>file</i>) that contains a list of filenames to be extracted from the archive (one filename per line).	
	-f	Copy in all files except those in <i>patterns</i> . (See OPERANDS for a description of <i>patterns</i> .)	
	–H header	Read or write header information in <i>header</i> format. Always use this option or the $-\mathbf{c}$ option when the origin and the destination machines are different types (mutually exclusive with $-\mathbf{c}$ and -6).	

	Valid values for	header are:	
	bar	bar head and format. Used only with the – i option (read only)	
	crc CRC	ASCII header with expanded device numbers and an additional per-file checksum	
	odc tar TAR ustar USTAR	ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the archive formats. It is the official format for transferring files between POSIX-conforming systems. Use this format to communicate with Solaris 1.x and Interactive UNIX. tar header and format IEEE/P1003 Data Interchange Standard tar header and format	
–I file	Read the contents of <i>file</i> as an input archive. If <i>file</i> is a character special device, and the current medium has been completely read, replace the medium and press RETURN to continue to the next medium. This option is used only with the $-\mathbf{i}$ option.		
- k	Attempt to skip corrupted file headers and I/O errors that may be encountered. If you want to copy files from a medium that is corrupted or out of sequence, this option lets you read only those files with good headers. (For cpio archives that contain other cpio archives, if an error is encountered cpio may terminate prematurely. cpio will find the next good header, which may be one for a smaller archive, and terminate when the smaller archive's trailer is encountered.) Used only with the $-i$ option.		
- l	Whenever possible, link files rather than copying them. (Usable only with the $-\mathbf{p}$ option.)		
-L	Follow symbolic links. The default is not to follow symbolic links.		
- m	Retain previous file modification time. This option is ineffective on directories that are being copied (mutually exclusive with $-\mathbf{a}$).		
– M message	Define a <i>message</i> to use when switching media. When you use the $-\mathbf{O}$ or $-\mathbf{I}$ options and specify a character special device, you can use this option to define the message that is printed when you reach the end of the medium. One %d can be placed in <i>message</i> to print the sequence number of the next medium needed to continue.		
–O file	the current med	It of cpio to <i>file</i> . If <i>file</i> is a character special device and ium is full, replace the medium and type a carriage ue to the next medium. Use only with the -0 option.	

	- P	Preserve ACLs. If the option is used for output, ACLs if existed are written along with other attributes to the standard output. ACLs are created as special files with a special file type. If the option is used for input, ACLs if existed are extracted along with other attributes from standard input. The option recognizes the special file type. Note that errors will occur if a cpio archive with ACLs is extracted by previous versions of cpio .		
	- r	Interactively rename files. If the user types a carriage return alone, the file is skipped. If the user types a "." the original pathname will be retained. (Not available with cpio $-\mathbf{p}$.)		
	$-\mathbf{R}$ id	Reassign ownership and group information for each file to <i>user ID</i> (<i>ID</i> must be a valid login ID from / etc/passwd). This option is valid only for the super-user.		
	- s	Swap bytes within each half word.		
	- S	Swap halfwords within each word.		
	-t	Print a table of contents of the input. No files are created (mutually exclusive with $-\mathbf{V}$).		
	- u	Copy unconditionally (normally, an older file will not replace a newer file with the same name).		
	- v	Verbose. Print a list of file names. When used with the $-t$ option, the table of contents looks like the output of an $ls - l$ command (see $ls(1)$).		
	-V	Special verbose. Print a dot for each file read or written. Useful to assure the user that cpio is working without printing out all file names.		
	-6	Process a UNIX System Sixth Edition archive format file. Use only with the $-i$ option (mutually exclusive with $-c$ and $-H$)).		
OPERANDS	The following operands are supported:			
	directory	A path name of an existing directory to be used as the target of cpio – p .		
	pattern	Expressions making use of a pattern-matching notation similar to that used by the shell (see $sh(1)$) for filename pattern matching, and similar to regular expressions. The following metacharacters are defined:		
		* Matches any string, including the empty string.		
		? Matches any single character.		
		[] Matches any one of the enclosed characters. A pair of characters separated by '-' matches any symbol between the pair (inclusive), as defined by the system default collating sequence. If the first character following the opening '[' is a '!', the results are unspecified.		
		! means <i>not</i> . (For example, the !abc * pattern would exclude all files that begin with abc .)		
	1	In <i>patterns</i> , metacharacters $?$, $*$, and $[]$ match the slash (/) character,		

	and backslash (\setminus) is an escape character. Multiple cases of <i>pattern</i> can be specified and if no <i>pattern</i> is specified, the default for <i>pattern</i> is $*$ (that is, select all files).			
	Each pattern must be enclosed in double quotes; otherwise, the name of a file in the current directory might be used.			
EXAMPLES	The following examples show three uses of cpio .			
	When standard input is directed through a pipe to cpio – o , it groups the files so they can be directed (>) to a single file (/newfile). The – c option insures that the file will be portable to other machines (as would the – H option). Instead of ls (1), you could use find (1), echo (1), cat (1), and so on, to pipe a list of names to cpio . You could direct the output to a device instead of a file.			
	example% ls cpio –oc >/newfile			
	cpio – i uses the output file of cpio – o (directed through a pipe with cat in the example below), extracts those files that match the patterns (memo/a1 , memo/b *), creates directories below the current directory as needed (– d option), and places the files in the appropriate directories. The – c option is used if the input file was created with a portable header. If no patterns were given, all files from newfile would be placed in the directory.			
	example% cat newfile cpio –icd "memo/a1" "memo/b*"			
	cpio – p takes the file names piped to it and copies or links (– l option) those files to another directory (newdir in the example below). The – d option says to create direc- tories as needed. The – m option says retain the modification time. (It is important to use the – depth option of find (1) to generate path names for cpio . This eliminates problems cpio could have trying to create files under read-only directories.) The destination direc- tory, newdir , must exist.			
	example% find . –depth –print cpio –pdlmv newdir			
	Note that when you use cpio in conjunction with find , if you use the $-L$ option with cpio then you must use the $-$ follow option with find and vice versa. Otherwise there will be undesirable results.			
	Note that for multi-reel archives, dismount the old volume, mount the new one, and con- tinue to the next tape by typing the name of the next device (probably the same as the first reel). To stop, type a RETURN and cpio will end.			
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cpio : LC_COLLATE , LC_CTYPE , LC_MESSAGES , LC_TIME , TZ , and NLSPATH .			
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.			
SEE ALSO	ar(1), cat(1), echo(1), find(1), ls(1), setfacl(1), sh(1), tar(1), archives(4), environ(5)			

NOTES Path names are restricted to 256 characters for the binary (the default) and **–H odc** header formats. Otherwise, path names are restricted to 1024 characters.

Only the super-user can copy special files.

Blocks are reported in 512-byte quantities.

If a file has **000** permissions, contains more than 0 characters of data, and the user is not root, the file will not be saved or restored.

The inode number stored in the header, (/usr/include/archives.h) is an unsigned short which is 2 bytes. This limits the range of inode numbers from 0 to 65535. Files which are hard linked must fall in this inode range. This could be a problem when moving **cpio** archives between different vendors' machines.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (eg, /dev/rdiskette) may not succeed. See **vold(1m)** for further details.

NAME	cpp – the C language preprocessor						
SYNOPSIS	/usr/ccs/lib/cpp [-BCHMpPRT] [-undef] [-Dname] [-Dname=def] [-Idirectory] [-Uname] [-Ydirectory] [input-file [output-file]]						
AVAILABILITY	SUNWsprot						
DESCRIPTION	cpp is the C language preprocessor. It is invoked as the first pass of any C c started with the cc (1B) command; however, cpp can also be used as a first-p cessor for other Sun compilers.						
	output is geared pass. Thus, the other compilati	Although cpp can be used as a macro processor, this is not normally recommended, as its output is geared toward that which would be acceptable as input to a compiler's second pass. Thus, the preferred way to invoke cpp is through the cc (1B) command, or some other compilation command. For general-purpose macro-processing, see m4 (1), and the chapter on m4 in <i>Programming Utilities Guide</i> .					
		accepts two filenames as arguments. <i>input-file</i> and <i>output-file</i> are, respec- t and output files for the preprocessor. They default to the standard input rd output.					
OPTIONS	The following o	options are supported:					
	-B	Support the C++ comment indicator '//'. With this indicator everything on the line after the // is treated as a comment.					
	- C	Pass all comments (except those that appear on cpp directive lines) through the preprocessor. By default, cpp strips out C-style comments.					
	–H	Print the pathnames of included files, one per line on the standard error.					
	- M	Generate a list of makefile dependencies and write them to the standard output. This list indicates that the object file which would be generated from the input file depends on the input file as well as the include files referenced.					
	-p	Use only the first eight characters to distinguish preprocessor symbols, and issue a warning if extra tokens appear at the end of a line containing a directive.					
	- P	Preprocess the input without producing the line control information used by the next pass of the C compiler.					
	$-\mathbf{R}$	Allow recursive macros.					
	-T	Use only the first eight characters for distinguishing different preproces- sor names. This option is included for backward compatibility with sys- tems which always use only the first eight characters.					
	–undef	Remove initial definitions for all predefined symbols.					
	- D name	Define <i>name</i> as 1 (one). This is the same as if a –D <i>name</i> =1 option appeared on the cpp command line, or as if a					

		#define name 1		
		line appeared in the source fil	e that cnn is processing	
	- D name=def		directive. This is the same as if a	
		#define name def		
		line appeared in the source fil has lower precedence than th	e that cpp is processing. The $-\mathbf{D}$ option e $-\mathbf{U}$ option. That is, if the same name is a $-\mathbf{D}$ option, the name will be undefined options.	
	-Idirectory	beginning with '/'. <i>directory</i> is "include" directories. Thus, # double-quotes (") are searched the #include line, then in dire in directories from the standa enclosed in angle-brackets (<	a path for #include files with names not inserted ahead of the standard list of #include files with names enclosed in d for first in the directory of the file with ctories named with –I options, and lastly, rd list. For #include files with names >), the directory of the file with the See Details below for exact details of this	
	-Uname	predefined by a particular pre-	of <i>name</i> , where <i>name</i> is a symbol that is eprocessor. Here is a partial list of symbols nding upon the architecture of the system:	
		Operating System: Hardware: UNIX system variant: The lint command: li		
			mix are defined for all Sun systems.	
	-Ydirectory	• -	e of the standard list of directories when	
USAGE Directives	All cpp directives start with a hash symbol (#) as the first character on a line. White space (SPACE or TAB characters) can appear after the initial # for proper indentation.			
	#define name to			
	-	e subsequent instances of <i>name</i>		
	#define name(argument [, argument]) token-string There can be no space between name and the '('. Replace subsequent instances of name, followed by a parenthesized list of arguments, with token-string, where each occurrence of an argument in the token-string is replaced by the correspond- ing token in the comma-separated list. When a macro with arguments is expanded, the arguments are placed into the expanded token-string unchanged. After the entire token-string has been expanded, cpp re-starts its scan for names to			

expand at the beginning of the newly created token-string.

#undef name

Remove any definition for the symbol *name*. No additional tokens are permitted on the directive line after *name*.

#include "filename"

#include <filename>

Read in the contents of *filename* at this location. This data is processed by **cpp** as if it were part of the current file. When the *<filename* > notation is used, *filename* is only searched for in the standard "include" directories. See the -I and -Y options above for more detail. No additional tokens are permitted on the directive line after the final "" or '>'.

#line integer-constant "filename"

Generate line control information for the next pass of the C compiler. *integer-constant* is interpreted as the line number of the next line and *filename* is interpreted as the file from where it comes. If "*filename*" is not given, the current filename is unchanged. No additional tokens are permitted on the directive line after the optional *filename*.

#if constant-expression

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** directive, appear in the output only if *constant-expression* yields a nonzero value. All binary non-assignment C operators, including '**&&**', '| |', and ',', are legal in *constant-expression*. The '?:' operator, and the unary '-', '!', and '~' operators, are also legal in *constant-expression*.

The precedence of these operators is the same as that for C. In addition, the unary operator **defined**, can be used in *constant-expression* in these two forms: '**defined** (*name*)' or '**defined** *name*'. This allows the effect of **#ifdef** and **#ifndef** directives (described below) in the **#if** directive. Only these operators, integer constants, and names that are known by **cpp** should be used within *constant-expression*. In particular, the **size of** operator is not available.

#ifdef name

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** appear in the output only if *name* has been defined, either with a **#define** directive or a **–D** option, and in the absence of an intervening **#undef** directive. Additional tokens after *name* on the directive line will be silently ignored.

#ifndef name

Subsequent lines up to the matching **#else**, **#elif**, or **#endif** appear in the output only if *name* has *not* been defined, or if its definition has been removed with an **#undef** directive. No additional tokens are permitted on the directive line after *name*.

	elif constant-expression			
	Any number of #elif directives may appear between an #if , #ifdef , or #ifndef directive and a matching #else or #endif directive. The lines following the #elif directive appear in the output only if all of the following conditions hold:			
	 The <i>constant-expression</i> in the preceding #if directive evaluated to zero, the <i>name</i> in the preceding #ifdef is not defined, or the <i>name</i> in the preceding #ifndef directive <i>was</i> defined. The <i>constant-expression</i> in all intervening #elif directives evaluated to Take 			
	zero.The current <i>constant-expression</i> evaluates to non-zero.			
	If the <i>constant-expression</i> evaluates to non-zero, subsequent #elif and #else directives are ignored up to the matching #endif . Any <i>constant-expression</i> allowed in an #if directive is allowed in an #elif directive.			
	telse This inverts the sense of the conditional directive otherwise in effect. If the preceding conditional would indicate that lines are to be included, then lines between the #else and the matching #endif are ignored. If the preceding conditional indicates that lines would be ignored, subsequent lines are included in the output. Conditional directives and corresponding #else directives can be nested.			
	tendif End a section of lines begun by one of the conditional directives #if, #ifdef , or #ifndef . Each such directive must have a matching #endif .			
Macros	Formal parameters for macros are recognized in #define directive bodies, even when they occur inside character constants and quoted strings. For instance, the output from			
	#define abc(a) ` a abc(xyz)			
	is:			
	#1""			
	` xyz			
	The second line is a NEWLINE. The last seven characters are " ` xyz " (vertical-bar, backquote, vertical-bar, x, y, z, vertical-bar). Macro names are not recognized within character constants or quoted strings during the regular scan. Thus:			
	#define abc_xyz printf("abc");			
	loes not expand abc in the second line, since it is inside a quoted string that is not part of # #define macro definition.	f		
	Macros are not expanded while processing a #define or #undef . Thus:			
	#define abc zingo #define xyz abc #undef abc xyz			

	produces abc . The token appearing immediately after an #ifdef or #ifndef is not expanded.
	Macros are not expanded during the scan which determines the actual parameters to another macro call. Thus:
	#define reverse(first,second)second first #define greeting hello reverse(greeting, #define greeting goodbye) produces '' #define hello goodbye hello''.
Output	Output consists of a copy of the input file, with modifications, plus lines of the form:
Output	#lineno " filename" "level"
	indicating the original source line number and filename of the following output line and whether this is the first such line after an include file has been entered (<i>level=1</i>), the first such line after an include file has been exited (<i>level=2</i>), or any other such line (<i>level</i> is empty).
Details	
Directory Search Order	#include files are searched for in the following order:
	1. The directory of the file that contains the #include request (that is, #include is relative to the file being scanned when the request is made).
	2. The directories specified by –I options, in left-to-right order.
	3. The standard directory(s) (/ usr/include on UNIX systems).
Special Names	Two special names are understood by cpp . The name _ _LINE is defined as the current line number (a decimal integer) as known by cpp , and _ _FILE is defined as the current filename (a C string) as known by cpp . They can be used anywhere (including in macros) just as any other defined name.
Newline Characters	A NEWLINE character terminates a character constant or quoted string. An escaped NEWLINE (that is, a backslash immediately followed by a NEWLINE) may be used in the body of a #define statement to continue the definition onto the next line. The escaped NEWLINE is not included in the macro value.
Comments	Comments are removed (unless the $-C$ option is used on the command line). Comments are also ignored, except that a comment terminates a token.
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.

Programming Utilities Guide DIAGNOSTICS The error messages produced by cpp are intended to be self-explanatory. The line	
DIACNOSTICS The amon maggaging produced by one are intended to be self explanatory. The line	
DIAGNOSTICS The error messages produced by cpp are intended to be self-explanatory. The line number and filename where the error occurred are printed along with the diagnostic.	
NOTES When NEWLINE characters were found in argument lists for macros to be expanded, some previous versions of cpp put out the NEWLINE characters as they were found ar expanded. The current version of cpp replaces them with SPACE characters.	nd
Because the standard directory for included files may be different in different environ ments, this form of #include directive:	1-
<pre>#include <file.h></file.h></pre>	
should be used, rather than one with an absolute path, like:	
#include "/usr/include/file.h"	
cpp warns about the use of the absolute pathname.	
While the compiler allows 8-bit strings and comments, 8-bits are not allowed anywhere else.	re

NAME	crontab – user crontab file
SYNOPSIS	crontab [filename] crontab [-elr] username
AVAILABILITY	SUNWcsu
DESCRIPTION	crontab manages a user's access with cron by copying, creating, listing, and removing crontab files. If invoked without options, crontab copies the specified file, or the standard input if no file is specified, into a directory that holds all users' crontabs.
crontab Access	Users: Access to crontab is allowed:
Control	• if the user's name appears in /etc/cron.d/cron.allow.
	 if /etc/cron.d/cron.allow does not exist and the user's name is not in /etc/cron.d/cron.deny.
	Users: Access to crontab is denied:
	• if /etc/cron.d/cron.allow exists and the user's name is not in it.
	• if /etc/cron.d/cron.allow does not exist and user's name is in /etc/cron.d/cron.deny.
	• if neither file exists.
	Note that the rules for allow and deny apply to root only if the allow/deny files exist.
	The allow/deny files consist of one user name per line.
crontab Entry Format	A crontab file consists of lines of six fields each. The fields are separated by spaces or tabs. The first five are integer patterns that specify the following: minute (0–59), hour (0–23), day of the month (1–31),
	month of the year $(1-12)$, day of the week $(0, 6)$ with 0 . Sunday)
	day of the week (0–6 with 0 =Sunday). Each of these patterns may be either an asterisk (meaning all legal values) or a list of ele- ments separated by commas. An element is either a number or two numbers separated by a minus sign (meaning an inclusive range). Note that the specification of days may be made by two fields (day of the month and day of the week). Both are adhered to if specified as a list of elements. See EXAMPLES .
	The sixth field of a line in a crontab file is a string that is executed by the shell at the specified times. A percent character in this field (unless escaped by \setminus) is translated to a NEWLINE character.
	Only the first line (up to a '%' or end of line) of the command field is executed by the shell. Other lines are made available to the command as standard input. Any line beginning with a '#' is a comment and will be ignored. The file should not contain blank lines.
	1

crontab(1)	User Commands	SunOS 5.5
	The shell is invoked from your \$HOME directory with an arg0 of sh . Us have their .profile executed must explicitly do so in the crontab file. It default environment for every shell, defining HOME, LOGNAME, SHEL and PATH. The default PATH for user cron jobs is /usr/bin ; while root to /usr/sbin:/usr/bin . The default PATH can be set in /etc/default/cron	ron supplies a LL(=/bin/sh), TZ, t cron jobs default
	If you do not redirect the standard output and standard error of your generated output or errors will be mailed to you.	commands, any
OPTIONS	 edits a copy of the current user's crontab file, or creates an encrontab does not exist. When editing is complete, the file is in user's crontab file. If a <i>username</i> is given, the specified user's edited, rather than the current user's crontab file; this may or super-user. The environment variable EDITOR determines we invoked with the -e option. The default editor is ed(1). Note jobs should be submitted using crontab; you should not add, the crontab file because cron will not be aware of changes matched. 	nstalled as the crontab file is nly be done by a which editor is that all crontab jobs by just editing
	 -I lists the crontab file for the invoking user. Only a super-user name following the -r or -l options to remove or list the cront specified user. 	
	-r removes a user's crontab from the crontab directory.	
EXAMPLES	1. Clean up core files every weekday morning at 3:15 am:	
	15 3 * * 1-5 find \$HOME -name core 2>/dev/null xargs rm -	f
	2. Mail a birthday greeting:	
	0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.	
	3. As an example of specifying the two types of days:	
	001,15 * 1 would run a command on the first and fifteenth of each month, as Monday. To specify days by only one field, the other field should l example:	
	00**1	
	would run a command only on Mondays.	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables cution of crontab : LC_TYPE, LC_MESSAGES, and NLSPATH.	s that affect the exe-
	EDITOR Determine the editor to be invoked when the $-\mathbf{e}$ optic default editor is $\mathbf{ed}(1)$.	on is specified. The
EXIT STATUS	The following exit values are returned:0 Successful completion.>0 An error occurred.	

ontains cron default settings st of denied users ecounting information bool area for crontab .

SEE ALSO atq(1), atrm(1), ed(1), sh(1), cron(1M), su(1M), environ(5)

NOTES If you inadvertently enter the **crontab** command with no argument(s), do not attempt to get out with CTRL-D. This removes all entries in your **crontab** file. Instead, exit with CTRL-C.

If a super-user modifies another user's **crontab** file, resulting behavior may be unpredictable. Instead, the privileged user should first $\mathbf{su}(1M)$ to the other user's login before making any changes to the **crontab** file.

NAME	crypt – encode or decode a file
SYNOPSIS	crypt [password]
AVAILABILITY	SUNWcsu
DESCRIPTION	crypt encrypts and decrypts the contents of a file. crypt reads from the standard input and writes on the standard output. The <i>password</i> is a key that selects a particular transformation. If no <i>password</i> is given, crypt demands a key from the terminal and turns off printing while the key is being typed in. crypt encrypts and decrypts with the same key:
	example% crypt key <clear.file>encrypted.file example% crypt key <encrypted.file pr<="" th=""></encrypted.file ></clear.file>
	will print the contents of <i>clear</i> . <i>file</i> .
	Files encrypted by crypt are compatible with those treated by the editors $ed(1)$, $ex(1)$ and $vi(1)$ in encryption mode.
	The security of encrypted files depends on three factors: the fundamental method must be hard to solve; direct search of the key space must be infeasible; "sneak paths" by which keys or cleartext can become visible must be minimized.
	crypt implements a one-rotor machine designed along the lines of the German Enigma, but with a 256-element rotor. Methods of attack on such machines are widely known, thus crypt provides minimal security.
	The transformation of a key into the internal settings of the machine is deliberately designed to be expensive, that is, to take a substantial fraction of a second to compute. However, if keys are restricted to (say) three lower-case letters, then encrypted files can be read by expending only a substantial fraction of five minutes of machine time.
	Since the key is an argument to the crypt command, it is potentially visible to users exe- cuting ps (1) or a derivative command. To minimize this possibility, crypt takes care to destroy any record of the key immediately upon entry. No doubt the choice of keys and key security are the most vulnerable aspect of crypt .

NAME	csh – shell command interpreter with a C-like syntax
SYNOPSIS	csh [-bcefinstvVxX] [argument]
AVAILABILITY	SUNWcsu
DESCRIPTION	csh , the C shell, is a command interpreter with a syntax reminiscent of the C language. It provides a number of convenient features for interactive use that are not available with the Bourne shell, including filename completion, command aliasing, history substitution, job control, and a number of built-in commands. As with the Bourne shell, the C shell provides variable, command and filename substitution.
Initialization and Termination	When first started, the C shell normally performs commands from the .cshrc file in your home directory, provided that it is readable and you either own it or your real group ID matches its group ID. If the shell is invoked with a name that starts with '-', as when started by login (1), the shell runs as a login shell.
	If the shell is a login shell, this is the sequence of invocations: First, commands in /etc/.login are executed. Next, commands from the .cshrc file your home directory are executed. Then the shell executes commands from the .login file in your home directory; the same permission checks as those for .cshrc are applied to this file. Typically, the .login file contains commands to specify the terminal type and environment. (For an explanation of file interpreters, see below "Command Execution" and exec(2).)
	As a login shell terminates, it performs commands from the .logout file in your home directory; the same permission checks as those for .cshrc are applied to this file.
Interactive Operation	After startup processing is complete, an interactive C shell begins reading commands from the terminal, prompting with <i>hostname</i> % (or <i>hostname</i> # for the privileged user). The shell then repeatedly performs the following actions: a line of command input is read and broken into <i>words</i> . This sequence of words is placed on the history list and then parsed, as described under USAGE, below. Finally, the shell executes each command in the current line.
Noninteractive Operation	When running noninteractively, the shell does not prompt for input from the terminal. A noninteractive C shell can execute a command supplied as an <i>argument</i> on its command line, or interpret commands from a file, also known as a script.
OPTIONS	 -b Force a "break" from option processing. Subsequent command line arguments are not interpreted as C shell options. This allows the passing of options to a script without confusion. The shell does not run set-user-ID or set-group-ID scripts unless this option is present.
	 -c Execute the first <i>argument</i> (which must be present). Remaining arguments are placed in <i>argv</i>, the argument-list variable, and passed directly to <i>csh</i>.
	-e Exit if a command terminates abnormally or yields a nonzero exit status.
	- f Fast start. Read neither the .cshrc file, nor the .login file (if a login shell) upon

startup.	

- -i Forced interactive. Prompt for command line input, even if the standard input does not appear to be a terminal (character-special device).
- –n Parse (interpret), but do not execute commands. This option can be used to check C shell scripts for syntax errors.
- -s Take commands from the standard input.
- -t Read and execute a single command line. A '\' (backslash) can be used to escape each newline for continuation of the command line onto subsequent input lines.
- -v Verbose. Set the **verbose** predefined variable; command input is echoed after history substitution (but before other substitutions) and before execution.
- -V Set **verbose** before reading .cshrc.
- -**x** Echo. Set the **echo** variable; echo commands after all substitutions and just before execution.
- -X Set echo before reading .cshrc.

Except with the options -c, -i, -s, or -t, the first nonoption *argument* is taken to be the name of a command or script. It is passed as argument zero, and subsequent arguments are added to the argument list for that command or script.

USAGE Filename Completion

When enabled by setting the variable **filec**, an interactive C shell can complete a partially typed filename or user name. When an unambiguous partial filename is followed by an ESC character on the terminal input line, the shell fills in the remaining characters of a matching filename from the working directory.

If a partial filename is followed by the EOF character (usually typed as CTRL-d), the shell lists all filenames that match. It then prompts once again, supplying the incomplete command line typed in so far.

When the last (partial) word begins with a tilde (~), the shell attempts completion with a user name, rather than a file in the working directory.

The terminal bell signals errors or multiple matches; this can be inhibited by setting the variable **nobeep**. You can exclude files with certain suffixes by listing those suffixes in the variable **fignore**. If, however, the only possible completion includes a suffix in the list, it is not ignored. **fignore** does not affect the listing of filenames by the EOF character.

Lexical StructureThe shell splits input lines into words at space and tab characters, except as noted below.
The characters &, |, ;, <, >, (, and) form separate words; if paired, the pairs form single
words. These shell metacharacters can be made part of other words, and their special
meaning can be suppressed by preceding them with a '\' (backslash). A newline pre-
ceded by a \ is equivalent to a space character.

SunOS 5.5	User Commands	$\cosh(1)$
	In addition, a string enclosed in matched pairs of single-quotes (`), double-quotes backquotes (`), forms a partial word; metacharacters in such a string, including as space or tab characters, do not form separate words. Within pairs of backquote (`double-quote (") characters, a newline preceded by a '\' (backslash) gives a true r character. Additional functions of each type of quote are described, below, under able Substitution , Command Substitution , and Filename Substitution .	ny `) or newline
	When the shell's input is not a terminal, the character $\#$ introduces a comment tha tinues to the end of the input line. Its special meaning is suppressed when preced \setminus or enclosed in matching quotes.	
Command Line Parsing	A <i>simple command</i> is composed of a sequence of words. The first word (that is not an I/O redirection) specifies the command to be executed. A simple command, or of simple commands separated by or & characters, forms a <i>pipeline</i> . With , th dard output of the preceding command is redirected to the standard input of the or mand that follows. With &, both the standard error and the standard output are redirected through the pipeline.	r a set ie stan- com-
	Pipelines can be separated by semicolons (;), in which case they are executed sequences that are separated by && or form conditional sequences in whe execution of pipelines on the right depends upon the success or failure, respective the pipeline on the left.	nich the
	A pipeline or sequence can be enclosed within parentheses '()' to form a simple com mand that can be a component in a pipeline or sequence.	om-
	A sequence of pipelines can be executed asynchronously or "in the background" happending an ' & '; rather than waiting for the sequence to finish before issuing a p the shell displays the job number (see Job Control , below) and associated process prompts immediately.	rompt,
History Substitution	History substitution allows you to use words from previous command lines in the mand line you are typing. This simplifies spelling corrections and the repetition of plicated commands or arguments. Command lines are saved in the history list, the of which is controlled by the history variable. The most recent command is retain any case. A history substitution begins with a ! (although you can change this with histchars variable) and may occur anywhere on the command line; history substitution do not nest. The ! can be escaped with \ to suppress its special meaning.	of com- ne size ned in th the
	Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets exec	
Event Designators	 An event designator is a reference to a command line entry in the history list. ! Start a history substitution, except when followed by a space char tab, newline, = or (. !! Refer to the previous command. By itself, this substitution repeats previous command. !n Refer to command line n. !-n Refer to the current command line minus n. 	

	 !str Refer to the most recent command starting with str. !?str? Refer to the most recent command containing str. !?str? additional Refer to the most recent command containing str and append additional to that referenced command. !{command} additional Refer to the most recent command beginning with command and append additional to that referenced command. ^previous_word`replacement` Repeat the previous command line replacing the string previous_word with the string replacement. This is equivalent to the history substitution: !:s/previous_word/replacement/. To re-execute a specific previous command AND make such a substitu- tion, say, re-executing command #6, !:6s/previous_word/replacement/.
Word Designators	 A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, \$, *, - or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, !!:1 and !:1 both refer to the first word of the previous command, while !!\$ and !\$ both refer to the last word in the previous command. Word designators include: # The entire command line typed so far. 0 The first input word (command). <i>n</i> The <i>n</i>'th argument. ^ The first argument, that is, 1. \$ The last argument. % The word matched by (the most recent) ?s search. x-y A range of words; -y abbreviates 0-y. * All the arguments, or a null value if there is just one word in the event. x* Abbreviates x-\$.
Modifiers	 x- Like x* but omitting word \$. After the optional word designator, you can add a sequence of one or more of the following modifiers, each preceded by a :. h Remove a trailing pathname component, leaving the head. r Remove a trailing suffix of the form '.xxx', leaving the basename. e Remove all but the suffix, leaving the Extension. s/l/r/ Substitute r for 1. t Remove all leading pathname components, leaving the tail. & Repeat the previous substitution. g Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, g&). p Print the new command but do not execute it. q Quote the substituted words, escaping further substitutions.

	x Like q , but break into words at each space character, tab or newline.
	Unless preceded by a g , the modification is applied only to the first string that matches <i>l</i> ; an error results if no string matches.
	The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of /. A backslash quotes the delimiter character. The character $\&$, in the right hand side, is replaced by the text from the left-hand-side. The $\&$ can be quoted with a backslash. A null <i>l</i> uses the previous string either from a <i>l</i> or from a contextual scan string <i>s</i> from <i>!s</i> . You can omit the rightmost delimiter if a newline immediately follows <i>r</i> ; the rightmost ? in a context scan can similarly be omitted.
	Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).
Quick Substitution	\hat{r} This is equivalent to the history substitution: !:s / <i>l</i> / <i>r</i> /.
Aliases	The C shell maintains a list of aliases that you can create, display, and modify using the alias and unalias commands. The shell checks the first word in each command to see if it matches the name of an existing alias. If it does, the command is reprocessed with the alias definition replacing its name; the history substitution mechanism is made available as though that command were the previous input line. This allows history substitutions, escaped with a backslash in the definition, to be replaced with actual command line arguments when the alias is used. If no history substitution is called for, the arguments remain unchanged.
	Aliases can be nested. That is, an alias definition can contain the name of another alias. Nested aliases are expanded before any history substitutions is applied. This is useful in pipelines such as
	alias lm ´ls –l \!* more´
	which when called, pipes the output of $ls(1)$ through more (1).
	Except for the first word, the name of the alias may not appear in its definition, nor in any alias referred to by its definition. Such loops are detected, and cause an error message.
I/O Redirection	The following metacharacters indicate that the subsequent word is the name of a file to which the command's standard input, standard output, or standard error is redirected; this word is variable, command, and filename expanded separately from the rest of the command.
	< Redirect the standard input.
	<< word Read the standard input, up to a line that is identical with <i>word</i> , and place the resulting lines in a temporary file. Unless <i>word</i> is escaped or quoted, variable and command substitutions are performed on these lines. Then, the pipeline is invoked with the temporary file as its standard input. <i>word</i> is not subjected to variable, filename, or command substitution, and each line is compared to it before any substitutions are performed by the shell.

> >! >& >&!	Redirect the standard output to a file. If the fil created. If it does exist, it is overwritten; its pr	le does not exist, it is

	F <i>i i</i>		
	-	d below, it is an error to refer to a variable that is not set.	
	\$var \${var}	These are replaced by words from the value of <i>var</i> , each separated by a space character. If <i>var</i> is an environment variable, its value is returned (but ':' modifiers and the other forms given below are not available).	
	<pre>\$var[index]</pre>		
	\${var[index]}	These select only the indicated words from the value of <i>var</i> . Variable substitution is applied to <i>index</i> , which may consist of (or result in) a either single number, two numbers separated by a '-', or an asterisk. Words are indexed starting from 1; a '*' selects all words. If the first number of a range is omitted (as with Sargv[-2]), it defaults to 1. If the last number of a range is omitted (as with Sargv[1–]), it defaults to S#var (the word count). It is not an error for a range to be empty if the second argument is omitted (or within range).	
	\$#name \${#name}	These give the number of words in the variable.	
	\$0	This substitutes the name of the file from which command input is being read except for setuid shell scripts. An error occurs if the name is not known.	
	\$ <i>n</i>		
	\${ <i>n</i> }	Equivalent to \$argv [<i>n</i>].	
	\$*	Equivalent to \$argv[*] .	
	The modifiers :e , :h , :q , :r , :t , and :x can be applied (see History Substitution), as can :gh :gt , and :gr . If {} (braces) are used, then the modifiers must appear within the braces. The current implementation allows only one such modifier per expansion.		
	The following references may not be modified with : modifiers.		
	\$?var		
	\$ {? <i>var</i> } Substitutes the string 1 if <i>var</i> is set or 0 if it is not set.		
	\$?0 Substitutes 1 if the current input filename is known or 0 if it is not.		
	\$\$ Substitute the process number of the (parent) shell.		
		tutes a line from the standard input, with no further interpretation fter. It can be used to read from the keyboard in a C shell script.	
Command and Filename Substitutions	Command and filename substitutions are applied selectively to the arguments of built-in commands. Portions of expressions that are not evaluated are not expanded. For non-built-in commands, filename expansion of the command name is done separately from that of the argument list; expansion occurs in a subshell, after I/O redirection is performed.		
Command Substitution	A command enclosed by backquotes $(``)$ is performed by a subshell. Its standard output is broken into separate words at each space character, tab and newline; null words are discarded. This text replaces the backquoted string on the current command line.		

csh(1)	User Commands SunOS 5		
	are preserved. Ho	otes, only newline characters force new words; space and ta wever, a final newline is ignored. It is therefore possible fo to yield a partial word.	
Filename Substitution	Unquoted words containing any of the characters *, ?, [or {, or that begin with ~, are expanded (also known as <i>globbing</i>) to an alphabetically sorted list of filenames, as follows:		
	* N	fatch any (zero or more) characters.	
	? N	fatch any single character.	
	a	fatch any single character in the enclosed list(s) or range(s). Tring of characters. A range is two characters separated by nd includes all the characters in between in the ASCII collati equence (see ascii (5)).	a dash (–),
	{ <i>str</i> , <i>str</i> , }		
	si e. 1	xpand to each string (or filename-matching pattern) in the eparated list. Unlike the pattern-matching expressions above xpansion of this construct is not sorted. For instance, {b,a} or ``a` , (not `a` `b`). As special cases, the characters { and } , altering {} , are passed undisturbed.	ve, the expands to
		our home directory, as indicated by the value of the variab nat of <i>user</i> , as indicated by the password entry for <i>user</i> .	le home , or

a = != = '!' or equal to equal to, not equal to, filename-substitution pattern match (described below), filename-substitution pattern mismatch bitwise AND & bitwise AND
(described below), filename-substitution pattern mismate & bitwise AND
& bitwise AND
^ hitriga VOD (avaluative av)
hitwise XOR (exclusive or)
bitwise inclusive OR
&& logical AND
logical OR
The operators: ==, !=, = [~] , and ! [~] compare their arguments as strings; other operators use
numbers. The operators = and ! each check whether or not a string to the left matches
filename substitution pattern on the right. This reduces the need for switch statements
when pattern-matching between strings is all that is required.
Also available are file inquiries:
-r <i>filename</i> Return true, or 1 if the user has read access. Otherwise it returns
false, or 0.
–w <i>filename</i> True if the user has write access.
-x <i>filename</i> True if the user has execute permission (or search permission on
directory).
–e filename True if filename exists.
-o filename True if the user owns filename.
-z filename True if filename is of zero length (empty).
-f filename True if filename is a plain file.
-d <i>filename</i> True if <i>filename</i> is a directory.
If <i>filename</i> does not exist or is inaccessible, then all inquiries return false.
An inquiry as to the success of a command is also available:
<i>{ command }</i> If <i>command</i> runs successfully, the expression evaluates to true, 1.
Otherwise, it evaluates to false, 0. (Note: Conversely, <i>command</i>
itself typically returns 0 when it runs successfully, or some other
value if it encounters a problem. If you want to get at the status
directly, use the value of the status variable rather than this
expression).
Control Flow The shell contains a number of commands to regulate the flow of control in scripts and
within limits, from the terminal. These commands operate by forcing the shell either to

reread input (to *loop*), or to skip input under certain conditions (to *branch*).

appear as the first word on its own input line.

able inputs.)

Each occurrence of a foreach, switch, while, if...then and else built-in command must

If the shell's input is not seekable and a loop is being read, that input is buffered. The shell performs seeks within the internal buffer to accomplish the rereading implied by the loop. (To the extent that this allows, backward **goto** commands will succeed on nonseek-

modified 5 May 1995

$\cosh(1)$	User Commands	SunOS 5.5
Command Execution	If the command is a C shell built-in command, the shell executes it direct the shell searches for a file by that name with execute access. If the com- tains a /, the shell takes it as a pathname, and searches for it. If the com- not contain a /, the shell attempts to resolve it to a pathname, searching the path variable for the command. To speed the search, the shell uses the rehash built-in command) to eliminate directories that have no app hashing can be disabled with the $-c$ or $-t$, options, or the unhash built-	nmand name con- mand name does g each directory in its hash table (see blicable files. This
	As a special case, if there is no / in the name of the script and there is an shell , the expansion of the shell alias is prepended (without modificati mand line. The system attempts to execute the first word of this special alias, which should be a full pathname. Remaining words of the alias's with the text of the input line, are treated as arguments.	on) to the com- l (late-occurring)
	When a pathname is found that has proper execute permissions, the sh process and passes it, along with its arguments, to the kernel using the call (see exec (2)). The kernel then attempts to overlay the new process program. If the file is an executable binary (in a.out (4) format) the kern begins executing the new process. If the file is a text file and the first lin the next word is taken to be the pathname of a shell (or command) to in Subsequent words on the first line are taken as options for that shell. T (overlays) the indicated shell, using the name of the script as an argum	execve () system with the desired hel succeeds and he begins with #! , hterpret that script. 'he kernel invokes
	If neither of the above conditions holds, the kernel cannot overlay the f execve() call fails (see exec(2)); the C shell then attempts to execute the new shell, as follows: • If the first character of the file is a #, a C shell is invoked. • Otherwise, a Bourne shell is invoked.	
Signal Handling	The shell normally ignores QUIT signals. Background jobs are immune erated from the keyboard, including hangups (HUP). Other signals hav the C shell inherited from its environment. The shell's handling of inte minate signals within scripts can be controlled by the onintr built-in co shells catch the TERM signal; otherwise, this signal is passed on to child case are interrupts allowed when a login shell is reading the .logout file	ve the values that errupt and ter- ommand. Login d processes. In no
Job Control	The shell associates a numbered <i>job</i> with each command sequence to ke commands that are running in the background or have been stopped w (typically CTRL-z). When a command or command sequence (semicold started in the background using the & metacharacter, the shell displays number in brackets and a list of associated process numbers:	vith TSTP signals on separated list) is
	[1] 1234	
	To see the current list of jobs, use the jobs built-in command. The job r stopped (or put into the background if none are stopped) is referred to and is indicated with a '+'. The previous job is indicated with a '-'; wh is terminated or moved to the foreground, this job takes its place (become current job).	as the <i>current</i> job en the current job
1-170	m	odified 5 May 1995

	To manipulate jobs, refer to the bg , fg , kill , stop , and % built-in commands.		
	A reference to a job begins with a '%'. By itself, the percent-sign refers to the curren		
	% %+ %	6% The current job.	
	%-	The previous job.	
	%j	Refer to job <i>j</i> as in: ' kill -9 % <i>j</i> '. <i>j</i> can be a job number, or a string that uniquely specifies the command line by which it was started; ' fg % vi ' might bring a stopped vi job to the foreground, for instance.	
	%?string	Specify the job for which the command line uniquely contains <i>string</i> .	
		ning in the background stops when it attempts to read from the terminal. Back- bs can normally produce output, but this can be suppressed using the ' stty tos - nand.	
Status Reporting	the job fin issues a pr notify var default, th	ning interactively, the shell tracks the status of each job and reports whenever ishes or becomes blocked. It normally displays a message to this effect as it rompt, in order to avoid disturbing the appearance of your input. When set, the iable indicates that the shell is to report status changes immediately. By the notify command marks the current process; after starting a background job, by to mark it.	
Built-In Commands	Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell.		
	:	Null command. This command is interpreted, but performs no action.	
	alias [nan	<pre>ne [def]] Assign def to the alias name. def is a list of words that may contain escaped history-substitution metasyntax. name is not allowed to be alias or unalias. If def is omitted, the alias name is displayed along with its current definition. If both name and def are omitted, all aliases are displayed.</pre>	
	bg [%job .		
	-81.55	Run the current or specified jobs in the background.	
	break	Resume execution after the end of the nearest enclosing foreach or while loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of break commands, all on one line.	
	breaksw	Break from a switch , resuming after the endsw .	
	case label:	A label in a switch statement.	
	cd [<i>dir</i>]		
	chdir [<i>dir</i>		
		Change the shell's working directory to directory <i>dir</i> . If no argument is given, change to the home directory of the user. If <i>dir</i> is a relative pathname not found in the current directory, check for it in those directories listed in the cdpath variable. If <i>dir</i> is the name of a shell variable whose value starts with a /, change to the directory named by that value.	
	continue	Continue execution of the next iteration of the nearest enclosing while or	
		6	

foreach loop.

- **default:** Labels the default case in a **switch** statement. The default should come after all **case** labels. Any remaining commands on the command line are first executed.
- dirs [-l]

Print the directory stack, most recent to the left; the first directory shown is the current directory. With the -l argument, produce an unabbreviated printout; use of the $\tilde{}$ notation is suppressed.

echo [–n] list

The words in *list* are written to the shell's standard output, separated by space characters. The output is terminated with a newline unless the -n option is used.

csh will, by default, invoke its built-in **echo**, if **echo** is called without the full pathname of a Unix command, regardless of the configuration of your **PATH** (see **echo**(1)).

eval argument ...

Reads the arguments as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution. See **tset**(1B) for an example of how to use **eval**.

exec command

Execute command in place of the current shell, which terminates.

exit [(expr)]

The calling shell or shell script exits, either with the value of the status variable or with the value specified by the expression *expr*.

fg [%job]

Bring the current or specified *job* into the foreground.

foreach var (wordlist)

... end

1 The variable *var* is successively set to each member of *wordlist*. The sequence of commands between this command and the matching **end** is executed for each new value of *var*. Both **foreach** and **end** must appear alone on separate lines.

The built-in command **continue** may be used to terminate the execution of the current iteration of the loop and the built-in command **break** may be used to terminate execution of the **foreach** command. When this command is read from the terminal, the loop is read once prompting with ? before any statements in the loop are executed.

glob wordlist

Perform filename expansion on *wordlist*. Like **echo**, but no $\$ escapes are recognized. Words are delimited by NULL characters in the output.

goto *label* The specified *label* is a filename and a command expanded to yield a label.

The shell rewinds its input as much as possible and searches for a line of the form *label*: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a **while** or **for** built-in command and its corresponding **end**.

hashstat Print a statistics line indicating how effective the internal hash table has been at locating commands (and avoiding **execs**). An **exec** is attempted for each component of the *path* where the hash function indicates a possible hit and in each component that does not begin with a '/'.

history [–**hr**] [*n*]

- Display the history list; if *n* is given, display only the *n* most recent events.
 - **-r** Reverse the order of printout to be most recent first rather than oldest first.
 - -h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the -h option to *source*.

if (expr) command

If the specified expression evaluates to true, the single *command* with arguments is executed. Variable substitution on *command* happens early, at the same time it does for the rest of the *if* command. *command* must be a simple command, not a pipeline, a command list, or a parenthesized command list. Note: I/O redirection occurs even if *expr* is false, when *command* is *not* executed (this is a bug).

if (expr) then

```
else if (expr2) then
```

... else

•••

- endif If *expr* is true, commands up to the first else are executed. Otherwise, if *expr2* is true, the commands between the else if and the second else are executed. Otherwise, commands between the else and the endif are executed. Any number of else if pairs are allowed, but only one else. Only one endif is needed, but it is required. The words else and endif must be the first nonwhite characters on a line. The if must appear alone on its input line or after an else.
- **jobs**[-**l**] List the active jobs under job control.

-l List process IDs, in addition to the normal information.

kill [-sig] [pid] [%job] ...

kill –l Send the TERM (terminate) signal, by default, or the signal specified, to the specified process ID, the *job* indicated, or the current *job*. Signals are either given by number or by name. There is no default. Typing kill does not send a signal to the current job. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal as well.

	-l	List the signal r	names that can be sent.	
limit [–h	-h] [resource [max-use]] Limit the consumption by the current process or any process it spawns, each			
	not to e current comma reporte	the consumption by the current process or any process it spawns, each o exceed <i>max-use</i> on the specified <i>resource</i> . If <i>max-use</i> is omitted, print the ent limit; if <i>resource</i> is omitted, display all limits. (Run the sysdef (1M) nand to obtain the maximum possible limits for your system. The values reted are in hexidecimal, but can be translated into decimal numbers using $c(1)$ command).		
	-h	Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.		
	resourc	e is one of:		
		cputime filesize	Maximum CPU seconds per process. Largest single file allowed; limited to the size of the filesystem. (see $df(1M)$).	
		datasize (heaps	size)	
			Maximum data size (including stack) for the process. This is the size of your virtual memory (see swap(1M)).	
		stacksize	Maximum stack size for the process. (see swap (1M)).	
		coredumpsize	Maximum size of a core dump (file). This limited to the size of the filesystem.	
		descriptors memorysize	Maximum number of file descriptors. (run sysdef(). Maximum size of virtual memory.	
	max-us	e is a number, wi	ith an optional scaling factor, as follows:	
			burs (for cputime).	
		<i>n</i> m <i>n</i> n	ilobytes. This is the default for all but cputime . negabytes or minutes (for cputime). nutes and seconds (for cputime).	
	followi		nit the size of a core file dump to 0 Megabytes, type the

		<i>command count</i> times. <i>command</i> is subject to the same restrictions as e one-line if statement.
set [var [=		
set var[n] =	With no values	o arguments, set displays the values of all shell variables. Multiword are displayed as a parenthesized list. With the <i>var</i> argument alone, set an empty (null) value to the variable <i>var</i> . With arguments of the form

var = *value* **set** assigns *value* to *var*, where *value* is one of:

word A single word (or quoted string).

(wordlist) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form **set** *var*[*n*] = *word* replaces the *n*'th word in a multiword value with *word*.

setenv [VAR [word]]

With no arguments, **setenv** displays all environment variables. With the *VAR* argument, **setenv** sets the environment variable *VAR* to have an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both *VAR* and *word* arguments, **setenv** sets the environment variable **NAME** to the value *word*, which must be either a single word or a quoted string. The most commonly used environment variables, **USER**, **TERM**, and **PATH**, are automatically imported to and exported from the **csh** variables **user**, **term**, and **path**; there is no need to use **setenv** for these. In addition, the shell sets the **PWD** environment variable from the **csh** variable **cwd** whenever the latter changes.

The environment variables LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY take immediate effect when changed within the C shell.

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of csh for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how csh behaves.

LC_CTYPE

Determines how **csh** handles characters. When **LC_CTYPE** is set to a valid value, **csh** can display and handle text and filenames containing valid characters for that locale. **csh** can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. **csh** can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S./English).

	LC_NUMERIC
	Determines the value of the radix character (decimal point (".") in the "C" locale) and thousand separator (empty string ("") in the "C" locale).
shift [var	iable]
	The components of argv , or <i>variable</i> , if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.
source [–	h] name
	Reads commands from <i>name</i> . source commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested source commands.
	-h Place commands from the file <i>name</i> on the history list without executing them.
stop %job	<i>id</i> Stop the current or specified background job.
stop pid	
	Stop the specified process, <i>pid.</i> (see ps (1)).
suspend	Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z . This is most often used to stop shells started by su .
switch (st	ring)
case label:	
 breaksw	
default:	
 breaksw	
endsw	
time [con	Each <i>label</i> is successively matched, against the specified <i>string</i> , which is first command and filename expanded. The file metacharacters *, ? and [] may be used in the case labels, which are variable expanded. If none of the labels match before a "default" label is found, execution begins after the default label. Each case statement and the default statement must appear at the beginning of a line. The command breaksw continues execution after the endsw . Otherwise control falls through subsequent case and default statements as with C. If no label matches and there is no default, execution continues after the endsw .
time [con	With no argument, print a summary of time used by this C shell and its children. With an optional <i>command</i> , execute <i>command</i> and print a summary of the time it uses.

As of this writing, the **time** built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "**0**" for these fields.

example %time ls -R 9.0u 11.0s 3:32 10%

(See below the "Environment Variables and Predefined Shell Variables" subsection on the **time** variable.)

umask [value]

Display the file creation mask. With *value*, set the file creation mask. With *value* given in octal, the user can turn-off any bits, but cannot turn-on bits to allow new permissions. Common values include 077, restricting all permissions from everyone else; 002, giving complete access to the group, and read (and directory search) access to others; or 022, giving read (and directory search) but not write permission to the group and others.

unalias pattern

Discard aliases that match (filename substitution) *pattern*. All aliases are removed by '**unalias** *'.

unhash Disable the internal hash table.

unlimit [–h] [resource]

Remove a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the **limit** command for the list of resource names.

-h Remove corresponding hard limits. Only the privileged user may do this.

unset pattern

Remove variables whose names match (filename substitution) *pattern*. All variables are removed by '**unset** *'; this has noticeably distasteful side effects.

unsetenv variable

Remove *variable* from the environment. As with **unset**, pattern matching is not performed.

wait Wait for background jobs to finish (or for an interrupt) before prompting.

while (expr)

... end

nd While *expr* is true (evaluates to nonzero), repeat commands between the while and the matching end statement. break and continue may be used to terminate or continue the loop prematurely. The while and end must appear alone on their input lines. If the shell's input is a terminal, it prompts for commands with a question-mark until the end command is entered and then performs the commands in the loop.

	%[job] [&] Bring th	e current or indicated <i>job</i> to the foreground. With the ampersand,
		e running <i>job</i> in the background.
	ments, s that <i>exp</i>	arguments, display the values for all shell variables. With argu- set the variable <i>var</i> , or the <i>n</i> 'th word in the value of <i>var</i> , to the value <i>r</i> evaluates to. (If [<i>n</i>] is supplied, both <i>var</i> and its <i>n</i> 'th component ready exist.)
		pression contains the characters $>$, $<$, $\&$, or $ $, then at least this part of st be placed within parentheses.
	the nam	erators $*=$, $+=$, and so forth, are available as in C. The space separating the from the assignment operator is optional. Spaces are, however, ory in separating components of <i>expr</i> that would otherwise be single

Environment Variables and Predefined Shell Variables	ables, which are au which are not. Bot The shell sets the v ization. The shell o TERM into term , ar ment variable when dled. You need on	shell, the C shell maintains a distinction between environment vari- tomatically exported to processes it invokes, and shell variables, h types of variables are treated similarly under variable substitution. ariables argv , cwd , home , path , prompt , shell , and status upon initial- opies the environment variable USER into the shell variable user , and HOME into home , and copies each back into the respective environ- never the shell variables are reset. PATH and path are similarly han- ly set path once in the .cshrc or .login file. The environment variable vd whenever the latter changes. The following shell variables have gs:
	argv	Argument list. Contains the list of command line arguments supplied to the current invocation of the shell. This variable determines the value of the positional parameters \$1 , \$2 , and so on.
	cdpath	Contains a list of directories to be searched by the cd , chdir , and popd commands, if the directory argument each accepts is not a sub- directory of the current directory.
	cwd	The full pathname of the current directory.
	echo	Echo commands (after substitutions) just before execution.
	fignore	A list of filename suffixes to ignore when attempting filename com- pletion. Typically the single word ' .o '.
	filec	Enable filename completion, in which case the CTRL-d character EOT and the ESC character have special significance when typed in at the end of a terminal input line:
		EOT Print a list of all filenames that start with the preceding

	string. ESC Replace the preceding string with the longest unambiguous extension.	
hardpaths	If set, pathnames in the directory stack are resolved to contain no symbolic-link components.	
histchars	A two-character string. The first character replaces ! as the history- substitution character. The second replaces the carat (^) for quick substitutions.	
history	The number of lines saved in the history list. A very large number may use up all of the C shell's memory. If not set, the C shell saves only the most recent command.	
home	The user's home directory. The filename expansion of $$ refers to the value of this variable.	
ignoreeof	If set, the shell ignores EOF from terminals. This protects against accidentally killing a C shell by typing a CTRL-d.	
mail	A list of files where the C shell checks for mail. If the first word of the value is a number, it specifies a mail checking interval in seconds (default 5 minutes).	\$
nobeep	Suppress the bell during command completion when asking the C shell to extend an ambiguous filename.	
noclobber	Restrict output redirection so that existing files are not destroyed by accident. > redirections can only be made to new files. >> redirections can only be made to existing files.	
noglob	Inhibit filename substitution. This is most useful in shell scripts once filenames (if any) are obtained and no further expansion is desired.	е
nonomatch	Returns the filename substitution pattern, rather than an error, if the pattern is not matched. Malformed patterns still result in errors.	
notify	If set, the shell notifies you immediately as jobs are completed, rathe than waiting until just before issuing a prompt.	r
path	The list of directories in which to search for commands. path is ini- tialized from the environment variable PATH , which the C shell updates whenever path changes. A null word specifies the current directory. The default is typically (/ usr/bin .). If path becomes unset only full pathnames will execute. An interactive C shell will nor- mally hash the contents of the directories listed after reading .cshrc , and whenever path is reset. If new commands are added, use the rehash command to update the table.	
prompt	The string an interactive C shell prompts with. Noninteractive shells leave the prompt variable unset. Aliases and other commands in the .cshrc file that are only useful interactively, can be placed after the following test: ' if (\$?prompt == 0) exit ', to reduce startup time for	

The setting of Sprompt has three meanings: Sprompt not set non-interactive shell, test \$?prompt. Sprompt set but == "" cshrc called by the which(1) command. Sprompt set and != "" cshrc called by the which(1) command. savehist The number of lines from the history list that are saved in "/.history when the user logs out. Large values for savehist slow down the C shell during startup. shell The file in which the C shell resides. This is used in forking shells to interpret files that have execute bits set, but that are not executable by the system. status The status returned by the most recent command. If that command terminated abnormally, 0200 is added to the status. Built-in commands that fail return exit status 1; all other built-in commands set status to 0. time Control automatic timing of commands. Can be supplied with one or two values. The first is the reporting threshold in CPU seconds. The second is a string of tags and text indicating which resources to report on. A tag is a percent sign (%) followed by a single uppercase letter (unrecognized tags print as text): %D Average amount of unshared data space used in Kilobytes. %E Elapsed (wallclock) time for the command. %F Page faults. %I Number of block input operations. %K Average amount of unshared stack space used in Kilobytes. %I Number of block output operations.		noninteractive shells. A ! in the prompt string is replaced by the current event number. The default prompt is <i>hostname</i> % for mere mortals, or <i>hostname</i> # for the privileged user.		
Sprompt not set non-interactive shell, test \$?prompt. Sprompt set but == "" cshrc called by the which(1) command. Sprompt set and != "" cshrc called by the which(1) command. savehist The number of lines from the history list that are saved in "/.history when the user logs out. Large values for savehist slow down the C shell during startup. shell The file in which the C shell resides. DIAGNOSTICS		oted to exit the C	C shell with stopped jobs under job control. An to exit will succeed, terminating the stopped jobs.
NOTES	TES Words can be no longer than 1024 characters. The system limits argument lists to 1,048,576 characters. However, the maximum number of arguments to a command which filename expansion applies is 1706. Command substitutions may expand to more characters than are allowed in the argument list. To detect looping, the shell retricts the number of alias substitutions on a single line to 20.		maximum number of arguments to a command for s 1706. Command substitutions may expand to no n the argument list. To detect looping, the shell res-
		e current directo	a a stop, the shell prints the directory it started in if this ory; this can be misleading (that is, wrong) as the job nally.
	<i>a</i> ; <i>b</i> ; <i>c</i> are also not shell never executes	handled gracefu s <i>c</i> . This is espe	pable/restartable. Command sequences of the form lly when stopping is attempted. If you suspend b , the cially noticeable if the expansion results from an alias. quence in parentheses to force it into a subshell.
	Control over termin system if you need		processes are started is primitive; use the Sun Window ontrol.
	Commands within	loops, prompte	d for by ?, are not placed in the <i>history</i> list.
		ontrol command	d rather than being recognized as built-in commands. ds to be placed anywhere, to be combined with , and c.

It should be possible to use the : modifiers on the output of command substitutions. There are two problems with : modifier usage on variable substitutions: not all of the modifiers are available, and only one modifier per substitution is allowed.

The **g** (global) flag in history substitutions applies only to the first match in each word, rather than all matches in all words. The common text editors consistently do the latter when given the **g** flag in a substitution command.

Quoting conventions are confusing. Overriding the escape character to force variable substitutions within double quotes is counterintuitive and inconsistent with the Bourne shell.

Symbolic links can fool the shell. Setting the **hardpaths** variable alleviates this.

It is up to the user to manually remove all duplicate pathnames accrued from using built-in commands as

set path = pathnames

or

setenv PATH pathnames

more than once. These often occur because a shell script or a **.cshrc** file does something like '**set path=(/usr/local /usr/hosts Spath)**' to ensure that the named directories are in the pathname list.

The only way to direct the standard output and standard error separately is by invoking a subshell, as follows:

example% (command > outfile) >& errorfile

Although robust enough for general use, adventures into the esoteric periphery of the C shell may reveal unexpected quirks.

If you start **csh** as a login shell and you do not have a **.login** in your home directory, then the **csh** reads in the **/etc/.login**.

BUGS As of this writing, the **time** built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "**0**" for these fields.

example %time ls -R 9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w

NAME	csplit – split files based on context		
SYNOPSIS	csplit [–ks] [-	-f prefix] [–n number] file arg1 …argn	
AVAILABILITY	SUNWesu		
DESCRIPTION	-	y reads the file named by the <i>file</i> operand, writes all or part of that file into rected by the <i>arg</i> operands, and writes the sizes of the files.	
OPTIONS	The following o	options are supported:	
	-f prefix	Name the created files <i>prefix</i> 00 , <i>prefix</i> 01 ,, <i>prefixn</i> . The default is xx00xx <i>n</i> . If the <i>prefix</i> argument would create a file name exceeding { NAME_MAX } bytes, an error will result; csplit will exit with a diagnostic message and no files will be created.	
	- k	Leave previously created files intact. By default, csplit will remove created files if an error occurs.	
	– n number	Use <i>number</i> decimal digits to form filenames for the file pieces. The default is 2 .	
	- S	Suppress the output of file size messages.	
OPERANDS	The following o	operands are supported:	
	file	The path name of a text file to be split. If <i>file</i> is -, the standard input will be used.	
The operan		<i>rg1argn</i> can be a combination of the following:	
	/rexp/[offset]	Create a file using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with <i>offset</i> , if any, applied. The regular expression <i>rexp</i> must follow the rules for basic regular expressions. The optional <i>offset</i> must be a positive or negative integer value representing a number of lines. The integer value must be preceded by $+$ or $-$. If the selection of lines from an offset expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line will be set to the line that results from the evaluation of the regular expres- sion with any offset applied. The pattern match of <i>rexp</i> always is applied from the current line to the end of the file.	
	%rexp%[offset]	This operand is the same as <i>/rexp/[offset</i>], except that no file will be created for the selected section of the input file.	
	line_no	Create a file from the current line up to (but not including) the line number <i>line_no</i> . Lines in the file will be numbered starting at one. The current line becomes <i>line_no</i> .	

	<pre>{num} Repeat operand. This operand can follow any of the operands described previously. If it follows a rexp type operand, that operand will be applied num more times. If it follows a line_no operand, the file will be split every line_no lines, num times, from that point. An error will be reported if an operand does not reference a line between the current position and the end of the file.</pre>		
EXAMPLES	This example creates four files, cobol00cobol03 .		
	example% csplit –f cobol filename '/procedure division/' /par5./ /par16./		
	After editing the "split" files, they can be recombined as follows:		
	example% cat cobol0[0–3] > filename		
	Note: This example overwrites the original file.		
	This example splits the file at every 100 lines, up to 10,000 lines. The – k option causes the created files to be retained if there are less than 10,000 lines; however, an error message would still be printed.		
	example% csplit –k filename 100 {99}		
	If prog.c follows the normal C coding convention (the last line of a routine consists only of a } in the first character position), this example creates a file for each separate C routine (up to 21) in prog.c .		
	example% csplit -k prog.c '%main(%´ '/^}/+1' {20}		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of csplit : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred.		
SEE ALSO	<pre>sed(1), split(1), environ(5)</pre>		
DIAGNOSTICS	The diagnostic messages are self-explanatory, except for the following:		
	<i>arg</i> – out of range The given argument did not reference a line between the current position and the end of the file.		

NAME	ct – spawn login to a remote terminal		
SYNOPSIS	ct [options] telno		
AVAILABILITY	SUNWbnuu		
DESCRIPTION	ct dials the telephone number of a modem that is attached to a terminal and spawns a login process to that terminal. The <i>telno</i> is a telephone number, with equal signs for secondary dial tones and minus signs for delays at appropriate places. (The set of legal characters for <i>telno</i> is 0 through 9, -, =, *, and #. The maximum length <i>telno</i> is 31 characters). If more than one telephone number is specified, ct will try each in succession until one answers; this is useful for specifying alternate dialing paths.		
	ct will try each line listed in the file / etc/uucp/Devices until it finds an available line with appropriate attributes, or runs out of entries.		
	After the user on the destination terminal logs out, there are two things that could occur depending on what type of port monitor is monitoring the port. In the case of no port monitor, ct prompts: Reconnect? If the response begins with the letter n , the line will be dropped; otherwise, <i>ttymon</i> will be started again and the login: prompt will be printed. In the second case, where a port monitor is monitoring the port, the port monitor reissues the login: prompt.		
	The user should log out properly before disconnecting.		
OPTIONS	 -h Normally, ct will hang up the current line so that it can be used to answer the incoming call. The -h option will prevent this action. The -h option will also wait for the termination of the specified ct process before returning control to the user's terminal. 		
	-sspeed The data rate may be set with the $-s$ option. <i>speed</i> is expressed in baud rates. The default baud rate is 1200.		
	 -v If the -v (verbose) option is used, ct will send a running narrative to the standard error output stream. 		
	-wn If there are no free lines ct will ask if it should if so, for how many minutes it should wait before it gives up. ct will continue to try to open the dialers at one- minute intervals until the specified limit is exceeded. This dialogue may be over- ridden by specifying the $-wn$ option. <i>n</i> is the maximum number of minutes that ct is to wait for a line.		
	-xn This option is used for debugging; it produces a detailed output of the program execution on stderr. n is a single number between 0 and 9. As n increases to 9, more detailed debugging information is given.		
FILES	/etc/uucp/Devices /var/adm/ctlog		

SEE ALSO cu(1C), **login**(1), **uucp**(1C), **ttymon**(1M)

NOTESThe ct program will not work with a DATAKIT Multiplex interface.For a shared port, one used for both dial-in and dial-out, the *ttymon* program running on
the line must have the -r and -b options specified (see ttymon(1M)).

1C-187

NAME	ctags – create a tags file for use with ex and vi		
SYNOPSIS	/usr/bin/ctags [–aBFtuvwx] [–f tagsfile] file		
	/usr/xpg4/bin/ctags [-aBFuvwx] [-f tagsfile	e] file	
AVAILABILITY			
/usr/bin/ctags	SUNWtoo		
/usr/xpg4/bin/ctags	SUNWxcu4		
DESCRIPTION	ctags makes a tags file for $ex(1)$ from the spe and $lex(1)$ sources. A tags file gives the locat tions and typedefs) in a group of files. Each the file in which it is defined, and an address tions are searched with a pattern, typedefs w separate fields on the line, separated by SPAC can quickly find these objects definitions.	ions of specified objects (in this case func- line of the tags file contains the object name, specification for the object definition. Func- rith a line number. Specifiers are given in	
	Normally ctags places the tag descriptions in with the $-\mathbf{f}$ option.	a file called tags ; this may be overridden	
	Files with names ending in .c or .h are assumed to be either C or C++ source files and are searched for C/C++ routine and macro definitions. Files with names ending in .cc, .C, or .cxx, are assumed to be C++ source files. Files with names ending in .y are assumed to be yacc source files. Files with names ending in .l are assumed to be lex files. Others are first examined to see if they contain any Pascal or FORTRAN routine definitions; if not, they are processed again looking for C definitions.		
	The tag main is treated specially in C or C++ programs. The tag formed is created by prepending M to <i>file</i> , with a trailing .c , .cc .C , or .cxx removed, if any, and leading path name components also removed. This makes use of ctags practical in directories with more than one program.		
OPTIONS	The precedence of the options that pertain to options. The following options are supported		
	-a Append output to an existing tag	s file.	
	-B Use backward searching patterns	(??).	
	-f tagsfile Places the tag descriptions in a fil	e called <i>tagsfile</i> instead of tags .	
	-F Use forward searching patterns (//) (default).	
	-t Create tags for typedefs. /usr/xpg default.	g4/bin/ctags creates tags for typedefs by	
	and the new values are appended	that is, all references to them are deleted, l to the file. Beware: this option is imple- slow; it is usually faster to simply rebuild the	

SunOS 5.5	User Commands		ctags(1)
	-V	Produce on the standard output an index listing th and page number (assuming 64 line pages). Since into lexicographic order, it may be desired to run	the output will be sorted
	$-\mathbf{w}$	Suppress warning diagnostics.	
	- X	Produce a list of object names, the line number and defined, as well as the text of that line and prints t This is a simple index which can be printed out as tion index.	his on the standard output.
OPERANDS	The foll	owing file operands are supported:	
	file.c	Files with basenames ending with the .c suffix are trocode.	eated as C-language source
	file. h	Files with basenames ending with the .h suffix are tr code.	eated as C-language source
	file.f	Files with basenames ending with the .f suffix are tre language source code.	eated as FORTRAN-
USAGE		option is mainly used with vgrind which will be part e Package.	of the optional BSD Compa-
EXAMPLES	Using ctags with the $-\mathbf{v}$ option produces entries in an order which may not always be appropriate for vgrind . To produce results in alphabetical order, you may want to run the output through ' sort $-\mathbf{f}$ '.		
		example% ctags –v filename.c filename.h sort –f > example% vgrind –x index	> index
		d a tags file for C sources in a directory hierarchy root ags file, and then run find (1):	ed at <i>sourcedir</i> , first create an

NOTES Recognition of **functions**, **subroutines** and **procedures** for FORTRAN and Pascal is done is a very simpleminded way. No attempt is made to deal with block structure; if you have two Pascal procedures in different blocks with the same name you lose.

The method of deciding whether to look for C or Pascal and FORTRAN functions is a hack.

ctags does not know about #ifdefs.

ctags should know about Pascal types. Relies on the input being well formed to detect typedefs. Use of **-tx** shows only the last line of typedefs.

Communication Commands

NAME	cu – call another UNIX system			
SYNOPSIS		cu [-c device -l line] [-s speed] [-b bits] [-h] [-n] [-t] [-d] [-o -e] [-L] [-C] [-H] telno systemname [local-cmd]		
AVAILABILITY	SUNWbn	uu		
DESCRIPTION	cu calls up another UNIX system, a terminal, or possibly a non-UNIX system. It manages an interactive conversation with possible transfers of files. It is convenient to think of cu as operating in two phases. The first phase is the connection phase in which the connection is established. cu then enters the conversation phase. The $-\mathbf{d}$ option is the only one that applies to both phases.			
OPTIONS		s many options. The -c , -l , and -s options play a part in selecting the medium; ning options are used in configuring the line.		
	–c device	Force cu to use only entries in the "Type" field (the first field in the / etc/uucp/Devices file) that match the user specified <i>device</i> , usually the name of a local area network.		
	–s speed	Specify the transmission speed (300 , 1200 , 2400 9600 , 19200 , 38400). The default value is "Any" speed which will depend on the order of the lines in the /etc/uucp/Devices file.		
	–1 line	Specify a device name to use as the communication line. This can be used to override the search that would otherwise take place for the first available line having the right speed. When the –l option is used without the –s option, the speed of a line is taken from the /etc/uucp/Devices file record in which line matches the second field (the Line field). When the –l and –s options are both used together, cu will search the /etc/uucp/Devices file to check if the requested speed for the requested line is available. If so, the connection will be made at the requested speed, otherwise, an error message will be printed and the call will not be made. In the general case where a specified device is a directly connected asynchronous line (for instance, /dev/term/a), a telephone number (<i>telno</i>) is not required. The specified device need not be in the /dev directory. If the specified device is associated with an auto dialer, a telephone number must be provided.		
	- b bits	Force <i>bits</i> to be the number of bits processed on the line. <i>bits</i> is either 7 or 8 . This allows connection between systems with different character sizes. By default, the character size of the line is set to the same as the current local terminal.		
	-h	Set communication mode to half-duplex. This option emulates local echo in order to support calls to other computer systems that expect terminals to be set to half-duplex mode.		

modified 28 Mar 1995

1C-191

	•	Request user prompt for telephone number. For added security, this option will prompt the user to provide the telephone number to be dialed, rather than taking it from the command line.
		Dial a terminal which has been set to auto answer. Appropriate mapping of carriage-return to carriage-return-line-feed pairs is set.
	- d	Print diagnostic traces.
		Set an ODD data parity. This option designates that ODD parity is to be generated for data sent to the remote system.
		Set an EVEN data parity. This option designates that EVEN parity is to be generated for data sent to the remote system.
]	Go through the login chat sequence specified in the /etc/uucp/Systems file. For more information about the chat sequence, see <i>TCP/IP</i> and Data Communi- cations Guide
	i	Run the <i>local-cmd</i> specified at the end of the command line instead of entering interactive mode. The stdin and stdout of the command that is run refer to the remote connection.
	ן פ ן נ	Ignore one hangup. This allows the user to remain in cu while the remote machine disconnects and places a call back to the local machine. This option should be used when connecting to systems with callback or dialback modems. Once the callback occurs subsequent hangups will cause cu to ter- minate. This option can be specified more than once. For more information about dialback configuration, see remote (4) and <i>TCP/IP and Data Communica-</i> <i>tions Guide</i>
OPERANDS	The followi	ng operands are supported:
	telno	When using an automatic dialler, specifies the telephone number with equal signs for secondary dial tone or minus signs placed appropriately for delays of 4 seconds.
	systemname	Specifies a uucp system name, which can be used rather than a tele- phone number; in this case, cu will obtain an appropriate direct line or telephone number from a system file.
USAGE	an uses the	some machine that $uum(1C)$ does to establish a connection. This means
Connection Phase	that it will u gives cu the The possible (LAN). The tem. The / e but it is not	same mechanism that uucp (1 <i>C</i>) does to establish a connection. This means use the uucp control files / etc/uucp/Devices and / etc/uucp/Systems . This e ability to choose from several different media to establish the connection. e media include telephone lines, direct connections, and local area networks / etc/uucp/Devices file contains a list of media that are available on your sys- tc/uucp/Systems file contains information for connecting to remote systems, generally readable.
	upon the na	termines which /etc/uucp/Systems and /etc/uucp/Devices files to use based me used to invoke cu. In the simple case, this name will be "cu", but you have created a link to cu with another name, such as "pppcu", in which case cu

1C-192

modified 28 Mar 1995

	would then look for a which / etc/uucp/Sys t	a "service=pppcu" entry in the / etc/uucp/Sysfiles file to determine t ems file to use.	
	The <i>telno</i> or <i>systemname</i> parameter from the command line is used to tell cu what system you wish to connect to. This parameter can be blank, a telephone number, a system name, or a LAN specific address.		
	telephone number	A telephone number is a string consisting of the tone dial charac- ters (the digits 0 through 9 , *, and #) plus the special characters = and –. The equal sign designates a secondary dial tone and the minus sign creates a 4 second delay.	
	system name	A system name is the name of any computer that uucp can call; the uuname (1C) command prints a list of these names.	
	LAN address	The documentation for your LAN will show the form of the LAN specific address.	
	systemname parameter specified, cu will assu automatic call unit (A follow the uucp callin / etc/uucp/Devices fil	or is invoked (not using the – c or – l options), cu will use the <i>telno</i> or er to determine which medium to use. If a telephone number is ume that you wish to use a telephone line and it will select an ACU). Otherwise, cu will assume that it is a system name. cu will ng mechanism and use the / etc/uucp/Systems and es to obtain the best available connection. Since cu will choose a riate for the medium that it selects, you may not use the – s option is a system name.	
	by specifying a Type telno or systemname v a connection will be a is used to specify a d direct connection to t This is the only case hand, there may be c	s modify this default behavior. $-\mathbf{c}$ is most often used to select a LAN field from the /etc/uucp/Devices file. You must include either a alue when using the $-\mathbf{c}$ option. If the connection to <i>systemname</i> fails, attempted using <i>systemname</i> as a LAN specific address. The $-\mathbf{l}$ option evice associated with a direct connection. If the connection is truly a the remote machine, then there is no need to specify a <i>systemname</i> . where a <i>telno</i> or <i>systemname</i> parameter is unnecessary. On the other ases in which the specified device connects to a dialer, so it is valid e number. The $-\mathbf{c}$ and $-\mathbf{l}$ options should not be specified on the	
Conversation Phase	from the standard in tem; the <i>receive</i> proce ning with ~, passes it	nection, cu runs as two processes: the <i>transmit</i> process reads data put and, except for lines beginning with ~, passes it to the remote sys- ss accepts data from the remote system and, except for lines begin- to the standard output. Normally, an automatic DC3/DC1 protocol out from the remote so the buffer is not overrun. Lines beginning heanings.	
Commands	The <i>transmit</i> process	interprets the following user initiated commands:	
	~. ~!	Terminate the conversation. Escape to an interactive shell on the local system.	
		Run <i>cmd</i> on the local system (via $\mathbf{sh} - \mathbf{c}$).	

1C-193

~ \$ <i>cmd</i>	Run <i>cmd</i> locally and send its output to the remote system.	
~%cd	Change the directory on the local system. Note: "!cd will cause the command to be run by a sub-shell, probably not what was intended.	
~%take from [to]		
	Copy file <i>from</i> (on the remote system) to file <i>to</i> on the local system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.	
~%put from [to]		
	Copy file <i>from</i> (on local system) to file <i>to</i> on remote system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.	
~~ line	Send the line ~ line to the remote system.	
~%break	Transmit a BREAK to the remote system (which can also be specified as ~%b).	
~%debug	Toggles the -d debugging option on or off (which can also be specified as ~%d).	
ĩt	Prints the values of the termio structure variables for the user's ter- minal (useful for debugging).	
า	Prints the values of the termio structure variables for the remote communication line (useful for debugging).	
~%ifc	Toggles between DC3/DC1 input control protocol and no input control. This is useful when the remote system does not respond properly to the DC3 and DC1 characters (can also be specified as ~%nostop).	
~%ofc	Toggles the output flow control setting. When enabled, outgoing data may be flow controlled by the remote host (can also be specified as ~% noostop).	
~%divert	Allow/disallow unsolicited diversions. That is, diversions not specified by ~%take .	
~%old	Allow/disallow old style syntax for received diversions.	
~%nostop	Same as ~%ifc .	
m) ;		

The *receive* process normally copies data from the remote system to the standard output of the local system. It may also direct the output to local files.

The use of **~%put** requires **stty**(1) and **cat**(1) on the remote side. It also requires that the current erase and kill characters on the remote system be identical to these current control characters on the local system. Backslashes are inserted at appropriate places.

The use of **~%take** requires the existence of **echo**(1) and **cat**(1) on the remote system, and that the remote system must be using the Bourne shell, **sh**. Also, **tabs** mode (see **stty**(1)) should be set on the remote system if tabs are to be copied without expansion to spaces.

modified 28 Mar 1995

	When cu is used on system X to connect to system Y and subsequently used on system Y to connect to system Z, commands on system Y can be executed by using ~. Executing a tilde command reminds the user of the local system uname . For example, uname can be executed on Z, X, and Y as follows: uname Z ~[X]!uname X ~~[Y]!uname
	Y In general, $$ causes the command to be executed on the original machine. $$ causes the command to be executed on the next machine in the chain.
EXAMPLES	To dial a system whose telephone number is 9 1 201 555 1234 using 1200 baud (where dialtone is expected after the 9):
	example% cu –s 1200 9=12015551234
	If the speed is not specified, "Any" is the default value.
	To login to a system connected by a direct line:
	example% cu –l /dev/term/b
	or
	example% cu –l term/b
	To dial a system with a specific line and speed:
	example% cu –s 1200 –l term/b
	To use a system name:
	example% cu systemname
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cu : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 Successful completion.
	>0 An error occurred.
FILES	/etc/uucp/Devices device file
	/etc/uucp/Sysfiles system file
	/etc/uucp/Systems system file /var/spool/locks/* lock file
	/var/spool/locks/* lock file
SEE ALSO	cat(1), echo(1), stty(1), uname(1), ct(1C), uuname(1C), uucp(1C), remote(4), environ(5)
	TCP/IP and Data Communications Guide

1C-195

NOTES The **cu** utility takes the default action upon receipt of signals, with the exception of:

SIGHUP Close the connection and terminate.

SIGINT Forward to the remote system.

SIGQUIT Forward to the remote system.

SIGUSR1 Terminate the **cu** process without the normal connection closing sequence.

The **cu** command does not do any integrity checking on data it transfers. Data fields with special **cu** characters may not be transmitted properly. Depending on the interconnection hardware, it may be necessary to use a ~. to terminate the conversion, even if **stty 0** has been used. Non-printing characters are not dependably transmitted using either the ~%**put** or ~%**take** commands. ~%**put** and ~%**take** cannot be used over multiple links. Files must be moved one link at a time.

There is an artificial slowing of transmission by **cu** during the **~%put** operation so that loss of data is unlikely. Files transferred using **~%take** or **~%put** must contain a trailing newline, otherwise, the operation will hang. Entering a CTRL-D command usually clears the hang condition.

modified 28 Mar 1995

NAME	cut – cut o	out selected fields of each line of a file
SYNOPSIS	cut –c list	t [- n] [file] [file] [- d delim] [- s] [file]
AVAILABILITY	SUNWcsı	1
DESCRIPTION	Use cut to cut out columns from a table or fields from each line of a file; in data base par- lance, it implements the projection of a relation. The fields as specified by <i>list</i> can be fixed length, that is, character positions as on a punched card (– c option) or the length can vary from line to line and be marked with a field delimiter character like TAB (– f option). cut can be used as a filter.	
	Either the	$-\mathbf{b}$, $-\mathbf{c}$, or $-\mathbf{f}$ option must be specified.
		(1) to make horizontal ''cuts'' (by context) through a file, or paste (1) to put files column-wise (that is, horizontally). To reorder columns in a table, use cut and
OPTIONS	list	A comma-separated or blank-character-separated list of integer field numbers (in increasing order), with optional – to indicate ranges (for instance, 1,4,7 ; 1–3,8 ; –5,10 (short for 1–5,10); or 3– (short for third through last field)).
	− b list	The <i>list</i> following $-\mathbf{b}$ specifies byte positions (for instance, $-\mathbf{b1}-72$ $-\mathbf{b1}-72$ would pass the first 72 bytes of each line). When $-\mathbf{b}$ and $-\mathbf{n}$ $-\mathbf{n}$ are used together, <i>list</i> is adjusted so that no multi-byte character is split. If $-\mathbf{b}$ is used, the input line should contain 1023 bytes or less.
	−c list	The <i>list</i> following – c specifies character positions (for instance, – c1–72 would pass the first 72 characters of each line).
	– d delim	The character following –d is the field delimiter (–f option only). Default is <i>tab</i> . Space or other characters with special meaning to the shell must be quoted. <i>delim</i> can be a multi-byte character.
	-f list	The <i>list</i> following $-\mathbf{f}$ is a list of fields assumed to be separated in the file by a delimiter character (see $-\mathbf{d}$); for instance, $-\mathbf{f1,7}$ copies the first and seventh field only. Lines with no field delimiters will be passed through intact (useful for table subheadings), unless $-\mathbf{s}$ is specified. If $-\mathbf{f}$ is used, the input line should contain 1023 characters or less.
	-n	Do not split characters. When $-\mathbf{b}$ <i>list</i> and $-\mathbf{n}$ are used together, <i>list</i> is adjusted so that no multi-byte character is split.
	- s	Suppresses lines with no delimiter characters in case of $-f$ option. Unless specified, lines with no delimiters will be passed through untouched.
OPERANDS	The follow	ving operands are supported:
	file	A path name of an input file. If no <i>file</i> operands are specified, or if a <i>file</i>

modified 1 Feb 1995

	operand is –, the standard input will be used.
EXAMPLES	A mapping of user IDs to names follows:
	example% cut –d: –f1,5 /etc/passwd
	To set name to current login name:
	example\$ name=`who am i cut –f1 –d' '`
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of cut : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 All input files were output successfully.
	>0 An error occurred.
SEE ALSO	<pre>grep(1), paste(1), environ(5)</pre>
DIAGNOSTICS	cut: –n may only be used with –b
	cut: –d may only be used with –f
	cut: –s may only be used with –f
	<pre>cut: cannot open <file> Either file cannot be read or does not exist. If multiple files are present, process- ing continues.</file></pre>
	cut: no delimiter specified Missing <i>delim</i> on – d option.
	cut: invalid delimiter
	cut: no list specified
	Missing <i>list</i> on $-\mathbf{b}$, $-\mathbf{c}$, or $-\mathbf{f}$, option.
	cut: invalid range specifier
	cut: too many ranges specified
	cut: range must be increasing
	cut: invalid character in range
	cut: internal error processing input
	cut: invalid multibyte character
	cut: unable to allocate enough memory

User Commands

NAME	date – write the date and time			
SYNOPSIS	<pre>/usr/bin/date [-u][+format] /usr/bin/date [-a [-] sss.fff] /usr/bin/date [-u][[mmdd]HHMM mmddHHMM[cc]yy] /usr/xpg4/bin/date [-u][+format] /usr/xpg4/bin/date [-a [-] sss.fff] /usr/xpg4/bin/date [-u][[mmdd]HHMM mmddHHMM[cc]yy]</pre>			
AVAILABILITY /usr/bin/date	SUNWcsu			
/usr/xpg4/bin/date	SUNWxcu4			
DESCRIPTION	The date utility writes the date and time to standard output or attendate and time. By default, the current date and time will be written			
	Specifications of native language translations of month and weekda ported. The month and weekday names used for a language are ba specified by the environment variable LC_TIME; see environ (5).			
	The following is the default form for the "C" locale:			
	%a %b %e %T %Z %Y			
	for example,			
	Fri Dec 23 10:10:42 EST 1988			
OPTIONS	The following options are supported:			
	 -a [-] sss.fff Slowly adjust the time by sss.fff seconds (fff represents second). This adjustment can be positive or negative. will be sped up or slowed down until it has drifted by seconds specified. 	The system's clock		
	 –u Display (or set) the date in Greenwich Mean Time (GM bypassing the normal conversion to (or from) local time 			
OPERANDS	The following operands are supported:			
	+format If the argument begins with +, the output of date is the mat and the current time to strftime(). date uses the or specifications listed on the strftime(3C) manual page, specification for %C determined by whether /usr/bin//usr/xpg4/bin/date is used:	conversion with the conversion

modified 1 Feb 1995

NAME	dc – desk calculator			
SYNOPSIS	dc [filename	dc [filename]		
AVAILABILITY	SUNWesu			
DESCRIPTION	dc is an arbitrary precision arithmetic package. Ordinarily it operates on decimal integers, but one may specify an input base, output base, and a number of fractional digits to be maintained. The overall structure of dc is a stacking (reverse Polish) calculator. If an argument is given, input is taken from that file until its end, then from the standard input.			
		rocessor for dc that provides infix notation and a C-like syntax that imple- ions. bc also provides reasonable control structures for programs. See bc (1).		
USAGE	The following	ng constructions are recognized:		
	number	The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (_) to input a negative number. Numbers may contain decimal points.		
	+-/*%^	The top two values on the stack are added (+), subtracted (–), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.		
	S <i>X</i>	The top of the stack is popped and stored into a register named x , where x may be any character. If the s is capitalized, x is treated as a stack and the value is pushed on it.		
	lx	The value in register x is pushed on the stack. The register x is not altered. All registers start with zero value. If the l is capitalized, register x is treated as a stack and its top value is popped onto the main stack.		
	d	The top value on the stack is duplicated.		
	р	The top value on the stack is printed. The top value remains unchanged.		
	Р	Interprets the top of the stack as an ASCII string, removes it, and prints it.		
	f	All values on the stack are printed.		
	q	Exits the program. If executing a string, the recursion level is popped by two.		
	Q	Exits the program. The top value on the stack is popped and the string exe- cution level is popped by that value.		
	x	Treats the top element of the stack as a character string and executes it as a string of dc commands.		
	X	Replaces the number on the top of the stack with its scale factor.		
	[]	Puts the bracketed ASCII string onto the top of the stack.		

	< <i>X</i> > <i>X</i> = <i>X</i>	-	elements of the stack are popped and compared. Register .Ix is hey obey the stated relation.
	v		top element on the stack by its square root. Any existing frac- the argument is taken into account, but otherwise the scale red.
	!	Interprets the	e rest of the line as a shell command.
	С	All values on	the stack are popped.
	i	The top value further input	e on the stack is popped and used as the number radix for
	Ι	Pushes the in	put base on the top of the stack.
	0	The top value further outpu	e on the stack is popped and used as the number radix for at.
	0	Pushes the ou	utput base on the top of the stack.
	k	scale factor: t maintained d	e stack is popped, and that value is used as a non-negative he appropriate number of places are printed on output, and luring multiplication, division, and exponentiation. The f scale factor, input base, and output base will be reasonable if ed together.
	К	Pushes the cu	urrent scale factor on the top of the stack.
	Z	The stack lev	el is pushed onto the stack.
	Z	Replaces the	number on the top of the stack with its length.
	?	A line of inpuexecuted.	ut is taken from the input source (usually the terminal) and
	Y	Displays dc c	lebugging information.
	;:	are used by b	oc(1) for array operations.
EXAMPLES	-	+dsa*pla10>y]	st ten values of n!: sy
SEE ALSO	bc (1)		
DIAGNOSTICS	<i>x</i> is unimpl		<i>x</i> is an octal number.
	out of space		The free list is exhausted (too many digits).
	out of stack	-	Too many pushes onto the stack (stack overflow).
	empty stack		Too many pops from the stack (stack underflow).
	nesting dep	oth	Too many levels of nested execution.
	divide by 0		Division by zero.

sqrt of neg number Square root of a negative number is not defined (ginary numbers).	
exp not an integer	dc only processes integer exponentiation.
exp too big	The largest exponent allowed is 999.
input base is too large	The input base x: $2 \le x \le 16$.
input base is too small	The input base x: $2 \le x \le 16$.
output base is too large	The output base must be no larger than BC_BASE_MAX .
invalid scale factor	Scale factor cannot be less than 1.
scale factor is too large	A scale factor cannot be larger than BC_SCALE_MAX.
symbol table overflow	Too many variables have been specified.
invalid index	Index cannot be less than 1.
index is too large	An index cannot be larger than BC_DIM_MAX .

NAME	deroff – remove nroff/troff, tbl, and eqn constructs		
SYNOPSIS	deroff [-m [m s l] [-w] [-i] [filename]		
AVAILABILITY	SUNWdoc		
DESCRIPTION	deroff reads each of the <i>filenames</i> in sequence and removes all troff (1) requests, macro calls, backslash constructs, eqn (1) constructs (between .EQ and .EN lines, and between delimiters), and tbl (1) descriptions, perhaps replacing them with white space (blanks and blank lines), and writes the remainder of the file on the standard output. deroff follows chains of included files (.so and .nx troff commands); if a file has already been included, a .so naming that file is ignored and a .nx naming that file terminates execution. If no input file is given, deroff reads the standard input.		
OPTIONS	 -m The -m option may be followed by an m, s, or l. The -mm option causes the macros to be interpreted so that only running text is output (that is, no text from macro lines.) The -ml option forces the -mm option and also causes deletion of lists associated with the mm macros. 		
	 If the -w option is given, the output is a word list, one "word" per line, with all other characters deleted. Otherwise, the output follows the original, with the deletions mentioned above. In text, a "word" is any string that <i>contains</i> at least two letters and is composed of letters, digits, ampersands (&), and apostrophes ('); in a macro call, however, a "word" is a string that <i>begins</i> with at least two letters and contains a total of at least three letters. Delimiters are any characters other than letters, digits, apostrophes, and ampersands. Trailing apostrophes and ampersands are removed from "words." 		
	$-\mathbf{i} The -\mathbf{i} ext{ option causes deroff to ignore .so and .nx commands.}$		
SEE ALSO	eqn (1), nroff (1), tbl (1), troff (1)		
NOTES	deroff is not a complete troff interpreter, so it can be confused by subtle constructs. Most such errors result in too much rather than too little output. The -ml option does not handle nested lists correctly.		

df(1B)	SunOS/BSD Compatibility Package Commands SunOS 5.5		
NAME	dfdicplay status of disk space on file systems		
	df – display status of disk space on file systems		
SYNOPSIS	/usr/ucb/df [-a][-i][-t type][filesystem][filename]		
AVAILABILITY	SUNWscpu		
DESCRIPTION	df displays the amount of disk space occupied by currently mounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used.		
	If arguments to df are path names, df produces a report on the file system containing the named file. Thus ' df .' shows the amount of space on the file system containing the current directory.		
OPTIONS	 -a Report on all filesystems including the uninteresting ones which have zero total blocks. (that is, auto- mounter) 		
	 -i Report the number of used and free inodes. Print '*' if no information is available. 		
	-t <i>type</i> Report on filesystems of a given type (for example, nfs or ufs).		
EXAMPLES	A sample of output for df looks like:		
	example% df Filesystem kbytes used avail capacity Mounted on sparky:/ 7445 4714 1986 70% / sparky:/usr 42277 35291 2758 93% /usr		
	Note: used+avail is less than the amount of space in the file system (kbytes); this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this may be adjusted using tunefs . When all the space on a file system except for this reserve is in use, only the super-user can allocate new files and data blocks to existing files. When a file system is overallocated in this way, df may report that the file system is more than 100% utilized.		
FILES	/etc/mnttablist of file systems currently mounted/etc/vfstablist of default parameters for each file system		
SEE ALSO	du(1M), quot(1M), tunefs(1M), mnttab(4)		

NAME	diff – display line-by-line differences between pairs of text files		
SYNOPSIS	diff [-bitw] [-c -e -f -h -n] file1 file2 diff [-bitw] [-C number] file1 file2 diff [-bitw] [-D string] file1 file2 diff [-bitw] [-c -e -f -h -n] [-l] [-r] [-s] [-S name] directory1 directory2		
AVAILABILITY	SUNWesu		
DESCRIPTION	The diff utility will compare the contents of <i>file1</i> and <i>file2</i> and write to standard output a list of changes necessary to convert <i>file1</i> into <i>file2</i> . This list should be minimal. No output will be produced if the files are identical.		
	The normal output contains lines of these forms:		
	n1 a n3,n4 n1,n2 d n3 n1,n2 c n3,n4		
	where $n1$ and $n2$ represent lines <i>file1</i> and $n3$ and $n4$ represent lines in <i>file2</i> These lines resemble ed (1) commands to convert <i>file1</i> to <i>file2</i> . By exchanging a for d and reading backward, <i>file2</i> can be converted to <i>file1</i> . As in ed , identical pairs, where $n1=n2$ or $n3=n4$ are abbreviated as a single number.		
	Following each of these lines come all the lines that are affected in the first file flagged by '<', then all the lines that are affected in the second file flagged by '>'.		
OPTIONS	- b Ignores trailing blanks (spaces and tabs) and treats other strings of blanks as equivalent.		
	-i Ignores the case of letters; for example, 'A' will compare equal to ' a '.		
	 -t Expands TAB characters in output lines. Normal or -c output adds character(s) to the front of each line that may adversely affect the indentation of the original source lines and make the output lines difficult to interpret. This option will preserve the original source's indentation. 		
	-w Ignores all blanks (SPACE and TAB characters) and treats all other string of blanks as equivalent; for example, 'if ($\mathbf{a} = = \mathbf{b}$)' will compare equal to 'if($\mathbf{a} = = \mathbf{b}$)'.		
	The following options are mutually exclusive:		
	-c Produces a listing of differences with three lines of context. With this option output format is modified slightly: output begins with identification of the files involved and their creation dates, then each change is separated by a line with a dozen *'s. The lines removed from <i>file1</i> are marked with '—'; those added to <i>file2</i> are marked '+'. Lines that are changed from one file to the other are marked in both files with '.'.'.		

	–C number	Produces a listing of differences identical to that produced by $-c$ with <i>number</i> lines of context.				
	- e	Produces a script of only a , c , and d commands for the editor ed , which will recreate <i>file2</i> from <i>file1</i> . In connection with – e , the following shell program may help maintain multiple versions of a file. Only an ancestral file (\$1) and a chain of version-to-version ed scripts (\$2,\$3,) made by diff need be on hand. A "latest version" appears on the standard output.				
		(shift; cat \$*; echo '1,\$p') ed – \$1				
	Except in rare circumstances, diff finds a smallest sufficient set of file differences.					
	$-\mathbf{f}$	Produces a similar script, not useful with ed , in the opposite order.				
	-h	Does a fast, half-hearted job. It works only when changed stretches are short and well separated, but does work on files of unlimited length. Options $-\mathbf{e}$ and $-\mathbf{f}$ are unavailable with $-\mathbf{h}$.				
	-n	Produces a script similar to $-\mathbf{e}$, but in the opposite order and with a count of changed lines on each insert or delete command.				
	– D string	Creates a merged version of <i>file1</i> and <i>file2</i> with C preprocessor controls included so that a compilation of the result without defining <i>string</i> is equivalent to compiling <i>file1</i> , while defining <i>string</i> will yield <i>file2</i> .				
	The followin	g options are used for comparing directories:				
	_l	Produce output in long format. Before the diff , each text file is piped through pr (1) to paginate it. Other differences are remembered and summarized after all text file differences are reported.				
	-r	Applies diff recursively to common subdirectories encountered.				
	— s	Reports files that are the identical; these would not otherwise be men- tioned.				
	-S name	Starts a directory diff in the middle, beginning with the file <i>name</i> .				
OPERANDS	The followin	g operands are supported:				
	file1 file2	A path name of a file or directory to be compared. If either <i>file1</i> or <i>file2</i> is –, the standard input will be used in its place.				
	directory1 directory2	A path name of a directory to be compared.				
	If only one of <i>file1</i> and <i>file2</i> is a directory, diff will be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.					
EXAMPLES	directory na	irectory containing a directory named x , dir2 is a directory containing a med x , dir1/x and dir2/x both contain files named date.out , and dir2/x con- amed y , the command:				

	example% diff -r dir1 dir2 could produce output similar to: Common subdirectories: dir1/x and dir2/x Only in dir2/x: y diff -r dir1/x/date.out dir2/x/date.out 1c1 < Mon Jul 2 13:12:16 PDT 1990
	> Tue Jun 19 21:41:39 PDT 1990
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of diff: LC_CTYPE , LC_MESSAGES , and NLSPATH .
	LC_TIME Determine the locale for affecting the format of file timestamps written with the – C and – c options.
	TZ Determine the locale for affecting the timezone used for calculating file times- tamps written with the –C and –c options.
EXIT STATUS	The following exit values are returned:
	0 No differences were found.
	1 Differences were found.
	>1 An error occurred.
FILES	/tmp/d????? temporary file used for comparison
	/usr/lib/diffh executable file for –h option
SEE ALSO	bdiff(1), cmp(1), comm(1), dircmp(1), ed(1), pr(1), sdiff(1), environ(5)
NOTES	Editing scripts produced under the $-\mathbf{e}$ or $-\mathbf{f}$ options are naive about creating lines consisting of a single period (.).
	Missing NEWLINE at end of file indicates that the last line of the file in question did not have a NEWLINE. If the lines are different, they will be flagged and output; although the output will seem to indicate they are the same.

NAME	diff3 – 3-way differential file comparison		
SYNOPSIS	diff3 [-exEX3] filename1 filename2 filename3		
AVAILABILITY	SUNWesu		
DESCRIPTION	diff3 compares three versions of a file, and publishes disagreeing ranges of text flagged with these codes:		
	====	all three files differ	
	====1	filename1 is different	
	====2	<i>filename2</i> is different	
	====3	filename3 is different	
	The type of change suffered in converting a given range of a given file to some other is indicated in one of these ways:		
	f: n1 a	Text is to be appended after line number $n1$ in file f , where $f = 1, 2$, or 3.	
	f: n1 , n2 c	Text is to be changed in the range line $n1$ to line $n2$. If $n1 = n2$, the range may be abbreviated to $n1$.	
		of the range follows immediately after a c indication. When the re identical, the contents of the lower-numbered file is suppressed.	
	The following comma	nd will apply the resulting script to <i>filename1</i> .	
	(cat script; ecł	no '1,\$p') ed – filename1	
OPTIONS	changes be	script for the editor ed (1) that will incorporate into <i>filename1</i> all tween <i>filename2</i> and <i>filename3</i> , i.e., the changes that normally lagged ==== and ==== 3 .	
	-x Produce a	script to incorporate only changes flagged ====.	
	-3 Produce as	script to incorporate only changes flagged ==== 3 .	
	<i>filename3</i> , b flagged wit	script that will incorporate all changes between <i>filename2</i> and out treat overlapping changes (that is, changes that would be th ==== in the normal listing) differently. The overlapping lines files will be inserted by the edit script, bracketed by <<<<< and nes.	
		script that will incorporate only changes flagged $====$, but treat ges in the manner of the $-E$ option.	
FILES	/tmp/d3* /usr/lib/diff3prog		

SEE ALSO	diff (1)
NOTES	Text lines that consist of a single '.' will defeat – e . Files longer than 64 Kbytes will not work.

NAME	diffmk – mark differences between versions of a troff input file		
SYNOPSIS	diffmk oldfile newfile markedfile		
AVAILABILITY	SUNWdoc		
DESCRIPTION	diffmk compares two versions of a file and creates a third version that includes "change mark" (. mc) commands for nroff (1) and troff (1). <i>oldfile</i> and <i>newfile</i> are the old and new versions of the file. diffmk generates <i>markedfile</i> , which, contains the text from <i>newfile</i> with troff (1) "change mark" requests (. mc) inserted where <i>newfile</i> differs from <i>oldfile</i> . When <i>markedfile</i> is formatted, changed or inserted text is shown by at the right margin of each line. The position of deleted text is shown by a single *.		
EXAMPLES	diffmk can also be used in conjunction with the proper troff requests to produce pro- gram listings with marked changes. In the following command line: example% diffmk old.c new.c marked.c ; nroff reqs marked.c pr		
	<pre>the file reqs contains the following troff requests: .pl 1 .ll 77 .nf .eo .nh which eliminate page breaks, adjust the line length, set no-fill mode, ignore escape characters, and turn off hyphenation, respectively. If the characters and * are inappropriate, you might run markedfile through sed(1) to globally change them.</pre>		
SEE ALSO	<pre>diff(1), nroff(1), sed(1), troff(1)</pre>		
BUGS	Aesthetic considerations may dictate manual adjustment of some output. File differences involving only formatting requests may produce undesirable output, that is, replacing .sp by .sp 2 will produce a "change mark" on the preceding or following line of output.		

NAME	dircmp – directory comparison		
SYNOPSIS	dircmp [– ds] [– w <i>n</i>] <i>dir1 dir2</i>		
AVAILABILITY	SUNWesu		
DESCRIPTION	The dircmp command examines <i>dir1</i> and <i>dir2</i> and generates various tabulated informa- tion about the contents of the directories. Listings of files that are unique to each directory are generated for all the options. If no option is entered, a list is output indicating whether the file names common to both directories have the same contents.		
OPTIONS	The following options are supported:		
	-d Compare the contents of files with the same name in both directories and output a list telling what must be changed in the two files to bring them into agreement. The list format is described in diff (1).		
	-s Suppress messages about identical files.		
	$-\mathbf{w}$ <i>n</i> Change the width of the output line to <i>n</i> characters. The default width is 72 .		
OPERANDS	The following operands are supported:		
	<i>dir1</i> <i>dir2</i> A path name of a directory to be compared.		
	<i>dir2</i> A path name of a directory to be compared.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of dircmp : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred. (differences in directory contents are not considered errors)		
SEE ALSO	cmp(1), diff(1), environ(5)		

modified 1 Feb 1995

NAME	dis – object code disassembler		
SYNOPSIS	/usr/ccs/bin/dis [-C] [-o] [-V] [-L] [-d sec] [-D sec] [-F function] [-l string] [-t sec] file		
AVAILABILITY	SUNWbtool		
DESCRIPTION	The dis command produces an assembly language listing of <i>file</i> , which may be an object file or an archive of object files. The listing includes assembly statements and an octal or hexadecimal representation of the binary that produced those statements.		
OPTIONS	The following options are interpreted by the disassembler and may be specified in any order.		
	- C	Display demangled C++ symbol names in the disassembly.	
	-d sec	Disassemble the named section as data, printing the offset of the data from the beginning of the section.	
	–D sec	Disassemble the named section as data, printing the actual address of the data.	
	-F function	Disassemble only the named function in each object file specified on the command line. The $-\mathbf{F}$ option may be specified multiple times on the command line.	
	-l string	Disassemble the archive file specified by <i>string</i> . For example, one would issue the command $dis -l x - l z$ to disassemble $libx.a$ and $libz.a$, which are assumed to be in LIBDIR .	
	–L	Invoke a lookup of C-language source labels in the symbol table for sub- sequent writing to standard output.	
	-0	Print numbers in octal. The default is hexadecimal.	
	-t sec	Disassemble the named section as text.	
	-V	Print, on standard error, the version number of the disassembler being executed.	
	If the $-d$, $-D$ or $-t$ options are specified, only those named sections from each user- supplied file will be disassembled. Otherwise, all sections containing text will be disassembled.		
	that the break- numbers will b tion, for examp	umber enclosed in brackets at the beginning of a line, such as [5] , indicates pointable line number starts with the following instruction. These line we printed only if the file was compiled with additional debugging informa- ole, the $-\mathbf{g}$ option of $\mathbf{cc}(1B)$. An expression such as $<40>$ in the operand ymbolic disassembly, following a relative displacement for control	

transfer instructions, is the computed address within the section to which control will be transferred. A function name will appear in the first column, followed by () if the object

·

file contains a symbol table.

modified 1 Feb 1995

OPERANDS	The following operands are supported:		
	<i>file</i> A path name of an object file or an archive (see ar (1)) of object files.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of dis : LC_CTYPE, LC_MESSAGES, and NLSPATH.		
	LIBDIRIf this environment variable contains a value, use this as the path to search for the library. If the variable contains a null value, or is not set, it defaults to searching for the library under /usr/ccs/lib.		
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
FILES	/usr/ccs/lib default LIBDIR		
SEE ALSO	as(1), cc(1B), ld(1), a.out(4), environ(5)		
DIAGNOSTICS	The self-explanatory diagnostics indicate errors in the command line or problems encountered with the specified files.

DESCRIPTION	dispuid display	ys a list of all user names on the system (one line per name).
EXIT CODES	0	Successful execution
	1	Cannot read the password file

1-217

NAME	dos2unix – convert text file from DOS format to ISO format		
SYNOPSIS	dos2unix [–ascii] [–iso] [–7] originalfile convertedfile		
AVAILABILITY	SUNWesu		
DESCRIPTION	dos2unix converts characters in the DOS extended character set to the corresponding ISO standard characters.		
	This command can be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.		
	If the original file and the converted file are the same, dos2unix will rewrite the original file after converting it.		
OPTIONS	-ascii Removes extra carriage returns and converts end of file characters in DOS format text files to conform to SunOS requirements.		
	-iso This is the default. It converts characters in the DOS extended character set to the corresponding ISO standard characters.		
	-7 Convert 8 bit DOS graphics characters to 7 bit space characters so that SunOS can read the file.		
SEE ALSO	unix2dos(1)		
DIAGNOSTICS	File <i>filename</i> not found, or no read permission The input file you specified does not exist, or you do not have read permission (check with the SunOS ls – l command).		
	Bad output filename <i>filename</i> , or no write permission The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.		
	 Error while writing to temporary file An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Note that when this error occurs, the ori- ginal file remains intact. Could not rename temporary file to Translated temporary file name = filename. The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this message. 		

NAME	download – host resident PostScript font downloader		
SYNOPSIS	download [-f] [-p printer] [-m name] [-H directory] [file] /usr/lib/lp/postscript/download		
DESCRIPTION	put. If no files a download assum	bends host resident fonts to <i>files</i> and writes the results on the standard out- are specified, or if – is one of the input <i>files</i> , the standard input is read. hes the input <i>files</i> make up a single PostScript job and that requested fonts d at the start of each input <i>file</i> .	
		s are named in a comment (marked with %% DocumentFonts:) in the ailable fonts are the ones listed in the map table selected using the -m	
	The map table consists of fontname–file pairs. The fontname is the full name of the PostScript font, exactly as it would appear in a %% DocumentFonts: comment. The file is the pathname of the host resident font. A file that begins with a / is used as is. Otherwise the pathname is relative to the host font directory. Comments are introduced by % (as in PostScript) and extend to the end of the line.		
	load to readabl	dates for downloading are fonts listed in the map table that point down - e files. A font is downloaded once, at most. Requests for unlisted fonts or as are ignored. All requests are ignored if the map table can not be read.	
OPTIONS	-f	Force a complete scan of each input <i>file.</i> In the absence of an explicit comment pointing <i>download</i> to the end of the file, the default scan stops immediately after the PostScript header comments.	
	– p printer	Check the list of printer-resident fonts in / etc/lp/printers / <i>printer</i> / residentfonts before downloading.	
	- m name	Use <i>name</i> as the font map table. A <i>name</i> that begins with / is the full pathname of the map table and is used as is. Otherwise <i>name</i> is appended to the pathname of the host font directory.	
	-H directory	Use <i>dir</i> as the host font directory. The default is /usr/lib/lp/postscript.	
EXAMPLES	The following map table could be used to control the downloading of the Bookman fon family:		
		ng is the full PostScript font name. The second string ne - relative to the host font directory unless it begins	
	Bookman-Ligl Bookman-Ligl Bookman-Den	htItalic bookman/lightitalic	

modified 12 Mar 1994

1-219

Bookman-DemiItalic	bookman/demiitalic
	bookinan/ ucininanc

Using the file **myprinter/map** (in the default host font directory) as the map table, you could download fonts by issuing the following command:

example% download -m myprinter/map file

SEE ALSO dpost(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), posttek(1)

The **download** program should be part of a more general program.

DIAGNOSTICS An exit status of **0** is returned if *files* were successfully processed.

NOTES

download does not look for %%**PageFonts:** comments and there is no way to force multiple downloads of a particular font.

We do not recommend the use of full pathnames in either map tables or the names of map tables.

NAME	dpost – troff postprocessor for PostScript printers		
SYNOPSIS	dpost [–c num] [–e num] [–m num] [–n num] [–o list] [–w num] [–x num] [–y num] [–F dir] [–H dir] [–L file] [–O] [–T name] [file]		
	/usr/lib/lp/post	tscript/dpost	
DESCRIPTION		s <i>files</i> created by troff (1) into PostScript and writes the results on the stan- f no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is	
	duce the best an used to format eqn and pic pro	be prepared by troff . The default font files in / usr/lib/font/devpost pro- nd most efficient output. They assume a resolution of 720 dpi, and can be files by adding the – Tpost option to the troff call. Older versions of the eprocessors need to know the resolution that troff will be using to format se are the versions installed on your system, use the – r720 option with eqn an pic .	
	tion used to tra / usr/lib/font/de	o assumptions about resolutions. The first x res command sets the resolu- nslate the input <i>files</i> , the DESC.out file, usually evpost/ DESC.out , defines the resolution used in the binary font files, and prologue is responsible for setting up an appropriate user coordinate sys-	
OPTIONS	–c num	Print <i>num</i> copies of each page. By default only one copy is printed.	
	−e num	Sets the text encoding level to <i>num</i> . The recognized choices are 0, 1, and 2. The size of the output file and print time should decrease as <i>num</i> increases. Level 2 encoding will typically be about 20 percent faster than level 0, which is the default and produces output essentially identical to previous versions of dpost .	
	– m num	Magnify each logical page by the factor <i>num</i> . Pages are scaled uni- formly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0 .	
	– n num	Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1 .	
	−o list	Print those pages for which numbers are given in the comma-separated <i>list</i> . The list contains single numbers <i>N</i> and ranges <i>N1–N2</i> . A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4 , then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4 , when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.	

modified 12 Mar 1994

1-221

	- p mode	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.
	–w num	Set the line width used to implement <i>troff</i> graphics commands to <i>num</i> points, where a point is approximately $1/72$ of an inch. By default, <i>num</i> is set to 0.3 points.
	−x num	Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive <i>num</i> moves everything right. The default offset is 0 inches.
	–y num	Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves text up the page. The default offset is 0 .
	–F dir	Use <i>dir</i> as the font directory. The default <i>dir</i> is / usr/lib/font , and dpost reads binary font files from directory / usr/lib/font/devpost .
	−H dir	Use <i>dir</i> as the host resident font directory. Files in this directory should be complete PostScript font descriptions, and must be assigned a name that corresponds to the appropriate two-character troff font name. Each font file is copied to the output file only when needed and at most once during each job. There is no default directory.
	–L file	Use <i>file</i> as the PostScript prologue which, by default, is / usr/lib/lp/postscript/dpost.ps .
	-0	Disables PostScript picture inclusion. A recommended option when dpost is run by a spooler in a networked environment.
	-T name	Use font files for device <i>name</i> as the best description of available PostScript fonts. By default, <i>name</i> is set to post and dpost reads binary files from / usr/lib/font/devpost .
EXAMPLES	If the old versions of eqn and pic are installed on your system, you can obtain the best possible looking output by issuing a command line such as the following:	
	exampl	e% pic –T720 file tbl eqn –r720 troff –mm –Tpost dpost
	Otherwise,	
	exampl	e% pic file tbl eqn troff –mm –Tpost dpost
	should give the	best results.
FILES	/usr/lib/font/de /usr/lib/font/de /usr/lib/lp/post /usr/lib/lp/post /usr/lib/lp/post /usr/lib/lp/post /usr/lib/macros /usr/lib/macros	vpost/charlib/* script/color.ps script/draw.ps script/forms.ps script/ps.requests /pictures

SEE ALSO	<pre>download(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), pos-</pre>
	treverse(1), posttek(1), troff(1)

DIAGNOSTICS An exit status of **0** is returned if *files* have been translated successfully, while **2** often indicates a syntax error in the input *files*.

NOTES Output files often do not conform to Adobe's file structuring conventions. Piping the output of **dpost** through **postreverse**(1) should produce a minimally conforming PostScript file.

Although **dpost** can handle files formatted for any device, emulation is expensive and can easily double the print time and the size of the output file. No attempt has been made to implement the character sets or fonts available on all devices supported by **troff**. Missing characters will be replaced by white space, and unrecognized fonts will usually default to one of the Times fonts (that is, **R**, **I**, **B**, or **BI**).

An **x** res command must precede the first **x** init command, and all the input *files* should have been prepared for the same output device.

Use of the -T option is not encouraged. Its only purpose is to enable the use of other PostScript font and device description files, that perhaps use different resolutions, character sets, or fonts.

Although level 0 encoding is the only scheme that has been thoroughly tested, level 2 is fast and may be worth a try.

du (1B)	SunOS/BSD Compatibility Package CommandsSunOS 5.5		
NAME SYNOPSIS	du – display the number of disk blocks used per directory or file /usr/ucb/du /usr/ucb/du [–a] [–s] [<i>filename</i>]		
AVAILABILITY	SUNWscpu		
DESCRIPTION	du gives the number of kilobytes contained in all files and, recursively, directories within each specified directory or file <i>filename</i> . If <i>filename</i> is missing, '.' (the current directory) is used. A file which has multiple links to it is only counted once.		
OPTIONS	- a Generate an entry for each file.		
	-s Only display the grand total for each of the specified <i>filenames</i> .		
	Entries are generated only for each directory in the absence of options.		
EXAMPLES	Here is an example of using du in a directory. We used the pwd(1) command to identify the directory, then used du to show the usage of all the subdirectories in that directory. The grand total for the directory is the last entry in the display: example% pwd /usr/ralph/misc example% du 5 ./jokes 33 ./squash 44 ./tech.papers/lpr.document 217 ./tech.papers/new.manager 401 ./tech.papers 144 ./memos 80 ./letters 388 ./window 93 ./messages 15 ./useful.news 1211 . example%		
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of du for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how du behaves.		

	LC_CTYPE
	Determines how du handles characters. When LC_CTYPE is set to a valid value, du can display and handle text and filenames containing valid characters for that locale. du can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. du can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.
	LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).
SEE ALSO	pwd(1), df(1M), quot(1M), environ(5)
NOTES	Filename arguments that are not directory names are ignored, unless you use $-a$.
	If there are too many distinct linked files, du will count the excess files more than once.

1B-225

NAME	dump – dump selected parts of an object file		
SYNOPSIS	dump [-aCcDfghLlorstV] [-T index [, indexn]] filename		
		fhorstL [v]] filename	
	-	sr [–d number [, numbern]]] filename	
	aump [–n	srt [-n name]] filename	
DESCRIPTION	The dump	command dumps selected parts of each of its object <i>file</i> arguments.	
OPTIONS	This command will accept both object files and archives of object files. It processes each file argument according to one or more of the following options:		
	-a	Dump the archive header of each member of an archive.	
	- c	Dump the string table(s).	
	- C	Dump decoded C++ symbol table names.	
	- D	Dump debugging information.	
	-f	Dump each file header.	
	g	Dump the global symbols in the symbol table of an archive.	
	-h	Dump the section headers.	
	- l	Dump line number information.	
	–L	Dump dynamic linking information and static shared library information, if available.	
	-0	Dump each program execution header.	
	-r	Dump relocation information.	
	s	Dump section contents in hexadecimal.	
	-t	Dump symbol table entries.	
	– T index or	-T index1,index2	
		Dump only the indexed symbol table entry defined by <i>index</i> or a range of	
		entries defined by <i>index1,index2</i> .	
	$-\mathbf{V}$	Print version information.	
	The following modifiers are used in conjunction with the options listed above to modify their capabilities. -d number or -d number1,number2		
		Dump the section number indicated by <i>number</i> or the range of sections start- ing at <i>number1</i> and ending at <i>number2</i> . This modifier can be used with – h , – s , and – r . When – d is used with – h or – s , the argument is treated as the number of a section or range of sections. When – d is used with – r , the argu- ment is treated as the number of the section or range of sections to which the	
		relocation applies. For example, to print out all relocation entries associated with the .text section, specify the number of the section as the argument to $-\mathbf{d}$. If .text is section number 2 in the file, dump $-\mathbf{r} - \mathbf{d} 2$ will print all	

modified 11 Oct 1990

associated entries. To print out a specific relocation section use **dump** –**s** –**n** *name* for raw data output, or **dump** –**sv** –**n** *name* for interpreted output.

- -**n** name Dump information pertaining only to the named entity. This modifier can be used with -h, -s, -r, and -t. When -n is used with -h or -s, the argument will be treated as the name of a section. When -n is used with -t or -r, the argument will be treated as the name of a symbol. For example, dump -t -n.text will dump the symbol table entry associated with the symbol whose name is .text, where dump -h -n.text will dump the section header information for the .text section.
- -p Suppress printing of the headings.
- Dump information in symbolic representation rather than numeric. This modifier can be used with -a (date, user id, group id), -f (class, data, type, machine, version, flags), -h (type, flags), -o (type, flags), -r (name, type), -s (interpret section contents wherever possible), -t (type, bind), and -L (value). When -v is used with -s, all sections that can be interpreted, such as the string table or symbol table, will be interpreted. For example, dump -sv -n .symtab filename... will produce the same formatted output as dump -tv filename..., but dump -s -n .symtab filename... will print raw data in hexadecimal. Without additional modifiers, dump -sv filename... will dump all sections in the files interpreting all those that it can and dumping the rest (such as .text or .data) as raw data.

The **dump** command attempts to format the information it dumps in a meaningful way, printing certain information in character, hexadecimal, octal or decimal representation as appropriate.

NAME	dumpcs – show codeset table for the current locale		
SYNOPSIS	dumpcs [–0123vw]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	 dumpcs shows a list of printable characters for the user's current locale, along with their hexadecimal code values. The display device is assumed to be capable of displaying characters for a given locale. With no option, dumpcs displays the entire list of printable characters for the current locale. With one or more numeric options specified, it shows EUC codeset(s) for the current locale according to the numbers specified, and in order of codeset number. Each non-printable character is represented by an asterisk "*" and enough ASCII space character(s) 		
	to fill that codeset's column width.		
OPTIONS	-0 Show ASCII (or EUC primary) codeset.		
	 Show EUC codeset 1, if used for the current locale. 		
	 -2 Show EUC codeset 2, if used for the current locale. -3 Show EUC codeset 3, if used for the current locale. 		
	 -s show EUC codeset 3, if used for the current locale. -v "Verbose. Normally, ranges of non-printable characters are collapsed into a sin- 		
	gle line. This option produces one line for each non-printable character.		
	-w Replace code values with corresponding wide character values (process codes).		
ENVIRONMENT	The environment variables LC_CTYPE and LANG control the character classification throughout dumpcs . On entry to dumpcs , these environment variables are checked in that order. This implies that a new setting for LANG does not override the setting of LC_CTYPE. When none of the values is valid, the character classification defaults to the POSIX.1 "C" locale.		
FILES	/ usr/lib/locale / <i>locale-name</i> / LC_CTYPE/ctype data file containing character classification, conversion, and char- acter set width information

modified 26 Jul 1994

NAME	echo – echo arguments		
SYNOPSIS	/usr/bin/echo [string]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The echo utility writes its arguments, separated by BLANKs and terminated by a NEW- LINE, to the standard output. If there are no arguments, only the NEWLINE character will be written. echo is useful for producing diagnostics in command files, for sending known data into a pipe, and for displaying the contents of environment variables. The C shell, the Korn shell, and the Bourne shell each have an echo built-in command, which, by default, will have precedence, and will be invoked if the user calls echo without a full pathname. See shell_builtins (1). sh 's echo , ksh 's echo , and / usr/bin/echo understand the black-slashed escape characters, except that sh 's echo does not under- stand \ a as the alert character; however, these commands do not have a –n option. csh 's echo and / usr/ucb/echo , on the other hand, have a –n option, but do not understand the back-slashed escape characters.		
OPERANDS	The following operands are supported:stringA string to be written to standard output. If any operand is "-n", it will be treated as a string, not an option. The following character sequences will be recognized within any of the arguments: \aalert character\bbackspace\cprint line without new-line\fform-feed\nnew-line\rcarriage return\ttab\vvertical tab\bbackslash\0nwhere n is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.		
USAGE	 Portable applications should not use -n (as the first argument) or escape sequences. The printf(1) utility can be used portably to emulate any of the traditional behaviours of the echo utility as follows: The Solaris 2.x /usr/bin/echo is equivalent to: printf "%b\n" "\$*" 		

	• The / usr/ucb/echo is equivalent to:
	if ["X\$1" = "X-n"]
	then
	shift
	printf "%s" "\$*" else
	printf "%s\n" "\$*"
	fi
	New applications are encouraged to use printf instead of echo .
EXAMPLES	You can use echo to determine how many subdirectories below the root directory (/) is your current directory, as follows:
	echo your current-working-directory's full pathname
	 pipe the output through tr to translate the path's embedded slash-characters into space-characters
	 pipe that output through wc -w for a count of the names in your path.
	example% /usr/bin/echo \$PWD tr '/' ' wc -w
	See $tr(1)$ and $wc(1)$ for their functionality.
	Below are the different flavors for echoing a string without a NEWLINE:
/usr/bin/echo	% /usr/bin/echo "\$USER's current directory is \$PWD\c"
sh/ksh shells	\$ echo "\$USER's current directory is \$PWD\c"
csh shell	% echo -n "\$USER's current directory is \$PWD"
/usr/ucb/echo	% /usr/ucb/echo -n "\$USER's current directory is \$PWD"
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of echo : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following error values are returned:
	0 Successful completion.
	>0 An error occurred.
SEE ALSO	<pre>echo(1B), printf(1), shell_builtins(1), ascii(5), environ(5)</pre>
NOTES	When representing an 8-bit character by using the escape convention $\ 0n$, the <i>n</i> must <i>always</i> be preceded by the digit zero (0).
	For example, typing: echo 'WARNING: 07' will print the phrase WARNING: and sound the "bell" on your terminal. The use of single (or double) quotes (or two backslashes) is required to protect the "\" that precedes the "07".
	Following the $\setminus 0$, up to three digits are used in constructing the octal output character. If, following the $\setminus 0n$, you want to echo additional digits that are not part of the octal representation, you must use the full 3-digit <i>n</i> . For example, if you want to echo "ESC 7" you must use the three digits "033" rather than just the two digits "33" after the $\setminus 0$.

User Commands

echo(1)

modified 28 Mar 1995

SunOS 5.5

User Commands

2 digits	Incorrect: produces:	echo "\0337" od -xc df0a 337	(hex) (ascii)
3 digits	Correct: produces:	echo "\00337" od -xc lb37 0a00 033 7	(hex) (ascii)

For the octal equivalents of each character, see **ascii**(5).

NAME	echo – echo arguments to standard output		
SYNOPSIS	/usr/ucb/echo [–n] [argument]		
AVAILABILITY	SUNWscpu		
DESCRIPTION	echo writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output.		
	echo is useful for producing diagnostics in command files and for sending known data into a pipe, and for displaying the contents of environment variables.		
	 For example, you can use echo to determine how many subdirectories below the root directory (/) is your current directory, as follows: echo your current-working-directory's full pathname pipe the output through tr to translate the path's embedded slash-characters into space-characters pipe that output through wc -w for a count of the names in your path. 		
	example% /usr/bin/echo "echo \$PWD tr '/' ' ' wc -w"		
	See $tr(1)$ and $wc(1)$ for their functionality.		
	The shells, $csh(1)$, $ksh(1)$, and $sh(1)$, each have an echo built-in command, which, by default, will have precedence, and will be invoked if the user calls echo without a full pathname. /usr/ucb/echo and csh's echo() have a –n option, but do not understand back-slashed escape characters. sh's echo(), ksh's echo(), and /usr/bin/echo, on the other hand, understand the black-slashed escape characters, and ksh's echo() also understands \ a as the audible bell character; however, these commands do not have a –n option.		
OPTIONS	- n Do not add the NEWLINE to the output.		
SEE ALSO	csh (1), echo (1), ksh (1), sh (1), tr (1), wc (1)		
NOTES	The $-\mathbf{n}$ option is a transition aid for BSD applications, and may not be supported in future releases.		

modified 3 Aug 1994

NAME	echo – put string on virtual output
SYNOPSIS	echo [string]
DESCRIPTION	The echo function directs each string it is passed to the standard output. If no argument is given, echo looks to the standard input for input. It is often used in conditional execution or for passing a string to another command.
EXAMPLES	Set the done descriptor to help if a test fails: done=`if [-s \$F1]; then echo close; else echo help; fi`
SEE ALSO	echo(1)

NAME	ed, red – text editor
SYNOPSIS	ed [-s -] [-p string] [-x] [-C] [file]
	red [- s -] [- p <i>string</i>] [- x] [- C] [<i>file</i>]
AVAILABILITY	SUNWcsu
DESCRIPTION	ed is the standard text editor. If the <i>file</i> argument is given, ed simulates an e command (see below) on the named file; that is to say, the file is read into ed 's buffer so that it can be edited.
	ed operates on a copy of the file it is editing; changes made to the copy have no effect on the file until a \mathbf{w} (write) command is given. The copy of the text being edited resides in a temporary file called the <i>buffer</i> . There is only one buffer.
	red is a restricted version of ed . It will only allow editing of files in the current directory. It prohibits executing shell commands via <i>!shell command</i> . Attempts to bypass these restrictions result in an error message (<i>restricted shell</i>).
	Both ed and red support the fspec (4) formatting capability. The default terminal mode is either stty – tabs or stty tab3 , where tab stops are set at eight columns (see stty (1)). If, however, the first line of <i>file</i> contains a format specification, that specification will override the default mode. For example, if the first line of <i>file</i> contains
	<:t5,10,15 s72:>
	tab stops would be set at 5, 10, and 15, and a maximum line length of 72 would be imposed.
	Commands to ed have a simple and regular structure: zero, one, or two <i>addresses</i> fol- lowed by a single-character <i>command</i> , possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses can very often be omitted.
	In general, only one command may appear on a line. Certain commands allow the input of text. This text is placed in the appropriate place in the buffer. While ed is accepting text, it is said to be in <i>input mode</i> . In this mode, <i>no</i> commands are recognized; all input is merely collected. Leave input mode by typing a period (.) at the beginning of a line, followed immediately by a carriage return.
Regular Expressions	ed supports a limited form of <i>regular expression</i> notation. Regular expressions are used in addresses to specify lines and in some commands (for example, s) to specify portions of a line that are to be substituted. To understand addressing in ed , it is necessary to know that at any time there is a <i>current line</i> . Generally speaking, the current line is the last line affected by a command; the exact effect on the current line is discussed under the description of each command.
	Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:

	 /usr/lib/locale/lcc_COLLATE/CollTable is present
	 /usr/lib/locale/locale/LC_COLLATE/coll.so is not present;
	otherwise, Simple Regular Expressions are used.
	Internationalized Regular Expressions are explained on regex (5). Simple Regular Expressions are explained on regexp (5).
ed Commands	Commands may require zero, one, or two addresses. Commands that require no addresses regard the presence of an address as an error. Commands that accept one or two addresses assume default addresses when an insufficient number of addresses is given; if more addresses are given than such a command requires, the last one(s) are used.
	Typically, addresses are separated from each other by a comma (,). They may also be separated by a semicolon (;). In the latter case, the first address is calculated, the current line (.) is set to that value, and then the second address is calculated. This feature can be used to determine the starting line for forward and backward searches (see Rules 5 and 6, above). The second address of any two-address sequence must correspond to a line in the buffer that follows the line corresponding to the first address.
	In the following list of ed commands, the parentheses shown prior to the command are <i>not</i> part of the address; rather they show the default address(es) for the command.
	Each address component can be preceded by zero or more blank characters. The com- mand letter can be preceded by zero or more blank characters. If a suffix letter (l, n or p) is given, it must immediately follow the command.
	The e , E , f , r , and w commands take an optional <i>file</i> parameter, separated from the command letter by one or more blank characters.
	If changes have been made in the buffer since the last w command that wrote the entire buffer, ed will warn the user if an attempt is made to destroy the editor buffer via the e or q commands. The ed utility will write the string: "?\n"
	(followed by an explanatory message if <i>help mode</i> has been enabled via the H command) to standard output and will continue in command mode with the current line number unchanged. If the e or q command is repeated with no intervening command, it will take effect.
	If an end-of-file is detected on standard input when a command is expected, the ed utility acts as if a q command had been entered.
	It is generally illegal for more than one command to appear on a line. However, any command (except \mathbf{e} , \mathbf{f} , \mathbf{r} , or \mathbf{w}) may be suffixed by \mathbf{l} , \mathbf{n} , or \mathbf{p} in which case the current line is either listed, numbered or written, respectively, as discussed below under the \mathbf{l} , \mathbf{n} , and \mathbf{p} commands.
	(.)a
	<text> . The append command accepts zero or more lines of text and appends it after the addressed line in the buffer. The current line (.) is left at the last inserted</text>

modified 28 Mar 1995

1-235

line, or, if there were none, at the addressed line. Address 0 is legal for this command: it causes the "appended" text to be placed at the beginning of the buffer. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

(.)	С
_	to	vt

() -	
<text></text>	The change command deletes the addressed lines from the buffer, then accepts zero or more lines of text that replaces these lines in the buffer. The current line (.) is left at the last line input, or, if there were none, at the first line that was not deleted; if the lines deleted were originally at the end of the buffer, the current line number will be set to the address of the new last line; if no lines remain in the buffer, the current line number will be set to zero.
С	Same as the X command, described later, except that ed assumes all text read in for the e and r commands is encrypted unless a null key is typed in.
(.,.)d	The delete command deletes the addressed lines from the buffer. The line after the last line deleted becomes the current line; if the lines deleted were originally at the end of the buffer, the new last line becomes the current line. If no lines remain in the buffer, the current line number will be set to zero.
e file	The edit command deletes the entire contents of the buffer and then reads the contents of <i>file</i> into the buffer. The current line (.) is set to the last line of the buffer. If <i>file</i> is not given, the currently remembered file name, if any, is used (see the f command). The number of bytes read will be written to standard output, unless the – s option was specified, in the following format: "% d \ n " < <i>number of bytes read</i> >
	<i>file</i> is remembered for possible use as a default file name in subsequent e , E , r , and w commands. If <i>file</i> is replaced by !, the rest of the line is taken to be a shell (sh (1)) command whose output is to be read. Such a shell command is <i>not</i> remembered as the current file name. See also DIAGNOSTICS below. All marks will be discarded upon the completion of a successful e command. If the buffer has changed since the last time the entire buffer was written, the user will be warned, as described previously.
E file	The Edit command is like \mathbf{e} , except that the editor does not check to see if any changes have been made to the buffer since the last \mathbf{w} command.
f file	If <i>file</i> is given, the f command will change the currently remembered path name to <i>file</i> ; whether the name is changed or not, it then will write the (possibly new) currently remembered path name to the standard output in the following format: "%s\n" pathname
	The current line number is unchanged.
(1,\$)g/RE	/ <i>command list</i> In the g lobal command, the first step is to mark every line that matches the given RE. Then, for every such line, the given <i>command list</i> is executed with

the current line (.) initially set to that line. When the **g** command completes, the current line number will have the value assigned by the last command in the command list. If there were no matching lines, the current line number will not be changed. A single command or the first of a list of commands appears on the same line as the global command. All lines of a multi-line list except the last line must be ended with a $\$; **a**, **i**, and **c** commands and associated input are permitted. The . terminating input mode may be omitted if it would be the last line of the *command list*. An empty *command list* is equivalent to the **p** command. The **g**, **G**, **v**, **V**, and ! commands are *not* permitted in the *command list*. See also the **NOTES** and the last paragraph before **FILES** below. Any character other than space or newline can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

(1,\$)G/RE/

In the interactive Global command, the first step is to mark every line that matches the given RE. Then, for every such line, that line is written to standard output, the current line (.) is changed to that line, and any one command (other than one of the a, c, i, g, G, v, and V commands) may be input and is executed. After the execution of that command, the next marked line is written, and so on; a new-line acts as a null command; an & causes the reexecution of the most recent non-null command executed within the current invocation of G. Note: The commands input as part of the execution of the G command may address and affect any lines in the buffer. The final value of the current line number will be the value set by the last command successfully executed. (Note that the last command successfully executed will be the G command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number will not be changed. The G command can be terminated by a SIGINT signal. The G command can be terminated by an interrupt signal (ASCII DEL or BREAK). Any character other than space or newline can be used instead of a slash to delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.

- **h** The **h**elp command gives a short error message that explains the reason for the most recent ? diagnostic. The current line number is unchanged.
- H The Help command causes **ed** to enter a mode in which error messages are written for all subsequent ? diagnostics. It will also explain the previous ? if there was one. The **H** command alternately turns this mode on and off; it is initially off. The current line number is unchanged.

(.)i <text>

The insert command accepts zero or more lines of text and inserts it before the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. This command differs from the **a** command only in the placement of the input text. Address 0 is not legal for

this command. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

- (.,.+1)j The join command joins contiguous lines by removing the appropriate newline characters. If exactly one address is given, this command does nothing. If lines are joined, the current line number will be set to the address of the joined line; otherwise, the current line number is unchanged.
- (.)**k***x* The mar**k** command marks the addressed line with name *x*, which must be an ASCII lower-case letter (**a**–**z**). The address '*x* then addresses this line; the current line (.) is unchanged.
- $(.,.) I \qquad \mbox{The l command writes to standard output the addressed lines in a visually unambiguous form. The characters (\\, \a, \b, \f, \r, \t, \v) will be written as the corresponding escape sequence; the \n in that table is not applicable. Non-printable characters not in the table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first).$

Long lines will be folded, with the point of folding indicated by writing backslash/newline character; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line will be marked with a **\$**. An **l** command can be appended to any other command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. The current line number will be set to the address of the last line written.

- (.,.)ma The move command repositions the addressed line(s) after the line addressed by *a*. Address **0** is legal for *a* and causes the addressed line(s) to be moved to the beginning of the file. It is an error if address *a* falls within the range of moved lines; the current line (.) is left at the last line moved.
- (.,.)n The number command writes the addressed lines, preceding each line by its line number and a tab character; the current line (.) is left at the last line written. The n command may be appended to any command other than e, E, f, q, Q, r, w, or !.
- (.,.)**p** The **p**rint command writes the addressed lines to standard output; the current line (.) is left at the last line written. The **p** command may be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. For example, **dp** deletes the current line and writes the new current line.
- P The P command causes ed to prompt with an asterisk (*) (or string, if -p is specified) for all subsequent commands. The P command alternatively turns this mode on and off; it is initially on if the -p option is specified, otherwise off. The current line is unchanged.
- **q** The **q**uit command causes **ed** to exit. If the buffer has changed since the last time the entire buffer was written, the user will be warned; see **DIAGNOS-TICS**.
- **Q** The editor exits without checking if changes have been made in the buffer since the last **w** command.

(S)r file The read command reads the contents of *file* into the buffer. If *file* is not given, the currently remembered file name, if any, is used (see the e and f commands). The currently remembered file name is not changed unless file is the very first file name mentioned since ed was invoked. Address 0 is legal for r and causes the file to be read in at the beginning of the buffer. If the read is successful and the -s option was not specified, the number of characters read is written to standard output in the following format: "%d\n", <number of bytes read>

The current line (.) is set to the last line read. If file is replaced by !, the rest of

the line is taken to be a shell (see sh(1)) command whose output is to be read. For example, \$r !ls appends current directory to the end of the file being edited. Such a shell command is not remembered as the current file name.

- (.,.)s/RE/replacement/
- (.,.)s/RE/replacement/count, count=[1-512]
- (.,.)s/RE/replacement/g
- (.,.)s/RE/replacement/l
- (.,.)s/RE/replacement/n
- (.,.)s/RE/replacement/p

The substitute command searches each addressed line for an occurrence of the specified RE. Zero or more substitution commands can be specified. In each line in which a match is found, all (non-overlapped) matched strings are replaced by the *replacement* if the global replacement indicator g appears after the command. If the global indicator does not appear, only the first occurrence of the matched string is replaced. If a number *count* appears after the command, only the *count*-th occurrence of the matched string on each addressed line is replaced. It is an error if the substitution fails on all addressed lines. Any character other than space or new-line may be used instead of / to delimit the RE and the *replacement*; the current line (.) is left at the last line on which a substitution occurred. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash. See also the last paragraph before FILES below.

An ampersand (&) appearing in the *replacement* is replaced by the string matching the RE on the current line. The special meaning of & in this context may be suppressed by preceding it by \backslash . As a more general feature, the characters n, where *n* is a digit, are replaced by the text matched by the *n*-th regular subexpression of the specified RE enclosed between $\ (and \)$. When nested parenthesized subexpressions are present, *n* is determined by counting occurrences of $\$ (starting from the left. When the character % is the only character in the *replacement*, the *replacement* used in the most recent substitute command is used as the replacement in the current substitute command; if there was no previous substitute command, the use of % in this manner is an error. The % loses its special meaning when it is in a replacement string of more than one character or is preceded by a \setminus . For each backslash (\setminus) encountered in scanning replacement from beginning to end, the following

modified 28 Mar 1995

1 - 239

character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than & , \setminus , % or digits.

A line may be split by substituting a new-line character into it. The new-line in the *replacement* must be escaped by preceding it by \setminus . Such substitution cannot be done as part of a **g** or **v** command list. The current line number will be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number is unchanged. If a line is split, a substitution is considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.

The substitute command supports the following indicators:

- *count* Substitute for the *count*th occurrence only of the RE found on each addressed line. *count* must be between **1-512**.
- **g** Globally substitute for all non-overlapping instances of the RE rather than just the first one. If both **g** and *count* are specified, the results are unspecified.
- I Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the I command.
- **n** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the **n** command.
- **p** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the **p** command.
- (.,.)ta This command acts just like the **m** command, except that a *copy* of the addressed lines is placed after address **a** (which may be 0); the current line (.) is left at the last line copied.
- The undo command nullifies the effect of the most recent command that modified anything in the buffer, namely the most recent a, c, d, g, i, j, m, r, s, t, u, v, G, or V command. All changes made to the buffer by a g, G, v or V global command will be undone as a single change; if no changes were made by the global command (such as with g/ RE/p), the u command will have no effect. The current line number will be set to the value it had immediately before the command being undone started.

(1,\$)v/RE/command list

This command is the same as the global command **g**, except that the lines marked during the first step are those that do *not* match the RE.

(1,\$)V/RE/

This command is the same as the interactive global command **G**, except that the lines that are marked during the first step are those that do *not* match the RE.

(1,\$)w file

The write command writes the addressed lines into *file*. If *file* does not exist, it is created with mode **666** (readable and writable by everyone), unless your file creation mask dictates otherwise; see the description of the **umask** special command on **sh**(1). The currently remembered file name is *not* changed unless *file* is the very first file name mentioned since **ed** was invoked. If no file name is given, the currently remembered file name, if any, is used (see the **e** and **f** commands); the current line (.) is unchanged. If the command is successful, the number of characters written is printed, unless the –**s** option is specified in the following format:

"%**d****n**", <*number of bytes written*>

If *file* is replaced by !, the rest of the line is taken to be a shell (see **sh**(1)) command whose standard input is the addressed lines. Such a shell command is *not* remembered as the current path name. This usage of the write command with ! is be considered as a "last w command that wrote the entire buffer".

(1,\$)W file

This command is the same as the write command above, except that it appends the addressed lines to the end of *file* if it exists. If *file* does not exist, it is created as described above for the *w* command.

- An educated guess is made to determine whether text read for the e and r commands is encrypted. A null key turns off encryption. Subsequent e, r, and w commands will use this key to encrypt or decrypt the text. An explicitly empty key turns off encryption. Also, see the -x option of ed.
- (\$)= The line number of the addressed line will be written to standard output in the following format:

"[®]∕d∖n" <*line number*>

The current line number is unchanged by this command.

!shell command

The remainder of the line after the ! is sent to the UNIX system shell (see **sh**(1)) to be interpreted as a command. Within the text of that command, the unescaped character % is replaced with the remembered file name; if a ! appears as the first character of the shell command, it is replaced with the text of the previous shell command. Thus, !! will repeat the last shell command. If any replacements of % or ! are performed, the modified line will be written to the standard output before *command* is executed. The ! command will write:

"!\n"

to standard output upon completion, unless the -s option is specified. The current line number is unchanged.

1-241

	(.+1) <nev< th=""><th>v-line> An address alone on a line causes the addressed line to be written. A new-line alone is equivalent to .+1p; it is useful for stepping forward through the buffer. The current line number will be set to the address of the written line.</th></nev<>	v-line> An address alone on a line causes the addressed line to be written. A new-line alone is equivalent to .+1p; it is useful for stepping forward through the buffer. The current line number will be set to the address of the written line.		
	If an inter command	terrupt signal (ASCII DEL or BREAK) is sent, ed writes a "? \n " and returns to <i>its</i> nd level.		
	The ed uti	utility will take the standard action for all signals with the following exceptions:		
	SIGINT	The ed utility will interrupt its current activity, write the string "?\ n" to stated ard output, and return to command mode.		
	SIGHUP	If the buffer is not empty and has changed since the last write, the ed utility will attempt to write a copy of the buffer in a file. First, the file named ed.hup in the current directory will be used; if that fails, the file named ed.hup in the directory named by the HOME environment variable will be used. In any case, the ed utility will exit without returning to command mode.		
	Some size limitation are in effect: 512 characters in a line, 256 characters in a global com- mand list, and 255 characters in the path name of a file (counting slashes). The limit on the number of lines depends on the amount of user memory; each line takes 1 word.			
	When rea	ding a file, ed discards ASCII and NUL characters.		
		file is not terminated by a new-line character, ed adds one and puts out a message plaining what it did.		
	last charad addressed s/ g/	closing delimiter of a RE or of a replacement string (for example, /) would be the haracter before a new-line, that delimiter may be omitted, in which case the essed line is written. The foll owing pairs of commands are equivalent: s/s1/s2 s/s1/s2/p g/s1 g/s1/p ?s1 ?s1?		
	If an inval	lid command is entered, ed will write the string: "?\ n "		
		by an explanatory message if <i>help mode</i> has been enabled by the H command) of output and will continue in command mode with the current line number		
OPTIONS	- C	Encryption option; the same as the $-x$ option, except that ed simulates a C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.		
	– p string	Allows the user to specify a prompt string. By default, there is no prompt string.		
	- s -	Suppresses the writing of character counts by e , r , and w commands, of diagnostics from e and q commands, and of the ! prompt after a ! <i>shell command</i> .		
	- x	Encryption option; when used, ed simulates an X command and prompts the user for a key. The X command makes an educated guess to determine whether text read in is encrypted or not.

NAME	edit – text editor (variant of ex for casual users)		
SYNOPSIS	/usr/bin/edit [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename		
	/usr/xpg4/bin/edit [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename		
AVAILABILITY /usr/bin/edit	SUNWcsu		
/usr/xpg4/bin/edit	SUNWxcu4		
DESCRIPTION	edit is a variant of the text editor ex recommended for new or casual users who wish to use a command-oriented editor. It operates precisely as ex with the following options automatically set:		
	novice ON		
	report ON		
	showmode ON		
	magic OFF		
	The following brief introduction should help you get started with edit . If you are using a CRT terminal you may want to learn about the display editor vi .		
	To edit the contents of an existing file you begin with the command edit <i>name</i> to the shell. edit makes a copy of the file that you can then edit, and tells you how many lines and characters are in the file. To create a new file, you also begin with the command edit with a filename: edit <i>name</i> ; the editor will tell you it is a [New File] .		
	The edit command prompt is the color (:), which you should see after starting the editor. If you are editing an existing file, then you will have some lines in edit's buffer (its name for the copy of the file you are editing). When you start editing, edit makes the last line of the file the current line. Most commands to edit use the current line if you do not tell them which line to use. Thus if you say print (which can be abbreviated p) and type car- riage return (as you should after all edit commands), the current line will be printed. If you delete (d) the current line, edit will print the new current line, which is usually the next line in the file. If you delete the last line, then the new last line becomes the current one. If you start with an empty file or wish to add some new lines, then the append (a) com- mand can be used. After you execute this command (typing a carriage return after the word append), edit will read lines from your terminal until you type a line consisting of just a dot (.); it places these lines after the current line. The last line you type then becomes the current line. The insert (i) command is like append , but places the lines you type before, rather than after, the current line.		
	I		

modified 10 Apr 1995

edit numbers the lines in the buffer, with the first line having number 1. If you execute the command **1**, then **edit** will type the first line of the buffer. If you then execute the command **d**, **edit** will delete the first line, line 2 will become line 1, and **edit** will print the current line (the new line 1) so you can see where you are. In general, the current line will always be the last line affected by a command.

You can make a change to some text within the current line by using the **substitute** (**s**) command: **s**/*old*/*new*/ where *old* is the string of characters you want to replace and *new* is the string of characters you want to replace *old* with.

The **filename** (**f**) command will tell you how many lines there are in the buffer you are editing and will say [**Modified**] if you have changed the buffer. After modifying a file, you can save the contents of the file by executing a **write** (**w**) command. You can leave the editor by issuing a **quit** (**q**) command. If you run **edit** on a file, but do not change it, it is not necessary (but does no harm) to **write** the file back. If you try to **quit** from **edit** after modifying the buffer without writing it out, you will receive the message **No write since last change (:quit! overrides)**, and **edit** will wait for another command. If you do not want to write the buffer out, issue the **quit** command followed by an exclamation point (**q**!). The buffer is then irretrievably discarded and you return to the shell.

By using the **d** and **a** commands and giving line numbers to see lines in the file, you can make any changes you want. You should learn at least a few more things, however, if you will use **edit** more than a few times.

The **change** (c) command changes the current line to a sequence of lines you supply (as in **append**, you type lines up to a line consisting of only a dot (.). You can tell **change** to change more than one line by giving the line numbers of the lines you want to change, that is, **3,5c**. You can print lines this way too: **1,23p** prints the first 23 lines of the file.

The **undo** (**u**) command reverses the effect of the last command you executed that changed the buffer. Thus if you execute a **substitute** command that does not do what you want, type **u** and the old contents of the line will be restored. You can also **undo** an **undo** command. **edit** will give you a warning message when a command affects more than one line of the buffer. Note that commands such as **write** and **quit** cannot be undone.

To look at the next line in the buffer, type carriage return. To look at a number of lines, type **^D** (while holding down the control key, press **d**) rather than carriage return. This will show you a half-screen of lines on a CRT or 12 lines on a hardcopy terminal. You can look at nearby text by executing the **z** command. The current line will appear in the middle of the text displayed, and the last line displayed will become the current line; you can get back to the line where you were before you executed the **z** command by typing ". The **z** command has other options: **z**– prints a screen of text (or 24 lines) ending where you are; **z**+ prints the next screenful. If you want less than a screenful of lines, type **z.11** to display five lines before and five lines after the current line. (Typing **z**.*n*, when *n* is an odd number, displays a total of *n* lines, centered about the current line; when *n* is an even number, it displays *n*–1 lines, so that the lines displayed are centered around the current line.) You can give counts after other commands; for example, you can delete 5 lines starting with the current line with the command **d5**.

modified 10 Apr 1995

	To find things in the file, you can use line numbers if you happen to know them; since the line numbers change when you insert and delete lines this is somewhat unreliable. You can search backwards and forwards in the file for strings by giving commands of the form /text/ to search forward for text or ?text? to search backward for text. If a search reaches the end of the file without finding text, it wraps around and continues to search back to the line where you are. A useful feature here is a search of the form /^text/ which searches for text at the beginning of a line. Similarly /text\$/ searches for text at the end of a line. You can leave off the trailing / or ? in these commands. The current line has the symbolic name dot (.); this is most useful in a range of lines as in			
	line in the file the last line in	ints the current line plus the rest of the lines in the file. To move to the last , you can refer to it by its symbolic name \$. Thus the command \$d deletes a the file, no matter what the current line is. Arithmetic with line references le. Thus the line \$-5 is the fifth before the last and .+20 is 20 lines after the		
	copy a section you wish to collines from the through z. To to move or co lines; followin edit chapter2 you wish to n	but the current line by typing '.='. This is useful if you wish to move or not text within a file or between files. Find the first and last line numbers opy or move. To move lines 10 through 20, type 10,20d a to delete these e file and place them in a buffer named a . edit has 26 such buffers named a o put the contents of buffer a after the current line, type put a . If you want py these lines to another file, execute an edit (e) command after copying the ng the e command with the name of the other file you wish to edit, that is, . To copy lines without deleting them, use yank (y) in place of d . If the text nove or copy is all within one file, it is not necessary to use named buffers. to move lines 10 through 20 to the end of the file, type 10,20m \$.		
OPTIONS	These options	s can be turned on or off using the set command in ex (1).		
	- - s	Suppress all interactive user feedback. This is useful when processing editor scripts.		
	-l	Set up for editing LISP programs.		
	-L	List the name of all files saved as the result of an editor or system crash.		
	- R	Readonly mode; the readonly flag is set, preventing accidental overwrit- ing of the file.		
	-r filename	Edit <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.)		
	–t tag	Edit the file containing the <i>tag</i> and position the editor at its definition.		
	$-\mathbf{v}$	Start up in display editing state using vi . You can achieve the same effect by simply typing the vi command itself.		
	-V	Verbose. Any non-tty input will be echoed on standard error. This may be useful when processing editor commands within shell scripts.		
	- x	Encryption option; when used, edit simulates the X command of ex and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an

User Commands

NAME	egrep – search a file for a pattern using full regular expressions		
SYNOPSIS	• •	[-bchilnsv] [-e pattern_list] [-f file] [strings] [file] grep [-bchilnsvx] [-e pattern_list] [-f file] [strings] [file]	
AVAILABILITY /usr/bin/egrep	SUNWcsu		
/usr/xpg4/bin/egrep	SUNWxcu4		
DESCRIPTION	 egrep (expression grep) searches files for a pattern of characters and prints all lines that contain that pattern. egrep uses full regular expressions (expressions that have string values that use the full set of alphanumeric and special characters) to match the patterns. It uses a fast deterministic algorithm that sometimes needs exponential space. If no files are specified, egrep assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file. 		
/usr/bin/egrep	page, except for 1. A full reg the full r 2. A full reg regular e 3. Full regu are matc	accepts full regular expressions as described on the regexp (5) manual (and \), and with the addition of: gular expression followed by + that matches one or more occurrences of egular expression. gular expression followed by ? that matches 0 or 1 occurrences of the full xpression. lar expressions separated by or by a NEWLINE that match strings that hed by any of the expressions. gular expression that may be enclosed in parentheses () for grouping.	
	 Be careful using the characters \$, *, [, ^, , (,), and \ in <i>full regular expression</i>, because they are also meaningful to the shell. It is safest to enclose the entire <i>full regular expression</i> in single quotes ''. The order of precedence of operators is [], then *?+, then concatenation, then and NEWLINE. 		
/usr/xpg4/bin/egrep	/ usr/xpg4/bin/egrep uses the regular expressions described in the EXTENDED REGU-LAR EXPRESSIONS section of the regex (5) manual page.		
OPTIONS	The following o	ptions are supported:	
	-b	Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).	
	- c	Print only a count of the lines that contain the pattern.	
	-e pattern_list	Search for a <i>pattern_list</i> (<i>full regular expression</i> that begins with a –).	
	−f file	Take the list of <i>full regular expressions</i> from <i>file</i> .

NAME	eject – eject media such as CI	D-ROM and f	loppy from drive	
SYNOPSIS	eject [-dfnq] [device nickname]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	 eject is used for those removable media devices that do not have a manual eject button, or for those that do, but are managed by Volume Management. The device may be specified by its name or by a nickname; if Volume Management is running and no device is specified, the default device is used. Only devices that support eject under program control respond to this command. eject responds differently, depending on whether or not Volume Management is running. 			
With Volume Management	When eject is used on media that can only be ejected manually, it will do everything except remove the media — including unmounting the file system if it is mounted. In this case, eject displays a message that the media can now be manually ejected. If a win- dow system is running, the message is displayed as a pop-up window. If no window system is running, a message is displayed both to stderr and to the system console that the media can now be physically removed. Volume Management has the concept of a default device, which eject uses if no path- name or nickname is specified. Use the – d parameter to check what default device will be used.			
Without Volume Management	When Volume Management is the eject command to that par eject will recognize the follow	thname. If a

		Nickname	Path	
		cd	/dev/rdsk/c0t6d0s2	
		cdrom	/dev/rdsk/c0t6d0s2	
		cd0	/dev/rdsk/c0t6d0s2	
		sr sr0	/dev/rdsk/c0t6d0s2 /dev/rdsk/c0t6d0s2	
		/dev/sr0	/dev/rdsk/c0t6d0s2	
		/dev/rsr0	/dev/rdsk/c0t6d0s2	
		c0t6d0s2	/dev/rdsk/c0t6d0s2	
	The lists above can be repro	oduced using	g the – n option to eject .	
	It is not recommended to physically eject media from a device which contains mounted filesystems. eject automatically searches for any mounted filesystems which reside on the device and attempts to umount them prior to ejecting the media (see mount (1M)). If the unmount operation fails, eject prints a warning message and exits. The – f flag may be used to specify an eject <i>even</i> if the device contains mounted partitions.			
	eject can also display its de	fault device	and a list of nicknames.

modified 25 Jan 1995

SEE ALSO	volcancel(1), volcheck(1), volmissing(1) mount(1M), rmmount(1M), vold(1M), rmmount.conf(4), vold.conf(4), volfs(7FS)		
EXAMPLES	To eject a CD from its drive, while Volume Management is running (assuming only one CD-ROM drive):		
	example> eject cdrom0		
	To eject a floppy disk (whether or not Volume Management is running):		
	example> eject floppy0		
	To eject a CD-ROM drive with pathname / dev/dsk/c0t3d0s2 , without Volume Manage- ment running:		
	example> eject /dev/dsk/c0t3d0s2		
DIAGNOSTICS	A short help message is printed if an unknown flag is specified. A diagnostic is printed if the device name cannot be opened or does not support eject .		
	Device Busy An attempt was made to eject a device that has a mounted filesystem. A warning message is printed when doing a forced eject of a mounted device.		
BUGS	There should be a way to change the default on a per-user basis.		
	If Volume Management is not running, it is possible to eject a volume that is currently mounted (see mount (1M)). For example, if you have a CD-ROM drive at / dev/dsk/c0t3d0s2 mounted on / mnt , the following command (withough Volume Management runnning) will work:		
	example> eject /dev/dsk/c0t3d0s0		
	since both slices s0 and s2 reference the whole CD-ROM drive.		

modified 25 Jan 1995

NAME	enable, disable – enable/disable LP printers		
SYNOPSIS	/usr/bin/enable printer /usr/bin/disable [–c –W] [–r [reason]] printer		
AVAILABILITY	SUNWlpu	L Contraction of the second	
DESCRIPTION	The enable command activates the named <i>printers</i> , enabling them to print requests sub- mitted by the lp command. If the printer is remote, the command will only enable the transfer of requests to the remote system; the enable command must be run again, on the remote system, to activate the printer. (Run lpstat – p to get the status of <i>printers</i> .)		
	The disable command deactivates the named <i>printer</i> , disabling it from printing requests submitted by lp . By default, any requests that are currently printing on the designated printer(s) will be reprinted in their entirety either on the same printer or on another member of the same class of printers. If the printer is remote, this command will only stop the transmission of jobs to the remote system. The disable command must be run on the remote system to disable the printer. (Run lpstat – p to get the status of <i>printers</i> .)		
OPTIONS	Options fo	or use with disable are:	
	- c	Cancel any requests that are currently printing on the designated printer(s). This option cannot be used with the $-\mathbf{W}$ option. If the printer is remote, the $-\mathbf{c}$ option will be silently ignored.	
	$-\mathbf{W}$	Wait until the request currently being printed is finished before disabling the specified printer. This option cannot be used with the $-c$ option. If the printer is remote, the $-W$ option will be silently ignored.	
	- r reason	Assign a <i>reason</i> for the disabling of the printer(s). This <i>reason</i> applies to all <i>printers</i> specified. This <i>reason</i> is reported by lpstat – p . <i>reason</i> must be enclosed in quotes if it contains blanks. The default reason is unknown reason for the existing printer, and new printer for a printer just added to the system but not yet enabled.

NAME	env – obtain or alter environment variables for command execution		
SYNOPSIS	env [-i -] [name=value] [utility [args]]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The env utility will obtain the current environment, modify it according to its arguments, then invoke the utility named by <i>utility</i> operand with the modified environment.		
	Optional argum	nents will be passed to <i>utility</i> .	
	If no <i>utility</i> operand is specified, the resulting environment will be written to the standard output, with one <i>name=value</i> pair per line.		
OPTIONS	The following o	ptions are supported:	
	- i -	Ignore the environment that would otherwise be inherited from the current shell. Restricts the environment for <i>utility</i> to that specified by the arguments.	
OPERANDS	The following o	perands are supported:	
	name=value	Arguments of the form <i>name=value</i> modify the execution environment, and are placed into the inherited environment before <i>utility</i> is invoked.	
	utility	The name of the utility to be invoked. If <i>utility</i> operand names any of the special shell built-in utilities, the results are undefined.	
	args	A string to pass as an argument for the invoked utility.	
EXAMPLES	The following utility: example% env -i PATH=/mybin mygrep xyz myfile invokes the utility mygrep with a new PATH value as the only entry in its environment. In this case, PATH is used to locate mygrep , which then must reside in / mybin .		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of env : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	If <i>utility</i> is invoked, the exit status of env will be the exit status of <i>utility</i> ; otherwise, the env utility will exit with one of the following values:		
	0	The env utility completed successfully.	
	1-125	An error occurred in the env utility.	
	126	The utility specified by <i>utility</i> was found but could not be invoked.	
	127	The utility specified by <i>utility</i> could not be found.

NAME	eqn, neqn, checkeq – typeset mathematics test		
SYNOPSIS	eqn $[-dxy]$ $[-fn]$ $[-pn]$ $[-sn]$ $[filename]$		
	neqn [filename]		
	checkeq [filename]		
AVAILABILITY	SUNWdoc		
DESCRIPTION	eqn and neqn are language processors to assist in describing equations. eqn is a preprocessor for troff (1) and is intended for devices that can print troff 's output. neqn is a preprocessor for nroff (1) and is intended for use with terminals. Usage is almost always:		
	example% eqn filename troff example% neqn filename nroff		
	If no <i>filenames</i> are specified, eqn and neqn read from the standard input. A line begin- ning with .EQ marks the start of an equation; the end of an equation is marked by a line beginning with .EN . Neither of these lines is altered, so they may be defined in macro packages to get centering, numbering, etc. It is also possible to set two characters as "del- imiters"; subsequent text between delimiters is also treated as eqn input.		
	checkeq reports missing or unbalanced delimiters and .EQ/.EN pairs.		
OPTIONS	 -dxy Set equation delimiters set to characters x and y with the command-line argument. The more common way to do this is with delim xy between .EQ and .EN. The left and right delimiters may be identical. Delimiters are turned off by delim off appearing in the text. All text that is neither between delimiters nor between .EQ and .EN is passed through untouched. 		
	-f <i>n</i> Change font to <i>n</i> globally in the document. The font can also be changed globally in the body of the document by using the gfont <i>n</i> directive, where <i>n</i> is the font specification.		
	 -pn Reduce subscripts and superscripts by <i>n</i> point sizes from the previous size. In the absence of the -p option, subscripts and superscripts are reduced by 3 point sizes from the previous size. 		
	-sn Change point size to <i>n</i> globally in the document. The point size can also be changed globally in the body of the document by using the gsize <i>n</i> directive, where <i>n</i> is the point size.		
EQN LANGUAGE	NOTE: The nroff version of this description depicts the output of neqn to the terminal screen exactly as neqn is able to display it. To see an accurate depiction of the output the printed version of this page should be viewed.		
	Tokens within eqn are separated by braces, double quotes, tildes, circumflexes, SPACE, TAB, or NEWLINE characters. Braces {} are used for grouping; generally speaking, any-where a single character like <i>x</i> could appear, a complicated construction enclosed in braces may be used instead. Tilde (~) represents a full SPACE in the output, circumflex (^)		

modified 14 Sep 1992

half as much. Subscripts and superscripts: These are produced with the keywords **sub** and **sup**. **x** sub i makes x_i **a sub i sup 2** produces a_i^2 e sup {x sup 2 + y sup 2} gives $e^{x^2+y^2}$ Fractions: Fractions are made with over. **a over b** yields $\frac{a}{b}$ **Square Roots:** These are made with sqrt 1 over sqrt {ax sup 2 +bx+c} results in $\frac{1}{\sqrt{ax^2+bx+c}}$ Limits: The keywords from and to introduce lower and upper limits on arbitrary things: lim from $\{n \rightarrow inf\}$ sum from 0 to n x sub i makes $\lim_{n\to\infty}\sum_{0}^{n} x_i$ **Brackets and Braces:** Left and right brackets, braces, etc., of the right height are made with left and right. left [x sup 2 + y sup 2 over alpha right] ~=~1 produces $\left[x^2+\frac{y^2}{\alpha}\right]=1.$ The right clause is optional. Legal characters after left and right are braces, brackets, bars, c and f for ceiling and floor, and "" for nothing at all (useful for a right-side-only bracket). Vertical piles: Vertical piles of things are made with pile, lpile, cpile, and rpile. pile {a above b above c} produces а b С There can be an arbitrary number of elements in a pile. lpile left-justifies, pile

and cpile center, with different vertical spacing, and rpile right justifies.

modified 14 Sep 1992

1-257

Matrices: Matrices are made with matrix. matrix { lcol { x sub i above y sub 2 } ccol { 1 above 2 } } produces $x_i = 1$ y₂ 2 In addition, there is rcol for a right-justified column. **Diacritical marks:** Diacritical marks are made with dot, dotdot, hat, tilde, bar, vec, dyad, and under. x dot = f(t) bar is $\dot{x} = \overline{f(t)}$ y dotdot bar ~=~ n under is $\overline{\ddot{y}} = \underline{n}$, x vec ~=~ y dyad is $\vec{x} = \vec{y}.$ Sizes and Fonts: Sizes and font can be changed with size *n* or size $\pm n$, roman, italic, bold, and font *n*. Size and fonts can be changed globally in a document by gsize *n* and **gfont** *n*, or by the command-line arguments –**s***n* and –**f***n*. Successive display arguments: Successive display arguments can be lined up. Place mark before the desired lineup point in the first equation; place **lineup** at the place that is to line up vertically in subsequent equations. Shorthands: Shorthands may be defined or existing keywords redefined with define: **define** thing % replacement % Defines a new token called thing which will be replaced by replacement whenever it appears thereafter. The % may be any character that does not occur in replacement. Keywords and Shorthands: Keywords like sum (Σ), int (\hat{I}), inf (∞), and shorthands like >= (\geq), \rightarrow (\rightarrow), and != (\neq) are recognized. Greek letters: Greek letters are spelled out in the desired case, as in alpha or GAMMA.

modified 14 Sep 1992

	Mathematical words: Mathematical words like sin , cos , and log are made Roman automatically. troff (1) four-character escapes like \(bu (•) can be used anywhere. Strings enclosed in double quotes "" are passed through untouched; this permits keywords to be entered as text, and can be used to communicate with troff when all else fails.
SEE ALSO	tbl (1), troff (1), ms (5)
BUGS	To embolden digits, parens, etc., it is necessary to quote them, as in ' bold "12.3 "'.

modified 14 Sep 1992

NAME	error – insert compiler error messages at right source lines		
SYNOPSIS	error [–n] [–q] [–s] [–v] [–t suffixlist] [–I ignorefile] [filename]		
DESCRIPTION	 error analyzes error messages produced by a number of compilers and language processors. It replaces the painful, traditional methods of scribbling abbreviations of errors on paper, and permits error messages and source code to be viewed simultaneously. error looks at error messages, either from the specified file <i>filename</i> or from the standard input, and: Determines which language processor produced each error message. Determines the file name and line number of the erroneous line. Inserts the error message into the source file immediately preceding the erroneous line. Error messages that can't be categorized by language processor or content are not inserted into any file, but are sent to the standard output. error touches source files only after all input has been read. error is intended to be run with its standard input connected with a pipe to the error message source. Some language processors put error messages on their standard error file; others put their messages on the standard output. Hence, both error sources should be piped together into error. For example, when using the csh syntax, the following command analyzes all the error messages produced by whatever programs make(1S) runs when making lint: example% make –s lint & error error knows about the error messages produced by: as(1), cpp(1), ld(1), cc(1B), make(1S) and other compilers. For all languages except Pascal, error messages are restricted to one line. Some error messages are fer to more than one line in more than one file, in which case error duplicates the error message and inserts it in all the appropriate places. 		
OPTIONS	 -n Do <i>not</i> touch any files; all error messages are sent to the standard output. -q error asks whether the file should be touched. A 'y' or 'n' to the question is necessary to continue. Absence of the -q option implies that all referenced files (except those referring to discarded error messages) are to be touched. -s Print out statistics regarding the error categorization. -v After all files have been touched, overlay the visual editor vi with it set up to edit all files touched, and positioned in the first touched file at the first error. If vi(1) can't be found, try ex(1) or ed(1) from standard places. 		

modified 5 Mar 1992

EXAMPLES	the suffix work. Th .c allows err error catches in In the following complier: exampl	Following argument as a suffix list. Files whose suffices do not appear in list are not touched. The suffix list is dot separated, and '*' wildcards us the suffix list: .y.f*.h ror to touch files ending with '.c', '.y', '.f*' and '.h'. terrupt and terminate signals, and terminates in an orderly fashion. g C shell (/usr/bin/csh) example, error takes its input from the FORTRAN le% f77 -c any.f & error" options
		e example using the Korn shell (/ usr/bin/ksh) : le% f77 –c any.f 2>&1 error" options
	examp	
USAGE		of six things with error messages.
	synchronize	Some language processors produce short errors describing which file they are processing. error uses these to determine the file name for languages that do not include the file name in each error message. These synchronization messages are consumed entirely by error .
	discard	Error messages from lint that refer to one of the two lint libraries, / usr/lib/lint/llib-lc and / usr/lib/lint/llib-port are discarded, to prevent accidentally touching these libraries. Again, these error messages are consumed entirely by error .
	nullify	Error messages from lint can be nullified if they refer to a specific func- tion, which is known to generate diagnostics which are not interesting. Nullified error messages are not inserted into the source file, but are written to the standard output. The names of functions to ignore are taken from either the file named .errorrc in the user's home directory, or from the file named by the -I option. If the file does not exist, no error messages are nullified. If the file does exist, there must be one function name per line.
	not file specific	Error messages that can't be intuited are grouped together, and written to the standard output before any files are touched. They are not inserted into any source file.
	file specific	Error messages that refer to a specific file but to no specific line are writ- ten to the standard output when that file is touched.
	true errors	Error messages that can be intuited are candidates for insertion into the file to which they refer.
	sumed entirely	messages are inserted into source files. Other error messages are con- by error or are written to the standard output. error inserts the error mes- burce file on the line preceding the line number in the error message.

modified 5 Mar 1992

1-261

Each error message is turned into a one line comment for the language, and is internally flagged with the string ### at the beginning of the error, and %%% at the end of the error. This makes pattern searching for errors easier with an editor, and allows the messages to be easily removed. In addition, each error message contains the source line number for the line the message refers to. A reasonably formatted source program can be recompiled with the error messages still in it, without having the error messages themselves cause future errors. For poorly formatted source programs in free format languages, such as C or Pascal, it is possible to insert a comment into another comment, which can wreak havoc with a future compilation. To avoid this, format the source program so there are no language statements on the same line as the end of a comment.

FILES	~/.errorrc	function names to ignore for lint error messages
	/dev/tty	user's teletype

SEE ALSO as(1), cc(1B), cpp(1), csh(1), ed(1), ex(1), make(1S), ld(1), vi(1)

BUGS

Opens the tty-device directly for user input.

Source files with links make a new copy of the file with only one link to it.

Changing a language processor's error message format may cause **error** to not understand the error message.

error, since it is purely mechanical, will not filter out subsequent errors caused by "floodgating" initiated by one syntactically trivial error. Humans are still much better at discarding these related errors.

Pascal error messages belong after the lines affected, error puts them before. The alignment of the '|' marking the point of error is also disturbed by **error**.

error was designed for work on CRT 's at reasonably high speed. It is less pleasant on slow speed terminals, and was not designed for use on hardcopy terminals.

modified 5 Mar 1992

NAME	ex – text editor
SYNOPSIS	/usr/bin/ex [− −s] [−l] [−L] [−R] [−r [file]] [−t tag] [−v] [−V] [−x] [−wn] [−C] [+command −c command] file
	/usr/xpg4/bin/ex [- -s] [-l] [-L] [-R] [-r [file]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] file
AVAILABILITY /usr/bin/ex	SUNWcsu
/usr/xpg4/bin/ex	SUNWxcu4
DESCRIPTION	ex is the root of a family of editors: ex and vi . ex is a superset of ed (1), with the most not- able extension being a display editing facility. Display based editing is the focus of vi . If you have a CRT terminal, you may wish to use a display based editor; in this case see vi (1), which is a command which focuses on the display-editing portion of ex .
For ed Users	If you have used ed you will find that, in addition to having all of the ed commands available, ex has a number of additional features useful on CRT terminals. Intelligent ter- minals and high speed terminals are very pleasant to use with vi . Generally, the ex edi- tor uses far more of the capabilities of terminals than ed does, and uses the terminal capa- bility data base (see terminfo (4)) and the type of the terminal you are using from the environment variable TERM to determine how to drive your terminal efficiently. The edi- tor makes use of features such as insert and delete character and line in its visual com- mand (which can be abbreviated vi) and which is the central mode of editing when using the vi command. ex contains a number of features for easily viewing the text of the file. The z command gives easy access to windows of text. Typing ^D (CTRL-D) causes the editor to scroll a
	half-window of text and is more useful for quickly stepping through a file than just typ- ing return. Of course, the screen-oriented visual mode gives constant access to editing context.
	ex gives you help when you make mistakes. The undo (u) command allows you to reverse any single change which goes astray. ex gives you a lot of feedback, normally printing changed lines, and indicates when more than a few lines are affected by a command so that it is easy to detect when a command has affected more lines than it should have.
	The editor also normally prevents overwriting existing files, unless you edited them, so that you do not accidentally overwrite a file other than the one you are editing. If the system (or editor) crashes, or you accidentally hang up the telephone, you can use the editor recover command (or $-\mathbf{r}$ <i>file</i> option) to retrieve your work. This will get you back to within a few lines of where you left off.

	of files on the of The next comm to specify a new formed with fu names and is re	features for dealing with more than one file at a time. You can give it a list command line and use the next (n) command to deal with each in turn. hand can also be given a list of file names, or a pattern as used by the shell w set of files to be dealt with. In general, file names in the editor may be all shell metasyntax. The metacharacter '%' is also available in forming file eplaced by the name of the current file. a group of buffers whose names are the ASCII lower-case letters (a-z). You					
	can place text in these named buffers where it is available to be inserted elsewhere in the file. The contents of these buffers remain available when you begin editing a new file using the edit (e) command.						
	There is a command & in ex which repeats the last substitute command. In addition, there is a confirmed substitute command. You give a range of substitutions to be done and the editor interactively asks whether each substitution is desired.						
	ular expressior	ignore the case of letters in searches and substitutions. ex also allows reg- ns which match words to be constructed. This is convenient, for example, r the word "edit" if your document also contains the word "editor."					
	ex has a set of options which you can set to tailor it to your liking. One option which is very useful is the autoindent option that allows the editor to supply leading white space to align text automatically. You can then use ^D as a backtab and space or tab to move forward to align new code easily.						
	space between	useful features include an intelligent join (j) command that supplies white joined lines automatically, commands < and > which shift groups of lines, to filter portions of the buffer through commands such as sort .					
OPTIONS	The following	options are supported:					
	- - s	Suppress all interactive user feedback. This is useful when processing editor scripts.					
	- l	Set up for editing LISP programs.					
	–L	List the name of all files saved as the result of an editor or system crash.					
	- R	Readonly mode; the readonly flag is set, preventing accidental overwriting of the file.					
	-r file	Edit <i>file</i> after an editor or system crash. (Recovers the version of <i>file</i> that was in the buffer when the crash occurred.)					
	–t tag	Edit the file containing the <i>tag</i> and position the editor at its definition.					
	$-\mathbf{v}$	Start up in display editing state using vi . You can achieve the same effect by simply typing the vi command itself.					
	$-\mathbf{V}$	Verbose. Any non-tty input will be echoed on standard error. This may be useful when processing editor commands within shell scripts.					
	- x	Encryption option. Simulates the X command and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an educated guess to

NAME	exec, eval, source – shell built-in functions to execute other commands
SYNOPSIS sh	exec [argument] eval [argument]
csh	exec command eval argument source [-h] name
ksh	† exec [arg] † eval [arg]
DESCRIPTION	
sh	The exec command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.
	The <i>arguments</i> to the eval built-in are read as input to the shell and the resulting command(s) executed.
csh	exec executes <i>command</i> in place of the current shell, which terminates.
	eval reads its <i>arguments</i> as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution.
	source reads commands from <i>name</i> . source commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested source commands.
	-h Place commands from the file <i>name</i> on the history list without executing them.
ksh	With the exec built-in, if <i>arg</i> is given, the command specified by the arguments is exe- cuted in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this com- mand is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.
	The arguments to eval are read as input to the shell and the resulting command(s) exe- cuted.
	 On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments.
	 a. Errors cause a script that contains them to abort.
I	

4.	Words, following a command preceded by <i>††</i> that are in the format of a vari-
	able assignment, are expanded with the same rules as a variable assignment.
	This means that tilde substitution is performed after the = sign and word
	splitting and file name generation are not performed.

SEE ALSO csh(1), ksh(1), sh(1)

NAME	exit, return, goto – shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps
SYNOPSIS sh	exit [<i>n</i>] return [<i>n</i>]
csh	exit [(expr)] goto label
ksh	† exit [<i>n</i>] † return [<i>n</i>]
DESCRIPTION sh	exit will cause the calling shell or shell script to exit with the exit status specified by <i>n</i> . If <i>n</i> is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)
	return causes a function to exit with the return value specified by <i>n</i> . If <i>n</i> is omitted, the return status is that of the last command executed.
csh	exit will cause the calling shell or shell script to exit, either with the value of the status variable or with the value specified by the expression <i>expr</i> .
	The goto built-in uses a specified <i>label</i> as a search string amongst commands. The shell rewinds its input as much as possible and searches for a line of the form <i>label</i> : possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a while or for built-in command and its corresponding end .
ksh	exit will cause the calling shell or shell script to exit with the exit status specified by <i>n</i> . The value will be the least significant 8 bits of the specified status. If <i>n</i> is omitted then the exit status is that of the last command executed. When exit occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An end-of-file will also cause the shell to exit except for a shell which has the ignoreeof option (See set below) turned on.
	return causes a shell function or '.' script to return to the invoking script with the return status specified by <i>n</i> . The value will be the least significant 8 bits of the specified status. If <i>n</i> is omitted then the return status is that of the last command executed. If return is invoked while not in a function or a '.' script, then it is the same as an exit .
	 On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments.
	 a. Errors cause a script that contains them to abort.
72	modified 15 Apr 1994

	4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	expand, unexpand – expand TAB characters to SPACE characters, and vice versa		
SYNOPSIS	expand [-t tablist] [file] expand [-tabstop] [-tab1, tab2,, tabn] [file]		
	unexpand	$[-\mathbf{a}] [-\mathbf{t} \ tablist] [file]$	
AVAILABILITY	SUNWesu	SUNWesu	
DESCRIPTION	expand copies <i>files</i> (or the standard input) to the standard output, with TAB characters expanded to SPACE characters. BACKSPACE characters are preserved into the output and decrement the column count for TAB calculations. expand is useful for pre-processing character files (before sorting, looking at specific columns, and so forth) that contain TAB characters.		
	ters back i	copies <i>files</i> (or the standard input) to the standard output, putting TAB charac- nto the data. By default, only leading SPACE and TAB characters are converted of tabs, but this can be overridden by the $-a$ option (see the OPTIONS section	
OPTIONS	expand op	otions are:	
	-t tablist	Specify the tab stops. The argument <i>tablist</i> must consist of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set <i>tablist</i> column positions apart instead of the default 8 . If multiple numbers are given, the tabs will be set at those specific column positions.	
		Each tab-stop position N must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position N causes the next character output to be in the (N +1)th column position on that line.	
		In the event of expand having to process a tab character at a position beyond the last of those specified in a multiple tab-stop list, the tab character is replaced by a single space character in the output.	
	-tabstop	Specify as a single argument, sets TAB characters <i>tabstop</i> SPACE characters apart instead of the default 8 .	
	-tab1, tab2	, <i>tabn</i> Set TAB characters at the columns specified by <i>—tab1, tab2,, tabn</i>	
	unexpand	options are:	
	- a	Insert TAB characters when replacing a run of two or more SPACE characters would produce a smaller output file.	
	−t tablist	Specify the tab stops. The option-argument <i>tablist</i> must be a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set <i>tablist</i> column positions apart instead

NAME	expr – evaluate arguments as an expression		
SYNOPSIS	expr arguments		
AVAILABILITY	SUNWcsu		
DESCRIPTION		will evaluate the expression and write the result to standard output. The l be written to indicate a zero value and nothing will be written to indicate	
OPERANDS	<i>arguments</i> are taken as an expression. Terms of the expression must be separated by blanks. Characters special to the shell must be escaped (see sh (1)). Strings containing blanks or other special characters should be quoted. The length of the expression is limited to 512 characters. The operators and keywords are listed below. The list is in order of increasing pre-		
	cedence, with equal precedence operators grouped within {} symbols. expr \ expr returns the first expr if it is neither NULL or 0, otherwise returns second expr.		
	expr∖& expr	returns the first <i>expr</i> if neither <i>expr</i> is NULL or 0 , otherwise returns 0 .	
	<pre>expr { =, \>, \>=, \<, \<=, != } expr returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.</pre>		
	$expr\{+, -\}$ expr addition or subtraction of integer-valued arguments.		
	<i>expr</i> { *, /, % } <i>expr</i>		
	multiplication, division, or remainder of the integer-valued a		
	expr : expr	The matching operator : compares the first argument with the second argument, which must be a regular expression (see NOTES). Normally, the matching operator returns the number of bytes matched (0 on failure).	
	(expr)	pattern symbols; can be used to return a portion of the first argument.	
	integer	An argument consisting only of an (optional) unary minus followed by digits.	
	string	A string argument that cannot be identified as an <i>integer</i> argument or as one of the expression operator symbols.	
EXAMPLES	Add 1 to the sh	ell variable a :	
		les a= expr sa + 1	
		-	

1-277

expr(1)	Us	er Commands	SunOS 5.5

DIAGNOSTICS	syntax error	for operator/operand errors	
	non-numeric argument	if arithmetic is attempted on such a string	
NOTES	After argument processing	by the shell, expr cannot tell the difference betweer by the value. If \$a is an =, the command:	ı an opera-
	example\$ expr \$a	= ´=´	
	looks like:		
	example\$ expr = =	=	
	as the arguments are passe lowing works: example\$ expr X\$a	d to $expr$ (and they are all taken as the = operator). x = X=	The fol-
Regular Expressions		Expressions are used in the POSIX and "C" locales. If the following two co	
	I		

- /usr/lib/locale/locale/LC_COLLATE/CollTable is present
- /usr/lib/locale/locale/LC_COLLATE/coll.so is not present;

otherwise, Simple Regular Expressions are used. Note that all patterns are "anchored" (that is, begin with $\hat{}$) and, therefore, $\hat{}$ is not a special character in that context.

Internationalized Regular Expressions are explained on **regex**(5). Simple Regular Expressions are explained on **regexp**(5).

or (1B)	SunOS/BSD Compatibility Package CommandsSunOS 5	.5
NAME	expr – evaluate arguments as a logical, arithmetic, or string expression	
SYNOPSIS	/usr/ucb/expr argument	
AVAILABILITY	SUNWscpu	
DESCRIPTION	expr evaluates expressions as specified by its arguments. After evaluation, the result is written on the standard output. Each token of the expression is a separate argument, so terms of the expression must be separated by blanks. Characters special to the shell must be escaped. Note: 0 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, two's-complement numbers.	
	The operators and keywords are listed below. Characters that need to be escaped are preceded by '\'. The list is in order of increasing precedence, with equal precedence operators grouped within $\}$ symbols.	
	<i>expr</i> \ <i>expr</i> Return the first <i>expr</i> if it is neither NULL nor 0 , otherwise returns the second <i>expr</i>	r.
	<i>expr</i> $\&$ <i>expr</i> Return the first <i>expr</i> if neither <i>expr</i> is NULL or 0 , otherwise returns 0 .	
	<pre>expr { =, \>, \>=, \<, \<=, != } expr Return the result of an integer comparison if both arguments are integers, other wise returns the result of a lexical comparison.</pre>	-
	expr { +, - } expr Addition or subtraction of integer-valued arguments.	
	expr { *, /, % } expr Multiplication, division, or remainder of the integer-valued arguments.	
	<pre>string : regular-expression match string regular-expression The two forms of the matching operator above are synonymous. The matching operators : and match compare the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of regexp(5), except that all patterns are "anchored" (treated as if they begin with ^) and, therefore, ^ is not a special character, in that context. Normally, the matching operator returns the number of characters matched (0 on failure). Alternatively, the \(\) pattern symbols can be used to return a portion of the first argument.</pre>	

1B-280

	substr string integer-1 integer-2 Extract the substring of string starting at position integer-1 and of length integer-2 characters. If integer-1 has a value greater than the length of string, expr returns a null string. If you try to extract more characters than there are in string, expr returns all the remaining characters from string. Beware of using negative values for either integer-1 or integer-2 as expr tends to run forever in these cases.
	index <i>string character-list</i> Report the first position in <i>string</i> at which any one of the characters in <i>character-list</i> matches a character in <i>string</i> .
	length <i>string</i> Return the length (that is, the number of characters) of <i>string</i> .
	(expr) Parentheses may be used for grouping.
EXAMPLES	1. $a='expr \ sa + 1'$
	Adds 1 to the shell variable a .
	2. # 'For \$a equal to either "/usr/abc/file" or just "file"' expr \$a : '.*/\(.*\)' \ \$a
	Returns the last segment of a path name (that is, the filename part). Watch out for / alone as an argument: <i>expr</i> will take it as the division operator (see BUGS below).
	3. # A better representation of example 2. expr //\$a : '.*/\(.*\)'
	The addition of the // characters eliminates any ambiguity about the divi- sion operator and simplifies the whole expression.
	4. expr \$VAR : '.*'
	Returns the number of characters in \$VAR .
EXIT STATUS	expr returns the following exit codes:
	0 if the expression is neither NULL nor 0
	1 if the expression <i>is</i> NULL or 0
	2 for invalid expressions.
SEE ALSO	sh (1), test (1), regexp (5)
DIAGNOSTICS	syntax error for operator/operand errors
	non-numeric argument
	if arithmetic is attempted on such a string
	division by zero
	if an attempt to divide by zero is made

BUGS After argument processing by the shell, **expr** cannot tell the difference between an operator and an operand except by the value. If **\$a** is an =, the command:

expr \$a = '='

looks like:

expr = = =

as the arguments are passed to **expr** (and they will all be taken as the = operator). The following works:

expr X\$a = X=

Note: the **match**, **substr**, **length**, and **index** operators cannot themselves be used as ordinary strings. That is, the expression:

example% expr index expurgatorious length syntax error example%

generates the 'syntax error' message as shown instead of the value 1 as you might expect.

NAME	exstr – extract strings from source files
SYNOPSIS	exstr filename exstr –e filename exstr –r [–d] filename
DESCRIPTION	The exstr utility is used to extract strings from C-language source files and replace them by calls to the message retrieval function (see gettxt (3C)). This utility will extract all char- acter strings surrounded by double quotes, not just strings used as arguments to the printf command or the printf routine. In the first form, exstr finds all strings in the source files and writes them on the standard output. Each string is preceded by the source file name and a colon.
	The first step is to use exstr – e to extract a list of strings and save it in a file. Next, examine this list and determine which strings can be translated and subsequently retrieved by the message retrieval function. Then, modify this file by deleting lines that can't be translated and, for lines that can be translated, by adding the message file names and the message numbers as the fourth (<i>msgfile</i>) and fifth (<i>msgnum</i>) entries on a line. The message files named must have been created by mkmsgs (1) and exist in / usr/lib/locale/lcC_MESSAGES . (The directory <i>locale</i> corresponds to the language in which the text strings are written; see setlocale (3C)). The message numbers used must correspond to the sequence numbers of strings in the message files.
	Now use this modified file as input to exstr – r to produce a new version of the original C-language source file in which the strings have been replaced by calls to the message retrieval function gettxt (). The <i>msgfile</i> and <i>msgnum</i> fields are used to construct the first argument to gettxt (). The second argument to gettxt () is printed if the message retrieval fails at run-time. This argument is the null string, unless the – d option is used.
	This utility cannot replace strings in all instances. For example, a static initialized character string cannot be replaced by a function call. A second example is that a string could be in a form of an escape sequence which could not be translated. In order not to break existing code, the files created by invoking exstr – e must be examined and lines containing strings not replaceable by function calls must be deleted. In some cases the code may require modifications so that strings can be extracted and replaced by calls to the message retrieval function.
OPTIONS	-e Extract a list of strings from the named C-language source files, with positional information. This list is produced on standard output in the following format:
	file:line:position:msgfile:msgnum:string
	filethe name of a C-language source filelineline number in the filepositioncharacter position in the linemsgfilenullmsgnumnull
	string the extracted text string

modified 5 Jul 1990

1-283

	Normally you would redirect this output into a file. Then you would edit this file to add the values you want to use for <i>msgfile</i> and <i>msgnum</i> : <i>msgfile</i> the file that contains the text strings that will replace <i>string</i> . A file with this name must be created and installed in the appropriate place by the mkmsgs (1) utility.		
	msgnum the sequence number of the string in msgfile.		
	The next step is to use exstr –r to replace <i>string</i> s in <i>file</i> .		
	 -r Replace strings in a C-language source file with function calls to the message retrieval function gettxt(). 		
	 -d This option is used together with the -r option. If the message retrieval fails when gettxt() is invoked at run-time, then the extracted string is printed. You would use the capability provided by exstr on an application program that needs to run in an international environment and have messages print in more than one language. exstr replaces text strings with function calls that point at strings in a message data base. The data base used depends on the run-time value of the LC_MESSAGES environment variable (see environ(5)). 		
EXAMPLES	The following examples show uses of exstr .		
	Assume that the file example.c contains two strings:		
	main()		
	{		
	The exstr utility, invoked with the argument example.c extracts strings from the named file and prints them on the standard output.		
	example% exstr example.c		
	produces the following output:		
	example.c:This is an example\n example.c:Hello world!\n		
	example% exstr -e example.c > example.stringsout		
	produces the following output in the file example.stringsout :		
	example.c:3:8:::This is an example\n example.c:4:8:::Hello world!\n		

modified 5 Jul 1990

	You must edit example.stringsout to add the values you want to use for the <i>msgfile</i> and <i>msgnum</i> fields before these strings can be replaced by calls to the retrieval function. If UX is the name of the message file, and the numbers 1 and 2 represent the sequence number of the strings in the file, here is what example.stringsout looks like after you add this information:					
	example.c:3:8:UX:1:This is an example\n example.c:4:8:UX:2:Hello world!\n					
	The exstr utility can now be invoked with the $-\mathbf{r}$ option to replace the strings in the source file by calls to the message retrieval function gettxt ().					
	example% exstr –r example.c <example.stringsout>intlexample.c</example.stringsout>					
	produces the following output:					
	extern char *gettxt(); main()					
	{					
	}					
	example% exstr –rd example.c <example.stringsout>intlexample.c</example.stringsout>					
	uses the extracted strings as a second argument to gettxt ().					
	extern char *gettxt(); main()					
	{ {					
	printf(gettxt("UX:1", "This is an example\n")); printf(gettxt("UX:2", "Hello world!\n"));					
	}					
FILES	/usr/lib/locale/lcc_MESSAGES/*					
	files created by mkmsgs (1)					
SEE ALSO	<pre>gettxt(1), mkmsgs(1), printf(1), srchtxt(1), gettxt(3C), printf(3S), setlocale(3C), environ(5)</pre>					
DIAGNOSTICS	The error messages produced by exstr are intended to be self-explanatory. They indicate errors in the command line or format errors encountered within the input file.					
	1					

NAME	face – executable for the Framed Access Command Environment Interface			
SYNOPSIS	face [– i init_file] [– c command_file] [– a alias_file] [filename .]			
DESCRIPTION	<i>filename</i> is the full pathname of the file describing the object to be opened initially, and must follow the naming convention Menu . <i>xxx</i> for a menu, Form . <i>xxx</i> for a form, and Text . <i>xxx</i> for a text file, where <i>xxx</i> is any string that conforms to the UNIX system file naming conventions. The Form and Menu Language Interpreter (FMLI) descriptor lifetime will be ignored for all frames opened by argument to face . These frames have a lifetime of immortal by default. If <i>filename</i> is not specified on the command line, the AT&T FACE Menu will be opened along with those objects specified by the LOGINWIN environment variables. These variables are found in the user's .environ file.			
OPTIONS	– a alias_file Alias file.			
	- c command_file Command file.			
	- i <i>init_file</i> Initial file.			
FILES	\$HOME/pref/.environ			
SEE ALSO	env (1)			
DIAGNOSTICS	The face command will exit with a non-zero exit code if the user is not properly set up as a FACE user.			

NAME	factor – obtain the prime factors of a number
SYNOPSIS	factor [integer]
AVAILABILITY	SUNWesu
DESCRIPTION	When you use factor without an argument, it waits for you to give it an integer. After you give it a positive integer less than or equal to 10^{14} , it factors the integer, prints its prime factors the proper number of times, and then waits for another integer. factor exits if it encounters a 0 or any non-numeric character.
	If you invoke factor with an argument, it factors the integer as described above, and then it exits.
	The maximum time to factor an integer is proportional to \sqrt{n} . factor will take this time when <i>n</i> is prime or the square of a prime.
DIAGNOSTICS	factor prints the error message, Ouch, for input out of range or for garbage input.

NAME	fdformat – format floppy diskette or PCMCIA memory card			
SYNOPSIS	fdformat [–dDeEfHlLmMUqvx] [–b label] [–B filename] [–t dostype] [devname]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	 fdformat is a utility for formatting both diskettes and PCMCIA memory cards. All new, blank diskettes or PCMCIA memory cards must be formatted before they can be used. fdformat formats and verifies the media, and indicates whether any bad sectors were encountered. All existing data on the diskette or PCMCIA memory card, if any, is destroyed by formatting. If no device name is given, fdformat uses the diskette as a default. By default, fdformat uses the configured capacity of the drive to format the diskette. A 3.5 inch high-density drive uses diskettes with a formatted capacity of 1.44 megabytes. A 5.25 inch high-density drive uses diskettes with a formatted capacity of 1.2 megabytes. In either case, a density option does not have to be specified to fdformat. However, a density option must be specified when using a diskette with a lower capacity than the drive's default. Use the -H option to format high-density diskettes (1.44-megabyte capacity) in an extra-high-density (ED) drive. Use the -D option, the -l option, or the -L option to format double-density (or "low-density") diskettes (720KB capacity) in an HD or ED drive. To format medium-density diskettes (1.2-megabyte capacity), use the -M option with -t nec (this is the same as using the -m option with -t nec). Extended density uses double-sided, extended-density (or extra-high-density) (DS/ED) diskettes. Medium and high densities use the same media: double-sided, high-density (DS/HD) diskettes. Double ("low") density uses double-sided, double-density (DS/DD) diskettes. Substituting diskettes of one density for diskettes of either a higher or lower density generally will not work. Data integrity cannot be assured whenever a diskette is formatted to a capacity not matching its density. A PCMCIA memory card with densities from 512 KBytes to 64 MBytes may be formatted. 			
	fdformat writes new identification and data fields for each sector on all tracks unless the $-\mathbf{x}$ option is specified. For diskettes, if the $-\mathbf{v}$ option is specified, each sector is verified.			
	After formatting and verifying, fdformat writes an operating-system label on block 0. Use the –t dos option (same as the –d option) to put an MS-DOS file system on the diskette or PCMCIA memory card after the format is done. Use the –t nec option with the –M option (same as the –m option) to put an NEC-DOS file system on a diskette. Oth- erwise, fdformat writes a SunOS label in block 0.			
OPTIONS	-D Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as the –l or –L options). This is the default for double-density type drives. It is needed if the drive is a high- or extended-density type.			
	-e Eject the diskette when done. (This feature is not available on all systems).			
	-E Format a 2.88-megabyte (3.5 inch) extended-density diskette. This is the default for extended-density type drives.			

modified 10 Feb 1995

$-\mathbf{f}$	Force. Do not ask for confirmation before starting format.				
-H	disket	Format a 1.44-megabyte (3.5 inch) or 1.2-megabyte (5.25 inch) high-density diskette. This is the default for high-density type drives; it is needed if the drive is the extended-density type.			
- M	disket	e a 1.2-megabyte (3.5 inch) medium-density format on a high-density ette (use only with the -t nec option). This is the same as using -m . feature is not available on all systems.)			
$-\mathbf{U}$	umou	umount any file systems and then format.			
- q	Quiet;	Quiet; do not print status messages.			
- v	Verify	Verify each block of the diskette after the format.			
- x	Skip tl	he format, and only write a SunOS label or an MS-DOS file system.			
- b label		Label the media with volume <i>label</i> . A SunOS volume label is restricted to 8 characters. A DOS volume label is restricted to 11 upper-case characters.			
– B filename		Install special boot loader in <i>filename</i> on an MS-DOS diskette. This option is only meaningful when the – d option (or – t dos) is also specified.			
-t dos		Install an MS-DOS file system and boot sector formatting. This is equivalent to the DOS format command or the $-\mathbf{d}$ option.			
-t nec	Install an NEC-DOS file system and boot sector on the disk after formatting. This should be used only with the $-\mathbf{M}$ option. (This feature is not available on all systems).				
devname	Replace <i>devname</i> with rdiskette0 (systems without Volume Management floppy0 (systems with Volume Management) to use the first drive or rdiskette1 (systems without Volume Management) or floppy1 (systems with Volume Management) to use the second drive. If <i>devname</i> is omittee the first drive, if one exists, will be used.				
	CMCIA memory cards, replace <i>devname</i> with the device name for the CIA memory card which resides in / dev/rdsk/c NtNdNsN or lsk/c NtNdNsN.				
	If devr	f <i>devname</i> is omitted, the default diskette drive, if one exists, will be used.			
	<i>N</i> represents a decimal number and can be specified as follows:				
	$\mathbf{c}N$	Controller N			
	tN	Technology type N:0x1ROM0x2OTPROM0x3EPROM0x4EEPROM0x5FLASH0x6SRAM0x7DRAM			
	$\mathbf{d}N$	Technology region in type N			

	s N Slice	N			
	The following options are provided for compatibility with previous versions of fdformat ;				
	their use is discouraged.				
	-d Format an MS-DOS floppy diskette or PCMCIA memory card. (same as -t dos). This is equivalent to the MS-DOS FORMAT command.				
	(same as – D	Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as $-D$ or $-L$). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type. Format a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as $-l$ or $-D$). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type. Write a 1.2-megabyte (3.5 inch) medium-density format on a high-density diskette (use only with the $-t$ nec option). This is the same as using $-M$. (This feature is not available on all systems.)			
	(same as − l o				
	diskette (use				
FILES	/vol/dev/diskette0	Directory providing block device access for the media in floppy drive 0.			
	/vol/dev/rdiskette0	Directory providing character device access for the media in floppy drive 0.			
	/vol/dev/aliases/floppy0	Symbolic link to the character device for the media in floppy drive 0.			
	/dev/rdiskette	Directory providing character device access for the media in the primary floppy drive, usually drive 0.			
	/vol/dev/dsk/cNtNdNsN	Directory providing block device access for the PCMCIA memory card.			
	/vol/dev/rdsk/cNtNdNsN	Directory providing character device access for the PCMCIA memory card.			
	/vol/dev/aliases/pcmemS	Symbolic link to the character device for the PCMCIA memory card in socket <i>S</i> where <i>S</i> represents a PCMCIA socket number.			
	/dev/rdsk/cNtNdNsN	Directory providing character device access for the PCMCIA memory card.

SEE ALSO	Note: See <i>devname</i> section above for a description of the values for <i>N</i> . cpio (1), eject (1), tar (1), volcancel (1), volcheck (1), volmissing (1), mount (1M), newfs (1M), rmmount (1M), vold (1M), rmmount.conf (4), vold.conf (4), pcfs (7FS), volfs (7FS)				
x86 Only	fd(7D)				
NOTES	A diskette or PCMCIA memory card containing a ufs file system created on a SPARC (big endian) system (by using fdformat and newfs (1M)) is not identical to a diskette or PCMCIA memory card containing a ufs file system created on an x86 (little endian) system. Do not interchange ufs diskettes or memory cards between these platforms; use cpio (1) or tar (1) to transfer files on diskettes or memory cards between them.				

A diskette or PCMCIA memory card formatted using the -t dos option (or -d) for MS-DOS will not have the necessary system files, and is therefore not bootable. Trying to boot from it on a PC will result in the following message:

Non-System disk or disk error Replace and strike any key when ready

BUGS Currently, bad sector mapping is not supported on floppy diskettes or PCMCIA memory cards. Therefore, a diskette or memory cards is unusable if **fdformat** finds an error (bad sector).

NAME	fgrep – search a file for a character string			
SYNOPSIS	/usr/bin/fgrep [–bchilnsvx] [–e pattern_list] [–f file] [pattern] [file]			
	/usr/xpg4/bin/fgrep [-bchilnsvx] [-e pattern_list] [-f file] [pattern] [file]			
AVAILABILITY				
/usr/bin/fgrep	SUNWcsu			
/usr/xpg4/bin/fgrep	SUNWxcu4			
DESCRIPTION	 fgrep (fast grep) searches files for a character string and prints all lines that contain that string. fgrep is different from grep(1) and egrep(1) because it searches for a string, instead of searching for a pattern that matches an expression. It uses a fast and compact algorithm. The characters \$, *, [, ^, , (,), and \ are interpreted literally by fgrep, that is, fgrep does not recognize full regular expressions as does egrep. Since these characters have special meaning to the shell, it is safest to enclose the entire <i>string</i> in single quotes ''. 			
	If no files are specified, fgrep assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.			
OPTIONS	The following options are supported:			
	-b	Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).		
	- c	Print only a count of the lines that contain the pattern.		
	–e pattern_list	Search for a <i>special string</i> (<i>string</i> begins with $a -$).		
	-f files	Take the list of patterns from <i>file</i> .		
	-h	Suppress printing of files when searching multiple files.		
	— i	Ignore upper/lower case distinction during comparisons.		
	- l	Print the names of files with matching lines once, separated by new- lines. Does not repeat the names of files when the pattern is found more than once.		
	-n	Precede each line by its line number in the file (first line is 1).		
	- S	Work silently, that is, display nothing except error messages. This is useful for checking the error status.		
	$-\mathbf{v}$	Print all lines except those that contain the pattern.		
	- x	Print only lines matched entirely.		
OPERANDS	The following o	operands are supported:		
		ath name of a file to be searched for the patterns. If no <i>file</i> operands are stified, the standard input will be used.		

modified 28 Mar 1995

fgrep(1)	User Commands SunOS 5.5			
/usr/bin/fgrep	<i>pattern</i> Specify a pattern to be used during the search for input.			
/usr/xpg4/bin/fgrep	<i>pattern</i> Specify one or more patterns to be used during the search for input operand is treated as if it were specified as –e <i>pattern_list</i> .	ut. This		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that as cution of fgrep : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .	See environ (5) for descriptions of the following environment variables that affect the exe- cution of fgrep : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	 The following exit values are returned: if any matches are found if no matches are found for syntax errors or inaccessible files (even if matches were found). 			
SEE ALSO	ed(1), egrep(1), grep(1), sed(1), sh(1), environ(5)			
NOTES	Ideally there should be only one grep command, but there is not a single algorithm that spans a wide enough range of space-time tradeoffs. Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in <stdio.h< b="">>.</stdio.h<>			
/usr/xpg4/bin/fgrep	/ usr/xpg4/bin/fgrep is identical to / usr/xpg4/bin/grep – F (see grep (1)). Portable applica- tions should use / usr/xpg4/bin/grep – F .			

modified 28 Mar 1995

NAME	file – determine file type			
SYNOPSIS	file [-h] [-m mfile] [-f ffile] file file [-h] [-m mfile] -f ffile file -c [-m mfile]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The file utility performs a series of tests on each file supplied by <i>file</i> and, optionally, on each file listed in <i>ffile</i> in an attempt to classify it. If the file is not a regular file, its file type is identified. The file types directory, FIFO, block special, and character special are identified as such. If the file is a regular file and the file is zero-length, it is identified as an empty file.			
	If <i>file</i> appears to be a text file, file examines the first 512 bytes and tries to determine its programming language. If <i>file</i> is an executable a.out , file prints the version stamp, provided it is greater than 0. If <i>file</i> is a symbolic link, by default the link is followed and file tests the file to which the symbolic link refers.			
	By default, file uses / etc/magic to identify files that have a magic number. A magic number is a numeric or string constant that indicates the file type. See magic (4) for an explanation of the format of / etc/magic .			
	If <i>file</i> does not exist, cannot be read, or its file status could not be determined, it is not considered an error that affects the exit status. The output will indicate that the file was processed, but that its type could not be determined.			
OPTIONS	The following options are supported:			
	- c	Check the magic file for format errors. For reasons of efficiency, this validation is normally not carried out.		
	-h	Do not follow symbolic links.		
	- f ffile	ffile contains a list of the files to be examined.		
	– m mfile	Use <i>mfile</i> as an alternate magic file, instead of / etc/magic .		
OPERANDS	The following operands are supported:			
	file	A path name of a file to be tested.		
EXAMPLES	Determine if an argument is a binary executable file:			
	file "\$1	" grep -Fq executable && printf "%s is executable.\n" "\$1"		
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- C_CTYPE, LC_MESSAGES, and NLSPATH.		

modified 1 Feb 1995

 The following exit values are returned: 0 Successful completion. >0 An error occurred. 			
/etc/magic file's magic number file			
ls(1), filehdr(4), magic(4), environ(5)			
If the -h option is specified and <i>file</i> is a symbolic link, file prints the error message: symbolic link to <i>file</i>			

NAME	file – determine the type of a file by examining its contents			
SYNOPSIS	/usr/ucb/f	ile [[- m mfile] filename	
AVAILABILITY	SUNWscp	ou		
DESCRIPTION	file performs a series of tests on each <i>filename</i> in an attempt to determine what it contains. If the contents of a file appear to be ASCII text, file examines the first 512 bytes and tries to guess its language.			
	file uses the file / etc/magic to identify files that have some sort of <i>magic number</i> , that is, any file containing a numeric or string constant that indicates its type.			
OPTIONS	OPTIONS – c Check for format errors in the magic number file. For reat this validation is not normally carried out. No file type-c under – c .			
	- f ffile	Get a list of filenar	nes to identify from <i>ffile.</i>	
	–L	If a file is a symbol itself.	lic link, test the file the link references rather than the link	
	– m mfile	m <i>mfile</i> Use <i>mfile</i> as the name of an alternate magic number file.		
EXAMPLES	This example illustrates the use of file on all the files in a specific user's directory: example% pwd /usr/blort/misc example% /usr/ucb/file *

	ez	xample%		

modified 14 Sep 1992

 ENVIRONMENT
 The environment variables LC_CTYPE, LANG, and LC_default control the character classification throughout file. On entry to file, these environment variables are checked in the following order: LC_CTYPE, LANG, and LC_default. When a valid value is found, remaining environment variables for character classification are ignored. For example, a new setting for LANG does not override the current valid character classification rules of LC_CTYPE. When none of the values is valid, the shell character classification defaults to the POSIX.1 "C" locale.

- FILES /etc/magic
- SEE ALSO magic(4)

BUGSfile often makes mistakes. In particular, it often suggests that command files are C programs.Classical constraints

file does not recognize Pascal or LISP.

modified 14 Sep 1992

NAME	find – find files			
SYNOPSIS	find path expr	ression		
AVAILABILITY	SUNWcsu			
DESCRIPTION		and recursively descends the directory hierarchy for each <i>path</i> seeking a Boolean <i>expression</i> written in the primaries given below.		
		to descend to arbitrary depths in a file hierarchy and will not fail due to tations (unless a <i>path</i> operand specified by the application exceeds uirements).		
OPERANDS	The following o	perands are supported:		
	path	a path name of a starting point in the directory hierarchy.		
	The first argument that starts with a –, or is a ! or a (, and all subsequent arguments will be interpreted as an <i>expression</i> made up of the following primaries and operators. In the descriptions, wherever <i>n</i> is used as a primary argument, it will be interpreted as a decimal integer optionally preceded by a plus (+) or minus (–) sign, as follows:			
	+ <i>n</i>	more than <i>n</i>		
	n —n	exactly <i>n</i> less than <i>n</i> .		
Expressions	Valid expression			
Expressions	-atime <i>n</i>	True if the file was accessed <i>n</i> days ago. The access time of directories in <i>path</i> is changed by find itself.		
	-cpio device	Always true; write the current file on <i>device</i> in cpio format (5120-byte records).		
	-ctime n	True if the file's status was changed <i>n</i> days ago.		
	-depth	Always true; causes descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. This can be useful when find is used with cpio (1) to transfer files that are con- tained in directories without write permission.		
	-exec command	True if the executed <i>command</i> returns a zero value as exit status. The end of <i>command</i> must be punctuated by an escaped semicolon. A command argument {} is replaced by the current path name.		
	-follow	Always true; causes symbolic links to be followed. When following symbolic links, find keeps track of the directories visited so that it can detect infinite loops; for example, such a loop would occur if a symbolic link pointed to an ancestor. This expression should not be used with the -type l expression.		

modified 1 Feb 1995

-fstype type	True if the filesystem to which the file belongs is of type <i>type</i> .
-group gname	True if the file belongs to the group <i>gname</i> . If <i>gname</i> is numeric and does not appear in the / etc / group file, it is taken as a group ID.
– inum <i>n</i>	True if the file has inode number <i>n</i> .
–links n	True if the file has <i>n</i> links.
-local	True if the file system type is not a remote file system type as defined in the /etc/dfs/fstypes file. nfs is used as the default remote filesystem type if the /etc/dfs/fstypes file is not present.
-ls	Always true; prints current path name together with its associated statistics. These include (respectively):
	 inode number size in kilobytes (1024 bytes) protection mode number of hard links user group size in bytes modification time.
	If the file is a special file the size field will instead contain the major and minor device numbers.
	If the file is a symbolic link the pathname of the linked-to file is printed preceded by ' \rightarrow '. The format is identical to that of ls – gilds (see ls (1)).
	Note: Formatting is done internally, without executing the ls program.
-mount	Always true; restricts the search to the file system containing the direc- tory specified. Does not list mount points to other file systems.
- mtime n	True if the file's data was modified <i>n</i> days ago.
– name pattern	True if <i>pattern</i> matches the current file name. Normal shell file name generation characters (see $sh(1)$) may be used. A backslash (\) is used as an escape character within the pattern. The pattern should be escaped or quoted when find is invoked from the shell.
-ncpio device	Always true; write the current file on <i>device</i> in cpio $-c$ format (5120 byte records).
-newer file	True if the current file has been modified more recently than the argument <i>file</i> .
-nogroup	True if the file belongs to a group not in the / etc/group file.
-nouser	True if the file belongs to a user not in the /etc/passwd file.
-ok command	Like – exec except that the generated command line is printed with a question mark first, and is executed only if the user responds by typing y .
-perm [-]mode	The <i>mode</i> argument is used to represent file mode bits. It will be

1-300

chmod	al in format to the <i><symbolic< i="">mode<i>></i> operand described in (1), and will be interpreted as follows. To start, a template will be</symbolic<></i>
assume	ed with all file mode bits cleared. An <i>op</i> symbol of:
+	will set the appropriate mode bits in the template;
_	will clear the appropriate bits;
=	will set the appropriate mode bits, without regard to the con- tents of process' file mode creation mask.
ambigu	symbol of – cannot be the first character of <i>mode</i> ; this avoids aity with the optional leading hyphen. Since the initial mode is all , there are not any symbolic modes that need to use – as the first ter.
	yphen is omitted, the primary will evaluate as true when the file sion bits exactly match the value of the resulting template.
Otherv	vise if <i>mode</i> is prefixed by a hyphen the primary will evaluate as

Otherwise, if *mode* is prefixed by a hyphen, the primary will evaluate as true if at least all the bits in the resulting template are set in the file permission bits.

- -**perm** [-]*onum* True if the file permission flags exactly match the octal number *onum* (see **chmod**(1)). If *onum* is prefixed by a minus sign (-), only the bits that are set in *onum* are compared with the file permission flags, and the expression evaluates true if they match.
- **–print** Always true; causes the current path name to be printed.
- -**prune** Always yields true. Do not examine any directories or files in the directory structure below the *pattern* just matched. See the examples, below.
- -**size** *n*[**c**] True if the file is *n* blocks long (512 bytes per block). If *n* is followed by a **c**, the size is in bytes.
- -type cTrue if the type of the file is c, where c is b, c, d, l, p, or f for block special file, character special file, directory, symbolic link, fifo (named pipe), or plain file, respectively.
- -**user** *uname* True if the file belongs to the user *uname*. If *uname* is numeric and does not appear as a login name in the /**etc/passwd** file, it is taken as a user ID.
- -xdev Same as the -mount primary.

find	(1)	
------	---	---	---	--

Complex Expressions	The primari	es may be combined u	sing the following operators (in order of decreasing			
	precedence):					
	1)	(expression)	True if the parenthesized expression is true (parentheses are special to the shell and must be escaped).			
	2)	! expression	The negation of a primary (! is the unary <i>not</i> operator).			
	3)	expression [-a] expres	sion			
	- ,		Concatenation of primaries (the <i>and</i> operation is implied by the juxtaposition of two primaries).			
	4)	expression –o expressi	on Alternation of primaries (– o is the <i>o</i> r operator).			
	then you mu	e: When you use find in conjunction with cpio , if you use the – L option with cpio you must use the – follow expression with find and vice versa. Otherwise there wi ndesirable results. • <i>expression</i> is present, – print will be used as the expression. Otherwise, if the given ession does not contain any of the primaries – exec , – ok or – print , the given expression will be effectively replaced by:				
	expression c					
	(giv	en_expression) –print	_expression) –print			
	The – user , – only once.	group, and –newer pr	imaries each will evaluate their respective arguments			
EXAMPLES	The followir	ıg commands are equi	valent:			
		nple% find . nple% findprint				
	They both w	rite out the entire dire	ctory hierarchy from the current directory.			
	Remove all files in your home directory named a.out or *.o that have not been accessed for a week: example% find \$HOME \ (–name a.out –o –name '*.o' \ –atime +7 \ –exec rm {} \;					
	Recursively print all file names in the current directory and below, but skipping SCC directories:					
	exai	nple% find . –name S	CCS –prune –o –print			
	Recursively	print all file names in	the current directory and below, skipping the contents at the SCCS directory name:			
		nple% find . –print –ı	-			
			•			

	The following command is roughly equivalent to the -nt extension to test(1): example\$ if [-n "\$(find file1 -prune -newer file2)"]; then printf %s\\n "file1 is newer than file2" fi					
	The descriptions of –atime , –ctime , and –mtime use the terminology <i>n</i> ''24-hour periods''. For example, a file accessed at 23:59 will be selected by:					
	example% findatime -1 -print					
	at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.					
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of find : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .					
EXIT STATUS	The following exit values are returned:0All path operands were traversed successfully.>0An error occurred.					
FILES	/etc/passwdpassword file/etc/groupgroup file/etc/dfs/fstypesfile that registers distributed file system packages					
SEE ALSO	chmod(1), ls(1), sh(1), test(1), stat(2), umask(2), environ(5)					
WARNINGS	The following options are obsolete and will not be supported in future releases:					
	-cpio <i>device</i> Always true; write the current file on <i>device</i> in cpio format (5120-byte records).					
	- ncpio <i>device</i> Always true; write the current file on <i>device</i> in cpio - c format (5120 byte records).					
NOTES	When using find to determine files modified within a range of time, one must use the ?time argument <i>before</i> the -print argument otherwise find will give all files.					

NAME	finger – display information about local and remote users					
SYNOPSIS	finger [–bfhilmpqsw] [username]					
	nger [–l] [username@hostname1[@hostname2@hostnamen]]					
	finger [-1] [@hostname1[@hostname2@hostnamen]]					
AVAILABILITY	SUNWcsu					
DESCRIPTION	By default, the finger command displays in multi-column format the following informa- tion about each logged-in user: user name user's full name terminal name (prepended with a '*' (asterisk) if write-permission is denied) idle time login time host name, if logged in remotely 					
	Idle time is in minutes if it is a single integer, in hours and minutes if a ':' (colon) is present, or in days and hours if a 'd' is present.					
	 when one or more username arguments are given, more detailed information is given for ach username specified, whether they are logged in or not. username must be that of a local user, and may be a first or last name, or an account name. Information is presented a multi-line format as follows: the user name and the user's full name the user's home directory and login shell time the user logged in if currently logged in, or the time the user last logge in; and the terminal or host from which the user logged in 					
	 last time the user received mail, and the last time the user read mail the first line of the \$HOME/.project file, if it exists the contents of the \$HOME/.plan file, if it exists 					
	• the contents of the shower .plan me, if it exists If the arguments username@hostname1[@hostname2@hostname1] or @hostname1[@hostname2@hostnamen] are used, the request is sent first to hostname forwarded through each hostnamen-1 to hostname1. The program uses the finger u information protocol (see RFC 1288) to query that remote host for information about named user (if username is specified), or about each logged-in user. The information displayed is server dependent.					
OPTIONS	The <i>username@hostname</i> form supports only the -l option.					
	-b Suppress printing the user's home directory and shell in a long format printout.					
	-f Suppress printing the header that is normally printed in a non-long format printout.					
	-h Suppress printing of the .project file in a long format printout.					
	-i Force "idle" output format, which is similar to short format except that only the					

modified 11 Oct 1993

login name, terminal, login time, and idle time are printed.

- -l Force long output format.
- -m Match arguments only on user name (not first or last name).
- -p Suppress printing of the **.plan** file in a long format printout.
- -**q** Force quick output format, which is similar to short format except that only the login name, terminal, and login time are printed.
- -s Force short output format.
- -w Suppress printing the full name in a short format printout.

FILES	\$HOME/. plan \$HOME/. project /etc/passwd /var/adm/lastlog /var/adm/utmp	user's plan user's projects password file time of last login accounting
	/vai/auii/uuiip	accounting

- SEE ALSO passwd(1), who(1), whois(1)
 - **NOTES** The **finger user information protocol** limits the options that may be used with the remote form of this command.

modified 11 Oct 1993

NAME	fmlcut – cut out selected fields of each line of a file			
SYNOPSIS	fmlcut –c <i>list</i> [fmlcut –f <i>list</i> [-			
DESCRIPTION	The fmlcut function cuts out columns from a table or fields from each line in <i>filename</i> ; in database parlance, it implements the projection of a relation. fmlcut can be used as a filter; if <i>filename</i> is not specified or is –, the standard input is read. <i>list</i> specifies the fields to be selected. Fields can be fixed length (character positions) or variable length (separated by a field delimiter character), depending on whether $-\mathbf{c}$ or $-\mathbf{f}$ is specified. Note: Either the $-\mathbf{c}$ or the $-\mathbf{f}$ option must be specified.			
OPTIONS	list	A comma-separated list of integer field numbers (in increasing order), with optional – to indicate ranges. For example: 1,4,7; 1–3,8; –5,10 (short for 1–5,10); or 3– (short for third through last field).		
	-clist	If $-c$ is specified, <i>list</i> specifies character positions (for instance, $-c1-72$ would pass the first 72 characters of each line). Note: No space intervenes between $-c$ and <i>list</i> .		
	-flist	If $-\mathbf{f}$ is specified, <i>list</i> is a list of fields assumed to be separated in the file by the default delimiter character, TAB, or by <i>char</i> if the $-\mathbf{d}$ option is specified. For example, $-\mathbf{f1,7}$ copies the first and seventh field only. Lines with no delimiter characters are passed through intact (useful for table subheadings), unless $-\mathbf{s}$ is specified. Note: No space intervenes between $-\mathbf{f}$ and <i>list</i> . The following options can be used if you have specified $-\mathbf{f}$.		
		– d char	If – d is specified, <i>char</i> is the field delimiter. Space or other characters with special meaning to FMLI must be quoted. Note: No space intervenes between – d and <i>char</i> . The default field delimiter is TAB.	
		S	Suppresses lines with no delimiter characters. If $-s$ is not specified, lines with no delimiters will be passed through untouched.	
EXAMPLES	The following example gets the login IDs and names.			
	example% fmlcut –d: –f1,5 /etc/passwd			
			e current login name.	
	examp	ble% who a	am i fmlcut -f1 -d" "`	
SEE ALSO	fmlgrep(1F)			

DIAGNOSTICS	fmlcut returns the following exit values:				
	0 when the selected field is successfully cut out				
	2 on syntax errors				
	The following error messages may be displayed on the FMLI message line:				
	ERROR: line too long A line has more than 1023 characters or fields, or there is no new-line character.				
	ERROR: bad list for c / f option Missing – c or – f option or incorrectly specified <i>list</i> . No error occurs if a line has fewer fields than the <i>list</i> calls for.				
	ERROR: no fields The <i>list</i> is empty.				
	ERROR: no delimiter Missing <i>char</i> on – d option.				
NOTES	fmlcut cannot correctly process lines longer than 1023 characters, or lines with no new- line character.				

1F-307

NAME	fmlexpr – evaluate arguments as an expression			
SYNOPSIS	fmlexpr argum	ents		
DESCRIPTION	The fmlexpr function evaluates its arguments as an expression. After evaluation, the result is written on the standard output. Terms of the expression must be separated by blanks. Characters special to FMLI must be escaped. Note that 30 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, 2s complement numbers.			
	preceded by \setminus .	and keywords are listed below. Characters that need to be escaped are The list is in order of increasing precedence, with equal precedence ped within {} symbols.		
USAGE				
Expressions	expr∖ expr	Returns the first <i>expr</i> if it is neither NULL nor 0 , otherwise returns the second <i>expr</i> .		
	expr∖& expr	Returns the first <i>expr</i> if neither <i>expr</i> is NULL or 0 , otherwise returns 0 .		
	expr { =, \>, \>	<pre>=, \<, \<=, != } expr Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.</pre>		
	$expr \{+, -\} expr$ Addition or subtraction of integer-valued arguments.			
	expr { *, /, % } expr			
		Multiplication, division, or remainder of the integer-valued arguments.		
	expr : expr	The matching operator : compares the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of $ed(1)$, except that all patterns are "anchored" (that is, begin with $$) and, therefore, $$ is not a special character, in that context. Normally, the matching operator returns the number of bytes matched (0 on failure). Alternatively, the $\backslash(\backslash)$ pattern symbols can be used to return a portion of the first argument.		
EXAMPLES	 Add 1 to the variable a: example% 'fmlexpr \$a + 1 set -l a' 			
	2. For \$a equal to either "/usr/abc/file" or just "file": example% fmlexpr \$a : .*/\(.*\) \ \$a			
	returns the last segment of a path name (that is, <i>file</i>). Watch out for / alone as an argument: fmlexpr will take it as the division operator (see NOTES below).			

SunOS 5.5		FMLI Commands	fmlexpr(1F)	
	3. A better rep exa			
	The addition of the // characters eliminates any ambiguity about the division opera (because it makes it impossible for the left-hand expression to be interpreted as the division operator), and simplifies the whole expression.			
		number of characters in \$VAR. mple% fmlexpr \$VAR : .*		
EXIT CODES	As a side effect	t of expression evaluation, fmlexpr retu	ırns the following exit values:	
	0	if the expression is neither NULL nor	• 0 (that is, TRUE)	
	1	if the expression <i>is</i> NULL or 0 (that is	s, FALSE)	
	2	for invalid expressions (that is, FALS	Е).	
SEE ALSO	ed(1), expr(1),	set(1F), sh(1)		
DIAGNOSTICS	CS syntax error for operator/operand errors non-numeric argument			
		if arithmetic is attempted on such a s	8	
		yntax errors and non-numeric argumen cursor position. Use refresh to redraw		
NOTES		nt processing by FMLI, fmlexpr cannot t rand except by the value. If \$a is an =,		
	examp	ole% fmlexpr \$a = =		
	looks like:	-		
	examp	ble% fmlexpr = = =		
		nts are passed to fmlexpr (and they wil ks, and returns TRUE:	l all be taken as the = operator). The	
	examp	ole% fmlexpr X\$a = X=		

NAME	fmlgrep – search a file for a pattern		
SYNOPSIS	fmlgrep [-b] [-c] [-i] [-l] [-n] [-s] [-v] limited_regular_expression [filename]		
DESCRIPTION	fmlgrep searches <i>filename</i> for a pattern and prints all lines that contain that pattern. fmlgrep uses limited regular expressions (expressions that have string values that use a subset of the possible alphanumeric and special characters) like those described on the regexp (5) manual page to match the patterns. It uses a compact non-deterministic algorithm.		
	Be careful when using FMLI special characters (for instance, \$, `, ', ") in <i>limited_regular_expression</i> . It is safest to enclose the entire <i>limited_regular_expression</i> in single quotes ' ' .		
	If <i>filename</i> is not specified, fmlgrep assumes standard input. Normally, each line matched is copied to standard output. The file name is printed before each line matched if there is more than one input-file.		
OPTIONS	- b Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).		
	-c Print only a count of the lines that contain the pattern.		
	-i Ignore upper/lower case distinction during comparisons.		
	-l Print only the names of files with matching lines, separated by new-lines. Does not repeat the names of files when the pattern is found more than once.		
	- n Precede each line by its line number in the file (first line is 1).		
	-s Suppress error messages about nonexistent or unreadable files.		
	- v Print all lines except those that contain the pattern.		
EXIT CODES	fmlgrep returns the following exit values:		
	0 if the pattern is found (that is, TRUE)		
	1 if the pattern is not found (that is, FALSE)		
	2 if an invalid expression was used or <i>filename</i> is inaccessible		
SEE ALSO	egrep(1), fgrep(1), fmlcut(1F), grep(1), regexp(5)		
NOTES	Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in / usr/include/stdio.h .		
	If there is a line with embedded nulls, fmlgrep will only match up to the first null; if it matches, it will print the entire line.		

modified 28 Mar 1995

NAME	fmli – invoke FMLI		
SYNOPSIS	fmli [–a alias_file] [–c command_file] [–i initialization_file] filename		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The fmli command invokes the Form and Menu Language Interpreter and opens the frame(s) specified by the <i>filename</i> argument. The <i>filename</i> argument is the pathname of the initial frame definition file(s), and must follow the naming convention Menu .xxx, Form .xxx or Text .xxx for a menu, form or text frame respectively, where xxx is any string that conforms to UNIX system file naming conventions. The FMLI descriptor lifetime will be ignored for all frames opened by argument to fmli . These frames have a lifetime of immortal by default.		
OPTIONS	 -a alias_file If -a is specified, alias_file is the name of a file which contains lines of the form alias=pathname. Thereafter, \$alias can be used in definition files to simplify references to objects or devices with lengthy pathnames, or to define a search path (similar to \$PATH in the UNIX system shell). 		
	-c command_file If -c is specified, command_file is the name of a file in which default FMLI com- mands can be disabled, and new application-specific commands can be defined. The contents of command_file are reflected in the FMLI Command Menu.		
	 -i initialization_file If -i is specified, initialization_file is the name of a file in which the following characteristics of the application as a whole can be specified: 		
	 A transient introductory frame displaying product information 		
	 A banner, its position, and other elements of the banner line 		
	 Color attributes for all elements of the screen 		
	 Screen Labeled Keys (SLKs) and their layout on the screen. 		
EXAMPLES	To invoke fmli :		
	example% fmli Menu.start		
	where Menu.start is an example of <i>filename</i> named according to the file name conventions for menu definition files explained above.		
	To invoke fmli and name an initialization file:		
	example% fmli -i init.myapp Menu.start		
	where init.myapp is an example of <i>initialization_file</i> .		

modified 14 Sep 1992

ENVIRONMENT				
Variables	LOADPFK	Leaving this environment variable unset tells FMLI, for certain terminals like the AT&T 5620 and 630, to download its equivalent character sequences for using function keys into the terminal's programmable function keys, wiping out any settings the user may already have set in the function keys. Setting LOADPFK=NO in the environment will prevent this downloading.		
	COLUMNS	Can be used to override the width of the logical screen defined for the terminal set in TERM. For terminals with a 132-column mode, for example, invoking FMLI with the line COLUMNS=132 fmli frame-file		
		will allow this wider screen width to be used.		
	LINES	Can be used to override the length of the logical screen defined for the terminal set in TERM .		
FILES	/usr/bin/fmli			
SEE ALSO	vsig(1F)			
DIAGNOSTICS	If <i>filename</i> is not supplied to the fmli command, fmli returns the message:			
	Initial	object must be specified.		
	If <i>filename</i> does not exist or is not readable, fmli returns an error message and exits. The example command line above returns the following message and exits:			
	Can't open object "Menu.start"			
	If <i>filename</i> exists, but does not start with one of the three correct object names (Menu ., Form. , or Text.) or if it is named correctly but does not contain the proper data, fmli starts to build the screen by putting out the screen labels for function keys, after which flashes the message: I do not recognize that kind of object			
	and then exits.			

modified 14 Sep 1992

NAME	fmt – simple text formatters		
SYNOPSIS	fmt [- c] [- s] [- w <i>width</i> - <i>width</i>] [<i>inputfile</i>]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	fmt is a simple text formatter that fills and joins lines to produce output lines of (up to) the number of characters specified in the – w <i>width</i> option. The default <i>width</i> is 72. fmt concatenates the <i>inputfiles</i> listed as arguments. If none are given, fmt formats text from the standard input.		
	Blank lines are preserved in the output, as is the spacing between words. fmt does not fill lines beginning with a '.' (dot), for compatibility with nroff (1). Nor does it fill lines starting with " From :".		
	Indentation is preserved in the output, and input lines with differing indentation are not joined (unless $-c$ is used).		
	fmt can also be used as an in-line text filter for vi (1); the vi command:		
	!}fmt		
	reformats the text between the cursor location and the end of the paragraph.		
OPTIONS	 -c Crown margin mode. Preserve the indentation of the first two lines within a paragraph, and align the left margin of each subsequent line with that of the second line. This is useful for tagged paragraphs. 		
	-s Split lines only. Do not join short lines to form longer ones. This prevents sample lines of code, and other such formatted text, from being unduly combined.		
	$-\mathbf{w}$ width $ $ -width		
	Fill output lines to up to <i>width</i> columns.		
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of fmt for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how fmt behaves.		
	LC_CTYPE Determines how fmt handles characters. When LC_CTYPE is set to a valid value, fmt can display and handle text and filenames containing valid characters for that locale. fmt can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. fmt can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.		

modified 26 Sep 1992

SEE ALSO	nroff (1), vi (1)
NOTES	The <i>–width</i> option is acceptable for BSD compatibility, but it may go away in future releases.
	modified 26 Sep 1992

NAME	fmtmsg – display a message on stderr or system console		
SYNOPSIS	fmtmsg [–c class] [–u subclass] [–l label] [–s severity] [–t tag] [–a action] text		
AVAILABILITY	SUNWcsu		
DESCRIPTION	Based on a message's classification component, fmtmsg either writes a formatted mes- sage to stderr or writes a formatted message to the console.		
	able MSGVERE class component	in the ENV nts are not di	sts of up to five standard components (see environment vari- IRONMENT section of this page.) The classification and sub- splayed as part of the standard message, but rather define the direct the display of the formatted message.
OPTIONS	–c class	Describes	the source of the message. Valid keywords are:
		hard soft firm	The source of the condition is hardware. The source of the condition is software. The source of the condition is firmware.
	– u subclass		eywords (separated by commas) that further defines the mes- lirects the display of the message. Valid keywords are:
		appl	The condition originated in an application. This keyword should not be used in combination with either util or opsys .
		util	The condition originated in a utility. This keyword should not be used in combination with either appl or opsys .
		opsys	The message originated in the kernel. This keyword should not be used in combination with either appl or util .
		recov	The application will recover from the condition. This key- word should not be used in combination with nrecov .
		nrecov	The application will not recover from the condition. This keyword should not be used in combination with recov .
		print console	Print the message to the standard error stream stderr . Write the message to the system console. print , console , or both may be used.
	-l label	Identifies t	he source of the message.
	-s severity		he seriousness of the error. The keywords and definitions of rd levels of <i>severity</i> are:
		halt	The application has encountered a severe fault and is halt- ing.
		error warn	The application has detected a fault. The application has detected a condition that is out of the ordinary and might be a problem.
		info	The application is providing information about a condition that is not in error.
	–t tag	The string	containing an identifier for the message.

modified 20 Jul 1994

	– a action	A text string describing the first step in the error recovery process. This string must be written so that the entire <i>action</i> argument is interpreted as a single argument. fmtmsg precedes each action string with the TO FIX : prefix.
	text	A text string describing the condition. Must be written so that the entire <i>text</i> argument is interpreted as a single argument.
EXAMPLES		following example of fmtmsg produces a complete message in the stan- ormat and displays it to the standard error stream:
		e% fmtmsg –c soft –u recov,print,appl –l UX:cat –s error -t UX:cat:001 er to manual" "invalid syntax"
	produces:	
		ERROR: invalid syntax refer to manual UX:cat:138
	Example 2: Whe	en the environment variable MSGVERB is set as follows:
	MSGVE	RB=severity:text:action
	and Example 1 i	is used, fmtmsg produces:
		: invalid syntax refer to manual
	Example 3: Whe	en the environment variable SEV_LEVEL is set as follows:
	SEV_LE	VEL=note,5,NOTE
	the following f n	ntmsg command:
	-	e% fmtmsg –c soft –u print –l UX:cat –s note –a "refer to manual" l syntax"
	produces:	
		invalid syntax refer to manual
	and displays the	e message on stderr .
ENVIRONMENT	MSGVERB is set ride the value of	nt variables MSGVERB and SEV_LEVEL control the behavior of fmtmsg. t by the administrator in the / etc/profile for the system. Users can over- f MSGVERB set by the system by resetting MSGVERB in their own .profile ging the value in their current shell session. SEV_LEVEL can be used in
		fmtmsg which message components to select when writing messages to ue of MSGVERB is a colon separated list of optional keywords. MSGVERB lows:
	MSGVER export M	B=[keyword[:keyword[:]]] SGVERB

modified 20 Jul 1994

	Valid <i>keywords</i> are: label , severity , text , action , and tag . If MSGVERB contains a keyword for a component and the component's value is not the component's null value, fmtmsg includes that component in the message when writing the message to stderr . If MSGVERB does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If MSGVERB is not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, fmtmsg selects all components.			
	MSGVERB affects only which message components are selected for display. All message components are included in console messages.			
	SEV_LEVEL defines severity levels and associates print strings with them for use by fmtmsg. The standard severity levels shown below cannot be modified. Additional severity levels can be defined, redefined, and removed.			
	 0 (no severity is used) 1 HALT 2 ERROR 3 WARNING 4 INFO 			
	SEV_LEVEL is set as follows:			
	SEV_LEVEL=[description[:description[:]]] export SEV_LEVEL			
	description is a comma-separated list containing three fields:			
	description=severity_keyword,level,printstring			
	<i>severity_keyword</i> is a character string used as the keyword with the -s <i>severity</i> option to fmtmsg .			
	<i>level</i> is a character string that evaluates to a positive integer (other than 0 , 1 , 2 , 3 , or 4 , which are reserved for the standard severity levels). If the keyword <i>severity_keyword</i> is used, <i>level</i> is the severity value passed on to fmtmsg (3C).			
	<i>printstring</i> is the character string used by fmtmsg in the standard message format when- ever the severity value <i>level</i> is used.			
	If SEV_LEVEL is not defined, or if its value is null, no severity levels other than the defaults are available. If a <i>description</i> in the colon separated list is not a comma separated list containing three fields, or if the second field of a comma separated list does not evaluate to a positive integer, that <i>description</i> in the colon separated list is ignored.			
EXIT CODES	The exit codes for fmtmsg are the following:			
	0 All the requested functions were executed successfully.			
	1 The command contains a syntax error, an invalid option, or an invalid argument to an option.			
	2 The function executed with partial success, however the message was not displayed on stderr .			

modified 20 Jul 1994

4	The function executed with partial success, however the message was not
	displayed on the system console.

32 No requested functions were executed successfully.

NAME	fnattr – Update and examine attributes associated with an FNS named object		
SYNOPSIS	fnattr – a [– s] composite_name [– O – U] identifier value1 [value2] fnattr – d composite_name [[– O – U] identifier [value1 [value2]]] fnattr – m composite_name [– O – U] identifier old_value new_value fnattr – l composite_name [[– O – U] identifier]		
DESCRIPTION	The fnattr command is for updating and examining attributes associated with an FNS named object. There are four uses for this command: add an attribute or value, delete an attribute or value, modify an attribute's value, and list the contents of an attribute.		
OPTIONS	 -a Add an attribute or add a value to an attribute associated with object named using <i>composite_name. identifier</i> is the identifier of the attribute to manipulate; its format is FN_ID_STRING unless the -O or -U option is given. <i>value1, value2</i> are attribute values to add. The attribute syntax used for storing <i>value1, value2</i> is fn_attr_syntax_ascii. 		
	 -d Delete attributes associated with object named by <i>composite_name</i>. If <i>identifier</i> is not specified, all attributes associated with the named object are deleted. If <i>identifier</i> is specified without accompanying values, <i>value1</i>, <i>value2</i>,, the entire attribute identified by <i>identifier</i> is removed. If individual attribute values, <i>value1</i>, <i>value2</i>,, are specified, then only these are removed from the attribute. Removal of the last value of an attribute entails removal of the attribute as well. The format of <i>identifier</i> is FN_ID_STRING unless the –O or –U option is given. 		
	 List the attribute (its identifier and values) associated with the object named by <i>composite_name</i>. If <i>identifier</i> is not specified, all the attribute associated with the named object are displayed. The format of <i>identifier</i> is FN_ID_STRING unless the -O or -U option is given. 		
	 -m Modify the values of the attribute identified by <i>identifier</i> associated with the object named by <i>composite_name. old_value</i> is replaced by <i>new_value</i> in the specified attribute. Other attributes and values associated with <i>composite_name</i> are not affected. The format of <i>identifier</i> is FN_ID_STRING unless the -O or -U option is given. 		
	-s Add in supersede mode. If an attribute with the same identifier as <i>identifier</i> already exists, remove <i>all</i> its values, and replace with <i>value1, value2</i> If this option is omitted, the resulting values for the specified attribute is a union of the existing values and <i>value1, value2</i>		
	-O The format of <i>identifier</i> is FN_ID_ISO_OID_STRING, an ASN.1 dot-separated integer list string.		
	-U The format of <i>identifier</i> is FN_ID_DCE_UUID , a DCE UUID in string form.		
EXAMPLES	The – a option is used for adding attributes and values. This following command replaces the value of the shoesize attribute of user/jane with the value 7.5 . eg% fnattr -as user/jane shoesize 7.5		

modified 4 Nov 1994

	The following command adds the value Chameleo to the project attribute of user/jane . eg% fnattr -a user/jsmith project Chameleo
	The – d option is used for deleting attributes and values. The following command deletes all the attributes associated with user/jane . eg% fnattr -d user/jane
	The following command deletes the attribute shoesize associated with user/jane . eg% fnattr -d user/jane shoesize
	The following command deletes the attribute value old_project from the projects attri- bute associated with user/jane . eg% fnattr -d user/jane projects old_project
	The – m option is for modifying an attribute value. The following command replaces the value Chameleo by Dungeon in the projects attribute associated with user/jsmith . eg% fnattr -m user/jsmith projects Chameleo Dungeon
	The –l option is used for listing attributes and their values. The following command lists all the attributes associated with user/jane . eg% fnattr -l user/jane
	The following command list the values of the project attribute of user/jane . eg% fnattr -l user/jane project

NAME	fnbind – Bind a reference to an FNS name		
SYNOPSIS	fnbind [– s] [– v] [– L] <i>name new_name</i>		
	fnbind $-\mathbf{r} [-\mathbf{s}] [-\mathbf{v}]$ new_name $[-\mathbf{O} -\mathbf{U}]$ ref_type { $[-\mathbf{O} -\mathbf{U}]$ addr_type $[-\mathbf{c} -\mathbf{x}]$ addr_contents }		
DESCRIPTION	fnbind binds the reference named by <i>name</i> to the name <i>new_name</i> . The second synopsis of fnbind (uses the –r option) allows the binding of <i>new_name</i> to the reference constructed using arguments supplied in the command line.		
OPTIONS	- s Bind to <i>new_name</i> even if it is already bound. If this option is omitted, fnbind fails if <i>new_name</i> is already bound.		
	-v Display the reference being bound to <i>new_name</i> .		
	-L Create an XFN link using <i>name</i> and bind it to <i>new_name</i> .		
	 -r Create a reference using <i>ref_type</i> as the reference's type, and one or more pairs of <i>addr_type</i> and <i>addr_contents</i> as the reference's list of addresses, and bind this reference to <i>new_name</i>. Unless the -O or -U options are used, FN_ID_STRING is used as the identifier format for <i>ref_type</i> and <i>addr_type</i>. Unless the -c or -x options are used, <i>addr_contents</i> is stored as an XDR-encoded string. 		
	-c Store <i>addr_contents</i> in the given form; do not use XDR-encoding.		
	 <i>addr_contents</i> specifies an hexidecimal string. Convert it to its hexidecimal representation and store it; do not use XDR-encoding. 		
	-O The identifier format is FN_ID_ISO_OID_STRING, an ASN.1 dot-separated integer list string.		
	-U The identifier format is FN_ID_DCE_UUID , a DCE UUID in string form.		
EXAMPLES	For example, the command eg% fnbind -s thisorgunit/service/printer thisorgunit/service/pr binds the name thisorgunit/service/pr to the reference named by thisorgunit/service/printer. Any reference bound to thisorgunit/service/pr is overwrit- ten.		
	For example, the command eg% fnbind -L thisorgunit/service/printer thisorgunit/service/pr binds the name thisorgunit/service/pr to the XFN link constructed using the name thisorgunit/service/printer.		
	For example, the command eg% fnbind -r thisorgunit/service/calendar SUNW_cal \ SUNW_cal_deskset_onc staff@exodus binds the name thisorgunit/service/calendar to the reference with reference type SUNW_cal and address type SUNW_cal_deskset_onc, and address contents of staff@exodus.		

SEE ALSO	===========
	xfn_links(3N)

NAME	fnlist – Display the names and references bound in an FNS context		
SYNOPSIS	fnlist [–l] [–v] composite_name		
DESCRIPTION	fnlist displays the names and references bound in the context of <i>composite_name</i> .		
OPTIONS	 -I Display the references as well as the names bound in the context of <i>composite_name</i>. Without this option, only the names are displayed. -v Display the references in detail. For onc_fn_* references, this option is useful to derive the name of the NIS+ table that stores the reference for every name bound in the context of <i>composite_name</i>. 		
EXAMPLES	For example, the command eg% fnlist user/ shows the names bound in the context of user/. The following example eg% fnlist -l user/ displays the names and references bound in the context of user/.		
SEE ALSO	fnbind(1), fncreate(1M), fndestroy(1M), fnlookup(1), fnunbind(1), fns(5), fns_references(5)		

NAME	fnlookup – Display the reference bound to an FNS name
SYNOPSIS	fnlookup [–v] [–L] composite_name
DESCRIPTION	fnlookup displays the binding of <i>composite_name</i> .
OPTIONS	 -v Display the binding in detail. For "onc_fn_*" references, this option is useful to derive the name of the NIS+ table that stores the reference for <i>composite_name</i> and a string representation of the reference, if applicable. -L If the composite name is bound to an XFN link, display the reference that the link is bound to. Without the -L option, fnlookup displays the XFN link.
EXAMPLES	 For example, the command eg% fnlookup user/jsmith/service/calendar shows the reference to which the name user/jsmith/service/calendar, that refers to the calendar of user jsmith, is bound. For example, the command eg% fnlookup user/jsmith/service shows the reference to which the name user/jsmith/service, that refers to the service context of user jsmith, is bound. If this is bound to an XFN link, then eg% fnlookup -L user/jsmith/service
SEE ALSO	fnbind(1), fncreate(1M), fndestroy(1M), fnlist(1), fnunbind(1), fns(5), fns_references(5), xfn_links(3N)

NAME	fnrename – Rename the binding of an FNS name		
SYNOPSIS	fnrename [– s] [– v] context_name old_atomic_name new_atomic_name		
DESCRIPTION	fnrename renames the binding of <i>old_atomic_name</i> to <i>new_atomic_name</i> in the context of <i>context_name</i> . Both <i>old_atomic_name</i> and <i>new_atomic_name</i> must be atomic names, to be resolved in the context named by <i>context_name</i> .		
OPTIONS	 -s Overwrite any reference already bound to <i>new_atomic_name</i>. If this options is omitted, <i>fnrename</i> fails if <i>new_atomic_name</i> is already bound. -v Display the binding being renamed. 		
EXAMPLES	For example, the command eg% fnrename user/jsmith/service/ clendar calendar binds calendar to the reference bound to clendar in the context named by user/jsmith/service/ and unbinds clendar.		
SEE ALSO	<pre>fnbind(1), fncreate(1M), fndestroy(1M), fnlist(1), fnunbind(1), fns(5), fns_references(5), xfn_links(3N)</pre>		

NAME	fnunbind – Unbind the reference from an FNS name
SYNOPSIS	fnunbind composite_name
DESCRIPTION	fnunbind unbinds the reference of <i>composite_name</i> .
	For example, eg% fnunbind user/jsmith/fs/ unbinds the reference to which the name user/jsmith/fs/ was bound.
	Note that an fnunbind on a name of a context will fail because such a context cannot be unbound without destroying it first with the command fndestroy .

NAME	fold – filter for	folding lines
SYNOPSIS	fold [- bs] [- w <i>width</i> - <i>width</i>] [<i>file</i>]	
AVAILABILITY	SUNWcsu	
DESCRIPTION	The fold utility is a filter that will fold lines from its input files, breaking the lines to have a maximum of <i>width</i> column positions (or bytes, if the $-\mathbf{b}$ option is specified). Lines will be broken by the insertion of a NEWLINE character such that each output line (referred to later in this section as a segment) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line will not be broken in the middle of a character. The behavior is undefined if <i>width</i> is less than the number of columns any single character in the input would occupy.	
		E-RETURN, BACKSPACE, or TAB characters are encountered in the input, on is not specified, they will be treated specially:
	BACKSPACE	The current count of line width will be decremented by one, although the count never will become negative. fold will not insert a NEWLINE character immediately before or after any BACKSPACE character.
	CARRIAGE-RET	URN The current count of line width will be set to 0 . fold will not insert a NEWLINE character immediately before or after any CARRIAGE-RETURN character.
	ТАВ	Each TAB character encountered will advance the column position pointer to the next tab stop. Tab stops will be at each column position <i>n</i> such that <i>n</i> modulo 8 equals 1.
OPTIONS	The following o	options are supported:
	$-\mathbf{b}$	Count width in bytes rather than column positions.
	S	If a segment of a line contains a blank character within the first <i>width</i> column positions (or bytes), break the line after the last such blank character meeting the width constraints. If there is no blank character meeting the requirements, the $-s$ option will have no effect for that output segment of the input line.
	$-\mathbf{w}$ width $ -wid$	
		Specify the maximum line length, in column positions (or bytes if –b is specified). If <i>width</i> is not a positive decimal number, an error is returned. The default value is 80.
OPERANDS	The following o	operand is supported:
		n name of a text file to be folded. If no <i>file</i> operands are specified, the stan- nput will be used.

NIANSE	
NAME	for, foreach, repeat – shell built-in functions to repeatedly execute action(s) for a selected number of times
SYNOPSIS sh	for word [in wordlist]; do actions; done
csh	foreach word (wordlist)
	end
	repeat count command
ksh	for word [in wordlist] ; do actions ; done
DESCRIPTION	
sh	Each time a for command is executed, <i>word</i> is set to the next item taken from the in <i>wordlist</i> . If in <i>wordlist</i> is omitted, then the for command executes the do <i>actions</i> once for each positional parameter that is set. Execution ends when there are no more words in the list.
csh	The variable <i>word</i> is successively set to each member of <i>wordlist</i> . The sequence of commands between this command and the matching end is executed for each new value of <i>word</i> . Both foreach and end must appear alone on separate lines.
	repeat executes <i>command</i> repeatedly <i>count</i> times. <i>count</i> must be a number. <i>command</i> is restricted to a one-line statement.
ksh	Each time a for command is executed, <i>word</i> is set to the next item taken from the in <i>wordlist</i> . If in <i>wordlist</i> is omitted, then the for command executes the do <i>actions</i> once for each positional parameter that is set. Execution ends when there are no more words in the list.
loop interrupts	The built-in command continue may be used to terminate the execution of the current iteration of a for or foreach loop, and the built-in command break may be used to terminate execution of a for or foreach command.
EXAMPLES	In the examples using for/foreach , the code counts the number of lines for each file in the current directory whose name ends with a ".c" extension. The repeat example prints "I will not chew gum in class" 500 times.
sh	for file in *.c ; do wc -l \$file ; done
csh	foreach file (*.c) wc -l \$file end

modified 15 Apr 1994

1-329

ksh	for file in *.c ; do wc -l \$file ; done
csh	The repeat command re-executes the single subsequent <i>command</i> for <i>count</i> number of times. @ repetition = 500 repeat Srepetition echo "I will not chew gum in class."
SEE ALSO	break (1), csh (1), ksh (1), sh (1)
NOTES	Both the Bourne shell, sh , and the Korn shell, ksh , can use the semicolon and the carriage return interchangeably in their syntax of the if , for , and while built-in commands.

NAME	ftp – file transfer program		
SYNOPSIS	ftp [-dgintv] [hostname]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The ftp command is the user interface to the Internet standard File Transfer Protocol (FTP). ftp transfers files to and from a remote network site.		
	The client host with which ftp is to communicate may be specified on the command line. If this is done, ftp immediately attempts to establish a connection to an FTP server on that host; otherwise, ftp enters its command interpreter and awaits instructions from the user. When ftp is awaiting commands from the user, it displays the prompt ftp >.		
OPTIONS	The following options may be specified at the command line, or to the command inter- preter:		
	-d Enable debugging.		
	− g Disable filename "globbing."		
	-i Turn off interactive prompting during multiple file transfers.		
	 -n Do not attempt "auto-login" upon initial connection. If auto-login is not disabled, ftp checks the .netrc file in the user's home directory for an entry describing an account on the remote machine. If no entry exists, ftp will prompt for the login name of the account on the remote machine (the default is the login name on the local machine), and, if necessary, prompts for a password and an account with which to login. 		
	-t Enable packet tracing (unimplemented).		
	-v Show all responses from the remote server, as well as report on data transfer statistics. This is turned on by default if ftp is running interactively with its input coming from the user's terminal.		
	The following commands can be specified to the command interpreter:		
	! [command]		
	Run <i>command</i> as a shell command on the local machine. If no <i>command</i> is given, invoke an interactive shell.		
	\$ macro-name [args] Execute the macro macro-name that was defined with the macdef command. Arguments are passed to the macro unglobbed.		
	account [<i>passwd</i>] Supply a supplemental password required by a remote system for access to resources once a login has been successfully completed. If no argument is included, the user will be prompted for an account password in a non-echoing input mode.		
332	modified 6 Jan 1994		
00~	mounted 0 Jan 1554		

append	d <i>local-file</i> [<i>remote-file</i>] Append a local file to a file on the remote machine. If <i>remote-file</i> is not specified, the local file name is used, subject to alteration by any ntrans or nmap settings. File transfer uses the current settings for "representation type", "file structure", and "transfer mode".
ascii	Set the "representation type" to "network ASCII". This is the default type.
bell	Sound a bell after each file transfer command is completed.
binary	Set the "representation type" to "image".
bye	Terminate the FTP session with the remote server and exit ftp . An EOF will also terminate the session and exit.
case	Toggle remote computer file name case mapping during mget commands. When case is on (default is off), remote computer file names with all letters in upper case are written in the local directory with the letters mapped to lower case.
cd remo	ote-directory
_	Change the working directory on the remote machine to <i>remote-directory</i> .
cdup	Change the remote machine working directory to the parent of the current remote machine working directory.
close	Terminate the FTP session with the remote server, and return to the command interpreter. Any defined macros are erased.
сг	Toggle RETURN stripping during "network ASCII" type file retrieval. Records are denoted by a RETURN/LINEFEED sequence during "network ASCII" type file transfer. When cr is on (the default), RETURN characters are stripped from this sequence to conform with the UNIX system single LINEFEED record delimiter. Records on non-UNIX-system remote hosts may contain single LINEFEED characters; when an "network ASCII" type transfer is made, these LINEFEED characters may be distinguished from a record delimiter only when cr is off.
delete	remote-file
	Delete the file <i>remote-file</i> on the remote machine.
debug	Toggle debugging mode. When debugging is on, ftp prints each command sent to the remote machine, preceded by the string —>.
dir [rea	<pre>mote-directory] [local-file] Print a listing of the directory contents in the directory, remote-directory, and, optionally, placing the output in local-file. If no directory is specified, the current working directory on the remote machine is used. If no local file is specified, or local-file is -, output is sent to the terminal. nect A synonym for close.</pre>

modified 6 Jan 1994

1-333

form [format-name] Set the carriage control format subtype of the "representation type" to formatname. The only valid format-name is **non-print**, which corresponds to the default "non-print" subtype. get remote-file [local-file] Retrieve the *remote-file* and store it on the local machine. If the local file name is not specified, it is given the same name it has on the remote machine, subject to alteration by the current **case**, **ntrans**, and **nmap** settings. The current settings for "representation type", "file structure", and "transfer mode" are used while transferring the file. Toggle filename expansion, or "globbing", for mdelete, mget and mput. If globglob bing is turned off, filenames are taken literally. Globbing for **mput** is done as in **sh**(1). For **mdelete** and **mget**, each remote file name is expanded separately on the remote machine, and the lists are not merged.

Expansion of a directory name is likely to be radically different from expansion of the name of an ordinary file: the exact result depends on the remote operating system and FTP server, and can be previewed by doing **mls** *remote-files* –.

mget and **mput** are not meant to transfer entire directory subtrees of files. You can do this by transferring a **tar**(1) archive of the subtree (using a "representation type" of "image" as set by the **binary** command).

- hash Toggle hash-sign (#) printing for each data block transferred. The size of a data block is 8192 bytes.
- help [command]

Print an informative message about the meaning of *command*. If no argument is given, **ftp** prints a list of the known commands.

lcd [directory]

Change the working directory on the local machine. If no *directory* is specified, the user's home directory is used.

ls [remote-directory | -al] [local-file]

Print an abbreviated listing of the contents of a directory on the remote machine. If *remote-directory* is left unspecified, the current working directory is used.

The -a option lists all entries, including those that begin with a dot (.), which are normally not listed. The -l option lists files in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file. If the file is a special file, the size field instead contains the major and minor device numbers rather than a size. If the file is a symbolic link, the filename is printed followed by " \rightarrow " and the pathname of the referenced file.

If no local file is specified, or if *local-file* is –, the output is sent to the terminal.

macdef macro-name

Define a macro. Subsequent lines are stored as the macro *macro-name*; a null line (consecutive NEWLINE characters in a file or RETURN characters from the terminal) terminates macro input mode. There is a limit of 16 macros and 4096 total characters in all defined macros. Macros remain defined until a **close** command is executed.

The macro processor interprets \$ and \ as special characters. A \$ followed by a number (or numbers) is replaced by the corresponding argument on the macro invocation command line. A \$ followed by an i signals that macro processor that the executing macro is to be looped. On the first pass \$i is replaced by the first argument on the macro invocation command line, on the second pass it is replaced by the second argument, and so on. A \ followed by any character is replaced by that character. Use the \ to prevent special treatment of the \$.

mdelete remote-files

Delete the *remote-files* on the remote machine.

mdir remote-files local-file

Like **dir**, except multiple remote files may be specified. If interactive prompting is on, **ftp** will prompt the user to verify that the last argument is indeed the target local file for receiving **mdir** output.

mget remote-files

Expand the *remote-files* on the remote machine and do a **get** for each file name thus produced. See **glob** for details on the filename expansion. Resulting file names will then be processed according to **case**, **ntrans**, and **nmap** settings. Files are transferred into the local working directory, which can be changed with **lcd** *directory*; new local directories can be created with **! mkdir** *directory*.

mkdir directory-name

Make a directory on the remote machine.

mls remote-files local-file

Like **ls**(1), except multiple remote files may be specified. If interactive prompting is on, **ftp** will prompt the user to verify that the last argument is indeed the target local file for receiving **mls** output.

mode [mode-name]

Set the "transfer mode" to *mode-name*. The only valid *mode-name* is **stream**, which corresponds to the default "stream" mode. This implementation only supports **stream**, and requires that it be specified.

mput local-files

Expand wild cards in the list of local files given as arguments and do a **put** for each file in the resulting list. See **glob** for details of filename expansion. Resulting file names will then be processed according to **ntrans** and **nmap** settings.

nmap [inpattern outpattern]

Set or unset the filename mapping mechanism. If no arguments are specified, the filename mapping mechanism is unset. If arguments are specified, remote filenames are mapped during **mput** commands and **put** commands issued without a specified remote target filename. If arguments are specified, local filenames are mapped during **mget** commands and **get** commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. The mapping follows the pattern set by *inpattern* and *outpattern*. *inpattern* is a template for incoming filenames (which may have already been processed according to the **ntrans** and **case** settings). Variable templating is accomplished by including the sequences **\$1, \$2, ..., \$9** in *inpattern*. Use \ to prevent this special treatment of the **\$** character. All other characters are treated literally, and are used to determine the **nmap** *inpattern* variable values.

For example, given *inpattern* **\$1.\$2** and the remote file name **mydata.data**, **\$1** would have the value **mydata**, and **\$2** would have the value **data**.

The *outpattern* determines the resulting mapped filename. The sequences **\$1**, **\$2**, ..., **\$9** are replaced by any value resulting from the *inpattern* template. The sequence **\$0** is replaced by the original filename. Additionally, the sequence [*seq1*, *seq2*] is replaced by *seq1* if *seq1* is not a null string; otherwise it is replaced by *seq2*.

For example, the command **nmap \$1.\$2.\$3 [\$1,\$2].[\$2,file]** would yield the output filename **myfile.data** for input filenames **myfile.data** and **myfile.data.old**, **myfile.file** for the input filename **myfile**, and **myfile.myfile** for the input filename **.myfile**. SPACE characters may be included in *outpattern*, as in the example **nmap \$1 | sed "s/ *\$//" > \$1.** Use the \ character to prevent special treatment of the \$, [,], and ,, characters.

ntrans [inchars [outchars]]

Set or unset the filename character translation mechanism. If no arguments are specified, the filename character translation mechanism is unset. If arguments are specified, characters in remote filenames are translated during **mput** commands and **put** commands issued without a specified remote target filename, and characters in local filenames are translated during **mget** commands and **get** commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. Characters in a filename matching a character in *inchars* are replaced with the corresponding character in *outchars*. If the character's position in *inchars* is longer than the length of *outchars*, the character is deleted from the file name.

Only 16 characters can be translated when using the **ntrans** command under **ftp**. Use **case** (described above) if needing to convert the entire alphabet.

open host [port]

Establish a connection to the specified *host* FTP server. An optional port number may be supplied, in which case, **ftp** will attempt to contact an FTP server at that port. If the *auto-login* option is on (default setting), **ftp** will also attempt to automatically log the user in to the FTP server.

prompt

Toggle interactive prompting. Interactive prompting occurs during multiple file transfers to allow the user to selectively retrieve or store files. By default, prompting is turned on. If prompting is turned off, any **mget** or **mput** will transfer all files, and any **mdelete** will delete all files.

proxy ftp-command

Execute an FTP command on a secondary control connection. This command allows simultaneous connection to two remote FTP servers for transferring files between the two servers. The first **proxy** command should be an **open**, to establish the secondary control connection. Enter the command **proxy**? to see other FTP commands executable on the secondary connection.

The following commands behave differently when prefaced by **proxy**: **open** will not define new macros during the auto-login process, **close** will not erase existing macro definitions, **get** and **mget** transfer files from the host on the primary control connection to the host on the secondary control connection, and **put**, **mputd**, and **append** transfer files from the host on the secondary control connection to the host on the primary control connection.

Third party file transfers depend upon support of the **PASV** command by the server on the secondary control connection.

put local-file [remote-file]

Store a local file on the remote machine. If *remote-file* is left unspecified, the local file name is used after processing according to any **ntrans** or **nmap** settings in naming the remote file. File transfer uses the current settings for "representation type", "file structure", and "transfer mode".

- **pwd** Print the name of the current working directory on the remote machine.
- **quit** A synonym for **bye**.

quote arg1 arg2...

Send the arguments specified, verbatim, to the remote FTP server. A single FTP reply code is expected in return. (The **remotehelp** command displays a list of valid arguments.)

quote should be used only by experienced users who are familiar with the FTP protocol.

recv remote-file [local-file]

A synonym for get.

remotehelp [command-name]

Request help from the remote FTP server. If a *command-name* is specified it is supplied to the server as well.

rename from to

Rename the file *from* on the remote machine to have the name to.

reset Clear reply queue. This command re-synchronizes command/reply sequencing with the remote FTP server. Resynchronization may be necessary following a violation of the FTP protocol by the remote server.

rmdir directory-name

Delete a directory on the remote machine.

runique

Toggle storing of files on the local system with unique filenames. If a file already exists with a name equal to the target local filename for a **get** or **mget** command, a **.1** is appended to the name. If the resulting name matches another existing file, a **.2** is appended to the original name. If this process continues up to **.99**, an error message is printed, and the transfer does not take place. The generated unique filename will be reported. **runique** will not affect local files generated from a shell command. The default value is off.

send local-file [remote-file]

A synonym for put.

sendport

Toggle the use of **PORT** commands. By default, **ftp** will attempt to use a **PORT** command when establishing a connection for each data transfer. The use of **PORT** commands can prevent delays when performing multiple file transfers. If the **PORT** command fails, **ftp** will use the default data port. When the use of **PORT** commands is disabled, no attempt will be made to use **PORT** commands for each data transfer. This is useful when connected to certain FTP implementations that ignore **PORT** commands but incorrectly indicate they have been accepted.

- status Show the current status of ftp.
- struct [struct-name]

Set the file structure to *struct-name*. The only valid *struct-name* is **file**, which corresponds to the default "file" structure. The implementation only supports **file**, and requires that it be specified.

sunique

Toggle storing of files on remote machine under unique file names. The remote FTP server must support the **STOU** command for successful completion. The remote server will report the unique name. Default value is off.

- tenex Set the "representation type" to that needed to talk to TENEX machines.
- trace Toggle packet tracing (unimplemented).

type [type-name]

Set the "representation type" to *type-name*. The valid *type-names* are **ascii** for "network ASCII", **binary** or **image** for "image", and **tenex** for "local byte size" with a byte size of 8 (used to talk to TENEX machines). If no type is specified, the current type is printed. The default type is "network ASCII".

	user user-name [password] [account] Identify yourself to the remote FTP server. If the password is not specified and the server requires it, ftp will prompt the user for it (after disabling local echo). If an account field is not specified, and the FTP server requires it, the user will be prompted for it. If an account field is specified, an account command will be relayed to the remote server after the login sequence is completed if the remote server did not require it for logging in. Unless ftp is invoked with "auto-login" disabled, this process is done automatically on initial connection to the FTP server.		
	verbose Toggle verbose mode. In verbose mode, all responses from the FTP server are		
	displayed to the user. In addition, if verbose mode is on, when a file transfer completes, statistics regarding the efficiency of the transfer are reported. By default, verbose mode is on if ftp 's commands are coming from a terminal, and off otherwise.		
	? [command] A synonym for help .		
	Command arguments which have embedded spaces may be quoted with quote (") marks.		
	If any command argument which is not indicated as being optional is not specified, ftp will prompt for that argument.		
ABORTING A FILE TRANSFER	To abort a file transfer, use the terminal interrupt key. Sending transfers will be immedi- ately halted. Receiving transfers will be halted by sending an FTP protocol ABOR com- mand to the remote server, and discarding any further data received. The speed at which this is accomplished depends upon the remote server's support for ABOR processing. If the remote server does not support the ABOR command, an ftp > prompt will not appear until the remote server has completed sending the requested file.		
	The terminal interrupt key sequence will be ignored when ftp has completed any local processing and is awaiting a reply from the remote server. A long delay in this mode may result from the ABOR processing described above, or from unexpected behavior by the remote server, including violations of the ftp protocol. If the delay results from unexpected remote server behavior, the local ftp program must be killed by hand.		
FILE NAMING CONVENTIONS	Local files specified as arguments to ftp commands are processed according to the fol- lowing rules.		
	1) If the file name – is specified, the standard input (for reading) or standard output (for writing) is used.		
	2) If the first character of the file name is , the remainder of the argument is inter- preted as a shell command. ftp then forks a shell, using popen (3S) with the argu- ment supplied, and reads (writes) from the standard output (standard input) of that shell. If the shell command includes SPACE characters, the argument must be quoted; for example " ls – lt ". A particularly useful example of this mechan- ism is: " dir more ".

FILE TRANSFER PARAMETERS	The FTP specification specifies many parameters which may affect a file transfer. The "representation type" may be one of "network ASCII", "EBCDIC", "image", or "local byte size" with a specified byte size (for PDP-10's and PDP-20's mostly). The "network ASCII" and "EBCDIC" types have a further subtype which specifies whether vertical format control (NEWLINE characters, form feeds, etc.) are to be passed through ("non-print"), provided in TELNET format ("TELNET format controls"), or provided in ASA (FORTRAN) ("carriage control (ASA)") format. ftp supports the "network ASCII" (subtype "non-print" only) and "image" types, plus "local byte size" with a byte size of 8 for communicating with TENEX machines.

NAME	function – shell built-in command to define a function which is usable within this shell
SYNOPSIS	
ksh	<pre>function identifier { list ;} identifier() { list ;}</pre>
DESCRIPTION	
ksh	function defines a function which is referenced by <i>identifier</i> . The body of the function is the <i>list</i> of commands between { and }.
	Alternatively, omitting the function keyword and appending the <i>identifier</i> with a set of enclosed parentheses will accomplish the same function definition.
SEE ALSO	ksh (1)

NAME	gcore – get core images of running processes
SYNOPSIS	gcore [–o filename] [–p procdir] process-id
DESCRIPTION	gcore creates a core image of each specified process. The name of the core image file for the process whose process ID is <i>process-id</i> will be core . <i>process-id</i> .
OPTIONS	- o Substitutes <i>filename</i> in place of core as the first part of the name of the core image files.
FILES	core.process-id core images

NAME	gencat – generate a formatted message catalog		
SYNOPSIS	gencat catfile msgfile.		
AVAILABILITY	SUNWloc		
DESCRIPTION	The gencat command merges the message text source file(s) <i>msgfile</i> into a formatted message database <i>catfile</i> . The database <i>catfile</i> is created if it does not already exist. If <i>catfile</i> does exist, its messages are included in the new <i>catfile</i> . If set and message numbers collide, the new message-text defined in <i>msgfile</i> replaces the old message text currently contained in <i>catfile</i> . The message text source file (or set of files) input to gencat can contain either set and message numbers or simply message numbers, in which case the set NL_SETD (see nl_types (5)) is assumed.		
Message Text Source File Format			
	\$delset n commentDeletes message set n from an existing message catalog. Any string following the set number is treated as a comment. (Note: if n is not a valid set it is ignored.)		
	\$ comment	A line beginning with a dollar symbol \$ followed by an ASCII space or tab character is treated as a comment.	
	m message-text	The <i>m</i> denotes the message identifier, a number in the range (1- {NL_MSGMAX}). The <i>message-text</i> is stored in the message catalog with the set identifier specified by the last Sset directive, and with message identifier <i>m</i> . If the <i>message-text</i> is empty, and an ASCII space or tab field separator is present, an empty string is stored in the message catalog. If a message source line has a message number, but neither a field separator nor <i>message-text</i> , the existing message with that number (if any) is deleted from the catalog. Message identifiers need not be contiguous. The length of <i>message-text</i> must be in the range (0 –{NL_TEXTMAX}).	

1-343

	Squote c	uote cThis line specifies an optional quote character c, which can be used to surround message-text so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty Squote directive is supplied, no quoting of message-text will be recognized.				
	Empty lir	ies in a mes	sage text source file	are ignored.		
	Text strin lowing ta	•	ontain the special characters and escape sequences defined in the fol-			
			Description	Symbol	Sequence

NAME getfacl – display discretionary information for a file or files

SYNOPSIS getfacl [-ad] file ...

DESCRIPTION

For each argument that is a regular file, special file, or named pipe, **getfacl** displays the owner, group, and the Access Control List (ACL). For each directory argument, **getfacl** displays the owner, group, and the ACL and/or the default ACL. Only directories contain default ACLs.

With the –a option specified, the filename, owner, group, and the ACL of the file will be displayed. With the –d option specified, the filename, owner, group, and the default ACL of the file, if it exists, will be displayed. With no options specified, the filename, owner, group, and both the ACL and the default ACL, if it exists, will be displayed.

This command may be executed on a file system that does not support ACLs. It will report the ACL based on the base permission bits.

When multiple files are specified on the command line, a blank line will separate the ACL for each file. The format of an ACL is:

file: filename # owner: uid # group: gid user::perm user:uid:perm group::perm group:gid:perm mask:perm other:perm default:user::perm default:user:uid:perm default:group::perm default:group::gid:perm default:group::gid:perm default:mask:perm default:other:perm

The first three lines show the filename, the file owner, and the file owning group. Note that when only the –d option is specified, and the file has no default ACL, only these three lines will be displayed.

The user entry without a user ID indicates the permissions that will be granted to the owner of the file. One or more additional user entries indicate the permissions that will be granted to the specified users. The group entry without a group ID indicates the permissions that will be granted to the owning group of the file. One or more additional group entries indicate the permissions that will be granted to the owning group of the file. One or more additional group entries indicate the permissions that will be granted to the specified groups. The mask entry indicates the file group mask permissions. These are the maximum permissions allowed to any user entries except the file owner, and to any group entries, including the owning group. These permissions restrict the permissions specified in other entries. The other entry indicates the permissions that will be granted to others.

The default entries may only exist for directories, and indicates the default entries that will be added to a file created within the directory.

The **uid** is a login name or a user ID if there is no entry for the **uid** in the system's password file. The **gid** is a group name or a group ID if there is no entry for the **gid** in the system's group file. The **perm** is a three character string composed of the letters representing the separate discretionaryy access rights: r (read), w (write), x (excute/search), or the place holder character -. The **perm** will be displayed in the following order: rwx. If a permission is not granted by an ACL entry, the place holder character will appear.

The ACL entries will be displayed in the order in which they will be evaluated when an access check is performed. The default ACL entries which may exist on a directory have no effect on access checks.

The file owner permission bits represent the access that the owning user ACL entry has. The file group class permission bits represent the most access that any additional user entries, additional group entries, or the owning group entry may grant. The file other class permission bits represent the access that the other ACL entry has. If a user invokes the **chmod**(1) command and changes the file group class permission bits, the access granted by additional ACL entries may be restricted.

In order to indicate that the file group class permission bits restrict an ACL entry, **getfacl** will display an additional tab character, pound sign ("#"), and the actual permissions granted, following the entry.

EXAMPLES 1) Given file "foo", with an ACL six entries long, the command

host% getfacl foo

would print:

file: foo
owner: shea
group: staff
user::rwx
user:spy: - - user:mookie:r - group::r mask::rw other:: - -

2) Continue with the above example, after "chmod 700 foo" was issued:

host% getfacl foo

would print:

file: foo
owner: shea
group: staff
user::rwx
user:spy:---

	user:mookie:r #effective: group::r #effective: mask::
	other:: 3) Given directory "doo", with an ACL conatining default entries, the command
	host% getfacl -d doo
	would print:
	<pre># file: doo # owner: shea # group: staff default:user::rwx default:user:spy: default:user:mookie:r default:group::r default:group::r default:mask:: default:mask::</pre>
FILES	/etc/passwd /etc/group
SEE ALSO	chmod(1), ls(1), setfacl(1), acl(2), aclsort(3)
NOTE	The output from getfacl will be in the correct format for input to the setfacl command. If the output from getfacl is redirected to a file, the file may be used as input to setfacl . In this way, a user may easily assign one file's ACL to another file.

NAME	getfrm – returns the current frameID number
SYNOPSIS	getfrm
DESCRIPTION	getfrm returns the current frameID number. The frameID number is a number assigned to the frame by FMLI and displayed flush left in the frame's title bar. If a frame is closed its frameID number may be reused when a new frame is opened. getfrm takes no arguments.
EXAMPLES	If a menu whose frameID is 3 defines an item to have this action descriptor:
	action=open text stdtext `getfrm`
	the text frame defined in the definition file stdtext would be passed the argument 3 when it is opened.
NOTES	It is not a good idea to use getfrm in a backquoted expression coded on a line by itself. Stand-alone backquoted expressions are evaluated before any descriptors are parsed, thus the frame is not yet fully current, and may not have been assigned a frameID number.

modified 5 Jul 1990

NAME	getitems – returns a list of currently marked menu items
SYNOPSIS	getitems [delimiter_string]
DESCRIPTION	The getitems function returns the value of lininfo if defined, else it returns the value of the name descriptor, for all currently marked menu items. Each value in the list is delimited by <i>delimiter_string</i> . The default value of <i>delimiter_string</i> is newline.
EXAMPLES	The done descriptor in the following menu definition file executes getitems when the user presses ENTER (note that the menu is multiselect):
	Menu="Example" multiselect=TRUE done=`getitems ":" message`
	name="Item 1" action=`message "You selected item 1"`
	name="Item 2" lininfo="This is item 2" action=`message "You selected item 2"`
	name="Item 3" action=`message "You selected item 3"`
	If a user marked all three items in this menu, pressing ENTER would cause the following string to be displayed on the message line:
	Item 1:This is item 2:Item 3
NOTES	Because lininfo is defined for the second menu item, its value is displayed instead of the value of the name descriptor.

modified 5 Jul 1990

NAME	getopt – parse command options
SYNOPSIS	<pre>set — `getopt optstring \$*`</pre>
AVAILABILITY	SUNWcsu
DESCRIPTION	The getopts command supersedes getopt . For more information, see NOTES below. getopt is used to break up options in command lines for easy parsing by shell procedures and to check for legal options. <i>optstring</i> is a string of recognized option letters; see getopt (3C). If a letter is followed by a colon, the option is expected to have an argument which may or may not be separated from it by white space. The special option — is used to delimit the end of the options. If it is used explicitly, getopt recognizes it; otherwise, getopt generates it; in either case, getopt places it at the end of the options. The posi- tional parameters (\$1 \$2) of the shell are reset so that each option is preceded by a – and is in its own positional parameter; each option argument is also parsed into its own positional parameter.
EXAMPLES	The following code fragment shows how one might process the arguments for a com- mand that can take the options a or b , as well as the option o , which requires an argu- ment: set — `getopt abo: \$*` if [\$? != 0] then
SEE ALSO	<pre>intro(1), shell_builtins(1), sh(1), getopt(3C)</pre>

modified 14 Sep 1992

DIAGNOSTICS getopt prints an error message on the standard error when it encounters an option letter not included in *optstring*.

NOTES getopt will not be supported in the next major release. For this release a conversion tool has been provided, getoptcvt. For more information about getopts and getoptcvt, see getopts(1).

Reset **optind** to 1 when rescanning the options.

getopt does not support the part of Rule 8 of the command syntax standard (see **intro**(1)) that permits groups of option-arguments following an option to be separated by white space and quoted. For example,

cmd –a –b –o "xxx z yy" filename

is not handled correctly. To correct this deficiency, use the **getopts** command in place of **getopt**.

If an option that takes an option-argument is followed by a value that is the same as one of the options listed in *optstring* (referring to the earlier **EXAMPLES** section, but using the following command line: **cmd -o -a filename**, **getopt** always treats **–a** as an option-argument to **–o**; it never recognizes **–a** as an option. For this case, the **for** loop in the example shifts past the *filename* argument.

modified 14 Sep 1992

NAME	getoptcvt – convert to getopts to parse command options
SYNOPSIS	/usr/lib/getoptcvt [–b] filename
	/usr/lib/getoptcvt
DESCRIPTION	/ usr/lib/getoptcvt reads the shell script in <i>filename</i> , converts it to use getopts instead of getopt , and writes the results on the standard output.
	getopts is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See sh (1). It supports all applicable rules of the command syntax standard (see Rules 3-10, intro (1)). It should be used in place of the getopt command. (See the NOTES section below.) The syntax for the shell's built-in getopts command is:
	getopts optstring name [argument]
	<i>optstring</i> must contain the option letters the command using getopts will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.
	Each time it is invoked, getopts places the next option in the shell variable <i>name</i> and the index of the next argument to be processed in the shell variable OPTIND . Whenever the shell or a shell script is invoked, OPTIND is initialized to 1 .
	When an option requires an option-argument, getopts places it in the shell variable OPTARG .
	If an illegal option is encountered, ? will be placed in <i>name</i> .
	When the end of options is encountered, getopts exits with a non-zero exit status. The special option — may be used to delimit the end of the options.
	By default, getopts parses the positional parameters. If extra arguments (<i>argument</i>) are given on the getopts command line, getopts parses them instead.
	So that all new commands will adhere to the command syntax standard described in intro (1), they should use getopts or getopt to parse positional parameters and check for options that are valid for that command (see the NOTES section below).
OPTIONS	 -b Make the converted script portable to earlier releases of the UNIX system. /usr/lib/getoptcvt modifies the shell script in <i>filename</i> so that when the resulting shell script is executed, it determines at run time whether to invoke getopts or getopt.
EXAMPLES	The following fragment of a shell program shows how one might process the arguments for a command that can take the options a or b , as well as the option o , which requires an option-argument:

modified 27 Feb 1994

	while getopts abo: c do case \$c in a b) FLAG=\$c;; o) OARG=\$OPTARG;; \?) echo \$USAGE exit 2;; esac done shift . expr \$OPTIND - 1. This code accepts any of the following as equivalent: cmd -a -b -o "xxx z yy" filename cmd -a b -o "xxx z yy" filename	
SEE ALSO	intro(1), sh(1), shell_builtins(1), getopt(3C)	
DIAGNOSTICS	getopts prints an error message on the standard error when it encounters an option letter not included in <i>optstring</i> .	
NOTES	Although the following command syntax rule (see intro(1)) relaxations are permitted under the current implementation, they should not be used because they may not be sup- ported in future releases of the system. As in the EXAMPLES section above, a and b are options, and the option o requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options: example% cmd –aboxxx filename The following example violates Rule 6: there must be white space after an option that takes an option-argument: example% cmd –ab –oxxx filename Changing the value of the shell variable OPTIND or parsing different sets of arguments may lead to unexpected results.	

modified 27 Feb 1994

NAME	getopts – parse utility options		
SYNOPSIS	/usr/bin/getopts optstring name [arg]		
sh	getopts optstring name [argument]		
ksh	getopts optstring name [arg]		
DESCRIPTION /usr/bin/getopts	The getopts utility can be used to retrieve options and option-arguments from a list of parameters.		
	Each time it is invoked, the getopts utility places the value of the next option in the shell variable specified by the <i>name</i> operand and the index of the next argument to be processed in the shell variable OPTIND . Whenever the shell is invoked, OPTIND will be initialised to 1.		
	When the option requires an option-argument, the getopts utility will place it in the shell variable OPTARG . If no option was found, or if the option that was found does not have an option-argument, OPTARG will be unset.		
	If an option character not contained in the <i>optstring</i> operand is found where an option character is expected, the shell variable specified by <i>name</i> will be set to the question-mark (?) character. In this case, if the first character in <i>optstring</i> is a colon (:), the shell variable OPTARG will be set to the option character found, but no output will be written to stan- dard error; otherwise, the shell variable OPTARG will be unset and a diagnostic message will be written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking application, but is not an error in getopts processing.		
	If an option-argument is missing:		
	• If the first character of <i>optstring</i> is a colon, the shell variable specified by <i>name</i> will be set to the colon character and the shell variable OPTARG will be set to the option character found.		
	• Otherwise, the shell variable specified by <i>name</i> will be set to the question- mark character, the shell variable OPTARG will be unset, and a diagnostic message will be written to standard error. This condition is considered to be an error detected in the way arguments were presented to the invoking appli- cation, but is not an error in getopts processing; a diagnostic message will be written as stated, but the exit status will be zero.		
	When the end of options is encountered, the getopts utility will exit with a return value greater than zero; the shell variable OPTIND will be set to the index of the first non-option-argument, where the first $$ argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value \$# + 1 if there are no non-option-arguments; the <i>name</i> variable will be set to the question-mark character. Any of the following identifies the end of options: the special option $$, finding an argument that does not begin with a $-$, or encountering an error.		

The shell variables **OPTIND** and **OPTARG** are local to the caller of **getopts** and are not exported by default.

The shell variable specified by the *name* operand, **OPTIND** and **OPTARG** affect the current shell execution environment.

If the application sets **OPTIND** to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke **getopts** multiple times in a single shell execution environment with parameters (positional parameters or *arg* operands) that are not the same in all invocations, or with an **OPTIND** value modified to be a value other than 1, produces unspecified results.

sh getopts is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See sh(1). It supports all applicable rules of the command syntax standard (see Rules 3-10, intro(1)). It should be used in place of the getopt command.

optstring must contain the option letters the command using **getopts** will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, **getopts** places the next option in the shell variable *name* and the index of the next argument to be processed in the shell variable **OPTIND**. Whenever the shell or a shell script is invoked, **OPTIND** is initialized to **1**.

When an option requires an option-argument, **getopts** places it in the shell variable **OPTARG**.

If an illegal option is encountered, ? will be placed in *name*.

When the end of options is encountered, **getopts** exits with a non-zero exit status. The special option — may be used to delimit the end of the options.

By default, **getopts** parses the positional parameters. If extra arguments (*argument*...) are given on the **getopts** command line, **getopts** parses them instead.

/usr/lib/getoptcvt reads the shell script in *filename*, converts it to use getopts instead of getopt, and writes the results on the standard output.

So that all new commands will adhere to the command syntax standard described in **intro**(1), they should use **getopts** or **getopt** to parse positional parameters and check for options that are valid for that command.

Examples:

The following fragment of a shell program shows how one might process the arguments for a command that can take the options **a** or **b**, as well as the option **o**, which requires an option-argument:

while getopts abo: c do

- case \$c in
- a b) FLAG=\$c;;
- o) OARG=\$OPTARG;;
- \?) echo \$USAGE
 - exit 2;;

	0520			
	esac done			
	shift `expr \$OPTIND – 1`			
	This code accepts any of the following as equivalent:			
	cmd –a –b –o "xxx z yy" filename cmd –a –b –o "xxx z yy" –– filename cmd –ab –o xxx,z,yy filename cmd –ab –o "xxx z yy" filename cmd –o xxx,z,yy –b –a filename			
	getopts prints an error message on the standard error when it encounters an option letter not included in <i>optstring</i> .			
	Although the following command syntax rule (see intro (1)) relaxations are permitted under the current implementation, they should not be used because they may not be sup- ported in future releases of the system. As in the EXAMPLES section above, a and b are options, and the option o requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options:			
	example% cmd –aboxxx filename			
	The following example violates Rule 6: there must be white space after an option that takes an option-argument:			
	example% cmd –ab –oxxx filename			
	Changing the value of the shell variable OPTIND or parsing different sets of arguments may lead to unexpected results.			
ksh	Checks <i>arg</i> for legal options. If <i>arg</i> is omitted, the positional parameters are used. An option argument begins with $a + or a -$. An option not beginning with $+ or - or$ the argument $$ ends the options. <i>optstring</i> contains the letters that getopts recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.			
	getopts places the next option letter it finds inside variable <i>name</i> each time it is invoked with a + prepended when <i>arg</i> begins with a +. The index of the next <i>arg</i> is stored in OPTIND . The option argument, if any, gets stored in OPTARG .			
	A leading : in <i>optstring</i> causes getopts to store the letter of an invalid option in OPTARG , and to set <i>name</i> to ? for an unknown option and to : when a required option is missing. Otherwise, getopts prints an error message. The exit status is non-zero when there are no more options.			
	For a further discussion of the Korn shell's getopts built-in command, see the previous discussion in the Bourne shell, sh , section of this manpage.			
OPERANDS	The following operands are supported:			
	<i>optstring</i> A string containing the option characters recognised by the utility invoking getopts . If a character is followed by a colon, the option will be expected to have an argument, which should be supplied as a separate argument.			

	Applications should specify an option character and its option-argument as separate arguments, but getopts will interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognised if it is not supplied as a separate argument when getopts is invoked; see getopt (3C). The characters question-mark and colon must not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in OPTARG will be stripped of the option character and the –. The first character in <i>optstring</i> will determine how getopts will behave if an option character is not known or an option-argument is missing.		
	<i>name</i> The name of a shell variable that will be set by the getopts utility to the option character that was found.		
	The getopts utility by default will parse positional parameters passed to the invoking shell procedure. If <i>arg s</i> are given, they will be parsed instead of the positional parameters.		
USAGE	Since getopts affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:		
	(getopts abc value "\$@")		
	nohup getopts		
	findexec getopts \;		
	it will not affect the shell variables in the caller's environment.		
	Note that shell functions share OPTIND with the calling shell even though the positional parameters are changed. Functions that want to use getopts to parse their arguments will usually want to save the value of OPTIND on entry and restore it before returning. However, there will be cases when a function will want to change OPTIND for the calling shell.		
EXAMPLES	The following example script parses and displays its arguments: aflag=		
	bflag=		
	while getopts ab: name		
	do		
	case \$name in		
	a) aflag=1;;		
	b) bflag=1		
	bval="\$OPTARG";;		
	?) printf "Usage: %s: [-a] [-b value] args\n" \$0		

	exit 2;;		
	esac		
	done		
	if [! -z "\$aflag"]; then		
	printf "Option -a specified \n"		
	fi		
	printf 'Option -b "%s" specified\n' "\$bval"		
	fi		
	shift \$((\$OPTIND - 1))		
	printf "Remaining arguments are: %s\n" "\$*"		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of getopts: LC_CTYPE, LC_MESSAGES , and NLSPATH .		
	OPTIND This variable is used by getopts as the index of the next argument to be processed.		
EXIT STATUS	The following exit values are returned:		
	0 An option, specified or unspecified by <i>optstring</i> , was found.		
	>0 The end of options was encountered or an error occurred.		
SEE ALSO	<pre>intro(1), getopt(1), getoptcvt(1), ksh(1), sh(1), getopt(3C), environ(5)</pre>		
DIAGNOSTICS	Whenever an error is detected and the first character in the <i>optstring</i> operand is not a colon (:), a diagnostic message will be written to standard error with the following infomation in an unspecified format:		
	 The invoking program name will be identified in the message. The invoking program name will be the value of the shell special parameter 0 at the time the getopts utility is invoked. A name equivalent to: basename "\$0" 		
	may be used.		
	• If an option is found that was not specified in <i>optstring</i> , this error will be identified and the invalid option character will be identified in the message.		
	 If an option requiring an option-argument is found, but an option-argument is not found, this error will be identified and the invalid option character will be identified in the message. 		

NAME	gettext – retrieve text string from message database		
SYNOPSIS	gettext [textdomain] msgid		
AVAILABILITY	SUNWcsu		
DESCRIPTION	gettext retrieves a translated text string corresponding to string <i>msgid</i> from a message object generated with msgfmt (1). The message object name is derived from the optional argument <i>textdomain</i> if present, otherwise from the TEXTDOMAIN environment. If no domain is specified, or if a corresponding string cannot be found, gettext prints <i>msgid</i> . Ordinarily gettext looks for its message object in / usr/lib/locale / <i>lang</i> / LC_MESSAGES where <i>lang</i> is the locale name. If present, the TEXTDOMAINDIR environment variable replaces the pathname component up to <i>lang</i> . This command interprets C escape sequences such as \t for tab. Use \\ to print a backslash. To produce a message on a line of its own, either put a \ n at the end of <i>msgid</i> ,		
	or use this command in conjunction with printf (1).		
ENVIRONMENT	 LANG Specifies locale name. LC_MESSAGES Specifies messaging locale, and if present overrides LANG for messages. TEXTDOMAIN Specifies the text domain name, which is identical to the message object filename without .mo suffix. TEXTDOMAINDIR Specifies the pathname to the message database, and if present replaces /usr/lib/locale. 		
SEE ALSO	<pre>msgfmt(1), printf(1), gettext(3I), setlocale(3C)</pre>		
NOTES	This is the shell equivalent of the library routine gettext (3I).		

modified 30 Sep 1992

(colon). msgnum Sequence number of the string to retrieve from msgfile. The strings in msgfi are numbered sequentially from 1 to n, where n is the number of strings in the file. dflt_msg Default string to be displayed if gettxt fails to retrieve msgnum from msgfile Nongraphic characters must be represented as alphabetic escape sequences. The text string to be retrieved is in the file msgfile, created by the mkmsgs(1) utility and installed under the directory /usr/lib/locale/lc_MESSAGES. You control which directory is searched by setting the environment variable LANG will be used. If LANG is not set, the files containing the strings are under the directory /usr/lib/locale/C/LC_MESSAGES. If gettxt fails to retrieve a message in the requested language, it will try to retrieve the same message from /usr/lib/locale/C/LC_MESSAGES/msgfile. If this also fails, and if dflt_msg is present and non-null, then it will display the value of dflt_msg; if dflt_msg is not present or is null, then it will display the string Message not found!!. EXAMPLES If the environment variables LANG or LC_MESSAGES have not been set to other than their default values, the following example: example% gettxt UX:10 "hello world\n" will try to retrieve the 10th message from /usr/lib/locale/C/UX/msgfile. If the retrieval fails, the message "hello world," followed by a newline, will be displayed. ENVIRONMENT If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_OLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, by the value of the LANG environment variables. If none of the above variables is override both the LANG and the other LC_* variables. If none of the above va				
AVAILABILITY SUNWloc DESCRIPTION getxt retrieves a text string from a message file in the directory /usr/lib/locale/locale/LC_MESSAGES. The directory name locale corresponds to the language in which the text strings are written; see selocale(3C). msgfile Name of the file in the directory /usr/lib/locale/locale/LC_MESSAGES to retrieve msgnum from. The name of msgfile can be up to 14 characters in length, but may not contain either \0 (null) or the ASCII code for / (slash) or (colon). msgnum Sequence number of the string to retrieve from msgfile. The strings in msgfile are numbered sequentially from 1 to n, where n is the number of strings in the file. dflt_msg Default string to be displayed if gettxt fails to retrieve msgnum from msgfile Nongraphic characters must be represented as alphabetic escape sequences The text string to be retrieved is in the file msgfile, created by the mkmsgs(1) utility and installed under the directory /usr/lib/locale/locale/LC_MESSAGES. 	 LC_CTYPE Determines how gettxt handles characters. When LC_CTYPE is set to a valid value, gettxt can display and handle text and filenames containing valid characters for that locale. gettxt can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. gettxt can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid. LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

NAME	glob – shell built-in function to expand a word list
SYNOPSIS csh	glob wordlist
DESCRIPTION csh	glob performs filename expansion on <i>wordlist</i> . Like echo (1), but no ' $\$ ' escapes are recognized. Words are delimited by null characters in the output.
SEE ALSO	csh (1), echo (1)

User Commands

NAME	gprof – display call-graph profile data		
SYNOPSIS	gprof [-abcCDlsz] [-e function-name] [-E function-name] [-f function-name] [-F function-name] [image-file [profile-file]] [-n number of functions]		
DESCRIPTION	gprof produces an execution profile of a program. The effect of called routines is incorporated in the profile of each caller. The profile data is taken from the call graph profile file which is created by programs compiled with the $-xpg$ option of $cc(1B)$, $-pg$ for other compilers, or by setting the LD_PROFILE environment variable for shared objects (see ld (1)). These compiler options also link in versions of the library routines which are compiled for profiling. The symbol table in the executable image file <i>image-file</i> (a.out by default) is read and correlated with the call graph profile file <i>profile-file</i> (gmon.out by default).		
	If more than one profile file is specified, the gprof output shows the sum of the profile information in the given profile files.		
	First, execution times for each routine are propagated along the edges of the call graph. Cycles are discovered, and calls into a cycle are made to share the time of the cycle. The first listing shows the functions sorted according to the time they represent, including the time of their call graph descendants. Below each function entry is shown its (direct) call- graph children, and how their times are propagated to this function. A similar display above the function shows how this function's time and the time of its descendants is pro- pagated to its (direct) call-graph parents.		
	Cycles are also shown, with an entry for the cycle as a whole and a listing of the members of the cycle and their contributions to the time and call counts of the cycle.		
	Next, a flat profile is given, similar to that provided by prof (1). This listing gives the to execution times and call counts for each of the functions in the program, sorted by decreasing time. Finally, an index is given, showing the correspondence between function names and call-graph profile index numbers.		
A single function may be split into subfunctions for profiling by means of the MA macro (see prof (5)).			
	Beware of quantization errors. The granularity of the sampling is shown, but remains statistical at best. It is assumed that the time for each execution of a function can be expressed by the total time for the function divided by the number of times the function is called. Thus the time propagated along the call-graph arcs to parents of that function is directly proportional to the number of times that arc is traversed.		
	The profiled program must call exit (2) or return normally for the profiling information to be saved in the gmon.out file.		
OPTIONS	-a Suppress printing statically declared functions. If this option is given, all relevant information about the static function (for instance, time samples, calls to other functions, calls from other functions) belongs to the function loaded just before the static function in the a.out file.		

modified 22 Mar 1994

- -**b** Brief. Suppress descriptions of each field in the profile.
- **-C** Demangle C++ symbol names before printing them out.
- -c Discover the static call-graph of the program by a heuristic which examines the text space of the object file. Static-only parents or children are indicated with call counts of 0.
- -D Produce a profile file gmon.sum that represents the difference of the profile information in all specified profile files. This summary profile file may be given to subsequent executions of gprof (also with -D) to summarize profile data across several runs of an a.out file. (See also the -s option.)

As an example, suppose function A calls function B **n** times in profile file **gmon.sum**, and **m** times in profile file **gmon.out**. With –**D**, a new **gmon.sum** file will be created showing the number of calls from A to B as **n-m**.

-E function-name

Suppress printing the graph profile entry for routine *function-name* (and its descendants) as $-\mathbf{e}$, below, and also exclude the time spent in *function-name* (and its descendants) from the total and percentage time computations. More than one $-\mathbf{E}$ option may be given. For example:

'-E mcount -E mcleanup'

is the default.

-e function-name

Suppress printing the graph profile entry for routine *function-name* and all its descendants (unless they have other ancestors that are not suppressed). More than one $-\mathbf{e}$ option may be given. Only one *function-name* may be given with each $-\mathbf{e}$ option.

-F function-name

Print the graph profile entry only for routine *function-name* and its descendants (as $-\mathbf{f}$, below) and also use only the times of the printed routines in total time and percentage computations. More than one $-\mathbf{F}$ option may be given. Only one *function-name* may be given with each $-\mathbf{F}$ option. The $-\mathbf{F}$ option overrides the $-\mathbf{E}$ option.

-f function-name

Print the graph profile entry only for routine *function-name* and its descendants. More than one $-\mathbf{f}$ option may be given. Only one *function-name* may be given with each $-\mathbf{f}$ option.

- -l Suppress the reporting of graph profile entries for all local symbols. This option would be the equivalant of placing all of the local symbols for the specified executable image on the –E exclusion list.
- -n Limits the size of flat and graph profile listings to the top **n** offending functions.
- -s Produce a profile file gmon.sum which represents the sum of the profile information in all of the specified profile files. This summary profile file may be given to subsequent executions of gprof (also with -s) to accumulate profile data across

modified 22 Mar 1994

	several runs of an a.out file. (See also the $-\mathbf{D}$ option.)	
	 -z Display routines which have zero usage (as indicated by call counts and accumulated time). This is useful in conjunction with the -c option for discovering which routines were never called. 	
ENVIRONMENT	PROFDIR If this environment variable contains a value, place profiling output within that directory, in a file named <i>pid.programname</i> . <i>pid</i> is the process ID, and <i>programname</i> is the name of the program being profiled, as determined by removing any path prefix from the argv[0] with which the program was called. If the variable contains a null value, no profiling output is produced. Otherwise, profiling output is placed in the file gmon.out .	
FILES	a.outexecutable file containing namelistgmon.outdynamic call-graph and profilegmon.sumsummarized dynamic call-graph and profile\$PROFDIR/pid.programname	
NOTES	If the executable image has been striped and it has no symbol table (.symtab) then gprof will read the dynamic symbol table (.dyntab) if present. If the dynamic symbol table is used then only the information for the global symbols will be available, the behavior will be identical to the $-a$ option.	
SEE ALSO	ld (1), cc (1B), prof (1), exit (2), profil (2), monitor (3C), prof (5)	
	Graham, S.L., Kessler, P.B., McKusick, M.K., 'gprof: A Call Graph Execution Profiler', Proceedings of the SIGPLAN '82 Symposium on Compiler Construction, SIGPLAN Notices, Vol 17, No. 6, pp. 120-126, June 1982.	
	Linker and Libraries Guide	
BUGS	Parents which are not themselves profiled will have the time of their profiled children propagated to them, but they will appear to be spontaneously invoked in the call-graph listing, and will not have their time propagated further. Similarly, signal catchers, even though profiled, will appear to be spontaneous (although for more obscure reasons). Any profiled children of signal catchers should have their times propagated properly, unless the signal catcher was invoked during the execution of the profiling routine, in which case all is lost.	

modified 22 Mar 1994

NAME	graph – draw a gra	ph	
SYNOPSIS	graph [-a spacing [start]] [-b] [-c string] [-g gridstyle] [-l label] [-m connectmode] [-s] [-x [l] lower [upper [spacing]]] [-y [l] lower [upper [spacing]]] [-h fraction] [-w fraction] [-r fraction] [-u fraction] [-t]		
AVAILABILITY	SUNWesu		
DESCRIPTION	graph with no options takes pairs of numbers from the standard input as abscissaes and ordinates of a graph. Successive points are connected by straight lines. The standard output from graph contains plotting instructions suitable for input to plot (1B) or to the command lpr – g (see lpr (1B)).		
	If the coordinates of a point are followed by a nonnumeric string, that string is printed at a label beginning on the point. Labels may be surrounded with quotes "", in which case they may be empty or contain blanks and numbers; labels never contain NEWLINE characters.		
	A legend indicating grid range is produced with a grid unless the – s option is presen		
OPTIONS	Each option is recognized as a separate argument. If a specified lower limit exceeds th upper limit, the axis is reversed.		
	-a spacing[start]	Supply abscissaes automatically (they are missing from the input); <i>spacing</i> is the spacing (default 1). <i>start</i> is the starting point for automatic abscissaes (default 0 or lower limit given by $-\mathbf{x}$).	
	- b	Break (disconnect) the graph after each label in the input.	
	–c string	String is the default label for each point.	
	– g gridstyle	<i>Gridstyle</i> is the grid style: 0 no grid, 1 frame with ticks, 2 full grid (default).	
	-l label	<i>label</i> is label for graph.	
	- m connectmode	Mode (style) of connecting lines: 0 disconnected, 1 connected (default). Some devices give distinguishable line styles for other small integers.	
	- S	Save screen, do not erase before plotting.	
	-x [1] lower [upper		
		If l is present, <i>x</i> axis is logarithmic. <i>lower</i> and <i>upper</i> are lower (and upper) <i>x</i> limits. <i>spacing</i> , if present, is grid spacing on <i>x</i> axis. Normally these quantities are determined automatically.	
	-y [1] lower [uppe	r [<i>spacing</i>]] If I is present, <i>y</i> axis is logarithmic. <i>lower</i> and <i>upper</i> are lower (and upper) <i>y</i> limits. <i>spacing</i> , if present, is grid spacing on <i>y</i> axis. Nor- mally these quantities are determined automatically.	

modified 14 Sep 1992

-h fraction	fraction of space for height.
-w fraction	fraction of space for width.
- r fraction	fraction of space to move right before plotting.
-u fraction	fraction of space to move up before plotting.
-t	Transpose horizontal and vertical axes. Option – x now applies to the vertical axis.

SEE ALSO | lpr(1B), plot(1B), spline(1), plot(3)

BUGSgraph stores all points internally and drops those for which there is no room.Segments that run out of bounds are dropped, not windowed.Logarithmic axes may not be reversed.

modified 14 Sep 1992

NAME	grep – search a	file for a pattern
SYNOPSIS	/usr/bin/grep [-bchilnsvw] limited-regular-expression [filename]
		$[-E -F] [-c -l -q] [-bhinsvwx] -e pattern_list$
		$[rn_file] \dots [file \dots]$ $[rep [-E -F] [-c -l -q] [-bhinsvwx] [-e pattern_list \dots]$
	–f pattern	<u>_file</u> [file]
	/usr/xpg4/bin/g	[-E -F] [-c -l -q] [-bhinsvwx] pattern [file]
AVAILABILITY /usr/bin/grep	SUNWcsu	
/usr/xpg4/bin/grep	SUNWxcu4	
DESCRIPTION		and searches files for a pattern and prints all lines that contain that pat- ompact non-deterministic algorithm.
		g the characters $\$$, $*$, $[, \hat{,}]$, $(,)$, and \setminus in the <i>pattern_list</i> because they are l to the shell. It is safest to enclose the entire <i>pattern_list</i> in single quotes
		pecified, grep assumes standard input. Normally, each line found is ard output. The file name is printed before each line found if there is input file.
/usr/bin/grep	grep uses limite to match the pa	ed regular expressions like those described on the regexp (5) manual page tterns.
/usr/xpg4/bin/grep	interprets <i>patter</i> specified, grep	and –F affect the way grep interprets <i>pattern_list</i> . If –E is specified, grep <i>cn_list</i> as a full regular expression (see –E for description). If –F is interprets <i>pattern_list</i> as a fixed string. If neither are specified, grep inter- tert as a basic regular expression as described on regex (5) manual page.
OPTIONS	The following o	options are supported:
	-b	Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).
	- c	Print only a count of the lines that contain the pattern.
	-h	Prevents the name of the file containing the matching line from being appended to that line. Used when searching multiple files.
	- i	Ignore upper/lower case distinction during comparisons.
	-1	Print only the names of files with matching lines, separated by NEWLINE characters. Does not repeat the names of files when the pattern is found more than once.
	-n	Precede each line by its line number in the file (first line is 1).

modified 28 Mar 1995

	I	
	- S	Suppress error messages about nonexistent or unreadable files
	- v	Print all lines except those that contain the pattern.
	$-\mathbf{w}$	Search for the expression as a word as if surrounded by \leq and \geq .
/usr/xpg4/bin/grep	The following o	options are supported by / usr/xpg4/bin/grep only:
	–e pattern_list	Specify one or more patterns to be used during the search for input. Patterns in <i>pattern_list</i> must be separated by a NEWLINE character. A null pattern can be specified by two adjacent newline characters in <i>pattern_list</i> . Unless the –E or –F option is also specified, each pattern will be treated as a basic regular expression. Multiple –e and –f options are accepted by grep . All of the specified patterns are used when match- ing lines, but the order of evaluation is unspecified.
	- E	Match using full regular expressions. Treat each pattern specified as an full regular expression. If any entire full regular expression pattern matches an input line, the line will be matched. A null full regular expression matches every line.
		Each pattern will be interpreted as a full regular expression as described on the regex (5) manual page, except for (and) , and including:
		 A full regular expression followed by + that matches one or more occurrences of the full regular expression.
		2. A full regular expression followed by ? that matches 0 or 1 occurrences of the full regular expression.
		3. Full regular expressions separated by or by a new-line that match strings that are matched by any of the expressions.
		4. A full regular expression that may be enclosed in parentheses () for grouping.
		The order of precedence of operators is [], then $*$?+, then concatenation, then and new-line.
	-f pattern_file	Read one or more patterns from the file named by the path name <i>pattern_file</i> . Patterns in <i>pattern_file</i> are terminated by a NEWLINE character. A null pattern can be specified by an empty line in <i>pattern_file</i> . Unless the –E or –F option is also specified, each pattern will be treated as a basic regular expression.
	- F	Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line will be matched. A null string matches every line. See fgrep (1) for more information.
	$-\mathbf{q}$	Quiet. Do not write anything to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.
	- x	Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

modified 28 Mar 1995

OPERANDS	The follow	wing operands are supported:
	file	A path name of a file to be searched for the patterns. If no <i>file</i> operands are specified, the standard input will be used.
/usr/bin/grep	pattern	Specify a pattern to be used during the search for input.
/usr/xpg4/bin/grep	pattern	Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as $-e$ pattern_list.
USAGE	when pat	attern_list option has the same effect as the <i>pattern_list</i> operand, but is useful <i>tern_list</i> begins with the hyphen delimiter. It is also useful when it is more con- o provide multiple patterns as separate arguments.
	while ma impleme	-e and -f options are accepted and grep will use all of the patterns it is given tching input text lines. (Note that the order of evaluation is not specified. If an ntation finds a null string as a pattern, it is allowed to use that pattern first, every line, and effectively ignore any other patterns.)
	exists in a improver by the use	ption provides a means of easily determining whether or not a pattern (or string) a group of files. When searching several files, it provides a performance nent (because it can quit as soon as it finds the first match) and requires less care er in choosing the set of files to supply as arguments (because it will exit zero if match even if grep detected an access or read error on earlier file operands).
EXAMPLES	To find al numbers:	ll uses of the word " Posix " (in any case) in the file text.mm , and write with line
	e	xample% /usr/bin/grep -i -n posix text.mm
	To find al	ll empty lines in the standard input:
	e	xample% /usr/bin/grep ^\$
	or	
		xample% /usr/bin/grep –v .
		ne following commands print all lines containing strings abc or def or both:
		xample% /usr/xpg4/bin/grep -E 'abc lef'
		xample% /usr/xpg4/bin/grep -F 'abc lef'
	e	ne following commands print all lines matching exactly abc or def : xample% /usr/xpg4/bin/grep -E `^abc\$ def\$'
		xample% /usr/xpg4/bin/grep -F -x 'abc ef'
ENVIRONMENT		on(5) for descriptions of the following environment variables that affect the exe- grep: LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

1-374

modified 28 Mar 1995

The following exit values are returned:
0 one or more matches were found
1 no matches were found
2 syntax errors or inaccessible files (even if matches were found).
egrep(1), fgrep(1), sed(1), sh(1), environ(5), regex(5), regexp(5)
Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in / usr/include/stdio.h . If there is a line with embedded nulls, grep will only match up to the first null; if it matches, it will print the entire line.

modified 28 Mar 1995

groups – print group membership of user
groups [user]
SUNWcsu
The command groups prints on standard output the groups to which you or the option- ally specified user belong. Each user belongs to a group specified in / etc/passwd and possibly to other groups as specified in / etc/group . Note that / etc/passwd specifies the numerical ID (gid) of the group. The groups command converts gid to the group name in the output.
The output takes the following form: example% groups tester01 tester02 tester01 : staff tester02 : staff example%
/etc/passwd /etc/group
group(4), passwd(4)

modified 14 Sep 1992

SunOS 5.5	SunOS/BSD Compatibility Package Commands groups (1B)
NAME SYNOPSIS	groups – display a user's group memberships / usr/ucb/groups [<i>user</i>]
AVAILABILITY	SUNWscpu
DESCRIPTION	With no arguments, groups displays the groups to which you belong; else it displays the groups to which the user belongs. Each user belongs to a group specified in the password file /etc/passwd and possibly to other groups as specified in the file /etc/group . If you do not own a file but belong to the group which it is owned by then you are granted group access to the file.
FILES	/etc/passwd /etc/group
SEE ALSO	getgroups(2)
NOTES	This command is obsolete.

modified 14 Sep 1992

grpck(1B)	SunOS/BSD Compatibility Package Commands SunOS 5.5
NAME SYNOPSIS	grpck – check group database entries / usr/etc/grpck [<i>filename</i>]
DESCRIPTION	grpck checks that a file in group (4) does not contain any errors; it checks the / etc/group file by default.
FILES	/etc/group
SEE ALSO	groups(1), group(4), passwd(4)
DIAGNOSTICS	Too many/few fields An entry in the group file does not have the proper number of fields.
	No group name The group name field of an entry is empty.
	 Bad character(s) in group name The group name in an entry contains characters other than lower-case letters and digits. Invalid GID The group ID field in an entry is not numeric or is greater than 65535.
	Null login name A login name in the list of login names in an entry is null.
	Logname not found in password file A login name in the list of login names in an entry is not in the password file.
	Line too long A line (including the newline character) in the group file exceeds the maximum length of 512 characters.
	Duplicate logname entry A login name appears more than once in the list of login names for a group file entry.
	Out of memory The program cannot allocate memory in order to continue.
	Maximum groups exceeded for logname A login name's group membership exceeds the maximum, NGROUPS_MAX.

modified 17 Sep 1990

NAME	hash, rehash, unhash, hashstat – evaluate the internal hash table of the contents of direc- tories
SYNOPSIS	/usr/bin/hash [<i>utility</i>] /usr/bin/hash [– r]
sh	$hash [-r] [name \dots]$
csh	rehash unhash hashstat
ksh	hash [name]
DESCRIPTION /usr/bin/hash	The / usr/bin/hash utility affects the way the current shell environment remembers the locations of utilities found. Depending on the arguments specified, it adds utility locations to its list of remembered locations or it purges the contents of the list. When no arguments are specified, it reports on the contents of the list. Utilities provided as built-ins to the shell are not reported by hash .
sh	For each <i>name</i> , the location in the search path of the command specified by <i>name</i> is determined and remembered by the shell. The – r option to the hash built-in causes the shell to forget all remembered locations. If no arguments are given, hash provides information about remembered commands. The <i>Hits</i> column of output is the number of times a command has been invoked by the shell process. The <i>Cost</i> column of output is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the <i>Hits</i> information. <i>Cost</i> will be incremented when the recalculation is done.
csh	 rehash recomputes the internal hash table of the contents of directories listed in the path environmental variable to account for new commands added. unhash disables the internal hash table. hashstat prints a statistics line indicating how effective the internal hash table has been at locating commands (and avoiding execs). An exec is attempted for each component of the <i>path</i> where the hash function indicates a possible hit and in each component that does not begin with a '/'.
ksh	For each <i>name</i> , the location in the search path of the command specified by <i>name</i> is determined and remembered by the shell. If no arguments are given, hash provides information about remembered commands.

modified 28 Mar 1995

OPERANDS	The following operand is supported by hash : <i>utility</i> The name of a utility to be searched for and added to the list of remembered locations.
OUTPUT	The standard output of hash is used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list consists of those utilities named in previous hash invocations that have been invoked, and may contain those invoked and found through the normal command search process.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of hash : LC_CTYPE , LC_MESSAGES , and NLSPATH . PATH Determine the location of <i>utility</i> .
EXIT STATUS	The following exit values are returned by hash:0Successful completion.>0An error occurred.
SEE ALSO	csh (1), ksh (1), sh (1), environ (5)

modified 28 Mar 1995

NAME	head – display first few lines of files
SYNOPSIS	head [-number -n number] [filename]
AVAILABILITY	SUNWcsu
DESCRIPTION	The head utility copies the first <i>number</i> of lines of each <i>filename</i> to the standard output. If no <i>filename</i> is given, head copies lines from the standard input. The default value of <i>number</i> is 10 lines.
	When more than one file is specified, the start of each file will look like:
	==> filename <==
	Thus, a common way to display a set of short files, identifying each one, is:
	example% head –9999 filename1 filename2
OPTIONS	The following options are supported:
	-n number
	The first <i>number</i> lines of each input file will be copied to standard output. The <i>number</i> option-argument must be a positive decimal integer.
	<i>–number</i> The <i>number</i> argument is a positive decimal integer with the same effect as the <i>-</i> n <i>number</i> option.
	If no options are specified, head will act as if $-n$ 10 had been specified.
OPERANDS	The following operand is supported:
	<i>file</i> A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.
EXAMPLES	To write the first ten lines of all files (except those with a leading period) in the directory: example% head *
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of head : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 Successful completion.
	>0 An error occurred.
SEE ALSO	cat (1), more (1), pg (1), tail (1), environ (5)

modified 1 Feb 1995

NAME	history, fc – process command history list
SYNOPSIS	/usr/bin/fc [first[last]] /usr/bin/fc –l [–nr] [first[last]] /usr/bin/fc –s [old=new] [first]
csh	history [– hr] [<i>n</i>]
ksh	fc –e – [old=new] [command] fc [–e ename] [–nlr] [first [last]]
DESCRIPTION /usr/bin/fc	The fc utility lists or edits and reexecutes, commands previously entered to an interactive sh. The command history list references commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command will not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches an implementation-dependent upper limit, which will be no smaller than the value in HISTSIZE or 32 767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, fc will maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher. When commands are edited (when the –l option is not specified), the resulting lines will be entered at the end of the history list and then reexecuted by sh. The fc command that caused the editing will not be entered into the history list. If the editor returns a non-zero exit status, this will suppress the entry into the history list and the command reexecution. Any command-line variable assignments or redirection operators used with fc will affect both the fc command itself as well as the command that results, for example: $fc -s12 >/dev/null$
	reinvokes the previous command, suppressing standard error for both fc and the previous command.
csh	Display the history list; if <i>n</i> is given, display only the <i>n</i> most recent events.
	- r Reverse the order of printout to be most recent first rather than oldest first.
	 -h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the -h option to the csh built-in command, source(1).
	History Substitution:
	History substitution allows you to use words from previous command lines in the com- mand line you are typing. This simplifies spelling corrections and the repetition of com- plicated commands or arguments. Command lines are saved in the history list, the size

of which is controlled by the **history** variable. The **history** shell variable may be set to the maximum number of command lines that will be saved in the history file; i.e.:

set history = 200

will allow the history list to keep track of the most recent 200 command lines. If not set, the C shell saves only the most recent command.

A history substitution begins with a ! (although you can change this with the **histchars** variable) and may occur anywhere on the command line; history substitutions do not nest. The ! can be escaped with $\$ to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

Event Designators:

An event designator is a reference to a command line entry in the history list.

- Start a history substitution, except when followed by a space character, tab, newline, = or (.
- **!!** Refer to the previous command. By itself, this substitution repeats the previous command.
- *In* Refer to command line *n*.
- !-n Refer to the current command line minus n.

!str Refer to the most recent command starting with *str*.

!?str? Refer to the most recent command containing *str.*

!?str? additional

Refer to the most recent command containing *str* and append *additional* to that referenced command.

!{command} additional

Refer to the most recent command beginning with *command* and append *additional* to that referenced command.

^previous_word`replacement`

Repeat the previous command line replacing the string *previous_word* with the string *replacement*. This is equivalent to the history substitution: !:s/previous_word/replacement/.

To re-execute a specific previous command AND make such a substitutution, say, re-executing command #6,

!:6s/previous_word/replacement/.

Word Designators:

A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, **\$**, *****, – or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, **!!:1** and **!:1** both refer to the first word of the previous command, while **!!\$** and **!\$** both refer to the last word in the previous command. Word designators include:

- # The entire command line typed so far.
- **0** The first input word (command).
- *n* The *n*'th argument.

- The first argument, that is, **1**.
- **\$** The last argument.
- % The word matched by (the most recent) *?s* search.
- x-y A range of words; -y abbreviates **0**-y.
- * All the arguments, or a null value if there is just one word in the event.
- *x** Abbreviates *x*–**\$**.
- *x* Like *x** but omitting word **\$**.

Modifiers:

After the optional word designator, you can add a sequence of one or more of the following modifiers, each preceded by a :.

- **h** Remove a trailing pathname component, leaving the head.
- **r** Remove a trailing suffix of the form '*.xxx*', leaving the basename.
- e Remove all but the suffix, leaving the Extension.
- s/oldchars/replacements/
 - Substitute *replacements* for *oldchars*. *oldchars* is a string that may contain embedded blank spaces, whereas *previous_word* in the event designator *^oldchars^replacements^*
 - may not.
- t Remove all leading pathname components, leaving the tail.
- & Repeat the previous substitution.
- **g** Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, **g&**).
- **p** Print the new command but do not execute it.
- **q** Quote the substituted words, escaping further substitutions.
- **x** Like **q**, but break into words at each space character, tab or newline.

Unless preceded by a **g**, the modification is applied only to the first string that matches *oldchars*; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of /. A backslash quotes the delimiter character. The character &, in the right hand side, is replaced by the text from the left-hand-side. The & can be quoted with a backslash. A null *oldchars* uses the previous string either from a *oldchars* or from a contextual scan string *s* from !?*s*. You can omit the right-most delimiter if a newline immediately follows *replacements*; the rightmost ? in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

ksh Using **fc**, in the form of

fc –**e** – [*old*=*new*] [*command*],

the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

Using	fc	in	the	form	of
Using	IU	111	unc	IOIIII	U

fc [-**e** ename] [-**nlr**] [first [last]],

a range of commands from *first* to *last* is selected from the last **HISTSIZE** commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the –I flag is selected, the commands are listed on standard output. Otherwise, the editor program –**e** *name* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable **FCEDIT** (default /**bin/ed**) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and –16 for listing. The flag –**r** reverses the order of the commands and the flag –**n** suppresses command numbers when listing. (See **ksh**(1) for more about command line editing.)

HISTFILE

If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history.

HISTSIZE

If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is **128**.

Command Re-entry:

The text of the last **HISTSIZE** (default 128) commands entered from a terminal device is saved in a **history** file. The file **\$HOME/.sh_history** is used if the **HISTFILE** variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named **HISTFILE**. The special command **fc** is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to **fc** then the value of the variable **FCEDIT** is used. If **FCEDIT** is not defined then /**bin/ed** is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name – is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form *old=new* can be used to modify the command before execution. For example, if **r** is aliased to '**fc** –**e** –' then typing '**r bad=good c**' will re-execute the most recent command which starts with the letter **c**, replacing the first occurrence of the string **bad** with the string **good**.

Using the **fc** built-in command within a compound command will cause the whole command to disappear from the history file.

OPTIONS

The following options are supported:

-e editor Use the editor named by editor to edit the commands. The editor string is a utility name, subject to search via the PATH variable. The value in the FCEDIT variable is used as a default when -e is not specified. If FCEDIT is null or unset, ed will be used as the editor.

	_ - l	(The letter ell.) List the commands rather than invoking an editor on them. The commands will be written in the sequence indicated by the <i>first</i> and <i>last</i> operands, as affected by $-\mathbf{r}$, with each command preceded by the command number.
	-n	Suppress command numbers when listing with – l .
	-r	Reverse the order of the commands listed (with $-l$) or edited (with neither $-l$ nor $-s$).
	- s	Re-execute the command without invoking an editor.
OPERANDS	The follow first	ring operands are supported:
	last	Select the commands to list or edit. The number of previous commands that can be accessed is determined by the value of the HISTSIZE variable. The value of <i>first</i> or <i>last</i> or both will be one of the following:
	[+]number	A positive number representing a command number; command numbers can be displayed with the –l option.
	-number	A negative decimal number representing the command that was executed <i>number</i> of commands previously. For example, -1 is the immediately previous command.
	string	A string indicating the most recently entered command that begins with that string. If the <i>old=new</i> operand is not also specified with $-s$, the string form of the <i>first</i> operand cannot contain an embedded equal sign.
		When the synopsis form with -s is used:
		• If <i>first</i> is omitted, the previous command will be used.
		For the synopsis forms without – s :
		• If <i>last</i> is omitted, <i>last</i> defaults to the previous command when –l is specified; otherwise, it defaults to <i>first</i> .
		• If <i>first</i> and <i>last</i> are both omitted, the previous 16 commands will be listed or the previous single command will be edited (based on the –l option).
		 If <i>first</i> and <i>last</i> are both present, all of the commands from <i>first</i> to <i>last</i> will be edited (without -1) or listed (with -1). Editing multiple commands will be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If <i>first</i> represents a newer command than <i>last</i>, the commands will be listed or edited in reverse sequence, equivalent to using -r. For example, the following commands on the first line are equivalent to the corresponding commands on the second:
		fc -r 10 20 fc 30 40
		fc 20 10 fc -r 40 30
		• When a range of commands is used, it will not be an error to specify <i>first</i> or <i>last</i> values that are not in the history list; fc will substitute the value

SunOS 5.5	User Commands	history (1)
		newest command in the list, as appropriate. nly ten commands in the history list, num-
	fc –l	
	fc 1 99	
	will list and edit, respectiv	ely, all ten commands.
	<i>old=new</i> Replace the first occurrence of by the string <i>new</i> .	f string <i>old</i> in the commands to be reexecuted
OUTPUT	When the –l option is used to list command follows:	s, the format of each command in the list is as
	"%d\t%s\n", <line number="">, <comm< th=""><th>nand></th></comm<></line>	nand>
	If both the $-\mathbf{l}$ and $-\mathbf{n}$ options are specified, t	he format of each command is:
	"\t%s\n", <command/>	
	If the <i>command</i> consists of more than one lin	e, the lines after the first are displayed as:
	"\ t%s\n ", < <i>continued-command</i> >

NAME	iconv – code set conversion utility

SYNOPSIS iconv –f fromcode –t tocode [file...]

AVAILABILITY SUNWcsu

DESCRIPTION

The **iconv** command converts the characters or sequences of characters in *file* from one code set to another and writes the results to standard output. Should no conversion exist for a particular character then it is converted to the underscore '_' in the target codeset.

iconv will always convert to or from the ISO 8859-1 Latin alphabet No.1, from or to an ISO 646 ASCII variant codeset for a particular language. The ISO 8859-1 codeset will support the majority of 8 bit codesets. The conversions attempted by **iconv** accommodate the most commonly used languages.

The following table lists the supported conversions.

			Code Set Conversions Supported				
		Code	Symbol	Target Code	Symbol	comment	
		ISO 646	646	ISO 8859-1	8859	US ASCII	
		ISO 646de	646de	ISO 8859-1	8859	German	
		ISO 646da	646da	ISO 8859-1	8859	Danish	
		ISO 646en	646en	ISO 8859-1	8859	English ASCII	
		ISO 646es	646es	ISO 8859-1	8859	Spanish	
		ISO 646fr	646fr	ISO 8859-1	8859	French	
		ISO 646it	646it	ISO 8859-1	8859	Italian	
		ISO 646sv	646sv	ISO 8859-1	8859	Swedish	
		ISO 8859-1	8859	ISO 646	646	7 bit ASCII	
		ISO 8859-1	8859	ISO 646de	646de	German	
		ISO 8859-1	8859	ISO 646da	646da	Danish	
		ISO 8859-1	8859	ISO 646en	646en	English ASCII	
		ISO 8859-1	8859	ISO 646es	646es	Spanish	
		ISO 8859-1	8859	ISO 646fr	646fr	French	
		ISO 8859-1	8859	ISO 646it	646it	Italian	
		ISO 8859-1	8859	ISO 646sv	646sv	Swedish	
	The conversion	ns are performed according to the tables found on iconv (5).					
OPTIONS	The following	options are supported:					
	-f fromcode	Identifies	the input	code set.			
	-t tocode	t <i>tocode</i> Identifies the output code set.					

OPERANDS The following operands are supported:

file A path name of the input file to be translated. If *file* is omitted, the standard input is used.

modified 28 Mar 1995

EXAMPLES	The following converts the contents of file mail1 from code set 8859 to 646fr and stores the results in file mail.local .		
	example% iconv –f 8859 –t 646fr mail1 > mail.local		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of iconv : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 upon successful completion		
	1 an error has occurred.		
FILES	/usr/lib/iconv/*.soconversion modules/usr/lib/iconv/*.tconversion tables/usr/lib/iconv/iconv_datalist of conversions supported by conversion tables		
SEE ALSO	iconv(3), environ(5), iconv(5)		
NOTES	<pre>iconv can use conversion modules (/usr/lib/iconv/*.so) or conversion tables (/usr/lib/iconv/*.t). If a conversion module and a conversion table both exist for a partic- ular codeset conversion, iconv uses the conversion module.</pre>		
	Refer to the / usr/share/man/man5/iconv_ <i>locale.5</i> manual page in the Asian localized releases for information on which codeset conversions are supported. For example, the command		
	% man –s 5 iconv_ja		
	would display the manual page describing the codeset conversions that are supported for the Japanese locale.		
	Note that the iconv_ <i>locale</i> .5 manual page may not exist in every localized release. Also, the iconv_ <i>locale</i> .5 manual page does not exist in the U. S. (non-localized) release.		

)	User Commands	SunOS 5.5
NAME	if, test – evaluate condition(s) or make execution of actions dependent upon the tion of condition(s)	e evalua -
SYNOPSIS	/usr/bin/test [condition] [condition]	
sh	<pre>if condition; then action; fi if condition; then action; else action2; fi if condition; then action; elif condition2; then action2;; fi if condition; then action; elif condition2; then action2;; else action3; fi test condition [condition]</pre>	
csh	if (condition) then action else if (condition2) then action2 else action3 endif	
	if (condition) action	
ksh	<pre>if condition; then action; fi if condition; then action; else action2; fi if condition; then action; elif condition2; then action2;; fi if condition; then action; elif condition2; then action2;; else action3; fi test condition [condition]</pre>	
DESCRIPTION /usr/bin/test	The test utility evaluates the <i>condition</i> and indicates the result of the evaluation status. An exit status of zero indicates that the condition evaluated as true and status of 1 indicates that the condition evaluated as false. In the second form of the utility, which uses [] rather than test , the square brac be separate arguments and <i>condition</i> is optional.	an exit
sh	The <i>condition</i> following if is executed and, if it returns a 0 exit status, the <i>action</i> the first then is executed. Otherwise, the <i>condition2</i> following elif is executed a value is 0 , the <i>action2</i> following the next then is executed. Failing the if and eli <i>tions</i> , the else <i>action3</i> is executed. If no else <i>action</i> or then <i>action</i> is executed, the	nd, if its f condi-

D

1-394

command returns a **0** exit status. Any number of **elif ... then ...** branching pairs are allowed, but only one **else**.

test evaluates the condition *condition* and, if its value is true, sets exit status to **0**; otherwise, a non-zero (false) exit status is set; **test** also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the second **SYNOPSIS** line) must be separate arguments to the **test** command; normally these items are separated by spaces.

Primitives:

The following primitives are used to construct *condition*:

- r filename	True if <i>filename</i> exists and is readable.
-w filename	True if <i>filename</i> exists and is writable.
-x filename	True if <i>filename</i> exists and is executable.
-f filename	True if <i>filename</i> exists and is a regular file. Alternatively, if / usr/bin/sh users specify / usr/ucb before / usr/bin in their PATH environment variable, then test will return true if <i>filename</i> exists and is (not–a–directory). This is also the default for / usr/bin/csh users.
- d filename	True if <i>filename</i> exists and is a directory.
-h filename	True if <i>filename</i> exists and is a symbolic link. With all other primitives (except –L <i>filename</i>), the symbolic links are followed by default.
-c filename	True if <i>filename</i> exists and is a character special file.
- b filename	True if <i>filename</i> exists and is a block special file.
- p filename	True if <i>filename</i> exists and is a named pipe (fifo).
- u filename	True if <i>filename</i> exists and its set-user-ID bit is set.
–g filename	True if <i>filename</i> exists and its set-group-ID bit is set.
$-\mathbf{k}$ filename	True if <i>filename</i> exists and its sticky bit is set.
-s filename	True if <i>filename</i> exists and has a size greater than zero.
-t [fildes]	True if the open file whose file descriptor number is <i>fildes</i> (1 by default) is associated with a terminal device.
- z s1	True if the length of string <i>s1</i> is zero.
— n <i>s1</i>	True if the length of the string <i>s1</i> is non-zero.
s1 = s2	True if strings <i>s1</i> and <i>s2</i> are identical.
<i>s1</i> != <i>s2</i>	True if strings <i>s1</i> and <i>s2</i> are <i>not</i> identical.
s1	True if <i>s1</i> is <i>not</i> the null string.
n1 – eq n2	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal. Any of the comparisons – ne , – gt , – ge , – lt , and – le may be used in place of – eq .
-L filename	True if <i>filename</i> exists and is a symbolic link. With all other primitives (except – h <i>filename</i>), the symbolic links are followed by default.

modified 28 Mar 1995

	Operators:	
	-	s may be combined with the following operators:
	!	Unary negation operator.
	-a	Binary and operator.
	-0	Binary <i>o</i> r operator (– a has higher precedence than – o).
	(condition)	Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.
		ctory alternative to the $-\mathbf{f}$ option is a transition aid for BSD applications supported in future releases.
		s a migration aid for users of other shells which have similar options and ported in future releases.
	the owner bit se	you own (the $-\mathbf{r} - \mathbf{w}$ or $-\mathbf{x}$ tests), but the permission tested does not have t, a non-zero (false) exit status will be returned even though the file may or <i>other</i> bit set for that permission. The correct exit status will be set if user.
		berators have a higher precedence than the $-\mathbf{r}$ through $-\mathbf{n}$ operators, and = expect arguments; therefore, = and != cannot be used with the $-\mathbf{r}$ through
		e argument follows the $-\mathbf{r}$ through $-\mathbf{n}$ operators, only the first argument is others are ignored, unless a $-\mathbf{a}$ or a $-\mathbf{o}$ is the second argument.
csh	With the multi-	line form of if :
	else if a	<i>tion</i> is true, the <i>action</i> up to the first else or then is executed. Otherwise, if <i>condition2</i> is true, the <i>action2</i> between the else if and the following else or executed. Otherwise, the <i>action3</i> between the else and the endif is exe-
	needed charact	nust appear alone on its input line or after an else . Only one endif is , but it is required. The words else and endif must be the first nonwhite ers on a line. Any number of else if then branching pairs are d, but only one else .
	With the one-lin	ne form of if , there are no else , then , or endif keywords:
	cuted. the rest comma	becified <i>condition</i> evaluates to true, the single <i>action</i> with arguments is exe- Variable substitution on <i>action</i> happens early, at the same time it does for of the <i>if</i> command. <i>action</i> must be a simple command, not a pipeline, a nd list, or a parenthesized command list. Note that I/O redirection even if <i>condition</i> is false, when <i>action</i> is <i>not</i> executed (this is a bug).
ksh	lowing the first if its value is 0 ,	llowing if is executed and, if it returns an exit status of 0 , the <i>action</i> fol- then is executed. Otherwise, the <i>condition2</i> following elif is executed and, the <i>action2</i> following the next then is executed. Failing that, the else ted. If no else <i>action</i> or then <i>action</i> is executed, then the if command

	returns an e but only one	xit status of 0 . Any number of elif then branching pairs are allowed, e else .
		ption of the test built-in, see the ksh (1) sections "Conditional Expressions" netic Evaluation" as well as the (sh) Bourne shell's test built-in above.
	[condition] conditions.	evaluates file attributes, string comparisons, and compound "and" or "or"
OPERANDS	All operator test utility.	s and elements of primaries must be presented as separate arguments to the
	The followir	ng primaries can be used to construct <i>condition</i> :
	– b file	True if <i>file</i> exists and is a block special file.
	-c file	True if <i>file</i> exists and is a character special file.
	-d file	True if <i>file</i> exists and is a directory.
	-e file	True if <i>file</i> exists.
	- f file	True if <i>file</i> exists and is a regular file.
	–g file	True if <i>file</i> exists and its set group ID flag is set.
	– n string	True if the length of <i>string</i> is non-zero.
	–p file	True if <i>file</i> is a named pipe (FIFO).
	–r file	True if <i>file</i> exists and is readable.
	–s file	True if <i>file</i> exists and has a size greater than zero.
	-t file_descri	ptor
		True if the file whose file descriptor number is <i>file_descriptor</i> is open and is associated with a terminal.
	– u file	True if <i>file</i> exists and its set-user-ID flag is set.
	-w file	True if <i>file</i> exists and is writable. True will indicate only that the write flag is on. The <i>file</i> will not be writable on a read-only file system even if this test indicates true.
	- x file	True if <i>file</i> exists and is executable. True will indicate only that the execute flag is on. If <i>file</i> is a directory, true indicates that <i>file</i> can be searched.
	–z string	True if the length of string <i>string</i> is zero.
	string	True if the string <i>string</i> is not the null string.
	s1 = s2	True if the strings <i>s1</i> and <i>s2</i> are identical.
	s1 != s2	True if the strings <i>s1</i> and <i>s2</i> are not identical.
	n1 – eq n2	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal.
	n1 – ne n2	True if the integers <i>n1</i> and <i>n2</i> are not algebraically equal.
	n1 – gt n2	True if the integer <i>n1</i> is algebraically greater than the integer <i>n2</i> .
	n1 – ge n2	True if the integer $n1$ is algebraically greater than or equal to the integer $n2$.
	n1 – lt n2	True if the integer <i>n1</i> is algebraically less than the integer <i>n2</i> .

	n1 –le $n2$ True if the integer $n1$ is algebraically less than or equal to the integer $n2$.
	These primaries can be combined with the following operator:
	! condition True if condition is false.
	The primaries with two elements of the form:
	primary_operand
	are known as <i>unary primaries.</i> The primaries with three elements in either of the two forms:
	primary_operand primary_operand
	primary_operand primary_operator primary_operand
	are known as <i>binary primaries</i> . Additional implementation-dependent operators and <i>primary_operator s</i> may be provided by implementations. They will be of the form <i>- operator</i> where the first character of <i>operator</i> is not a digit.
	The algorithm for determining the precedence of the operators and the return value that will be generated is based on the number of arguments presented to test . (However, when using the [] form, the right-bracket final argument will not be counted in this algorithm.)
	In the following list, \$1 , \$2 , \$3 and \$4 represent the arguments presented to test .
	0 arguments:
	Exit false (1).
	1 argument:
	Exit true (0) if \$1 is not null; otherwise, exit false.
	2 arguments:
	• If \$1 is !, exit true if \$2 is null, false if \$2 is not null.
	• If \$1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
	 Otherwise, produce unspecified results.
	3 arguments:
	• If \$2 is a binary primary, perform the binary test of \$1 and \$3 .
	• If \$1 is !, negate the two-argument test of \$2 and \$3.
	• Otherwise, produce unspecified results.
	4 arguments:
	• If \$1 is ! , negate the three-argument test of \$2 , \$3 , and \$4 .
	• Otherwise, the results are unspecified.
USAGE	Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like: test "\$1" -a "\$2"

should be written as:

test "\$1" && test "\$2"

to avoid problems if a user supplied values such as **\$1** set to ! and **\$2** set to the null string. That is, in cases where maximal portability is of concern, replace:

test expr1 -a expr2

with:

test expr1 && test expr2

and replace:

test expr1 -o expr2

with:

test expr1 | | test expr2

but note that, in **test**, -a has higher precedence than -o while && and | | have equal precedence in the shell.

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using **sh**; for example:

test \(expr1 -a expr2 \) -o expr3

This command is not always portable outside XSI-conformant systems. The following form can be used instead:

(test expr1 && test expr2) | | test expr3

The two commands:

test "\$1"

test ! "\$1"

could not be used reliably on some historical systems. Unexpected results would occur if such a *string* condition were used and **\$1** expanded to !, (or a known unary primary. Better constructs are:

test -n "\$1" test -z "\$1"

respectively.

Historical systems have also been unreliable given the common construct:

test "\$response" = "expected string"

One of the following is a more reliable form:

test "X\$response" = "Xexpected string"

test "expected string" = "\$response"

Note that the second form assumes that **expected string** could not be confused with any unary primary. If **expected string** starts with –, (, ! or even =, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted

modified 28 Mar 1995

I	· · · · · ·
	in all cases.)
	Because the string comparison binary primaries, = and !=, have a higher precedence than any unary primary in the >4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in
	test -d \$1 -o -d \$2
	If \$1 evaluates to a possible directory name of =, the first three arguments are considered a string comparison, which causes a syntax error when the second $-\mathbf{d}$ is encountered. is encountered. One of the following forms prevents this; the second is preferred:
	test \(-d "\$1" \) -o \(-d "\$2" \)
	test -d "\$1" test -d "\$2"
	Also in the >4 argument case,
	test "\$1" = "bat" -a "\$2" = "ball"
	Syntax errors will occur if \$1 evaluates to (or !. One of the following forms prevents this; the third is preferred:
	test "X\$1" = "Xbat" -a "X\$2" = "Xball"
	test "\$1" = "bat" && test "\$2" = "ball"
	test "X\$1" = "Xbat" && test "X\$2" = "Xball"
EXAMPLES	In the if command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen.
	The 3 tests are: if a variable set to 1 is greater than 0, if a variable set to 2 is equal to 2, and if the word "root" is included in the text file /etc/passwd.
/usr/bin/test	1. Perform a mkdir if a directory does not exist:
	test ! -d tempdir && mkdir tempdir
	2. Wait for a file to become non-readable:
	while test -r thefile
	do
	sleep 30
	done
	echo '"thefile" is no longer readable'
	3. Perform a command if the argument is one of three strings (two variations):
	if ["\$1" = "pear"] ["\$1" = "grape"] ["\$1" = "apple"]
	then
	command

1-400

	case "\$1" in
	pear grape apple) command ; ;
	esac
	The two forms of the test built-in follow the Bourne shell's if example.
sh	ZERO=0 ONE=1 TWO=2 ROOT=root
	if [\$ONE -gt \$ZERO]
	[\$TWO -eq 2]
	grep \$ROOT /etc/passwd >&1 > /dev/null # discard output then
	echo "\$ONE is greater than 0, \$TWO equals 2, and \$ROOT is a user-name in the password file"
	else
	echo "At least one of the three test conditions is false"
	fi
	Examples of the test built-in:
	<pre>test `grep \$ROOT /etc/passwd >&1 /dev/null` # discard output echo \$? # test for success</pre>
	[`grep nosuchname /etc/passwd >&1 /dev/null`] echo \$? # test for failure
csh	@ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
	grep \$ROOT /etc/passwd >&1 /dev/null # discard output
	# Sstatus must be tested for immediately following grep
	if ("\$status" == "0" && \$ONE > \$ZERO && \$TWO == 2) then
	echo "\$ONE is greater than 0, \$TWO equals 2, and \$ROOT is a user-name
	in the password file" endif
	enan
ksh	ZERO=0 ONE=1 TWO=\$((ONE+ONE)) ROOT=root
	if ((ONE > ZERO)) # arithmetical comparison
	[[STWO = 2]] # string comparison
	[`grep \$ROOT /etc/passwd >&1 /dev/null`] # discard output
	then echo "\$ONE is greater than 0, \$TWO equals 2, and \$ROOT is a user-name
	in the password file"
	else
	echo "At least one of the three test conditions is false"
	fi
	The Korn shell will also accept the syntax of both the if command and the test command of the Bourne shell.

if(1)	User Commands SunOS 5	.5
	When using the brackets ([]) within if commands, you must separate both inside ends o the brackets from the inside characters with a space.	f
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of test : LC_CTYPE , LC_MESSAGES , and NLSPATH .	<u>-</u>
EXIT STATUS	The following exit values are returned:	
	0 <i>condition</i> evaluated to true.	
	1 condition evaluated to false or condition was missing.	
	>1 An error occurred.	
SEE ALSO	csh (1), ksh (1), sh (1), test (1B), environ (5)	
NOTES	Both the Bourne shell, sh , and the Korn shell, ksh , can use the semicolon and the carriag return interchangeably in their syntax of the if , for , and while built-in commands.	e

NAME	indicator – display application specific alarms and/or the "working" indicator		
SYNOPSIS	indicator [–b	[n]] [– c column] [– l length] [– o] [– w] [string]	
DESCRIPTION	The indicator function displays application specific alarms or the "working" indicator, or both, on the FMLI banner line. The argument <i>string</i> is a string to be displayed on the banner line, and should always be the last argument given. Note that <i>string</i> is not automatically cleared from the banner line.		
OPTIONS	- b n	The $-\mathbf{b}$ option rings the terminal bell <i>n</i> times, where <i>n</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen is flashed instead, if possible.	
	–c column	The $-c$ option defines the column of the banner line at which to start the indicator string. The argument <i>column</i> must be an integer from 0 to DISPLAYW-1 . If the $-c$ option is not used, <i>column</i> defaults to 0 .	
	–1 length	The –l option defines the maximum length of the string displayed. If <i>string</i> is longer than <i>length</i> characters, it will be truncated. The argument <i>length</i> must be an integer from 1 to DISPLAYW . If the –l option is not used, <i>length</i> defaults to DISPLAYW . Note that if <i>string</i> doesn't fit it will be truncated.	
	-0	The $-\mathbf{o}$ option causes indicator to duplicate its output to <i>stdout</i> .	
	$-\mathbf{w}$	The $-\mathbf{w}$ option turns on the "working" indicator.	
EXAMPLES	the bell three ti	e entered in a form field is invalid, the following use of indicator will ring imes and display the word WRONG starting at column 1 of the banner line.	
		dmsg=`indicator -b 3 -c 1 "WRONG"`	
		dicator after telling the user the entry is wrong:	
	invalio	dmsg=`indicator –b 9 –c 1 "WRONG"; sleep 3; indicator –c 1 " "`	
	-	e the value of invalidmsg (in this case the default value Input is not valid), n the FMLI message line.

NAME	indxbib – create an inverted index to a bibliographic database		
SYNOPSIS	indxbib database-file		
AVAILABILITY	SUNWdoc		
DESCRIPTION	indxbib makes an inverted index to the named <i>database-file</i> (which must reside within the current directory), typically for use by lookbib (1) and refer (1). A <i>database</i> contains bibliographic references (or other kinds of information) separated by blank lines.		
	A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.		
	indxbib is a shell script that calls two programs: /usr/lib/refer/mkey and /usr/lib/refer/inv. mkey truncates words to 6 characters, and maps upper case to lower case. It also discards words shorter than 3 characters, words among the 100 most common English words, and numbers (dates) < 1000 or > 2099. These parameters can be changed.		
	indxbib creates an entry file (with a .ia suffix), a posting file (.ib), and a tag file (.ic), in the working directory.		
FILES	/usr/lib/refer/mkey/usr/lib/refer/invx.iaentry filex.ibposting filex.ictag filex.igreference file		
SEE ALSO	<pre>addbib(1), lookbib(1), refer(1), roffbib(1), sortbib(1)</pre>		
BUGS	All dates should probably be indexed, since many disciplines refer to literature written in the 1800s or earlier. indxbib does not recognize pathnames.		

SunOS 5.5	SunOS/BSD Compatibility Package Commands install (1B)	
NAME	install – install files	
SYNOPSIS	/usr/ucb/install [–cs] [–g group] [–m mode] [–o owner] filename1 filename2 /usr/ucb/install [–cs] [–g group] [–m mode] [–o owner] filename directory /usr/ucb/install –d [–g group] [–m mode] [–o owner] directory	
AVAILABILITY	SUNWscpu	
DESCRIPTION	Install is used within makefiles to copy new versions of files into a destination directory and to create the destination directory itself.	
	The first two forms are similar to the $cp(1)$ command with the addition that executable files can be stripped during the copy and the owner, group, and mode of the installed file(s) can be given.	
	The third form can be used to create a destination directory with the required owner, group and permissions.	
	Note: install uses no special privileges to copy files from one place to another. The implications of this are:	
	 You must have permission to read the files to be installed. You must have permission to copy into the destination file or directory. You must have permission to change the modes on the final copy of the file if you want to use the -m option to change modes. You must be superuser if you want to specify the ownership of the installed file with -o. If you are not the super-user, or if -o is not in effect, the installed file will be owned by you, regardless of who owns the original. 	
OPTIONS	 -c Copy files. In fact install <i>always</i> copies files, but the –c option is retained for backwards compatibility with old shell scripts that might otherwise break. 	
	 -d Create a directory. Missing parent directories are created as required as in mkdir –p. If the directory already exists, the owner, group and mode will be set to the values given on the command line. 	
	-s Strip executable files as they are copied.	
	-g group Set the group ownership of the installed file or directory. (staff by default.)	
	- m <i>mode</i> Set the mode for the installed file or directory. (0755 by default.)	
	-o <i>owner</i> If run as root, set the ownership of the installed file to the user-ID of <i>owner</i> .	
SEE ALSO	chgrp(1), chmod(1), chown(1), cp(1), mkdir(1), strip(1), install(1M)	

NAME	ipcrm – remove a message queue, semaphore set, or shared memory ID		
SYNOPSIS	ipcrm [–m shmid] [–q msqid] [–s semid] [–M shmkey] [–Q msgkey] [–S semkey]		
AVAILABILITY	SUNWipc		
DESCRIPTION	ipcrm removes one or more messages, semaphores, or shared memory identifiers.		
OPTIONS	The identifiers are specified by the following <i>options</i> :		
	– m shmid	Remove the shared memory identifier <i>shmid</i> from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.	
	– q msqid	Remove the message queue identifier <i>msqid</i> from the system and destroy the message queue and data structure associated with it.	
	– s semid	Remove the semaphore identifier <i>semid</i> from the system and destroy the set of semaphores and data structure associated with it.	
	- M shmkey	Removes the shared memory identifier, created with key <i>shmkey</i> , from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.	
	– Q msgkey	Remove the message queue identifier, created with key <i>msgkey</i> , from the system and destroy the message queue and data structure associated with it.	
	–S semkey	Remove the semaphore identifier, created with key <i>semkey</i> , from the system and destroy the set of semaphores and data structure associated with it.	
		the removes are described in msgctl (2), shmctl (2), and semctl (2). Use the l to find the identifiers and keys.	
SEE ALSO	ipcs(1), msgctl shmget(2), shr	l(2), msgget(2), msgop(2), semctl(2), semget(2), semop(2), shmctl(2), nop(2)	

NAME	ipcs – report inter-process communication facilities status			
SYNOPSIS	ipcs [–abcmopqst] [–C corefile] [–N namelist]			
AVAILABILITY	SUNWipc			
DESCRIPTION	ipcs prints information about active inter-process communication facilities. Without <i>options</i> , information is printed in short format for message queues, shared memory, and semaphores that are currently active in the system.			
	The information that is displayed is controlled by the options supplied.			
OPTIONS	-m	Print information about active shared memory segments.		
	$-\mathbf{q}$	Print information about active message queues.		
	-s Print information about active semaphores.			
	If $-\mathbf{q}$, $-\mathbf{m}$, or $-\mathbf{s}$ are specified, information about only those indicated is printed. If none of these three are specified, information about all three is printed subject to these options:			
	-a	Use all print options. (This is a shorthand notation for $-\mathbf{b}$, $-\mathbf{c}$, $-\mathbf{o}$, $-\mathbf{p}$, and $-\mathbf{t}$.)		
	- b	Print information on biggest allowable size: maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores. See below for meaning of columns in a listing.		
	- c	Print creator's login name and group name. See below.		
	-0	Print information on outstanding usage: number of messages on queue and total number of bytes in messages on queue for message queues and number of processes attached to shared memory segments.		
	- p	Print process number information: process ID of last process to send a message, process ID of last process to receive a message on message queues, process ID of creating process, and process ID of last process to attach or detach on shared memory segments. See below.		
	-t	Print time information: time of the last control operation that changed the access permissions for all facilities, time of last msgsnd and last msgrcv on message queues, time of last shmat and last shmdt on shared memory, time of last semop on semaphores. See below.		
	-C corefile	Use the file <i>corefile</i> in place of / dev/mem and / dev/kmem . Use a core dump obtained from savecore (1M) in place of / dev/mem and / dev/kmem . Without the – C option (default), the running system image is used.		
	–N namelist	Use the file <i>namelist</i> in place of / dev/ksyms .		

modified 2 Feb 1994

The column headings and the meaning of the columns in an **ipcs** listing are given below; the letters in parentheses indicate the options that cause the corresponding heading to appear; "all" means that the heading always appears. Note: These options only determine what information is provided for each facility; they do not determine which facilities are listed.

ties are list	icu.	
Т	(all)	Type of the facility: q message queue m shared memory segment s semaphore
ID	(all)	The identifier for the facility entry.
KEY	(all)	The key used as an argument to msgget , semget , or shmget to create the facility entry. (Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.)
MODE	(all)	 The facility access modes and flags: The mode consists of 11 characters that are interpreted as follows. The first two characters are: R A process is waiting on a <i>msgrcv</i>. S A process is waiting on a <i>msgsnd</i>. D The associated shared memory segment has been removed. It will disappear when the last process attached to the segment detaches it. C The associated shared memory segment is to be cleared when the first attach is executed. The corresponding special flag is not set.
		The next nine characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the facility entry; and the last to all oth- ers. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is currently unused.
		 The permissions are indicated as follows: r Read permission is granted. w Write permission is granted. a Alter permission is granted. - The indicated permission is not granted.
OWNER	(all)	The login name of the owner of the facility entry.
GROUP	(all)	The group name of the group of the owner of the facility entry.
CREATOR	(a,c)	The login name of the creator of the facility entry.
CGROUP	(a,c)	The group name of the group of the creator of the facility entry.
CBYTES	(a,o)	The number of bytes in messages currently outstanding on the associ- ated message queue.
QNUM	(a,o)	The number of messages currently outstanding on the associated

modified 2 Feb 1994

			message queue.
	QBYTES	(a,b)	The maximum number of bytes allowed in messages outstanding on the associated message queue.
	LSPID (a,p)		The process ID of the last process to send a message to the associated queue.
	LRPID	(a,p)	The process ID of the last process to receive a message from the associ- ated queue.
	STIME	(a,t)	The time the last message was sent to the associated queue.
	RTIME	(a,t)	The time the last message was received from the associated queue.
	CTIME	(a,t)	The time when the associated entry was created or changed.
	NATTCH	(a,o)	The number of processes attached to the associated shared memory segment.
	SEGSZ	(a,b)	The size of the associated shared memory segment.
	CPID	(a,p)	The process ID of the creator of the shared memory entry.
	LPID	(a,p)	The process ID of the last process to attach or detach the shared memory segment.
	ATIME	(a,t)	The time the last attach was completed to the associated shared memory segment.
	DTIME	(a,t)	The time the last detach was completed on the associated shared memory segment.
	NSEMS	(a,b)	The number of semaphores in the set associated with the semaphore entry.
	OTIME	(a,t)	The time the last semaphore operation was completed on the set associ- ated with the semaphore entry.
FILES	5 /etc/group /etc/passwd /dev/mem /dev/ksyms		group names user names memory system namelist
SEE ALSO	msgop(2), semop(2), shmop(2)		
NOTES	If the user specifies either the $-C$ or $-N$ flag, the real and effective UID/GID is set to the real UID/GID of the user invoking ipcs .		
	Things can change while ipcs is running; the information it gives is guaranteed to be accurate only when it was retrieved.		

modified 2 Feb 1994

NAME	jobs, fg, bg, stop, notify – control process execution
SYNOPSIS sh	jobs [-p -l] [%job_id] jobs -x command [arguments] fg [%job_id] bg [%job_id] stop %job_id stop pid
csh	jobs[-1] fg [%job_id] bg [%job_id] notify [%job_id] stop %job_id stop pid
ksh	jobs [-lnp] [%job_id] fg [%job_id] bg [%job_id] stop %job_id stop pid
DESCRIPTION sh	 When Job Control is enabled, the Bourne shell built-in jobs reports all jobs that are stopped or executing in the background. If %job_id is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of jobs: -I Report the process group ID and working directory of the jobs. -p Report only the process group ID of the jobs. -x Replace any job_id found in command or arguments with the corresponding process group ID, and then execute command passing it arguments. When the shell is invoked as jsh, Job Control is enabled in addition to all of the functionality described previously for sh. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control. With Job Control enabled every command or pipeline the user enters at the terminal is called a job_id. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal; 2) a job in the background is denied read access and has been placed in a suspended state, usually as a result of a SIGTSTP signal (see signal(5)).

modified 11 Apr 1995

Every job that the shell starts is assigned a positive integer, called a *job_id number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

%job_id

where, *job_id* may be specified in any of the following formats:

% or +	for the current job	
--------	---------------------	--

- for the previous job
- *?<string>* specify the job for which the command line uniquely contains *string*.
- *n* for job number *n*, where *n* is a job number
- *pref* where *pref* is a unique prefix of the command name (for example, if the command **ls** –**l name** were running in the background, it could be referred to as %**ls**); *pref* cannot contain blanks unless it is quoted.

When Job Control is enabled, **fg** resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If %*job_id* is omitted the current job is assumed.

When Job Control is enabled, **bg** resumes the execution of a stopped job in the background. If %*job_id* is omitted the current job is assumed.

stop stops the execution of a background job(s) by using its *job_id*, or of any process by using its *pid*; see **ps**(1).

The C shell built-in, **jobs**, without an argument, lists the active jobs under job control.

-l List process IDs, in addition to the normal information.

The shell associates a numbered *job_id* with each command sequence to keep track of those commands that are running in the background or have been stopped with **TSTP** signals (typically CTRL-Z). When a command or command sequence (semicolon separated list) is started in the background using the **&** metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

[1] 1234

To see the current list of jobs, use the **jobs** built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the *current* job and is indicated with a +. The previous job is indicated with a -; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the **bg**, **fg**, **kill**, **stop**, and % built-in commands.

A reference to a job begins with a `%´. By itself, the percent-sign refers to the current job.

% %+ %%	The current job.
%-	The previous job.
%ј	Refer to job j as in: ` kill –9 % j ´. j can be a job number, or a string that

modified 11 Apr 1995

csh

uniquely specifies the command line by which it was started; **`fg %vi**` might bring a stopped **vi** job to the foreground, for instance. Specify the job for which the command line uniquely contains *string*.

%?string

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the `stty tostop' command.

fg brings the current or specified *job_id* into the foreground.

bg runs the current or specified jobs in the background.

stop stops the execution of a background job(s) by using its *job_id*, or of any process by using its *pid*; see **ps**(1).

notify will notify the user asynchronously when the status of the current job or specified jobs changes.

ksh **jobs** displays the status of the jobs that were started in the current shell environment. When **jobs** reports the termination status of a job, the shell removes its process ID from the list of those "known in the current shell execution environment."

job_id specifies the jobs for which the status is to be displayed. If no *job_id* is given, the status information for all jobs will be displayed.

The following options will modify/enhance the output of **jobs**:

- -1 (The letter ell.) Provide more information about each job listed. This information includes the job number, current job, process group ID, state and the command that formed the job.
- -n Display only jobs that have stopped or exited since last notified.
- -**p** Displays only the process IDs for the process group leaders of the selected jobs.

By default, **jobs** displays the status of all the stopped jobs, running background jobs, and all jobs whose status has changed and have not been reported by the shell.

If the **monitor** option of the **set** command is turned on, an interactive shell associates a **job** with each pipeline. It keeps a table of current jobs, printed by the **jobs** command, and assigns them small integer numbers. When a job is started asynchronously with **&**, the shell prints a line which looks like:

[1] 1234

indicating that the **job**, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key 2 (CTRL-Z) which sends a **STOP** signal to the current job. The shell will then normally indicate that the job has been `**Stopped**' (see **OUTPUT** below), and print another prompt. You can then manipulate the state of this job, putting it in the background with the **bg** command, or run some other commands and then eventually bring the job back into the foreground with the foreground command **fg**. A '**Z** takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

modified 11 Apr 1995

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

	iu or any process of	of the job or by one of the following:
	%number %string	The job with the given number. Any job whose command line begins with <i>string</i> ; works only in the
	%?string	interactive mode when the history file is active. Any job whose command line contains <i>string</i> ; works only in the interactive mode when the history file is active.
	%%	Current job.
	%+	Equivalent to %%.
	%-	Previous job.
	whenever a job be before it prints a p When the monitor for CHLD. When warned that `You what they are. If y	nmediately whenever a process changes state. It normally informs you comes blocked so that no further progress is possible, but only just prompt. This is done so that it does not otherwise disturb your work. In mode is on, each background job that completes triggers any trap set you try to leave the shell while jobs are running or stopped, you will be have stopped (running) jobs. You may use the jobs command to see you do this or immediately try to exit again, the shell will not warn you d the stopped jobs will be terminated.
	fg will move a bac fg to place a job in "known in the cur	ckground job from the current environment into the foreground. Using a the foreground will remove its process ID from the list of those rent shell execution environment." The fg command is available only apport job control. If <i>job_id</i> is not specified, the current job is brought
	ground jobs. If th effect and will exit process ID to becc been started as an	nded jobs from the current environment by running them as back- e job specified by <i>job_id</i> is already a running background job, bg has no t successfully. Using bg to place a job into the background causes its ome "known in the current shell execution environment", as if it had asynchronous list. The bg command is available only on systems that ol. If <i>job_id</i> is not specified, the current job is placed in the background.
	stop stops the exe using its <i>pid</i> ; see p	cution of a background job(s) by using its <i>job_id</i> , or of any process by s (1).
OUTPUT	If the – p option is	specified, the output consists of one line for each process ID:
	"% d\n ", < "pro	
	· •	-l option is not specified, the output is a series of lines of the form:
		6s\n", <job-number>, <current>, <state>, <command/></state></current></job-number>
	where the fields a	
		The character + identifies the job that would be used as a default for the fg or bg commands; this job can also be specified using the <i>job_id</i> %+ or %%. The character – identifies the job that would become the default if the current default job were to exit; this job can also be specified using the <i>job_id</i> % For other jobs, this field is a space character. At most one job can be identified with + and at most one job can be identified

modified 11 Apr 1995

		with –. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.
	<job-number></job-number>	A number that can be used to identify the process group to the wait , fg , bg , and kill utilities. Using these utilities, the job can be identified by prefixing the job number with %.
	<state></state>	One of the following strings (in the POSIX Locale):
		Running Indicates that the job has not been suspended by a signal and has not exited.
		Done Indicates that the job completed and returned exit status zero.
		Done(code)
		Indicates that the job completed normally and that it exited with the specified non-zero exit status, <i>code</i> , expressed as a decimal number.
		Stopped
		Stopped (SIGTSTP) Indicates that the job was suspended by the SIGTSTP signal.
		Stopped (SIGSTOP) Indicates that the job was suspended by the SIGSTOP sig- nal.
		Stopped (SIGTTIN) Indicates that the job was suspended by the SIGTTIN signal.
		Stopped (SIGTTOU) Indicates that the job was suspended by the SIGTTOU sig- nal.
		The implementation may substitute the string Suspended in place of Stopped . If the job was terminated by a signal, the format of state is unspecified, but it will be visibly distinct from all of the other state formats shown here and will indicate the name or description of the signal causing the termination.
	<command/>	The associated command that was given to the shell.
	state field. Also	s specified, a field containing the process group ID is inserted before the , more processes in a process group may be output on separate lines, rocess ID and command fields.
ENVIRONMENT		or descriptions of the following environment variables that affect the exe- g, and bg: LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	0 Succ	xit values are returned for jobs , fg , and bg : essful completion. rror occurred.

join	(1)
J	`		/

NAME	join – relational database operator			
SYNOPSIS	join [–a filenumber –v filenumber] [–1 fieldnumber] [–2 fieldnumber] [–o list] [–e string] [–t char] file1 file2			
	•	ber] [–j fieldnumber] [–j1 fieldnumber] [–j2 fieldnumber] -e string] [–t char] file1 file2		
AVAILABILITY	SUNWcsu			
DESCRIPTION	The join comma the lines of <i>file1</i>	and forms, on the standard output, a join of the two relations specified by and <i>file2</i> .		
	join fields. The from <i>file1</i> , then option (see belo	e in the output for each pair of lines in <i>file1</i> and <i>file2</i> that have identical output line normally consists of the common field, then the rest of the line the rest of the line from <i>file2</i> . This format can be changed by using the $-\mathbf{o}$ w). The $-\mathbf{a}$ option can be used to add unmatched lines to the output. The e used to output only unmatched lines.		
	The default input field separators are blank, tab, or new-line. In this case, multiple separators count as one field separator, and leading separators are ignored. The default output field separator is a blank.			
	If the input files	are not in the appropriate collating sequence, the results are unspecified.		
OPTIONS	Some of the options below use the argument <i>filenumber</i> . This argument should be a 1 or 2 referring to either <i>file1</i> or <i>file2</i> , respectively.			
	–a filenumber	In addition to the normal output, produce a line for each unpairable line in file <i>filenumber</i> , where <i>filenumber</i> is 1 or 2. If both $-a$ 1 and $-a$ 2 are specified, all unpairable lines will be output.		
	–e string	Replace empty output fields with <i>string</i> .		
	–j fieldnumber	Equivalent to –1 <i>fieldnumber</i> –2 <i>fieldnumber</i> .		
	–j1 fieldnumber	Equivalent to -1 <i>fieldnumber</i> .		
	– j2 fieldnumber	Equivalent to -2 fieldnumber Fields are numbered starting with 1.		
	−o list	Each output line includes the fields specified in <i>list</i> . Fields selected by <i>list</i> that do not appear in the input will be treated as empty output fields. (See the –e option.) Each element of which has the either the form <i>filenumber.fieldnumber</i> , or 0 , which represents the join field. The common field is not printed unless specifically requested.		
	–t char	Use character <i>char</i> as a separator. Every appearance of <i>char</i> in a line is significant. The character <i>char</i> is used as the field separator for both input and output. With this option specified, the collating term should be the same as sort without the $-\mathbf{b}$ option.		
	−v filenumber	Instead of the default output, produce a line only for each unpairable line in <i>filenumber</i> , where <i>filenumber</i> is $1 \text{ or } 2$. If both $-\mathbf{v} 1$ and $-\mathbf{v} 2$ are		

modified 1 Feb 1995

		specified, all unpairab	le lines will be output.	
	-1 fieldnumber	Join on the <i>fieldnumbe</i> ing with 1 .	rth field of file 1. Fields are decimal integers start-	
	–2 fieldnumber	Join on the <i>fieldnumbe</i> ing with 1 .	rth field of file 2. Fields are decimal integers start-	
OPERANDS	The following o	parands are supported		
OFERANDS	The following operands are supported: <i>file1</i>			
	file2 A pa	th name of a file to be j tandard input is used i	oined. If either of the <i>file1</i> or <i>file2</i> operands is –, n its place.	
			ng collating sequence as determined by ey are to be joined, normally the first in each line	
EXAMPLES	The following command line will join the password file and the group file, matching on the numeric group ID, and outputting the login name, the group name and the login directory. It is assumed that the files have been sorted in ASCII collating sequence on the group ID fields.			
		example% join –j1 4 –j2 3 –o 1.1 2.1 1.6 –t: /etc/passwd /etc/group		
	phone:	The –o 0 field essentially selects the union of the join fields. For example, given file phone :		
	!Name	Phone Number		
	Don	+1 123-456-7890		
	Hal Yasushi	+1 234-567-8901 +2 345-678-9012		
	and file fax :	+2 343-078-3012		
	Ind me lax. Name!	Fax Number		
	Don	+1 123-456-7899		
	Keith Yasushi	+1 456-789-0122 +2 345-678-9011		
	(where the large expanses of white space are meant to each represent a single tab charac- ter), the command:			
	example% join -t " <i><tab></tab></i> " -a 1 -a 2 -e '(unknown)' -o 0,1.2,2.2 phone fax			
	would produce:			
	!Name	Phone Number	Fax Number	
	Don	+1 123-456-7890	+1 123-456-7899	
	Hal Kaith	+1 234-567-8901	(unknown)	

+1 456-789-0122

+2 345-678-9011

modified 1 Feb 1995

Keith

Yasushi

(unknown)

+2 345-678-9012

ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of join : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 All input files were output successfully.

- >**0** An error occurred.
- **SEE ALSO** awk(1), comm(1), sort(1), uniq(1), environ(5)
 - **NOTES** With default field separation, the collating sequence is that of **sort** –**b**; with –**t**, the sequence is that of a plain sort.
 - The conventions of the **join**, **sort**, **comm**, **uniq**, and **awk** commands are wildly incongruous.

NAME	kbd – manipulate the state of keyboard or display the type of keyboard		
SYNOPSIS	kbd [–r] [–t] [–c on off] [–d keyboard device]		
AVAILABILITY	SPARC SUNWcsu		
DESCRIPTION	kbd manipulates the state of the keyboard, or displays the keyboard type. The default keyboard device being set is / dev/kbd . Only keyboards that support a clicker respond to the – c option. If you want to turn clicking on by default, this can be set in the / etc/rcS file.		
OPTIONS	 −r −t −c on/off state −d keyboard device 	Reset the keyboard as if power-up. Return the type of the keyboard being used. Turn the clicking of the keyboard on or off. on Enable clicking. off Disable clicking.	
EXAMPLES	The following example displays the keyboard type. example% kbd –t type 4 Sun keyboard example% To enable clicking by default, add the following line to your / etc/rcS file. kbd –c on		
FILES	/etc/rcS /dev/kbd	shell script containing commands necessary to get the system to single-user mode keyboard device file	
SEE ALSO	loadkeys(1), keytables(4), kb(7M)		
BUGS		determine the state of the keyboard click setting.	

modified 18 Jul 1994

NAME	kdestroy – destroy Kerberos tickets
SYNOPSIS	/usr/bin/kdestroy [–fnq]
AVAILABILITY	SUNWcsu
DESCRIPTION	kdestroy destroys the user's active Kerberos authorization tickets by writing zeros to the file that contains them. If the ticket file does not exist, kdestroy displays a message to that effect.
	After overwriting the file, kdestroy removes the file from the system. The utility displays a message indicating the success or failure of the operation. If kdestroy is unable to destroy the ticket file, it will warn you by making your terminal beep.
	In addition to removing the ticket file, kdestroy also invalidates all Kerberos credentials for this user being held in the kernel for use with NFS requests.
	If desired, you can place the kdestroy command in your .logout file so that your tickets are destroyed automatically when you logout. Note, however, that doing this will cause NFS operations done on your behalf to fail after you logout.
OPTIONS	-f Do not display the status message.
	-n Do not invalidate NFS credentials in the kernel. The credentials will continue to be valid until their normal expiration time, although new ones cannot be obtained until kinit(1) is run again for this user.
	- q Do not make your terminal beep if kdestroy fails to destroy the tickets.
FILES	The file specified by the KRBTKFILE environment variable if set, otherwise / tmp / tkt <i>uid</i>
SEE ALSO	kerberos(1), kinit(1), klist(1)
BUGS	Only the tickets in the user's current ticket file are destroyed. Separate ticket files are used to hold root instance and password changing tickets. These files should probably be destroyed too, or all of a user's tickets should be kept in a single ticket file.
AUTHORS	Steve Miller, MIT Project Athena/Digital Equipment Corporation Clifford Neuman, MIT Project Athena Bill Sommerfeld, MIT Project Athena

NAME

kerberos – introduction to the Kerberos system

DESCRIPTION

The Kerberos system authenticates individual users in a network environment. After authenticating yourself to Kerberos, you can use the **kerberos** authentication option of network services such as NFS. In addition, in some environments you can use network utilities such as **rlogin**(1), **rcp**(1), and **rsh**(1) without having to present passwords to remote hosts and without having to bother with **.rhosts** files. See your system administrator for more information about Kerberos support at your site.

Before you can use Kerberos, you must be registered as a user in the Kerberos database. You can use the **kinit**(1) command to find out your status. This command tries to log you into the Kerberos system. **kinit** will prompt you for a username and password. Enter your username and password. If the utility lets you login without giving you a message, you have already been registered.

If you enter your username and **kinit** responds with this message:

Principal unknown (kerberos)

you haven't been registered as a Kerberos user. See your system administrator.

A Kerberos name contains three parts. The first is the *principal name*, which is usually a user's or service's name. The second is the *instance*, which in the case of a user is usually NULL. Some users may have privileged instances, however, such as **root** or **admin**. In the case of a service, the instance is the name of the machine on which it runs; that is, there can be an NFS service running on the machine ABC, which is different from the NFS service running on the machine XYZ. The third part of a Kerberos name is the *realm*. The realm corresponds to the Kerberos service providing authentication for the principal. For example, at MIT there is a Kerberos running at the Laboratory for Computer Science and one running at Project Athena.

When writing a Kerberos name, the principal name is separated from the instance (if not NULL) by a period, and the realm (if not the local realm) follows, preceded by an "@" sign. The following are examples of valid Kerberos names:

billb jis.admin srz@lcs.mit.edu treese.root@athena.mit.edu

When you authenticate yourself with Kerberos, typically through the **kinit** command, Kerberos gives you an initial Kerberos *ticket*. (A Kerberos ticket is an encrypted protocol message that provides authentication.) Kerberos uses this ticket for network utilities such as NFS, **rlogin** and **rcp**. The ticket transactions are done transparently, so you do not have to worry about their management.

modified 6 Jan 1992

	Note, however, that tickets expire. Privileged tickets, such as root instance tickets, expire in a few minutes, while tickets that carry more ordinary privileges may be good for several hours or a day, depending on the installation's policy. If your login session extends beyond the time limit, you will have to re-authenticate yourself to Kerberos to get new tickets. Use the kinit command to re-authenticate yourself.
	If you use the kinit command to get your tickets, you can use the kdestroy (1) command to destroy your tickets before you end your login session. For more information about the kinit and kdestroy commands, see the kinit (1) and kdestroy (1) manual pages.
	Currently, Kerberos supports NFS and other RPC network services using the AUTH_KERB authentication type. In some environments, the following network services are also supported: rlogin , rsh , and rcp . Other services are being worked on, such as the pop mail system, but are not yet available.
SEE ALSO	kdestroy(1), kinit(1), klist(1), kerbd(1M), kerberos(3N), krb.conf(4)
BUGS	Kerberos will not do authentication forwarding. In other words, if you use rlogin to login to a remote host, you cannot use Kerberos services from that host until you authenticate yourself explicitly on that host. Although you may need to authenticate yourself on the remote host, be aware that when you do so, rlogin sends your password across the network in clear text.
AUTHORS	Steve Miller, MIT Project Athena/Digital Equipment Corporation Clifford Neuman, MIT Project Athena
	The following people helped out on various aspects of the system:
	Jeff Schiller designed and wrote the administration server and its user interface, kadmin . He also wrote the dbm version of the database management system.
	Mark Colan developed the Kerberos versions of rlogin , rsh , and rcp , as well as contribut- ing work on the servers.
	John Ostlund developed the Kerberos versions of passwd and userreg .
	Stan Zanarotti pioneered Kerberos in a foreign realm (LCS), and made many contribu- tions based on that experience.
	Many people contributed code and/or useful ideas. These include, Jim Aspnes, Bob Baldwin, John Barba, Richard Basch, Jim Bloom, Bill Bryant, Rob French, Dan Geer, David Jedlinsky, John Kohl, John Kubiatowicz, Bob McKie, Brian Murphy, Ken Raeburn, Chris Reed, Jon Rochlis, Mike Shanzer, Bill Sommerfeld, Jennifer Steiner, Ted Ts'o, and Win Treese.

NAME	keylogin – decrypt and store secret key with keyserv		
SYNOPSIS	/usr/bin/keylogin [–r]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The keylogin command prompts for a password, and uses it to decrypt the user's secret key. The key may be found in the /etc/publickey file (see publickey (4)) or the NIS map "publickey.byname" or the NIS+ table "cred.org_dir" in the user's home domain. The sources and their lookup order are specified in the /etc/nsswitch.conf file (see nsswitch.conf (4)). Once decrypted, the user's secret key is stored by the local key server process, keyserv (1M). This stored key is used when issuing requests to any secure RPC services, such as NFS or NIS+. The program keylogout (1) can be used to delete the key stored by keyserv .		
	keylogin will fail if it cannot get the caller's key, or the password given is incorrect. For a new user or host, a new key can be added using newkey (1M), nisaddcred (1M), or nisclient (1M).		
OPTIONS	 -r Update the /etc/.rootkey file. This file holds the unencrypted secret key of the super-user. Only the super-user may use this option. It is used so that processes running as super-user can issue authenticated requests without requiring that the administrator explicitly run keylogin as super-user at system startup time (see keyserv(1M)). The -r option should be used by the administrator when the host's entry in the publickey database has changed, and the /etc/.rootkey file has become out-of-date with respect to the actual key pair stored in the publickey database. The permissions on the /etc/.rootkey file are such that it may be read and written by the super-user but by no other user on the system. 		
FILES	/etc/.rootkey super-user's secret key		
SEE ALSO	chkey(1), keylogout(1), login(1), keyserv(1M), newkey(1M), nisaddcred(1M), nisclient(1M), publickey(4), nsswitch.conf(4)		

modified 25 Jan 1993

NAME	keylogout – delete stored secret key with keyserv		
SYNOPSIS	/usr/bin/keylogout [-f]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	keylogout deletes the key stored by the key server process keyserv (1M). Further access to the key is revoked; however, current session keys may remain valid until they expire or are refreshed.		
	Deleting the keys stored by keyserv will cause any background jobs or scheduled at (1) jobs that need secure RPC services to fail. Since only one copy of the key is kept on a machine, it is a bad idea to place a call to this command in your .logout file since it will affect other sessions on the same machine.		
OPTIONS	-f Force keylogout to delete the secret key for the super-user. By default, keylogout by the super-user is disallowed because it would break all RPC services, such as NFS, that are started by the super-user.		
SEE ALSO	at(1), chkey(1), login(1), keylogin(1), keyserv(1M), newkey(1M), publickey(4)		

NAME	kill – terminate	or signal processes
SYNOPSIS	/usr/bin/kill –s /usr/bin/kill –l /usr/bin/kill [–	[exit_status]
AVAILABILITY	SUNWcsu	
DESCRIPTION	For each <i>pid</i> ope tion called with 1. 2. The signalled p	sends a signal to the process or processes specified by each <i>pid</i> operand. erand, the kill utility will perform actions equivalent to the kill (2) func- the following arguments: The value of the <i>pid</i> operand will be used as the <i>pid</i> argument. The <i>sig</i> argument is the value specified by the – s option, or by SIGTERM , if none of these options is specified. rocess must belong to the current user unless the user is the super-user. descriptions of the shell built-in versions of kill .
OPTIONS	The following o – l – s signal	options are supported: (The letter ell.) Write all values of <i>signal</i> supported by the implementation, if no operand is given. If an <i>exit_status</i> operand is given and it is a value of the ? shell special parameter and wait corresponding to a process that was terminated by a signal, the <i>signal</i> corresponding to the signal that terminated the process will be written. If an <i>exit_status</i> operand is given and it is the unsigned decimal integer value of a signal number, the <i>signal</i> corresponding to that signal will be written. Otherwise, the results are unspecified. Specify the signal to send, using one of the symbolic names defined in the < signal.h > description. Values of <i>signal</i> will be recognised in a case-independent fashion, without the SIG prefix. In addition, the sym-
OPERANDS	pid O	 bolic name 0 will be recognised, representing the signal value zero. The corresponding signal will be sent instead of SIGTERM. operands are supported: ne of the following: A decimal integer specifying a process or process group to be signalled. The process or processes selected by positive, negative and zero values of the <i>pid</i> operand will be as described for the kill function. If process number 0 is specified, all processes in the process group are signalled. If the first <i>pid</i> operand is negative, it should be preceded by to keep it from being interpreted as an option. A job control job ID that identifies a background process group to be signalled. The job control job ID notation is applicable only for invocations
10 144 4 4005		4.407

modified 11 Apr 1995

		of kill in the current shell execution environment.
		Note the job control job ID type of <i>pid</i> is available only on systems support- ing the job control option.
	exit_status	A decimal integer specifying a signal number or the exit status of a process terminated by a signal.
USAGE	Process nun	nbers can be found by using ps (1).
		rol job ID notation is not required to work as expected when kill is operating tility execution environment. In either of the following examples:
	noh	up kill %1 &
	syst	em(kill %1");"
	kill operate job numbers	s in a different environment and will not share the shell's understanding of 5.
OUTPUT	When the –l	option is not specified, the standard output will not be used.
		option is specified, the symbolic name of each signal will be written in the
	"%s	%c", <signal>, <separator></separator></signal>
	either a new	<i>signal</i> > is in upper-case, without the SIG prefix, and the <i><separator></separator></i> will be line character or a space character. For the last signal written, <i><separator></separator></i> wline character.
	correspondi	the – l option and <i>exit_status</i> operand are specified, the symbolic name of the ng signal will be written in the following format: 0 , < <i>signal</i> >
	/03	0 , <51g11a1>
EXAMPLES	Any of the c	ommands:
	kill	-9 100 -165
	kill	–s kill 100 –165
	kill	-s KILL 100 -165
	whose proce	GKILL signal to the process whose process ID is 100 and to all processes ess group ID is 165 , assuming the sending process has permission to send that specified processes, and that they exist.
	number or a default sign	ambiguity of an initial negative number argument specifying either a signal process group, the former will always be the case. Therefore, to send the al to a process group (for example, 123), an application should use a com- tr to one of the following:
		-TERM -123
	kill	

modified 11 Apr 1995

ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe-
	cution of kill: LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:0At least one matching process was found for each <i>pid</i> operand, and the specified signal was successfully processed for at least one matching process.>0An error occurred.
SEE ALSO	csh(1), jobs(1), ksh(1), ps(1), sh(1), shell_builtins(1), wait(1), kill(2), signal(3C), environ(5), signal(5)
NOTES	
sh	The Bourne shell, sh , has a built-in version of kill to provide the functionality of the kill command for processes identified with a <i>jobid</i> . The sh syntax is:
	kill [–sig] [pid] [%job] kill –l
csh	The C-shell, csh , also has a built-in kill command, whose syntax is:
	kill [–sig] [pid] [%job] kill –l
	The csh kill built-in sends the TERM (terminate) signal, by default, or the signal specified, to the specified process ID, the <i>job</i> indicated, or the current <i>job</i> . Signals are either given by number or by name. There is no default. Typing kill does not send a signal to the current job. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal as well.
	-l List the signal names that can be sent.
ksh	The ksh kill 's syntax is:
	kill [-sig] [pid] [%job] kill –l
	The ksh kill sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in signal (5) stripped of the prefix "SIG"). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument <i>job</i> can be the process id of a process that is not a member of one of the active jobs. In the second form, kill – l , the signal numbers and names are listed.

modified 11 Apr 1995

NAME	kinit – Kerberos login utility		
SYNOPSIS	kinit [–ilrv] [username]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The kinit command is used to login to the Kerberos authentication and authorization sys- tem. Note that only registered Kerberos users can use the Kerberos system. For informa- tion about registering as a Kerberos user, see the kerberos (1) manual page.		
	When you use kinit without options, the utility prompts for your <i>username</i> and Kerberos password, and tries to authenticate your login with the local Kerberos server. The <i>username</i> can be specified on the command line if desired.		
	If Kerberos authenticates the login attempt, kinit retrieves your initial ticket (i.e., ticket- granting ticket) and puts it in the ticket file specified by your KRBTKFILE environment variable. If this variable is undefined, your ticket will be stored in the file / tmp / tkt <i>uid</i> , where <i>uid</i> specifies your user identification number. Tickets expire after a specified life- time, after which kinit must be run again to refresh the tickets. The default ticket lifetime is 8 hours.		
	The kdestroy (1) command may be used to destroy any active tickets before you end your login session.		
OPTIONS	-i kinit prompts you for a Kerberos instance.		
	 -I kinit prompts you for a ticket lifetime in minutes. Due to protocol restrictions in Kerberos Version 4, this value must be between 5 and 1275 minutes; values less than 5 will be set to 5; values greater than 1275 will be set to 1275; values between the limits will be rounded down to a multiple of 5 (e.g., a value of 7 will be set to 5, 9 will be set to 5, 10 will remain unchanged). 		
	 -r kinit prompts you for a Kerberos realm. This option lets you authenticate your- self with a remote Kerberos server. 		
	 -v Verbose mode. kinit prints a status message indicating the success or failure of your login attempt. 		
SEE ALSO	kdestroy(1), kerberos(1), klist(1)		
BUGS	The $-\mathbf{r}$ option has not been fully implemented.		
AUTHORS	Steve Miller, MIT Project Athena/Digital Equipment Corporation Clifford Neuman, MIT Project Athena		

modified 27 Sep 1994

NAME	klist – list currently held Kerberos tickets			
SYNOPSIS	klist [-st] [-file name] [-srvtab]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	klist prints the name of the ticket file, the identity of the principal that the tickets are for (as listed in the ticket file), and the principal names of all Kerberos tickets currently held by the user, along with the issue and expire time for each authenticator. Principal names are listed in the form <i>name.instance@realm</i> , with the '.' omitted if the instance is null, and the '@' omitted if the realm is null.			
	The value of the KRBTKFILE environment variable is used as the name of the ticket file. If this environment variable is not set, then the file / tmp / tkt <i>uid</i> is used, where <i>uid</i> is the current user-id of the user.			
OPTIONS	- S	Silent. Do not print the issue and expire times, the name of the ticket file, or the identity of the principal.		
	-t	klist checks for the existence of a non-expired ticket-granting-ticket in the ticket file. If one is present, it exits with status 0 , else it exits with status 1 . No output is generated when this option is specified.		
	-file name	File <i>name</i> is used as the ticket file.		
	–srvtab	The file is treated as a service key file, and the names of the keys con- tained therein are printed. If no file is specified with a –file option, the default is /etc/srvtab .		
FILES	/etc/krb.conf /tmp/tkt <i>uid</i> /etc/srvtab	to get the name of the local realm as the default ticket file as the default service key file		
SEE ALSO	kdestroy(1), ke	erberos(1), kinit(1), ksrvtgt(1)		
BUGS	When reading a file as a service key file, very little sanity or error checking is performed.			

modified 1 Aug 1994

NAME	ksh, rksh – KornShell, a standard/restricted command and programming language		
SYNOPSIS	/usr/bin/ksh [±abCefhikmnoprstuvx] [±o option] [–c string] [arg] /usr/xpg4/bin/sh [±abCefhikmnoprstuvx] [±o option] [–c string] [arg]		
	/usr/bin/rksh [±abCefhikmnoprstuvx] [±o option] [–c string] [arg]		
AVAILABILITY /usr/bin/ksh /usr/bin/rksh	SUNWcsu		
/usr/xpg4/bin/sh	SUNWxcu4		
DESCRIPTION	/usr/xpg4/bin/sh is identical to /usr/bin/ksh, a command and programming language that executes commands read from a terminal or a file. rksh is a restricted version of the command interpreter ksh; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. See Invocation below for the meaning of arguments to the shell.		
Definitions	A metacharacter is one of the following characters:		
	; & () $ $ < > NEWLINE SPACE TAB		
	A <i>blank</i> is a TAB or a SPACE. An <i>identifier</i> is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as names for <i>functions</i> and <i>variables</i> . A <i>word</i> is a sequence of <i>characters</i> separated by one or more non-quoted <i>metacharacters</i> .		
	A <i>command</i> is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A <i>special-command</i> is a command that is carried out by the shell without creating a separate process. Except for documented side effects, most special commands can be implemented as separate utilities.		
Commands	A <i>simple-command</i> is a sequence of blank-separated words which may be preceded by a variable assignment list. (See Environment below.) The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see exec (2)). The <i>value</i> of a simple-command is its exit status if it terminates normally, or (octal) 200+ <i>status</i> if it terminates abnormally (see signal (3C) for a list of status values).		
	A <i>pipeline</i> is a sequence of one or more <i>commands</i> separated by . The standard output of each command but the last is connected by a pipe (2) to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.		
	A <i>list</i> is a sequence of one or more <i>pipelines</i> separated by ;, &, &&, or $ $, and optionally terminated by ;, &, or $ $ &. Of these five symbols, ;, &, and $ $ & have equal precedence, which is lower than that of && and $ $. The symbols && and $ $ also have equal precedence. A semicolon (;) causes sequential execution of the preceding pipeline; an		

ampersand (&) causes asynchronous execution of the preceding pipeline (that is, the shell does *not* wait for that pipeline to finish). The symbol | & causes asynchronous execution of the preceding command or pipeline with a two-way pipe established to the parent shell.

The standard input and output of the spawned command can be written to and read from by the parent shell using the $-\mathbf{p}$ option of the special commands **read** and **print** described in **Special Commands**. The symbol **&&** (| |) causes the *list* following it to be executed only if the preceding pipeline returns **0** (or a non-zero) value. An arbitrary number of new-lines may appear in a *list*, instead of a semicolon, to delimit a command.

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

for identifier [in word ...] ; do list ; done

Each time a **for** command is executed, *identifier* is set to the next *word* taken from the **in** *word* list. If **in** *word*... is omitted, then the **for** command executes the **do** *list* once for each positional parameter that is set (see **Parameter Substitution** below). Execution ends when there are no more words in the list.

select identifier [in word ...] ; do list ; done

A **select** command prints to standard error (file descriptor 2), the set of *words*, each preceded by a number. If **in** *word*... is omitted, then the positional parameters are used instead (see **Parameter Substitution** below). The **PS3** prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed *words*, then the value of the variable *identifier* is set to the *word* corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable *identifier* is set to **NULL**. (See **Blank Interpretation** about **NULL**). The contents of the line read from standard input is saved in the shell variable **REPLY**. The *list* is executed for each selection until a **break** or EOF is encountered. If the **REPLY** variable is set to **NULL** by the execution of *list*, then the selection list is printed before displaying the **PS3** prompt for the next selection.

case word **in** [pattern [| pattern]) list ;;] ... **esac**

A **case** command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see **File Name Generation** below).

if list; then list; [elif list; then list; ...] [else list;] fi

The *list* following **if** is executed and, if it returns an exit status of **0**, the *list* following the first **then** is executed. Otherwise, the *list* following **elif** is executed and, if its value is **0**, the *list* following the next **then** is executed. Failing that, the **else** *list* is executed. If no **else** *list* or **then** *list* is executed, then the **if** command returns **0** exit status.

while list; do list; done

until list ; do list ; done

A while command repeatedly executes the while *list* and, if the exit status of the

modified 13 Jun 1995

	last command in the list is 0 , executes the do <i>list</i> ; otherwise the loop terminates. If no commands in the do <i>list</i> are executed, then the while command returns 0 exit status; until may be used in place of while to negate the loop termination test.		
	(<i>list</i>) Execute <i>list</i> in a separate environment. Note, that if two adjacent open parentheses are needed for nesting, a space must be inserted to avoid arithmetic evaluation as described below.		
	<i>{list</i> is simply executed. Note that unlike the metacharacters (and), { and } are <i>reserved words</i> and must occur at the beginning of a line or after a ; in order to be recognized.		
	[[<i>expression</i>]] Evaluates <i>expression</i> and returns 0 exit status when <i>expression</i> is true. See Condi - tional Expressions below, for a description of <i>expression</i> .		
	<pre>function identifier { list ;}</pre>		
	<pre>identifier() { list ;} Define a function which is referenced by identifier. The body of the function is the list of commands between { and }. (See Functions below).</pre>		
	time <i>pipeline</i> The <i>pipeline</i> is executed and the elapsed time as well as the user and system time are printed to standard error.		
	The following reserved words are only recognized as the first word of a command and when not quoted:		
	! if then else elif fi case esac for while until do done { } function select time [[]]		
Comments	A word beginning with # causes that word and all the following characters up to a new- line to be ignored.		
Aliasing	The first word of each command is replaced by the text of an alias if an alias for this word has been defined. An alias name consists of any number of characters excluding meta- characters, quoting characters, file expansion characters, parameter and command substi- tution characters, and =. The replacement string can contain any valid shell script includ- ing the metacharacters listed above. The first word of each command in the replaced text, other than any that are in the process of being replaced, will be tested for aliases. If the last character of the alias value is a <i>blank</i> then the word following the alias will also be checked for alias substitution. Aliases can be used to redefine special builtin commands but cannot be used to redefine the reserved words listed above. Aliases can be created, listed, and exported with the alias command and can be removed with the unalias com- mand. Exported aliases remain in effect for scripts invoked by name, but must be reini- tialized for separate invocations of the shell (see Invocation below). To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word will be replaced by the value of the alias; otherwise, it will not be replaced.		

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect the **alias** definition command has to be executed before the command which references the alias is read.

Aliases are frequently used as a short hand for full path names. An option to the aliasing facility allows the value of the alias to be automatically set to the full pathname of the corresponding command. These aliases are called *tracked* aliases. The value of a *tracked* alias is defined the first time the corresponding command is looked up and becomes undefined each time the **PATH** variable is reset. These aliases remain *tracked* so that the next subsequent reference will redefine the value. Several tracked aliases are compiled into the shell. The -h option of the **set** command makes each referenced command name into a tracked alias.

The following *exported aliases* are compiled into (and built-in to) the shell but can be unset or redefined:

```
autoload='typeset -fu'
false='let 0'
functions='typeset -f'
hash='alias -t'
history='fc -l'
integer='typeset -i'
nohup='nohup '
r='fc -e -'
true=':'
type='whence -v'
```

An example concerning trailing blank characters and reserved words follows. If the user types:

\$ alias foo="/bin/ls " *\$* alias while="/"

The effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of **Hello**, **World** strings to the screen. However, if the user types:

\$ foo while

the result will be an **ls** listing of /. Since the alias substitution for **foo** ends in a space character, the next word is checked for alias substitution. The next word, **while**, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

	<i>\$</i> foo; while
	while retains its normal reserved-word properties.
Tilde Substitution	After alias substitution is performed, each word is checked to see if it begins with an unquoted ~. If it does, then the word up to a / is checked to see if it matches a user name. If a match is found, the ~ and the matched login name are replaced by the login directory of the matched user. This is called a <i>tilde</i> substitution. If no match is found, the original text is left unchanged. A ~ by itself, or in front of a /, is replaced by \$HOME . A ~ followed by a + or – is replaced by \$PWD and \$OLDPWD respectively.
	In addition, <i>tilde</i> substitution is attempted when the value of a <i>variable assignment</i> begins with a ~.
Tilde Expansion	A <i>tilde-prefix</i> consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the charac- ters in the word if there is no slash. In an assignment, multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), follow- ing any unquoted colon or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the char- acters in the tilde-prefix following the tilde are treated as a possible login name from the user database.
	A portable login name cannot contain characters outside the set given in the description of the LOGNAME environment variable. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix will be replaced by the value of the variable HOME. If HOME is unset, the results are unspecified. Otherwise, the tilde-prefix will be replaced by a pathname of the home directory associated with the login name obtained using the getpwnam function. If the system does not recognize the login name, the results are undefined.
	Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:
	PATH=/posix/bin:~dgk/bin
	is eligible for tilde expansion because tilde follows a colon and none of the relevant char- acters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:
	PATH=\$(printf %s ~karels/bin : ~bostic/bin) for Dir in ~maart/bin ~srb/bin do PATH=\${PATH:+\$PATH:}\$Dir
	done
	With the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.
	Note that expressions in operands such as:

	make -k mumble LIBDIR=~chet/lib		
	do not qualify as shell variable assignments and tilde expansion is not performed (the command does so itself, which make does not).		
	The special sequence \$ ~ has been designated for future implementations to evaluate as a means of forcing tilde expansion in any word.		
	Because of the requirement that the word not be quoted, the following are not equivalent; only the last will cause tilde expansion:		
	\~hlj/ ~h\ lj / ~"hlj"/ ~hlj \ / ~hlj/		
	The results of giving tilde with an unknown login name are undefined because the Korn- Shell ~+ and ~- constructs make use of this condition, but, in general it is an error to give an incorrect login name with tilde. The results of having HOME unset are unspecified because some historical shells treat this as an error.		
Command Substitution	The standard output from a <i>command</i> enclosed in parenthesis preceded by a dollar sign (\$ (<i>command</i>)) or a pair of grave accents (``) may be used as part or all of a word; trailing new-lines are removed. In the second (archaic) form, the string between the quotes is processed for special quoting characters before the command is executed. (See Quoting below.) The command substitution \$(cat <i>file</i>) can be replaced by the equivalent but faster (<i><file< i="">). Command substitution of most special commands that do not perform input/output redirection are carried out without creating a separate process.</file<></i>		
	Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution occurs when the command is enclosed as follows:		
	\$(command)		
	or (backquoted version):		
	`command'		
	The shell will expand the command substitution by executing <i>command</i> in a subshell environment and replacing the command substitution (the text of <i>command</i> plus the enclosing \$() or backquotes) with the standard output of the command, removing sequences of one or more newline characters at the end of the substitution. Embedded newline characters before the end of the output will not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting that is in effect.		
Within the backquoted style of command substitution, backslash shall retain its meaning, except when followed by:			
\$ ` \			
	(dollar-sign, backquote, backslash). The search for the matching backquote is satisfied by the first backquote found without a preceding backslash; during this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the \$(<i>command</i>) form, or a quoted string, undefined results occur. A single- or double-quoted string that begins, but does not end, within the sequence produces undefined results.		
modified 13 Jun 1995	1-435		

With the \$(*command*) form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except:

- A script consisting solely of redirections produces unspecified results.
- See the restriction on single subshells described below.

The results of command substitution will not be field splitting and pathname expansion processed for further tilde expansion, parameter expansion, command substitution or arithmetic expansion. If a command substitution occurs inside double-quotes, it will not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application must precede the inner backquotes with backslashes; for example:

\`command \``

The $\$) form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

Command	Output
echo '\\$x'	\\$x
echo`echo`\\$x'`	\$x
echo \$(echo ' \\$x')	\\$x

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the new **\$(**) form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

echo` cat << eeof a here-doc with` eof	echo \$(cat << eeof a here-doc with) eof)
echo` echo abc # a comment with` `	echo \$(echo abc # a comment with))
echo`` echo``'	echo \$(echo ')')

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

If the command substitution consists of a single subshell, such as:

\$((command))

SunOS 5.5	User Commands	ksh(1)
	a portable application must separate the \$(and (into two tokens (that is, separate with white space). This is required to avoid any ambiguities with arithmetic expa	
Arithmetic Expansion	An arithmetic expression enclosed in double parentheses preceded by a dollar sig (\$((<i>arithmetic-expression</i>))) is replaced by the value of the arithmetic expression w the double parenthesis. Arithmetic expansion provides a mechanism for evaluating arithmetic expression and substituting its value. The format for arithmetic expansion as follows:	rithin ng an
	\$((expression))	
	The expression is treated as if it were in double-quotes, except that a double-quote the expression is not treated specially. The shell will expand all tokens in the expression for parameter expansion, command substitution and quote removal.	
	Next, the shell will treat this as an arithmetic expression and substitute the value of expression. The arithmetic expression will be processed according to the rules of C with the following exceptions:	
	Only integer arithmetic is required.	
	• The sizeof() operator and the prefix and postfix ++ and operators are required.	not
	• Selection, iteration and jump statements are not supported.	
	As an extension, the shell may recognize arithmetic expressions beyond those liste the expression is invalid, the expansion will fail and the shell will write a message dard error indicating the failure.	
	A simple example using arithmetic expansion:	
	# repeat a command 100 times	
	$\mathbf{x} = 100$	
	while [\$x -gt 0] do	
	command	
	x=\$((\$x-1))	
	done	
Process Substitution	This feature is available in SunOS and only on versions of the UNIX operating syst that support the / dev / fd directory for naming open files. Each command argument form <(<i>list</i>) or >(<i>list</i>) will run process <i>list</i> asynchronously connected to some file in / dev / fd . The name of this file will become the argument to the command. If the few with > is selected then writing on this file will provide input for <i>list</i> . If < is used, the file passed as an argument will contain the output of the <i>list</i> process. For example,	nt of the n `orm then the
	<pre>paste <(cut -f1 file1) <(cut -f3 file2) tee >(process1) >(process2)</pre>	
	cuts fields 1 and 3 from the files <i>file1</i> and <i>file2</i> respectively, pastes the results toget and sends it to the processes <i>process1</i> and <i>process2</i> , as well as putting it onto the statoutput. Note that the file, which is passed as an argument to the command, is a U pipe (2) so programs that expect to lseek (2) on the file will not work.	andard

Parameter Substitution	A <i>parameter</i> is an <i>identifier</i> , one or more digits, or any of the characters *, @, #, ?, –, \$, and !. A <i>variable</i> (a <i>parameter</i> denoted by an <i>identifier</i>) has a <i>value</i> and zero or more <i>attributes</i> . <i>variables</i> can be assigned <i>values</i> and <i>attributes</i> by using the typeset special command. The attributes supported by the shell are described later with the typeset special command. Exported variables pass values and attributes to the environment.
	The shell supports a one-dimensional array facility. An element of an array variable is referenced by a <i>subscript</i> . A <i>subscript</i> is denoted by a [, followed by an <i>arithmetic expression</i> (see Arithmetic Evaluation below) followed by a]. To assign values to an array, use set – A <i>name value</i> The <i>value</i> of all subscripts must be in the range of 0 through 1023. Arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array will be created if necessary. Referencing an array without a subscript is equivalent to referencing the element 0 . If an array <i>identifier</i> with subscript * or @ is used, then the value for each of the elements is substituted (separated by a field separator character).
	The value of a variable may be assigned by writing:
	name=value [name=value]
	If the integer attribute, $-\mathbf{i}$, is set for <i>name</i> , the <i>value</i> is subject to arithmetic evaluation as described below.
	Positional parameters, parameters denoted by a number, may be assigned values with the set special command. Parameter \$0 is set from argument zero when the shell is invoked. If <i>parameter</i> is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces.
Parameter Expansion	The format for parameter expansion is as follows: <i>\${expression</i> }
	where <i>expression</i> consists of all characters until the matching }. Any } escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions and variable expansions, are not examined in determining the matching }.
	The simplest form for parameter expansion is: \${parameter}
	The value, if any, of <i>parameter</i> will be substituted.
	The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when <i>parameter</i> is followed by a character that could be interpreted as part of the name. The matching closing brace will be determined by counting brace levels, skipping over enclosed quoted strings and command substitutions.
	If the parameter name or symbol is not enclosed in braces, the expansion will use the longest valid name whether or not the symbol represented by that name exists. When the shell is scanning its input to determine the boundaries of a name, it is not bound by its knowledge of what names are already defined. For example, if F is a defined shell variable, the command:

echo \$Fred

does not echo the value of **SF** followed by **red**; it selects the longest possible valid name, **Fred**, which in this case might be unset.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion will not be performed on the results of the expansion.
- Field splitting will not be performed on the results of the expansion, with the exception of @.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* will be subjected to tilde expansion, parameter expansion, command substitution and arithmetic expansion. If *word* is not needed, it will not be expanded. The } character that delimits the following parameter expansion modifications is determined as described previously in this section and in **dquote**. (For example, **\${foo-bar}xyz}** would result in the expansion of **foo** followed by the string **xyz}** if **foo** is set, else the string **barxyz**}.

0	•
\${parameter:-word}	Use Default Values. If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be substituted; otherwise, the value of <i>parameter</i> will be substituted.
\${parameter:=word}	Assign Default Values. If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be assigned to <i>parameter</i> . In all cases, the final value of <i>parameter</i> will be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.
\${parameter:?[word]}	Indicate Error if Null or Unset. If <i>parameter</i> is unset or null, the expansion of <i>word</i> (or a message indicating it is unset if <i>word</i> is omitted) will be written to standard error and the shell will exit with a non-zero exit status. Otherwise, the value of <i>parameter</i> will be substituted. An interactive shell need not exit.
\${parameter:+[word]}	Use Alternative Value. If <i>parameter</i> is unset or null, null will be substituted; otherwise, the expansion of <i>word</i> will be substituted.

In the parameter expansions shown previously, use of the colon in the format results in a test for a parameter that is unset or null; omission of the colon results in a test for a parameter that is only unset. The following table summarizes the effect of the colon:

	parameter	parameter	parameter
	set and not null	set but null	unset
\${parameter:-word}	substitute	substitute	substitute
	<i>parameter</i>	<i>word</i>	word
\${parameter-word}	substitute	substitute	substitute
	parameter	null	<i>word</i>
\${parameter:=word}	substitute	assign	assign
	<i>parameter</i>	<i>word</i>	<i>word</i>

\${parameter=word}	substitute	substitute	assign
	parameter	parameter	null
\${parameter:?word}	substitute	error,	error,
	parameter	exit	exit
\${parameter?word}	substitute	substitute	error,
	<i>parameter</i>	null	exit
\${parameter:+word}	substitute	substitute	substitute
	<i>word</i>	null	null
\${parameter+word}	substitute	substitute	substitute
	word	word	null

In all cases shown with "substitute", the expression is replaced with the value shown. In all cases shown with "assign" *parameter* is assigned that value, which also replaces the expression.

\${#parameter}	String Length. The length in characters of the value of parameter. If
	<i>parameter</i> is * or @, then all the positional parameters, starting with
	\$1 , are substituted (separated by a field separator character).

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see **patmat**), rather than regular expression notation, will be used to evaluate the patterns. If *parameter* is * or @, then all the positional parameters, starting with **\$1**, are substituted (separated by a field separator character). Enclosing the full parameter expansion string in double-quotes will not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces will have this effect.

\${parameter%word}	Remove Smallest Suffix Pattern . The <i>word</i> will be expanded to produce a pattern. The parameter expansion then will result in <i>parameter</i> , with the smallest portion of the suffix matched by the <i>pattern</i> deleted.
\${parameter%%word}	Remove Largest Suffix Pattern . The <i>word</i> will be expanded to produce a pattern. The parameter expansion then will result in <i>parameter</i> , with the largest portion of the suffix matched by the <i>pattern</i> deleted.
\${parameter#word}	Remove Smallest Prefix Pattern . The <i>word</i> will be expanded to produce a pattern. The parameter expansion then will result in <i>parameter</i> , with the smallest portion of the prefix matched by the <i>pattern</i> deleted.
\${parameter##word}	Remove Largest Prefix Pattern . The <i>word</i> will be expanded to produce a pattern. The parameter expansion then will result in <i>parameter</i> , with the largest portion of the prefix matched by the <i>pattern</i> deleted.

```
Examples:
${parameter:-word}
   In this example, ls is executed only if x is null or unset. (The $(ls) command substitu-
   tion notation is explained in Command Substitution above.)
        ${x:-$(ls)}
${parameter:=word}
        unset X
        echo ${X:=abc}
       abc
${parameter:?word}
       unset posix
        echo ${posix:?}
        sh: posix: parameter null or not set
${parameter:+word}
       set a b c
        echo ${3:+posix}
       posix
${#parameter}
       HOME=/usr/posix
        echo ${#HOME}
        10
${parameter%word}
       x=file.c
        echo ${x%.c}.o
       file.o
${parameter%%word}
       x=posix/src/std
        echo ${x%%/*}
       posix
${parameter#word}
       x=$HOME/src/cmd
        echo ${x#$HOME}
       /src/cmd
${parameter##word}
       x=/one/two/three
        echo ${x##*/}
        three
```

		we at the set of the line of the set of the
Parameters Set by Shell	01	meters are automatically set by the shell:
	#	The number of positional parameters in decimal.
	-	Flags supplied to the shell on invocation or by the set command.
	?	The decimal value returned by the last executed command.
	\$	The process number of this shell.
	_	Initially, the value of _ is an absolute pathname of the shell or script being executed as passed in the <i>environment</i> . Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching MAIL file when checking for mail.
	!	The process number of the last background command invoked.
	ERRNO	The value of errno as set by the most recently failed system call. This value is system dependent and is intended for debugging purposes.
	LINENO	The line number of the current line within the script or function being executed.
	OLDPWD	The previous working directory set by the cd command.
	OPTARG	The value of the last option argument processed by the getopts spe- cial command.
	OPTIND	The index of the last option argument processed by the getopts special command.
	PPID	The process number of the parent of the shell.
	PWD	The present working directory set by the cd command.
	RANDOM	Each time this variable is referenced, a random integer, uniformly dis- tributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to RANDOM .
	REPLY	This variable is set by the select statement and by the read special command when no arguments are supplied.
	SECONDS	Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference will be the value that was assigned plus the number of seconds since the assignment.
Variables Used by	The following varia	ables are used by the shell:
Shell	CDPATH	The search path for the cd command.
	COLUMNS	
		If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing select lists.
	EDITOR	If the value of this variable ends in emacs , gmacs , or vi and the VISUAL variable is not set, then the corresponding option (see the set

1-442

	special command below) will be turned on.
ENV	This variable, when the shell is invoked, is subjected to parameter expansion by the shell and the resulting value is used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of ENV is not an absolute pathname, the results are unspecified. ENV will be ignored if the user's real and effective user IDs or real and effective group IDs are different.
	This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by ENV differs from \$HOME/.profile in that .profile is typically executed at session startup, whereas the ENV file is executed at the beginning of each shell invocation. The ENV value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no PATH searching is performed. This is used as a guard against Trojan Horse security breaches.
FCEDIT	The default editor name for the fc command.
FPATH	The search path for function definitions. By default the FPATH directories are searched after the PATH variable. If an executable file is found, then it is read and executed in the current environment. FPATH is searched before PATH when a function with the – u attribute is referenced. The preset alias autoload preset alias causes a function with the – u attribute to be created.
IFS	Internal field separators, normally space , tab , and new-line that are used to separate command words which result from command or parameter substitution and for separating words with the special command read . The first character of the IFS variable is used to separate arguments for the \$ * substitution (See Quoting below).
HISTFILE	If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history. (See Command re-entry below.)
HISTSIZE	If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128 .
HOME	The default argument (home directory) for the cd command.
LC_ALL	This variable provides a default value for the LC_* variables.
LC_COLLA	TE This variable determines the behavior of range expressions, equivalence classes and multi-character collating elements within pat- tern matching.
LC_CTYPE	Determines how the shell handles characters. When LC_CTYPE is set

to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. However, the shell is not multibyte (EUC) capable. In the "C" locale, only ASCII characters are valid. If LC_CTYPE (see **environ**(5)) is not set in the environment, the operational behavior of the shell is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale prevails.

LC_MESSAGES

This variable determines the language in which messages should be written.

- LANG Provide a default value for the internationalization variables that are unset or null. If LANG is unset or null, the corresponding value from the default "C" locale will be used. If any of the internationalization variables contains an invalid setting, the utility will behave as if none of the variables had been defined.
- LINENO This variable is set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets LINENO, the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of LINENO is unspecified.
- LINES If this variable is set, the value is used to determine the column length for printing **select** lists. Select lists will print vertically until about two-thirds of **LINES** lines are filled.
- MAIL If this variable is set to the name of a mail file *and* the MAILPATH variable is not set, then the shell informs the user of arrival of mail in the specified file.

MAILCHECK

This variable specifies how often (in seconds) the shell will check for changes in the modification time of any of the files specified by the **MAILPATH** or **MAIL** variables. The default value is **600** seconds. When the time has elapsed the shell will check before issuing the next prompt.

MAILPATH

A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last **MAILCHECK** seconds. Each file name can be followed by a ? and a message that will be printed. The message will undergo parameter substitution with the variable **\$_** defined as the name of the file that has changed. The default message is **you have mail in \$_**.

	NLSPATH	Determine the location of message catalogues for the processing of LC_MESSAGES.
	РАТН	The search path for commands (see Execution below). The user may not change PATH if executing under rksh (except in .profile).
	PPID	This variable is set by the shell to the decimal process ID of the pro- cess that invoked the shell. In a subshell, PPID will be set to the current shell. For example, echo SPPID and (echo SPPID) would produce the same value.
	PS1	The value of this variable is expanded for parameter substitution to define the primary prompt string which by default is " \$ ". The character ! in the primary prompt string is replaced by the <i>command</i> number (see <i>Command Re-entry</i> below). Two successive occurrences of ! will produce a single ! when the prompt string is printed.
	PS2	Secondary prompt string, by default "> ".
	PS3	Selection prompt string used within a select loop, by default "#? ".
	PS4	The value of this variable is expanded for parameter substitution and precedes each line of an execution trace. If omitted, the execution trace prompt is "+".
	SHELL	The pathname of the <i>shell</i> is kept in the environment. At invocation, if the basename of this variable is rsh , rksh , or krsh , then the shell becomes restricted.
	TMOUT	If set to a value greater than zero, the shell will terminate if a com- mand is not entered within the prescribed number of seconds after issuing the PS1 prompt. (Note that the shell can be compiled with a maximum bound for this value which cannot be exceeded.)
	VISUAL	If the value of this variable ends in emacs , gmacs , or vi then the corresponding option (see Special Command set below) will be turned on.
	and IFS, while HO	ault values to PATH , PS1 , PS2 , PS3 , PS4 , MAILCHECK , FCEDIT , TMOUT ME , SHELL ENV and MAIL are not set at all by the shell (although gin (1)). On some systems MAIL and SHELL are also set by login .
Blank Interpretation	the field separator such characters are	ad command substitution, the results of substitutions are scanned for characters (those found in IFS) and split into distinct arguments where a found. Explicit null arguments ("") or (") are retained. Implicit null resulting from <i>parameters</i> that have no values) are removed.
File Name Generation	unless the -f option regarded as a <i>patte</i> match the pattern. unchanged. When	tion, each command <i>word</i> is scanned for the characters *, ?, and [n has been set . If one of these characters appears then the word is <i>rn</i> . The word is replaced with lexicographically sorted file names that If no file name is found that matches the pattern, then the word is left a <i>pattern</i> is used for file name generation, the character period (.) at ume or immediately following a /, as well as the character / itself, must

be matched explicitly. A file name beginning with a period will not be matched with a pattern with the period inside parentheses; that is

ls .@(r*)

would locate a file named **.restore**, but **ls** @(**.r***) would not. In other instances of pattern matching the / and . are not treated specially.

- * Matches any string, including the null string.
- ? Matches any single character.
- [...] Matches any one of the enclosed characters. A pair of characters separated by matches any character lexically between the pair, inclusive. If the first character following the opening "[" is a "! ", then any character not enclosed is matched. A can be included in the character set by putting it as the first or last character.

A *pattern-list* is a list of one or more patterns separated from each other with $a \mid$. Composite patterns can be formed with one or more of the following:

Optionally matches any one of the given patterns.
Matches zero or more occurrences of the given patterns.
Matches one or more occurrences of the given patterns.
Matches exactly one of the given patterns.
Matches anything, except one of the given patterns.

QuotingEach of the *metacharacters* listed above (See Definitions) has a special meaning to the shell
and causes termination of a word unless quoted. A character may be *quoted* (that is,
made to stand for itself) by preceding it with a \setminus . The pair \setminus NEWLINE is removed. All
characters enclosed between a pair of single quote marks (") are quoted. A single quote
cannot appear within single quotes. Inside double quote marks ("), parameter and com-
mand substitution occur and \setminus quotes the characters \setminus , `, ", and \$. The meaning of \$*
and \$@ is identical when not quoted or when used as a parameter assignment value or as
a file name. However, when used as a command argument, \$* is equivalent to
"\$1d \$2d ...", where d is the first character of the IFS variable, whereas \$@ is equivalent to
\$1 \$2 Inside grave quote marks (``), \setminus quotes the characters \setminus , ', and \$. If the grave
quotes occur within double quotes, then \setminus also quotes the character ".

The special meaning of reserved words or aliases can be removed by quoting any character of the reserved word. The recognition of function names or special command names listed below cannot be altered by quoting them.

ArithmeticAn ability to perform integer arithmetic is provided with the special command let.EvaluationEvaluations are performed using *long* arithmetic. Constants are of the form [*base#*] *n*where *base* is a decimal number between two and thirty-six representing the arithmeticbase and *n* is a number in that base. If *base* is omitted then base 10 is used.

An arithmetic expression uses the same syntax, precedence, and associativity of expression as the C language. All the integral operators, other than ++, --, ?; and , are supported. Variables can be referenced by name within an arithmetic expression without using the parameter substitution syntax. When a variable is referenced, its value is

modified 13 Jun 1995

	evaluated as an arith	metic expression.
	typeset special comm assignment to a varia	epresentation of a <i>variable</i> can be specified with the $-i$ option of the nand. Arithmetic evaluation is performed on the value of each able with the $-i$ attribute. If you do not specify an arithmetic base, to the variable determines the arithmetic base. This base is used stitution occurs.
	command is provide	ithmetic operators require quoting, an alternative form of the let d. For any command which begins with a ((, all the characters until ated as a quoted expression. More precisely, (()) is equivalent to
Prompting	before reading a com	vely, the shell prompts with the parameter expanded value of PS1 mand. If at any time a new-line is typed and further input is needed and, then the secondary prompt (that is, the value of PS2) is issued.
Conditional Expressions	A <i>conditional expression</i> is used with the [[compound command to test attributes of files and to compare strings. Word splitting and file name generation are not performed on the words between [[and]]. Each expression can be constructed from one or more of the following unary or binary expressions:	
	–a file	True, if <i>file</i> exists.
	- b file	True, if <i>file</i> exists and is a block special file.
	–c file	True, if <i>file</i> exists and is a character special file.
	-d file	True, if <i>file</i> exists and is a character special file.
	-e file	True, if <i>file</i> exists.
	- f file	True, if <i>file</i> exists and is an ordinary file.
	-g file	True, if <i>file</i> exists and is has its setgid bit set.
	- k file	True, if <i>file</i> exists and is has its sticky bit set.
	– n string	True, if length of <i>string</i> is non-zero.
	–o option	True, if option named <i>option</i> is on.
	- p file	True, if <i>file</i> exists and is a fifo special file or a pipe.
	- r file	True, if <i>file</i> exists and is readable by current process.
	–s file –t fildes	True, if <i>file</i> exists and has size greater than zero. True, if file descriptor number <i>fildes</i> is open and associated with a
	-t mues	terminal device.
	–u file	True, if <i>file</i> exists and has its setuid bit set.
	-w file	True, if <i>file</i> exists and is writable by current process.
	- x file	True, if <i>file</i> exists and is executable by current process. If <i>file</i> exists
		and is a directory, then the current process has permission to search in the directory.
	– z string	True, if length of <i>string</i> is zero.
	–L file	True, if <i>file</i> exists and is a symbolic link.
	–O file	True, if file exists and is owned by the effective user id of this pro-
	-G file	cess. True, if <i>file</i> exists and its group matches the effective group id of this process.

User Commands

	-S file	True, if <i>file</i> exists and is a socket.
	file1 –nt file2	True, if <i>file1</i> exists and is newer than <i>file2</i> .
	file1 –ot file2	True, if <i>file1</i> exists and is older than <i>file2</i> .
	file1 – ef file2	True, if <i>file1</i> and <i>file2</i> exist and refer to the same file.
	string = pattern	
	string != pattern	
	string1 < string	
	at min of a string	characters.
	string1 > string	<i>2</i> True, if <i>string1</i> comes after <i>string2</i> based on ASCII value of their characters.
	exp1 –eq exp2	True, if <i>exp1</i> is equal to <i>exp2</i> .
	exp1 - ne exp2	True, if <i>exp1</i> is not equal to <i>exp2</i> .
	exp1 –lt exp2	True, if <i>exp1</i> is less than <i>exp2</i> .
	exp1 –gt exp2	True, if $exp1$ is greater than $exp2$.
	exp1 –le exp2	True, if <i>exp1</i> is less than or equal to <i>exp2</i> .
	exp1 –ge exp2	True, if <i>exp1</i> is greater than or equal to <i>exp2</i> .
		bove expressions, if <i>file</i> is of the form $/\text{dev}/\text{fd}/n$, where <i>n</i> is an integer, then ed to the open file whose descriptor number is <i>n</i> .
		xpression can be constructed from these primitives by using any of the fol- n decreasing order of precedence.
	(expression) ! expression expression1 && expression1 e	
Input/Output	Before a comm	and is executed, its input and output may be redirected using a special reted by the shell. The following may appear anywhere in a simple-
	command or m command. Co except as noted	hay precede or follow a <i>command</i> and are <i>not</i> passed on to the invoked mmand and parameter substitution occur before <i>word</i> or <i>digit</i> is used I below. File name generation occurs only if the pattern matches a single interpretation is not performed.
	<word< th=""><th>Use file <i>word</i> as standard input (file descriptor 0).</th></word<>	Use file <i>word</i> as standard input (file descriptor 0).
	>word	Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist then it is created. If the file exists, and the noclobber option is on, this causes an error; otherwise, it is truncated to zero length.
	> word	Sames as >, except that it overrides the noclobber option.
	>>word	Use file <i>word</i> as standard output. If the file exists then output is appended to it (by first seeking to the EOF); otherwise, the file is created.
	<>word	Open file <i>word</i> for reading and writing as standard input.
	<< [–]word	The shell input is read up to a line that is the same as <i>word</i> , or to an EOF. No parameter substitution, command substitution or file name genera- tion is performed on <i>word</i> . The resulting document, called a <i>here-</i> <i>document</i> , becomes the standard input. If any character of <i>word</i> is

		quoted, then no interpretation is placed upon the characters of the document; otherwise, parameter and command substitution occur, $\NEW-$ LINE is ignored, and \mbox{must} be used to quote the characters $ $ \$, $$ and the first character of <i>word</i> . If – is appended to <<, then all leading tabs are stripped from <i>word</i> and from the document.
	<&digit	The standard input is duplicated from file descriptor <i>digit</i> (see dup (2)). Similarly for the standard output using > & <i>digit</i> .
	<&-	The standard input is closed. Similarly for the standard output using >&
	<&p	The input from the co-process is moved to standard input.
	>&p	The output to the co-process is moved to standard output.
		ove is preceded by a digit, then the file descriptor number referred to is y the digit (instead of the default 0 or 1). For example:
	2>&	1
	means file descr	iptor 2 is to be opened for writing as a duplicate of file descriptor 1.
		tich redirections are specified is significant. The shell evaluates each rms of the (<i>file descriptor, file</i>) association at the time of evaluation. For
	1 >fn	ame 2>&1
	file associated w reversed, file de	the descriptor 1 with file <i>fname</i> . It then associates file descriptor 2 with the with file descriptor 1 (that is <i>fname</i>). If the order of redirections were scriptor 2 would be associated with the terminal (assuming file descriptor then file descriptor 1 would be associated with file <i>fname</i> .
	If a command is input for the co	followed by & and job control is not active, then the default standard mmand is the empty file / dev/null . Otherwise, the environment for the ommand contains the file descriptors of the invoking shell as modified by
Environment	program in the the values are cl On invocation, t found, giving it inherit the envir ones, using the The environmen pairs originally plus any addition	t (see environ (5)) is a list of name-value pairs that is passed to an executed same way as a normal argument list. The names must be <i>identifiers</i> and haracter strings. The shell interacts with the environment in several ways. the shell scans the environment and creates a variable for each name the corresponding value and marking it <i>export</i> . Executed commands ronment. If the user modifies the values of these variables or creates new export or typeset – x commands they become part of the environment. In seen by any executed command is thus composed of any name-value inherited by the shell, whose values may be modified by the current shell, ons which must be noted in export or typeset – x commands.
		nt for any <i>simple-command</i> or <i>function</i> may be augmented by prefixing it re variable assignments. A variable assignment argument is a word of the <i>value</i> . Thus:

	TERM=450 cmd args and
	(export TERM; TERM=450; cmd args)
	are equivalent (as far as the above execution of <i>cmd</i> is concerned except for special com- mands listed below that are preceded with a dagger).
	If the $-\mathbf{k}$ flag is set, <i>all</i> variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints $\mathbf{a}=\mathbf{b} \mathbf{c}$ and then \mathbf{c} :
	echo a=b c set –k echo a=b c
	This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.
Functions	The function reserved word, described in the Commands section above, is used to define shell functions. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. (See Execution below.)
	Functions execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller. A trap on EXIT set inside a function is executed after the function completes in the environment of the caller. Ordinarily, variables are shared between the calling program and the function. However, the typeset special command used within a function defines local variables whose scope includes the current function and all functions it calls.
	The special command return is used to return from function calls. Errors within func- tions return control to the caller.
	The names of all functions can be listed with typeset + f . typeset - f lists all function names as well as the text of all functions. typeset - f <i>function-names</i> lists the text of the named functions only. Functions can be undefined with the - f option of the unset special command.
	Ordinarily, functions are unset when the shell executes a shell script. The –xf option of the typeset command allows a function to be exported to scripts that are executed without a separate invocation of the shell. Functions that need to be defined across separate invocations of the shell should be specified in the ENV file with the –xf option of typeset .
Function Definition Command	A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a <i>function definition command</i> .
	The format of a function definition command is as follows:

fname() compound-command[io-redirect ...]

The function is named **fname**; it must be a name. An implementation may allow other characters in a function name as an extension. The implementation will maintain separate name spaces for functions and variables.

The () in the function definition command consists of two operators. Therefore, intermixing blank characters with the **fname**, (, and) is allowed, but unnecessary.

The argument *compound-command* represents a compound command.

When the function is declared, none of the expansions in **wordexp** will be performed on the text in *compound-command* or *io-redirect*; all expansions will be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* will be performed during the execution of the function itself, not the function definition.

When a function is executed, it will have the syntax-error and variable-assignment properties described for the special built-in utilities.

The *compound-command* will be executed whenever the function name is specified as the name of a simple command The operands to the command temporarily will become the positional parameters during the execution of the *compound-command*; the special parameter **#** will also be changed to reflect the number of operands. The special parameter **0** will be unchanged. When the function completes, the values of the positional parameters and the special parameter **#** will be restored to the values they had before the function was executed. If the special built-in **return** is executed in the *compound-command*, the function will complete and execution will resume with the next command after the function call.

An example of how a function definition can be used wherever a simple command is allowed:

```
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
    ls -l
}
```

The exit status of a function definition will be $\mathbf{0}$ if the function was declared successfully; otherwise, it will be greater than zero. The exit status of a function invocation will be the exit status of the last command executed by the function.

Jobs If the monitor option of the set command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the jobs command, and assigns them small integer numbers. When a job is started asynchronously with &, the shell prints a line which looks like:

[1] 1234

indicating that the **job**, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key 2 (CTRL-Z) which sends a **STOP** signal to the current job. The shell will then normally indicate that the job has been '**Stopped**', and print another prompt. You can then manipulate the state of this job, putting it in the background with the **bg** command, or run some other commands and then eventually bring the job back into the foreground with the foreground command **fg**. A 'Z takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

A job being run in the background will stop if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command "**stty tostop**". If you set this tty option, then background jobs will stop when they try to produce output like they do when they try to read input.

There are several ways to refer to **jobs** in the shell. A **job** can be referred to by the process id of any process of the **job** or by one of the following:

%number	The job with the given number.
%string	Any job whose command line begins with <i>string</i> .
%?string	Any job whose command line contains string.
%%	Current job.
%+	Equivalent to %%.
%-	Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work.

When the monitor mode is on, each background job that completes triggers any trap set for CHLD.

When you try to leave the shell while jobs are running or stopped, you will be warned that 'You have stopped(running) jobs.' You may use the **jobs** command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated. If you have **nohup**'ed jobs running when you attempt to logout, you will be warned with the message

You have jobs running.

You will then need to logout a second time to actually logout; however, your background jobs will continue to run.

- **Signals** The INT and QUIT signals for an invoked command are ignored if the command is followed by & and the **monitor** option is not active. Otherwise, signals have the values inherited by the shell from its parent (but see also the **trap** special command below).
- **Execution** Each time a command is executed, the above substitutions are carried out. If the command name matches one of the **Special Commands** listed below, it is executed within the current shell process. Next, the command name is checked to see if it matches one of the user defined functions. If it does, the positional parameters are saved and then reset to

	the arguments of the function call. When the function completes or issues a return , the positional parameter list is restored and any trap set on EXIT within the function is executed. The value of a function is the value of the last command executed. A function is also executed in the current shell process. If a command name is not a special command or a user defined function , a process is created and an attempt is made to execute the command via exec (2). The shell variable PATH defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is / bin:/usr/bin: (specifying / bin , / usr/bin , and the current directory in that order). The current directory can be specified by two or more adjacent colons, or by a colon at the beginning or end of the path list. If the command name contains a / then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not a directory or an a.out file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. All non-exported aliases, functions, and variables are removed in this case. A parenthesized command is executed in a sub-shell without removing non-exported quantities.
Command Re-entry	The text of the last HISTSIZE (default 128) commands entered from a terminal device is saved in a history file. The file \$HOME/.sh_history is used if the HISTFILE variable is not set or if the file it names is not writable. A shell can access the commands of all <i>interactive</i> shells which use the same named HISTFILE . The special command fc is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to fc then the value of the variable FCEDIT is used. If FCEDIT is not defined then / bin/ed is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name – is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form <i>old=new</i> can be used to modify the command before execution. For example, if r is aliased to ' fc – e –' then typing ' r bad=good c' will re-execute the most recent command which starts with the letter c , replacing the first occurrence of the string bad with the string good .
In-line Editing Option	Normally, each command line entered from a terminal device is simply typed followed by a new-line (RETURN or LINEFEED). If either the emacs , gmacs , or vi option is active, the user can edit the command line. To be in either of these edit modes set the corresponding option. An editing option is automatically selected each time the VISUAL or EDITOR variable is assigned a value ending in either of these option names. The editing features require that the user's terminal accept RETURN as carriage return without line feed and that a space must overwrite the current character on the screen. The editing modes implement a concept where the user is looking through a window at the current line. The window width is the value of COLUMNS if it is defined, otherwise 80. If the window width is too small to display the prompt and leave at least 8 columns to enter input, the prompt is truncated from the left. If the line is longer than the window width minus two, a mark is displayed at the end of the window will be centered about the

ksh(1)	User Commands SunOS 5.		SunOS 5.5
		ark is a > if the line extends on the right side of the window, < i left, and * if the line extends on both sides of the window.	if the line
		nmands in each edit mode provide access to the history file. O ot patterns, although a leading ^ in the string restricts the matc ter in the line.	
emacs Editing Mode	This mode is entered by enabling either the emacs or gmacs option. The only difference between these two modes is the way they handle ^T . To edit, the user moves the cursor to the point needing correction and then inserts or deletes characters or words as needed. All the editing commands are control characters or escape sequences. The notation for control characters is caret (^) followed by the character. For example, ^F is the notation for control F . This is entered by depressing 'f while holding down the CTRL (control) key. The SHIFT key is <i>not</i> depressed. (The notation ^? indicates the DEL (delete) key.)		
	The notation for escape sequences is M - followed by a character. For example, M - f (pro- nounced Meta f) is entered by depressing ESC (ascii 033) followed by 'f'. (M - F would be the notation for ESC followed by SHIFT (capital) 'F'.)		
	All edit commands operate from any place on the line (not just at the beginning). Neither the RETURN nor the LINEFEED key is entered after edit commands except when noted.		
	^F M-f	Move cursor forward (right) one character. Move cursor forward one word. (The emacs editor's idea of string of characters consisting of only letters, digits and und	
	^B	Move cursor backward (left) one character.	
	M-b	Move cursor backward one word.	
	^A	Move cursor to start of line.	
	^E	Move cursor to end of line.	
	^] <i>char</i>	Move cursor forward to character <i>char</i> on current line.	
	M-^]char	Move cursor backward to character <i>char</i> on current line.	
	^X^X	Interchange the cursor and mark.	and use
	erase	(User defined erase character as defined by the stty (1) commoly `H or #). Delete previous character	iand, usu-
	^D	ally ^H or #.) Delete previous character. Delete current character.	
	M-d	Delete current word.	
	M- [°] H	(Meta-backspace) Delete previous word.	
	M-h	Delete previous word.	
	M-^?	(Meta-DEL) Delete previous word (if your interrupt characte	er is ^? (DEL
		the default) then this command will not work).	
	^T	Transpose current character with next character in emacs me	ode. Tran-
	-	spose two previous characters in gmacs mode.	
	^C	Capitalize current character.	
	M-c	Capitalize current word.	
	M-l	Change the current word to lower case.	
	^K	Delete from the cursor to the end of the line. If preceded by	a numerical
		parameter whose value is less than the current cursor position	
		delete from given position up to the cursor. If preceded by a	
		- •	

ATT 7	parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position.
^W	Kill from the cursor to the mark.
M-p kill	Push the region from the cursor to the mark on the stack. (User defined kill character as defined by the stty (1) command, usually ^G or @.) Kill the entire current line. If two <i>kill</i> characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals).
^Y	Restore last item removed from line. (Yank item back to the line.)
٦ ٦	Line feed and print current line.
^@	(null character) Set mark.
M-space	(Meta space) Set mark.
J	(New line) Execute the current line.
Μ	(Return) Execute the current line.
eof	End-of-file character, normally ^D , is processed as an End-of-file only if the current line is null.
^р	Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command.
M-<	Fetch the least recent (oldest) history line.
M->	Fetch the most recent (youngest) history line.
^N	Fetch next command line. Each time ^N is entered the next command line forward in time is accessed.
^R string	Reverse search history for a previous command line containing <i>string</i> . If a parameter of zero is given, the search is forward. <i>string</i> is terminated by a RETURN or NEW LINE. If string is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is omitted, then the next command line containing the most recent <i>string</i> is accessed. In this case a parameter of zero reverses the direction of the search.
^O	Operate. Execute the current line and fetch the next line relative to current line from the history file.
M-digits	(Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are ^F , ^B , <i>erase</i> , ^C , ^D , ^K , ^R , ^P , ^N , ^] , M, M- ^], M, M-b, M-c, M-d, M-f, M-h, M-l and M- [^] H.
M-letter	Soft-key. Your alias list is searched for an alias by the name _ <i>letter</i> and if an alias of this name is defined, its value will be inserted on the input queue. The <i>letter</i> must not be one of the above meta-functions.
M-[letter	Soft-key. Your alias list is searched for an alias by the name <u>letter</u> and if an alias of this name is defined, its value will be inserted on the input queue. The can be used to program functions keys on many terminals.
M–.	The last word of the previous command is inserted on the line. If pre- ceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word.
M	Same as M–

		An asterisk is appended to the end of the word and a file name expan-	
	M−ESC M−= ^U ∖	sion is attempted. File name completion. Replaces the current word with the longest com- mon prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a direc- tory and a space is appended if the file is not a directory. List files matching current word pattern if an asterisk were appended. Multiply parameter of next command by 4. Escape next character. Editing characters, the user's erase, kill and inter- rupt (normally ~?) characters may be entered in a command line or in a search string if preceded by a \. 		Display version of the shell.	
	M -#	Insert a # at the beginning of the line and execute it. This causes a comment to be inserted in the history file.	
vi Editing Mode	mode. To edit, the point needing	ping modes. Initially, when you enter a command you are in the <i>input</i> he user enters <i>control</i> mode by typing ESC (033) and moves the cursor to g correction and then inserts or deletes characters or words as needed. Inmands accept an optional repeat <i>count</i> prior to the command.	
	When in vi mode on most systems, canonical processing is initially enabled and the mand will be echoed again if the speed is 1200 baud or greater and it contains any characters or less than one second has elapsed since the prompt was printed. The character terminates canonical processing for the remainder of the command and user can then modify the command line. This scheme has the advantages of cano processing with the type-ahead echoing of raw mode.		
	If the option viraw is also set, the terminal will always have canonical processi abled. This mode is implicit for systems that do not support two alternate end imiters, and may be helpful for certain terminals.		
Input Edit	By default the ed	litor is in input mode.	
Commands	erase	(User defined erase character as defined by the stty (1) command, usu- ally ^H or # .) Delete previous character.	
	^W	Delete the previous blank separated word.	
	^D	Terminate the shell.	
	Ŷ	Escape next character. Editing characters and the user's erase or kill characters may be entered in a command line or in a search string if preceded by a \mathbf{V} . The \mathbf{V} removes the next character's editing features (if any).	
	\setminus	Escape the next <i>erase</i> or <i>kill</i> character.	

string. string is terminated by a RETURN or NEWLINE. If string is pre- ceded by a ^, the matched line must begin with string. If string is NULL, the previous string will be used.	Motion Edit	These commands	will move the cursor.

	[count]~	Invert the case of the <i>count</i> character(s) starting position and advance the cursor.	g at the current cursor
	[count]_	Causes the <i>count</i> word of the previous comma input mode entered. The last word is used if a	
	*	Causes an * to be appended to the current wor tion attempted. If no match is found, it rings t word is replaced by the matching pattern and	he bell. Otherwise, the

		Filename completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory.
Other Edit	Miscellaneous	
Commands	[count]ymotion	
	y[count	<i>]motion</i> Yank current character through character that <i>motion</i> would move the cursor to and puts them into the delete buffer. The text and cursor are unchanged.
	Y	Yanks from current position to end of line. Equivalent to y \$.
	u	Undo the last text modifying command.
	U	Undo all the text modifying commands performed on the line.
	[count]	
		Returns the command fc – e {VISUAL: – \${EDITOR: – vi}} <i>count</i> in the input buffer. If <i>count</i> is omitted, then the current line is used.
	^L	Line feed and print current line. Has effect only in control mode.
	J	(New line) Execute the current line, regardless of mode.
	Μ	(Return) Execute the current line, regardless of mode.
	#	If the first character of the command is a #, then this command deletes this # and each # that follows a newline. Otherwise, sends the line after inserting a # in front of each line in the command. Useful for causing the current line to be inserted in the history as a comment and removing comments from previous comment commands in the history file.
	=	List the file names that match the current word if an asterisk were appended it.
	@letter	Your alias list is searched for an alias by the name _ <i>letter</i> and if an alias of this name is defined, its value will be inserted on the input queue for processing.
Special Commands	The following <i>simple-commands</i> are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is 0 . Commands that are preceded by one or two † (daggers) are treated specially in the following ways:	
	com 2. I/O 3. Erro 4. Wo able	iable assignment lists preceding the command remain in effect when the mand completes. redirections are processed after variable assignments. ors cause a script that contains them to abort. rds, following a command preceded by †† that are in the format of a vari- e assignment, are expanded with the same rules as a variable assignment. s means that tilde substitution is performed after the = sign and word

splitting and file name generation are not performed.

```
†:[arg...]
```

The command only expands parameters.

† . file [arg . . .]

Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by **PATH** is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.

†† alias [-tx] [name[=value]] ...

alias with no arguments prints the list of aliases in the form *name=value* on standard output. An *alias* is defined for each name whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The –t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of **PATH** is reset but the aliases remained tracked. Without the –t flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The –**x** flag is used to set or print *exported aliases*. An *exported alias* is defined for scripts invoked by name. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.

bg [%job...]

This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See "**Jobs**" section above for a description of the format of *job*.

† **break** [*n*]

Exit from the enclosed **for**, **while**, **until**, or **select** loop, if any. If *n* is specified then **break** *n* levels.

† continue [n]

Resume the next iteration of the enclosed **for**, **while**, **until**, or **select** loop. If *n* is specified then resume at the *n*-th enclosed loop.

cd [arg]

cd old new

This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is – the directory is changed to the previous directory. The shell variable **HOME** is the default *arg*. The variable **PWD** is set to the current directory. The shell variable **CDPATH** defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (:). The default path is null (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of **cd** substitutes the string *new* for the string *old* in the current

directory name, PWD and tries to change to this new directory.

The **cd** command may not be executed by **rksh**.

command [-p] [command_name] [argument ...]

command [-v –V] command_name

The **command** utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The $-\mathbf{p}$ flag performs the command search using a default value for **PATH** that is guaranteed to find all of the standard utilities. The $-\mathbf{v}$ flag writes a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment, to invoke *command_name*. The $-\mathbf{V}$ flag writes a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment.

echo [arg ...]

See echo(1) for usage and description.

† eval [*arg* . . .]

The arguments are read as input to the shell and the resulting command(s) executed.

† **exec** [*arg* . . .]

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

† **exit** [*n*]

Causes the calling shell or shell script to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When **exit** occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An EOF will also cause the shell to exit except for a shell which has the **ignoreeof** option (See **set** below) turned on.

†† export [name[=value]] ...

The given *names* are marked for automatic export to the **environment** of subsequently-executed commands.

fc [-e ename] [-nlr] [first [last]]

fc -e - [old=new] [command]

In the first form, a range of commands from *first* to *last* is selected from the last **HISTSIZE** commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the –l flag is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is

invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable **FCEDIT** (default /**bin**/**ed**) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and -16 for listing. The flag -**r** reverses the order of the commands and the flag -**n** suppresses command numbers when listing. In the second form the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

fg [%job...]

This command is only on systems that support job control. Each *job* specified is brought to the foreground. Otherwise, the current job is brought into the foreground. See "**Jobs**" section above for a description of the format of *job*.

getopts optstring name [arg ...]

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a –. An option not beginning with + or – or the argument – – ends the options. *optstring* contains the letters that **getopts** recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

getopts places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in **OPTIND**. The option argument, if any, gets stored in **OPTARG**.

A leading : in *optstring* causes **getopts** to store the letter of an invalid option in **OPTARG**, and to set *name* to **?** for an unknown option and to : when a required option is missing. Otherwise, **getopts** prints an error message. The exit status is non-zero when there are no more options. See **getoptcvt**(1) for usage and description.

hash [name . . .]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The –**r** option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

jobs [-lnp] [%job ...]

Lists information about each given job; or all active jobs if *job* is omitted. The $-\mathbf{l}$ flag lists process ids in addition to the normal information. The $-\mathbf{n}$ flag displays only jobs that have stopped or exited since last notified. The $-\mathbf{p}$ flag causes only the process group to be listed. See "**Jobs**" section above and **jobs**(1) for a

description of the format of job.

kill [-sig] %job ...

kill [–sig] pid . . .

kill –l

Sends either the **TERM** (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in **signal**(5) stripped of the prefix "SIG" with the exception that **SIGCHD** is named **CHLD**). If the signal being sent is **TERM** (terminate) or **HUP** (hangup), then the job or process will be sent a **CONT** (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See **Jobs** for a description of the format of *job*. In the second form, **kill** –**l**, the signal numbers and names are listed.

let arg..

Each *arg* is a separate *arithmetic expression* to be evaluated. See the **Arithmetic Evaluation** section above, for a description of arithmetic expression evaluation.

The exit status is **0** if the value of the last expression is non-zero, and **1** otherwise.

login argument ...

Equivalent to 'exec login *argument*....' See login(1) for usage and description.

† **newgrp** [*arg* . . .]

Equivalent to **exec** /**bin/newgrp** arg

print [-Rnprsu[n]] [arg ...]

The shell output mechanism. With no flags or with flag – or – –, the arguments are printed on standard output as described by echo(1). The exit status is **0**, unless the output file is not open for writing.

- -n Suppress NEWLINE from being added to the output.
- $-\mathbf{R} \mid -\mathbf{r}$ Raw mode. Ignore the escape conventions of **echo**. The $-\mathbf{R}$ option will print all subsequent arguments and options other than $-\mathbf{n}$.
- -**p** Write the arguments to the pipe of the process spawned with | & instead of standard output.
- -**s** Write the arguments to the history file instead of standard output.
- **–u** [*n*] Specify a one digit file descriptor unit number *n* on which the output will be placed. The default is **1**.

pwd Equivalent to print -r - \$PWD print -r - \$PWD

read [-**prsu**[n]] [name?prompt] [name...]

The shell input mechanism. One line is read and is broken up into fields using the characters in **IFS** as separators. The escape character, (\), is used to remove any special meaning for the next character and for line continuation. In raw mode, $-\mathbf{r}$, the \ character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The $-\mathbf{p}$ option causes the input line to be taken from the input pipe of a process spawned by the shell using **&**. If the $-\mathbf{s}$ flag is present, the

input will be saved as a command in the history file. The flag -u can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the **exec** special command. The default value of *n* is **0**. If *name* is omitted then **REPLY** is used as the default *name*. The exit status is **0** unless the input file is not open for reading or an EOF is encountered. An EOF with the $-\mathbf{p}$ option causes cleanup for this process so that another can be spawned. If the first argument contains a ?, the remainder of this word is used as a prompt on standard error when the shell is interactive. The exit status is **0** unless an EOF is encountered.

†† readonly [name[=value]] ...

The given *names* are marked **readonly** and these names cannot be changed by subsequent assignment.

† return [n]

Causes a shell function or '.' script to return to the invoking script with the return status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the return status is that of the last command executed. If **return** is invoked while not in a function or a '.' script, then it is the same as an exit.

set [±abCefhkmnopstuvx] [±o option]... [±A name] [arg...]

The flags for this command have meaning as follows:

- Array assignment. Unset the variable *name* and assign values sequen- $-\mathbf{A}$ tially from the list arg. If +A is used, the variable name is not unset first.
- All subsequent variables that are defined are automatically exported. -a
- Causes the shell to notify the user asynchronously of background job -b completions. The following message will be written to standard error:

"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name> where the fields are as follows:

<current></current>	The character + identifies the job that would be used as a default for the fg or bg utilities; this job can also be specified using the <i>job_id</i> %+ or %%. The character – identifies the job that would become the default if the current default job were to exit; this job can also be specified using the <i>job_id</i> %–. For other jobs, this field is a space character. At most one job can be identified with + and at most one job can be identified with –. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.
<job-number></job-number>	A number that can be used to identify the process group to the wait , fg , bg , and kill utilities. Using these utilities, the job can be identified by prefixing the job

modified 13 Jun 1995

		number with %.
	<status></status>	Unspecified.
	<job-name></job-name>	Unspecified.
	When the sł the job's pro	nell notifies the user a job has been completed, it may remove ocess ID from the list of those known in the current shell exe- conment. Asynchronous notification will not be enabled by
- C		sting files from being overwritten by the shell's $>$ redirection e $> $ redirection operator will override this noclobber option idual file.
- e		nd has a non-zero exit status, execute the ERR trap, if set, and node is disabled while reading profiles.
-f	Disables file	name generation.
-h	Each comm	and becomes a tracked alias when first encountered.
- k	All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.	
- m	Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.	
-n	Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.	
-0	The followin allexport errexit bgnice emacs	ng argument can be one of the following option names: Same as – a . Same as – e . All background jobs are run at a lower priority. This is the default mode. Puts you in an emacs style in-line editor for command
		entry.
	gmacs ignoreeof	Puts you in a gmacs style in-line editor for command entry. The shell will not exit on EOF. The command exit must be used.
	keyword	Same as $-\mathbf{k}$.
	markdirs	All directory names resulting from file name generation have a trailing / appended.
	monitor	Same as – m .
	noclobber	Prevents redirection > from truncating existing files. Require > to truncate a file when turned on. Equivalent to
		-C.
	noexec	Same as – n .
	noglob nolog	Same as – f . Do not save function definitions in history file.
	norog	

modified 13 Jun 1995

1-465

		notify	Equivalent to – b .	
		nounset	Same as – u .	
		privileged verbose	Same as – p . Same as – v .	
		trackall	Same as $-\mathbf{h}$.	
		vi	Puts you in insert mode of a vi style in-line editor until you hit escape character 033 . This puts you in control mode. A return sends the line.	
		viraw xtrace	Each character is processed as it is typed in vi mode. Same as – x .	
		If no option printed.	name is supplied then the current option settings are	
	- p	Disables processing of the \$HOME/.profile file and uses the file / etc/suid_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.		
	-S	Sort the positional parameters lexicographically.		
	-t	Exit after reading and executing one command.		
	–u	Treat unset	parameters as an error when substituting.	
	- v	Print shell ir	nput lines as they are read.	
	- x	Print commands and their arguments as they are executed.		
	_	Turns off $-\mathbf{x}$ and $-\mathbf{v}$ flags and stops examining arguments for flags.		
		Do not change any of the flags; useful in setting \$1 to a value beginning with –. If no arguments follow this flag then the positional parameters are unset.		
	Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in $-$. Unless – A is specified, the remaining arguments are positional parameters and are assigned, in order, to $1 $ $2 $ If no arguments are given then the names and values of all variables are printed on the standard output.			
† shift [<i>n</i>]			
The positional parameters from $n+1$ are renamed 1 , default <i>n</i> is 1. The parameter <i>n</i> can be any arithmetic expression that evaluates to a non- negative number less than or equal to $#$.				
stop %jobid				
stop pid		.1		
	stop stops the execution of a background job(s) by using its <i>jobid</i> , or of any process by using its <i>pid</i> . (see $ps(1)$).			
suspend		. .		
	Stops t	he execution of	of the current shell (but not if it is the login shell).	
			modified 13 Jun 1995	

test expression

Evaluate conditional expressions. See **Conditional Expressions** section above and **test**(1) for usage and description.

- † **times** Print the accumulated user and system times for the shell and for processes run from the shell.
- † trap [arg sig [sig2 ...]]

arg is a command to be read and executed when the shell receives signal(s) sig. (Note that arg is scanned once when the trap is set and once when the trap is taken.) Each sig can be given as a number or as the name of the signal. trap commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If arg is omitted or is –, then the trap(s) for each sig are reset to their original values. If arg is the null (or empty) string, then this signal is ignored by the shell and by the commands it invokes. If sig is ERR then arg will be executed whenever a command has a non-zero exit status. If *sig* is **DEBUG** then *arg* will be executed after each command. If sig is **0** or **EXIT** and the **trap** statement is executed inside the body of a function, then the command *arg* is executed after the function completes. If sig is 0 or EXIT for a trap set outside any function then the command arg is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number. If action is -, the shell will reset each **condition** to the default value. If *action* is null ("), the shell will ignore each specified *condition* if it arises. Otherwise, the argument *action* will be read and executed by the shell when one of the corresponding conditions arises. The action of the trap will override a previous action (either default action or one explicitly set). The value of \$? after the trap action completes will be the value it had before the trap was invoked.

The condition can be **EXIT**, **0** (equivalent to **EXIT**) or a signal specified using a symbolic name, without the **SIG** prefix, for example, **HUP**, **INT**, **QUIT**, **TERM**.

The environment in which the shell executes a trap on **EXIT** will be identical to the environment immediately after the last command executed before the trap on **EXIT** was taken.

Each time the trap is invoked, the **action** argument will be processed in a manner equivalent to:

eval "\$action"

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps will remain in place for a given shell until explicitly changed with another **trap** command.

When a subshell is entered, traps are set to the default actions. This does not imply that the **trap** command cannot be used within the subshell **trap** command cannot be used within the subshell to set new traps.

The **trap** command with no arguments will write to standard output a list of commands associated with each condition. The format is:

trap --- %s %s ... <action>, <condition>

The shell will format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

save_traps=\$(trap)

eval "\$save_traps"

If the trap name or number is invalid, a non-zero exit status will be returned; otherwise, **0** will be returned. For both interactive and non-interactive shells, invalid signal names or numbers will not be considered a syntax error and will not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on **CHLD** won't be executed until the foreground job terminates.

type name ...

For each *name*, indicate how it would be interpreted if used as a command name.

†† typeset [±HLRZfilrtux[n]] [name[=value]] ...

Sets attributes and values for shell variables and functions. When **typeset** is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and *type* are restored when the function completes. The following list of attributes may be specified:

- **-H** This flag provides UNIX to host-name file mapping on non-UNIX machines.
- -L Left justify and remove leading blanks from *value*. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the $-\mathbf{Z}$ flag is also set. The $-\mathbf{R}$ flag is turned off.
- $-\mathbf{R}$ Right justify and fill with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The $-\mathbf{L}$ flag is turned off.
- -Z Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.
- -f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced.

The flag -x allows the function definition to remain in effect across shell procedures invoked by name.

- -i Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.
- -I All upper-case characters are converted to lower-case. The upper-case flag, -**u** is turned off.
- -**r** The given *names* are marked **readonly** and these names cannot be changed by subsequent assignment.
- -t Tags the variables. Tags are user definable and have no special meaning to the shell.
- -u All lower-case characters are converted to upper-case characters. The lower-case flag, –l is turned off.
- -x The given *names* are marked for automatic export to the **environment** of subsequently-executed commands.

The -i attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than – causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than – keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

ulimit [-HSacdfnstv] [limit]

Set or display a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value **unlimited**. The **H** and **S** flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the **H** or **S** options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless **H** is specified. When more that one resource is specified, then the limit name and unit is printed before the value.

- -**a** Lists all of the current resource limits.
- -c The number of 512-byte blocks on the size of core dumps.
- -d The number of K-bytes on the size of the data area.
- -f The number of 512-byte blocks on files written by child processes (files of any size may be read).
- -**n** The number of file descriptors plus 1.
- -s The number of K-bytes on the size of the stack area.
- -t The number of seconds to be used by each process.
- -v The number of K-bytes for virtual memory.

If no option is given, –**f** is assumed.

umask	[-S]	mask
amasin		masn

The user file-creation mask is set to *mask* (see **umask**(2)). *mask* can either be an octal number or a symbolic value as described in **chmod**(1). If a symbolic value is given, the new **umask** value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed. The -S flag produces symbolic output.

The *alias*es given by the list of *names* are removed from the *alias* list.

unset [–f] name . . .

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. **readonly** variables cannot be unset. If the –**f**, flag is set, then the names refer to *function* names. Unsetting **ERRNO**, **LINENO**, **MAIL-CHECK**, **OPTARG**, **OPTIND**, **RANDOM**, **SECONDS**, **TMOUT**, and _ removes their special meaning even if they are subsequently assigned to.

† wait [job]

Wait for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See **Jobs** for a description of the format of *job*.

whence [–pv] name . . .

For each *name*, indicate how it would be interpreted if used as a command name.

The –v flag produces a more verbose report.

The $-\mathbf{p}$ flag does a path search for *name* even if name is an alias, a function, or a reserved word.

Invocation If the shell is invoked by exec(2), and the first character of argument zero (**\$0**) is –, then the shell is assumed to be a **login** shell and commands are read from /etc/profile and then from either .profile in the current directory or **\$HOME/.profile**, if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable ENV if the file exists. If the –**s** flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any **setuid** and **setgid** settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a builtin command or function. Commands are then read as described below; the following flags are interpreted by the shell when it is invoked:

-c string If the -c flag is present then commands are read from string.

- -s If the -s flag is present or if no arguments remain then commands are read from the standard input. Shell output, except for the output of the Special Commands listed above, is written to file descriptor 2.
- -i If the -i flag is present or if the shell input and output are attached to a terminal (as told by ioctl(2)) then this shell is *interactive*. In this case TERM is ignored (so that kill 0 does not kill an interactive shell) and INTR is caught

and ignored (so that **wait** is interruptible). In all cases, QUIT is ignored by the shell.

-**r** If the -**r** flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the **set** command above.

rksh Onlyrksh is used to set up login names and execution environments whose capabilities are
more controlled than those of the standard shell. The actions of **rksh** are identical to
those of **ksh**, except that the following are disallowed:

- changing directory (see cd(1))
- setting the value of SHELL, ENV, or PATH
- specifying path or command names containing /
- redirecting output (>, > |, <>, and >>)
- changing group (see **newgrp**(1)).

The restrictions above are enforced after **.profile** and the **ENV** files are interpreted.

When a command to be executed is found to be a shell procedure, **rksh** invokes **ksh** to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the **.profile** has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, /**usr**/**rbin**) that can be safely invoked by **rksh**.

ERRORS Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the **exit** command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets ([]) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility will cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

	Error	Special Built-in		
	Shell language syntax error	will exit	will exit	
	Utility syntax error (option or operand error)	will exit	will not exit	
	Redirection error	will exit	will not exit	
	Variable assignment error	will exit	will not exit will exit	
	Expansion error Command not found	will exit n∕a	may exit	
	Dot script not found	will exit	n/a	
	An expansion error is one that occurs when the shell expansions are carried out (fee example, \${x!y} , because ! is not a valid operator); an implementation may treat the syntax errors if it is able to detect them during tokenization, rather than during existen.			nese as
	If any of the errors shown as "will (may) exit" occur in a subshell, the subshell will (may exit with a non-zero status, but the script containing the subshell will not exit because of the error.			
	In all of the cases shown in the table, an interact to standard error without exiting.	ctive shell will wr	ite a diagnostic m	essage
EXIT STATUS	Each command has an exit status that can influence the behavior of other shell com- mands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.			
	If a command is not found, the exit status will it is not an executable utility, the exit status wi without using the shell should use these exit st	ll be 126 . Applica	tions that invoke	utilities
	If a command fails during word expansion or than zero.	redirection, its exi	it status will be gr	eater
	When reporting the exit status with the special eight bits of exit status available. The exit statu received a signal will be reported as greater th	us of a command		
FILES	/etc/profile /etc/suid_profile \$HOME/.profile /tmp/sh* /dev/null

	Morris I. Bolsky and David G. Korn, <i>The KornS</i> Prentice Hall, 1989.	Shell Command and	Programming Lan	iguage,

NOTES If a command which is a *tracked alias* is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to **exec** the original command. Use the **-t** option of the **alias** command to correct this situation.

Some very old shell scripts contain a ^ as a synonym for the pipe character | .

Using the **fc** built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command . *file* reads the whole file before any commands are executed. Therefore, **alias** and **unalias** commands in the file will not apply to any functions defined in the file.

NAME	ksrvtgt – fetch and store Kerberos ticket-granting ticket using a service key			
SYNOPSIS	/usr/bin/ksrvtgt name instance [[realm] srvtab]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	ksrvtgt retrieves a ticket-granting ticket with a lifetime of five minutes for the principal <i>name.instance@realm</i> (or <i>name.instance@localrealm</i> if <i>realm</i> is not supplied on the command line), decrypts the response using the service key found in the file <i>srvtab</i> (or in /etc/srvtab if <i>srvtab</i> is not specified on the command line), and stores the ticket in the standard ticket cache.			
	This command is intended primarily for use in shell scripts and other batch-type facili- ties.			
DIAGNOSTICS	Generic kerberos failure (kfailure) can indicate a whole range of problems, the most common of which is the inability to read the service key file.			
FILES	/etc/krb.confto get the name of the local realm./tmp/tktuidThe default ticket file./etc/srvtabThe default service key file.			
SEE ALSO	kdestroy(1), kerberos(1), kinit(1), klist(1)			

modified 14 Sep 1992

NAME	last – display login and logout information about users and terminals			
SYNOPSIS	last [– n number –number] [– f filename] [name tty]			
AVAILABILITY	SUNWesu			
DESCRIPTION	The last command looks in the / var/adm/wtmpx file, which records all logins and logouts, for information about a user, a terminal, or any group of users and terminals. Arguments specify names of users or terminals of interest. If multiple arguments are given, the information applicable to any of the arguments is printed. For example, last root console lists all of root's sessions, as well as all sessions on the console terminal. last displays the session of the specified users and terminals, most recent first, indicating the times at which the session began, the duration of the session, and the terminal on which the session took place. last also indicates whether the session is continuing or was cut short by a reboot.			
	The pseudo-user rebo	oot logs in when the system reboots. Thus,		
	last reboot			
	will give an indication	n of mean time between reboots.		
	last with no argumen	ts displays a record of all logins and logouts, in reverse order.		
	If last is interrupted, it indicates how far the search has progressed in / var /a If interrupted with a quit signal (generated by a CTRL–\), last indicates how search has progressed, and then continues the search.			
OPTIONS	–n number –number	Limit the number of entries displayed to that specified by <i>number</i> . These options are identical; the $-number$ option is provided as a transition tool only and will be removed in future releases.		
	-f filename	Use <i>filename</i> as the name of the accounting file instead of /var/adm/wtmpx.		
ENVIRONMENT	Date and time format is based on locale specified by the LC_ALL, LC_TIME, or LANG environments, in that order of priority.			
FILES	/var/adm/wtmpx	accounting file		
SEE ALSO	utmp(4)			

NAME	lastcomm – display the last commands executed, in reverse order		
SYNOPSIS	lastcomm [command-name] [user-name] [terminal-name]		
AVAILABILITY	SUNWesu		
DESCRIPTION	The lastcomm command gives information on previously executed commands. lastcomm with no arguments displays information about all the commands recorded during the current accounting file's lifetime. If called with arguments, lastcomm only displays accounting entries with a matching <i>command-name</i> , <i>user-name</i> , or <i>terminal-name</i> . If <i>terminal-name</i> is `´ there was no controlling TTY for the process. The process was probably executed during boot time. If <i>terminal-name</i> is `??´, the controlling TTY could		
	not be decoded into a printable name.		
EXAMPLES	The command: example% lastcomm a.out root term/01		
	produces a listing of all the executions of commands named a.out , by user root while using the terminal term/01 .		
	The command: example% lastcomm root		
	produces a listing of all the commands executed by user root .		
	For each process entry, lastcomm displays the following items of information:		
	• The command name under which the process was called.		
	• One or more flags indicating special information about the process. The flags have the following meanings:		
	F The process performed a fork but not an exec .		
	S The process ran as a set-user-id program.		
	• The name of the user who ran the process.		
	• The terminal which the user was logged in on at the time (if applicable).		
	• The amount of CPU time used by the process (in seconds).		
	• The date and time the process exited.

NAME	ld – link editor for object files		
SYNOPSIS	/usr/ccs/bin/ld [-a -r] [-b] [-G] [-i] [-m] [-s] [-t] [-V] [-B dynamic static] [-B local] [-B reduce] [-B symbolic] [-d y n] [-D token] [-e epsym] [-F name] [-f name] [-h name] [-I name] [-L path] [-l x] [-M mapfile] [-o outfile] [-Q y n] [-R path] [-u symname] [-Y P, dirlist] [-z defs nodefs] [-z muldefs] [-z noversion] [-z text] filename		
AVAILABILITY	SUNWtoo		
DESCRIPTION	The ld command combines relocatable object files, performs relocation, and resolves external symbols. ld operates in two modes, static or dynamic, as governed by the $-\mathbf{d}$ option. In static mode, $-\mathbf{dn}$, relocatable object files given as arguments are combined to produce an executable object file; if the $-\mathbf{r}$ option is specified, relocatable object files are combined to produce one relocatable object file. In dynamic mode, $-\mathbf{dy}$, the default, relocatable object files given as arguments are combined to produce an executable object file that will be linked at execution with any shared object files given as arguments; if the $-\mathbf{G}$ option is specified, relocatable object files are combined to produce a shared object. In all cases, the output of ld is left in a.out by default.		
	If any argument is a library, it is searched exactly once at the point it is encountered in the argument list. The library may be either a relocatable archive or a shared object. For an archive library, only those routines defining an unresolved external reference are loaded. The archive library symbol table (see ar (4)) is searched sequentially with as many passes as are necessary to resolve external references that can be satisfied by library members. Thus, the ordering of members in the library is functionally unimportant, unless there exist multiple library members defining the same external symbol. A shared object consists of a single entity all of whose references must be resolved within the executable being built or within other shared objects with which it is linked.		
OPTIONS	 -a In static mode only, produce an executable object file; give errors for undefined references. This is the default behavior for static modea may not be used with the -r option. 		
	 -r Combine relocatable object files to produce one relocatable object file. ld will not complain about unresolved references. This option cannot be used in dynamic mode or with -a. 		
	 -b In dynamic mode only, when creating an executable, do not do special processing for relocations that reference symbols in shared objects. Without the -b option, the link editor creates special position-independent relocations for references to functions defined in shared objects and arranges for data objects defined in shared objects to be copied into the memory image of the executable by the runtime linker. With the -b option, the output code may be more efficient, but it will be less sharable. 		

1-477

-G	In dynamic mode only, produce a shared object. Undefined symbols are allowed.
— i	Ignore LD_LIBRARY_PATH setting. This option is useful when an LD_LIBRARY_PATH setting is in effect to influence the runtime library search, which would interfere with the link editing being performed.
- m	Produce a memory map or listing of the input/output sections, together with any non-fatal multiply defined symbols, on the standard output.
S	Strip symbolic information from the output file. Any debugging informa- tion, that is <i>.debug</i> , <i>.line</i> , and <i>.stab</i> sections, and their associated relocation entries will be removed. Except for relocatable files or shared objects, the symbol table and string table sections will also be removed from the output object file.
-t	Turn off the warning about multiply defined symbols that are not the same size.
$-\mathbf{V}$	Output a message giving information about the version of ld being used.
-B dynamic	
	Options governing library inclusion. – B dynamic is valid in dynamic mode only. These options may be specified any number of times on the command line as toggles: if the – B static option is given, no shared objects will be accepted until – B dynamic is seen. See also the – l option.
–B local	Cause any global symbols, not assigned to a version definition, to be reduced to local. Version definitions can be supplied via a <i>mapfile</i> , and indi- cate the global symbols that should remain visible in the generated object. This option achieves the same symbol reduction as the <i>auto-reduction</i> direc- tive available as part of a <i>mapfile</i> version definition, and may be useful when combining versioned and non-versioned relocatable objects.
–B reduce	When generating a relocatable object, cause the reduction of symbolic infor- mation as defined by any version definitions. Version definitions can be supplied via a <i>mapfile</i> , and indicate the global symbols that should remain visible in the generated object. By default, when generating a relocatable object, version definitions are only recorded in the output image. The actual reduction of symbolic information will be carried out when the object itself is used in the construction of a dynamic executable or shared object. When creating a dynamic executable or shared object, this option is applied automatically.
–B symbolic	In dynamic mode only, when building a shared object, bind references to global symbols to their definitions within the object, if definitions are available. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available, so that definitions of the same symbol in an executable or other shared objects can override the object's own definition. Id will issue warnings for undefined symbols unless – z defs overrides.

– D token,tok	en,
	Print debugging information, as specified by each <i>token</i> , to the standard error. The special token <i>help</i> indicates the full list of tokens available.
-e epsym	Set the entry point address for the output file to be that of the symbol <i>epsym</i> .
-F name	Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a "filter" on the symbol table of the shared object specified by <i>name</i> .
−f name	Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an "auxiliary filter" on the symbol table of the shared object specified by <i>name</i> .
−h name	In dynamic mode only, when building a shared object, record <i>name</i> in the object's dynamic section. <i>name</i> will be recorded in executables that are linked with this object rather than the object's UNIX System file name. Accordingly, <i>name</i> will be used by the runtime linker as the name of the shared object to search for at runtime.
-I name	When building an executable, use <i>name</i> as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter; in dynamic mode, the default is the name of the runtime linker, /usr/lib/ld.so.1. Either case may be overridden by –Iname. exec will load this interpreter when it loads the a.out and will pass control to the interpreter rather than to the a.out directly.
–L path	Add <i>path</i> to the library search directories. Id searches for libraries first in any directories specified by the – L options, and then in the standard direc- tories. This option is useful only if it precedes the – I options to which it applies on the command line. The environment variable LD_LIBRARY_PATH may be used to supplement the library search path (see LD_LIBRARY_PATH below).
- l x	Search a library libx.so or libx.a , the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the –B static option is in effect, ld searches each directory specified in the library search path for a file libx.so or libx.a . The directory search stops at the first direc- tory containing either. ld chooses the file ending in .so if –lx expands to two files whose names are of the form libx.so and libx.a . If no libx.so is found, then ld accepts libx.a . In static mode, or when the –B static option is in effect, ld selects only the file ending in .a . A library is searched when its name is encountered, so the placement of –l is significant.
- M mapfile	Read <i>mapfile</i> as a text file of directives to ld . This option may be specified multiple times. If <i>mapfile</i> is a directory then all regular files (as defined by stat (2)) within the directory will be processed. See <i>Linker and Libraries Guide</i> for description of mapfiles.
–o outfile	Produce an output object file named <i>outfile</i> . The name of the default object file is a.out .

1-479

	$-\mathbf{Q} \mathbf{y} \mid \mathbf{n}$	Under $-\mathbf{Q}\mathbf{y}$, an ident string is added to the <i>.comment</i> section of the output file to identify the version of the link editor used to create the file. This will result in multiple ld idents when there have been multiple linking steps, such as when using ld $-\mathbf{r}$. This is identical with the default action of the cc command. $-\mathbf{Q}\mathbf{n}$ suppresses version identification.
	- R path	A colon-separated list of directories used to specify library search direc- tories to the runtime linker. If present and not null, it is recorded in the out- put object file and passed to the runtime linker. Multiple instances of this option are concatenated together with each <i>path</i> separated by a colon.
	– u symname	Enter <i>symname</i> as an undefined symbol in the symbol table. This is useful for loading entirely from an archive library, since initially the symbol table is empty and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant; it must be placed before the library that will define the symbol.
	-Y P,dirlist	Change the default directories used for finding libraries. <i>dirlist</i> is a colon-separated path list.
	–z defs	Force a fatal error if any undefined symbols remain at the end of the link. This is the default when building an executable. It is also useful when building a shared object to assure that the object is self-contained, that is, that all its symbolic references are resolved internally.
	–z muldefs	Allows multiple symbol definitions. By default, multiple symbol definitions occurring between relocatable objects will result in a fatal error condition. This option suppresses the error condition, and allows the first symbol definition to be taken.
	–z nodefs	Allow undefined symbols. This is the default when building a shared object. When used with executables, the behavior of references to such "undefined symbols" is unspecified.
	-z noversior	1
		Do not record any versioning sections. Any version sections or associated <i>.dynamic</i> section entries will not be generated in the output image.
	−z text	In dynamic mode only, force a fatal error if any relocations against non- writable, allocatable sections remain.
ENVIRONMENT	LD_LIBRARY	(_PATH
	A lis Mult	t of directories in which to search for libraries specified with the -1 option. tiple directories are separated by a colon. In the most general case, it will ain two directory lists separated by a semicolon: <i>dirlist1;dirlist2</i>

- If **ld** is called with any number of occurrences of -**L**, as in: **ld** ... -**L***path*1 ... -**L***path*n ...
- then the search path ordering is: dirlist1 path1 ... pathn dirlist2 LIBPATH

When the list of directories does not contain a semicolon, it is interpreted as *dir*-*list2*.

LD_LIBRARY_PATH is also used to specify library search directories to the runtime linker. That is, if **LD_LIBRARY_PATH** exists in the environment, the runtime linker will search the directories named in it, before its default directory, for shared objects to be linked with the program at execution.

Note: When running a set-user-ID or set-group-ID program, the runtime linker will only search for libraries in any full pathname specified within the executable as a result of a runpath being specified when the executable was constructed, or in /**usr/lib**. Any library dependencies specified as relative pathnames will be silently ignored.

LD_OPTIONS

A default set of options to **ld**. **LD_OPTIONS** is interpreted by **ld** just as though its value had been placed on the command line, immediately following the name used to invoke **ld**, as in:

ld \$LD_OPTIONS ... other-arguments ...

LD_PRELOAD

A list of shared objects that are to be interpreted by the runtime linker. The specified shared objects are linked in after the program being executed and before any other shared objects that the program references.

Note: When running a set-user-ID or set-group-ID program, this option has some restrictions. The runtime linker will only search for these shared objects in any full pathname specified within the executable as a result of a runpath being specified when the executable was constructed, or in /usr/lib. Any shared object specified as a relative, or full pathname, will be silently ignored.

LD_RUN_PATH

An alternative mechanism for specifying a runpath to the link editor (see -**R** option). If both LD_RUN_PATH and the -**R** option are specified, -**R** supersedes.

LD_DEBUG

Provide a list of tokens that will cause the runtime linker to print debugging information to the standard error. The special token *help* indicates the full list of tokens available. The environment variable **LD_DEBUG_OUTPUT** may also be supplied to specify a file to which the debugging information is sent. The filename will be suffixed with the process id of the application generating the debugging information.

LD_PROFILE

A shared object that will be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file

modified 16 Nov 1994

ld(1)	User Commands Sur	nOS 5.5	
	 is the name of the shared object being profiled with a `.profile ´ extension. By default this buffer is placed under /var/tmp. The environment variable LD_PROFILE_OUTPUT may also be supplied to indicate an alternative directory in which to place the profiling buffer. This buffer contains profil(2) and call count information similar to the <i>gmon.out</i> information generated by programs that have been linked with the -xpg option of cc. Any applications that use the named shared object and run while this environment variable is set, will accumulate data in the profile buffer. The profile buffer information may be examined using gprof(1). Note that environment variable-names beginning with the characters `LD_´ are reserved for possible future enhancements to ld.

NAME	ldd – list dynamic dependencies of executable files or shared objects		
SYNOPSIS	ldd $[-d \mid -r] [-f] [-s] [-v] filename$		
AVAILABILITY	SUNWtoo		
DESCRIPTION	Idd lists the dynamic dependencies of executable files or shared objects. If <i>filename</i> is an executable file, Idd lists the pathnames of all shared objects that would be loaded as a result of executing <i>filename</i> .		
	If <i>filename</i> is a shared object, ldd lists the pathnames of all shared objects that would be loaded as a result of loading <i>filename</i> . ldd expects shared objects to have execute permission, and if this is not the case will issue a warning before attempting to process the file.		
	ldd processes its input one file at a time. For each input file ldd performs one of the following:		
	 Lists the object dependencies if they exist. Succeeds quietly if dependencies do not exit. Prints an error message if processing fails. 		
OPTIONS	Idd can also check the compatibility of <i>filename</i> with the shared objects it uses. The fol- lowing options indicate to Idd to print warnings for any unresolved symbol references that would occur if <i>filename</i> were executed.		
	-d Check references to data objects.		
	-r Check references to both data objects and functions.		
	Only one of the above options may be given during any single invocation of ldd .		
	 -f Force the checking of an insecure executable file. By default, when ldd is invoked by the super-user it will not process an insecure executable. An executable is determined to be insecure if the interpretor it specifies does not reside under /usr/lib, or /etc/lib, or if the interpretor cannot be determined. 		
	-s Displays the search path used to locate shared object dependencies.		
	 -v Displays all dependency relationships incurred when processing <i>filename</i>. This options also displays any dependency version requirements (see pvs(1)). 		
	A super-user should use the –f option only if the executable being examined is known to be trustworthy, as use of –f while super-user on an untrustworthy executable may compromise system security. If it is unknown if the executable being examined is trustworthy, it is suggested that a super-user temporarily become a regular user, and invoke ldd as that regular user. Untrustworthy objects can be safely examined with dump (1), and with adb (1) as long as the :r subcommand is not used. In addition, a non- super-user can use the :r subcommand of adb , and can also use truss (1), to examine an untrustworthy executable without too much risk of compromise. To minimize risk, it is recommended that the user id of "nobody" be used when using ldd , adb :r , or truss on an untrustworthy executable.

User Commands

NAME	lex – gener	rate programs for lexical tasks	
SYNOPSIS	$lex [-cntv] [-e -w] [-V - Q [y n]] [file] \dots$		
DESCRIPTION	The lex utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to yacc . The C programs are generated from lex source code and conform to the ISO C standard. Usually, the lex utility writes the program it generates to the file lex.yy.c ; the state of this file is unspecified if lex exits with a non-zero exit status. See EXTENDED DESCRIPTION for a complete description of the lex input language.		
OPTIONS	The follow	ing options are supported:	
	- c	Indicate C-language action (default option).	
	- e	Generate a program that can handle EUC characters (cannot be used with the –w option). yytext[] is of type unsigned char[].	
	-n	Suppress the summary of statistics usually written with the $-v$ option. If no table sizes are specified in the lex source code and the $-v$ option is not specified, then $-n$ is implied.	
	-t	Write the resulting program to standard output instead of lex.yy.c .	
	$-\mathbf{v}$	Write a summary of lex statistics to the standard error. (See the discussion of lex table sizes under the heading Definitions in lex .) If table sizes are specified in the lex source code, and if the $-\mathbf{n}$ option is not specified, the $-\mathbf{v}$ option may be enabled.	
	$-\mathbf{W}$	Generate a program that can handle EUC characters (cannot be used with the –e option). Unlike the –e option, yytext[] is of type wchar_t[].	
	$-\mathbf{V}$	Print out version information on standard error.	
	$-\mathbf{Q}[\mathbf{y} \mathbf{n}]$	Print out version information to output file lex.yy.c by using -Qy . The -Qn option does not print out version information and is the default.	
OPERANDS	The follow	ring operand is supported:	
	file A b	a pathname of an input file. If more than one such <i>file</i> is specified, all files will e concatenated to produce a single lex program. If no <i>file</i> operands are pecified, or if a <i>file</i> operand is –, the standard input will be used.	
OUTPUT Stdout	If the –t op standard o	ption is specified, the text file of C source code output of lex will be written to putput.

These statistics may also sizes are specified with a % operator in the Definitions in I EXTENDED DESCRIPTION), as long as the -n option is not specified with a statement of the state	be generated if table ex section (see
Output Files	A text file containing C source code will be written to lex.yy.c , or to if the –t option is present.	the standard output
EXTENDED DESCRIPTION	Each input file contains lex source code, which is a table of regular corresponding actions in the form of C program fragments.	expressions with
	When lex.yy.c is compiled and linked with the lex library (using the c89 or cc), the resulting program reads character input from the stations it into strings that match the given expressions.	
	When an expression is matched, these actions will occur:	
	• The input string that was matched is left in <i>yytext</i> as a null-ter is either an external character array or a pointer to a character in Definitions in lex , the type can be explicitly selected using % pointer declarations, but the default is % array .	string. As explained
	• The external int <i>yyleng</i> is set to the length of the matching strip	ng.
	• The expression's corresponding program fragment, or action,	is executed.
	During pattern matching, lex searches the set of patterns for the sin match. Among rules that match the same number of characters, the be chosen.	
	The general format of lex source is: Definitions %% Rules %% User Subroutines	
	The first %% is required to mark the beginning of the rules (regular actions); the second %% is required only if user subroutines follow.	
	Any line in the Definitions in lex section beginning with a blank ch assumed to be a C program fragment and will be copied to the exter the lex.yy.c file. Similarly, anything in the Definitions in lex section delimiter lines containing only %{ and %} will also be copied unchar definition area of the lex.yy.c file.	rnal definition area of n included between
1-488		modified 11 Jul 1995

Any such input (beginning with a blank character or within %{ and %} delimiter lines) appearing at the beginning of the *Rules* section before any rules are specified will be written to **lex.yy.c** after the declarations of variables for the **yylex** function and before the first line of code in **yylex**. Thus, user variables local to **yylex** can be declared here, as well as application code to execute upon entry to **yylex**.

The action taken by **lex** when encountering any input beginning with a blank character or within %{ and %} delimiter lines appearing in the *Rules* section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the **yylex** function.

Definitions in lex Definitions in lex appear before the first %% delimiter. Any line in this section not contained between %{ and %} lines and not beginning with a blank character is assumed to define a **lex** substitution string. The format of these lines is:

name substitute

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string *{ name }* when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the **Definitions in lex** section, any line beginning with a % (percent sign) character and followed by an alphanumeric word beginning with either **s** or **S** defines a set of start conditions. Any line beginning with a % followed by a word beginning with either **x** or **X** defines a set of exclusive start conditions. When the generated scanner is in a %**s** state, patterns with no state specified will be also active; in a %**x** state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in **Regular expressions in lex**.

Implementations accept either of the following two mutually exclusive declarations in the **Definitions in lex** section:

%array Declare the type of *yytext* to be a null-terminated character array.

%pointer Declare the type of *yytext* to be a pointer to a null-terminated character string.

The default type of *yytext* is **char[]**. If an application refers to *yytext* outside of the scanner source file (that is, via an **extern**), the application will include the appropriate **%array** or **%pointer** declaration in the scanner source file.

lex will accept declarations in the **Definitions in lex** section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex	
-------------------------------	--

	Declaration	Description	Default		
	% p <i>n</i>	Number of positions	2500		
	% n n % a n	Number of states Number of transitions	500 2000		
	% e n	Number of parse tree nodes	1000		
	%k n	Number of packed character classes	10000		
	% o n	Size of the output array	3000		
	EUC characters from supp	ex need either the $-e$ or $-w$ option to hand plementary codesets. If neither of these o], and the generated program can handle	ptions is specified,		
	total number of <i>bytes</i> in th unput(<i>c</i>), and output(<i>c</i>) s ASCII lex . Two more vari	hen the $-e$ option is used, yytext is of the type unsigned char[] and yyleng gives the tal number of <i>bytes</i> in the matched string. With this option, the macros input() , uput(<i>c</i>) , and output(<i>c</i>) should do a byte-based I/O in the same way as with the regulat SCII lex . Two more variables are available with the $-e$ option, yywtext and yywleng , hich behave the same as yytext and yyleng would under the $-w$ option.			
	When the – w option is used, yytext is of the type wchar_t[] and yyleng gives the total number of <i>characters</i> in the matched string. If you supply your own input() , unput(<i>c</i>) , or output(<i>c</i>) macros with this option, they must return or accept EUC characters in the form of wide character (wchar_t). This allows a different interface between your program and the lex internals, to expedite some programs.

1-490

Regular Expressions in lex	The lex utility supports the set of Extended Regular Expressions (ERE's) described on regex (5) with the following additions and exceptions to the syntax:
	Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, " \ 01""1" represents a single string: the octal value 1 followed by the character 1.
	<state>r</state>
	< <i>state1, state2,>r</i> The regular expression <i>r</i> will be matched only when the program is in one of the start conditions indicated by <i>state, state1</i> , and so forth; for more information see Actions in lex (As an exception to the typographical conventions of the rest of
	this document, in this case <i><state></state></i> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition is recognized as such only at the beginning of a regular expression.
	r/x The regular expression <i>r</i> will be matched only if it is followed by an occurrence of regular expression <i>x</i> . The token returned in <i>yytext</i> will only match <i>r</i> . If the trailing portion of <i>r</i> matches the beginning of <i>x</i> , the result is unspecified. The <i>r</i> expression cannot include further trailing context or the \$ (match-end-of-line) operator; <i>x</i> cannot include the ^ (match-beginning-of-line) operator, nor trailing context, nor the \$ operator. That is, only one occurrence of trailing context is allowed in a lex regular expression, and the ^ operator only can be used at the beginning of such an expression.
	<i>{name}</i> When <i>name</i> is one of the substitution symbols from the <i>Definitions</i> section, the string, including the enclosing braces, will be replaced by the <i>substitute</i> value. The <i>substitute</i> value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if <i>{name}</i> occurs within a bracket expression or within double-quotes.
	Within an ERE, a backslash character $(\ \ \mathbf{a}, \mathbf{b}, \mathbf{f}, \mathbf{n}, \mathbf{r}, \mathbf{v})$ is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.
	A literal newline character cannot occur within an ERE; the escape sequence $\ n$ can be used to represent a newline character. A newline character cannot be matched by a period operator.

Escape Sequence	Description	Meaning
\ digits	A backslash character fol- lowed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encod ing is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple concatenated escape sequences of this type, including the leading \ for each byte.
\ x digits	A backslash character fol- lowed by the longest sequence of hexadecimal- digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encod ing is represented by the hexadecimal integer.
\ <i>c</i>	A backslash character fol- lowed by any character not described in this table. (\setminus , $\setminus a$, $\setminus b$, $\setminus f$, $\setminus n$, $\setminus r$, $\setminus t$, $\setminus v$).	The character <i>c</i> , unchanged

Escape Sequences in lex

The order of precedence given to extended regular expressions for **lex** is as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

ERE Precedence	in	lex
----------------	----	-----

collation-related bracket symbols escaped characters	[= =] [: :] [] \ <special character=""></special>
bracket expression	
quoting	""
grouping	()
definition	{name}
single-character RE duplication	* + ?
concatenation	
interval expression	{ <i>m</i> , <i>n</i> }
alternation	

The ERE anchoring operators (^ and \$) do not appear in the table. With **lex** regular expressions, these operators are restricted in their use: the ^ operator can only be used at the beginning of an entire regular expression, and the \$ operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern (^abc) | (def\$) is undefined; it can instead be written as two separate rules, one with the regular expression **^abc** and one with **def\$**, which share a common action via the special | action (see below). If the pattern were written **^abc** | **def\$**, it would match either of **abc** or **def** on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical **lex** implementations. An example of embedded anchoring would be for patterns such as (^)foo(\$) to match **foo** when it exists as a complete word. This functionality can be obtained using existing **lex** features:

^foo/[$\ n$] | " foo"/[$\ n$] /* found foo as a separate word */

Note also that \$ is a form of trailing context (it is equivalent to $/\n)$ and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator / can be used as an ordinary character if presented within double-quotes, "/"; preceded by a backslash, \/; or within a bracket expression, [/]. The start-condition < and > operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between **lex** regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form r/x, the string matching r is always returned; confusion may arise when the beginning of x matches the trailing portion of r. For example, given the regular expression a*b/cc and the input **aaabcc**, *yytext* would contain the string **aaab** on this match. But given the regular expression x*/xy and the input **xxxy**, the token **xxx**, not **xx**, is returned by some implementations because **xxx** matches x*.

In the rule ab*/bc, the b* at the end of r will extend r's match into the beginning of the trailing context, so the result is unspecified. If this rule were ab/bc, however, the rule matches the text **ab** when it is followed by the text **bc**. In this latter case, the matching of r cannot extend into the beginning of x, so the result is specified.

Actions in lex The action to be taken when an *ERE* is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement ; is a valid action; any string in the **lex.yy.c** input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action **lex** takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

ERE <one or more blanks> { program statement program statement }

The default action when a string in the input to a **lex.yy.c** program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by **lex** is to read the input and copy it to the output, a minimal **lex** source program that has just %% generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

T

| ECHO; REJECT; BEGIN

- The action | means that the action for the next rule is the action for this rule. Unlike the other three actions, | cannot be enclosed in braces or be semicolon-terminated; it must be specified alone, with no other actions.
- **ECHO**; Write the contents of the string *yytext* on the output.
- REJECT; Usually only a single expression is matched by a given string in the input. REJECT means "continue to the next expression that matches the current input," and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions xyz and xy and the input xyz, usually only the regular expression xyz would match. The next attempted match would start after z. If the last action in the xyz rule is REJECT, both this rule and the xy rule would be executed. The REJECT action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a goto to another part of yylex. The use of REJECT may result in somewhat larger and slower scanners.

BEGIN The action: BEGIN newstate:

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the **Definitions in lex** section, the results are unspecified. The initial state is indicated by the digit **0**

or the token INITIAL.

The functions or macros described below are accessible to user code included in the **lex** input. It is unspecified whether they appear in the C code output of **lex**, or are accessible only through the -l l operand to **c89** or **cc** (the **lex** library).

int yylex(void)

Performs lexical analysis on the input; this is the primary function generated by the **lex** utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.

int yymore(void)

When called, indicates that when the next input string is recognized, it is to be appended to the current value of *yytext* rather than replacing it; the value in *yyleng* is adjusted accordingly.

int yyless(int n)

Retains *n* initial characters in *yytext*, NUL-terminated, and treats the remaining characters as if they had not been read; the value in *yyleng* is adjusted accordingly.

int input(void)

Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer *yyin*, although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of *yyin* is undefined. The character read is removed from the input stream of the scanner without any processing by the scanner.

int unput(int c)

Returns the character *c* to the input; *yytext* and *yyleng* are undefined until the next expression is matched. The result of using *unput* for more characters than have been input is unspecified.

The following functions appear only in the **lex** library accessible through the -l l operand; they can therefore be redefined by a portable application:

int yywrap(void)

Called by **yylex** at end-of-file; the default **yywrap** always will return 1. If the application requires **yylex** to continue processing with another source of input, then the application can include a function **yywrap**, which associates another file with the external variable **FILE** **yyin* and will return a value of zero.

int main(int argc, char *argv[])

Calls **yylex** to perform lexical analysis, then exits. The user code can contain **main** to perform application-specific operations, calling **yylex** as applicable.

The reason for breaking these functions into two lists is that only those functions in **libl.a** can be reliably redefined by a portable application.

Except for **input**, **unput** and **main**, all external and static names generated by **lex** begin with the prefix **yy** or **YY**.

USAGE

GE Portable applications are warned that in the **Rules in lex** section, an *ERE* without an action is not acceptable, but need not be detected as erroneous by **lex**. This may result in compilation or run-time errors.

The purpose of **input** is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The **lex** utility is not fully internationalized in its treatment of regular expressions in the **lex** source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the **lex** source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current **lex** technology. Furthermore, the very nature of the lexical analyzers produced by **lex** must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

EXAMPLES	The following is an example of a lex program that implements a rudimentary scanner for a Pascal-like syntax:		
	%{ /* need this for the call to atof() below */		
	#include <math.h></math.h>		
	/* need this for printf(), fopen() and stdin below */		
	#include <stdio.h> %}</stdio.h>		
	DIGIT [0-9] ID [a-z][a-z0-9]*		
	%%		
	{DIGIT}+	{	
		printf("An integer: %s (%d)\n", yytext,	
		atoi(yytext)); }	
	{DIGIT}+"."{DIGIT}*	{	
		printf("A float: %s (%g)\n", yytext,	
		atof(yytext));	
	if then begin end procedure function {		
		printf("A keyword: %s\n", yytext); }	
	{ID}	printf("An identifier: %s\n", yytext);	
	"+" "-" "*" "/"	printf("An operator: %s\n", yytext);	
	"{"[^}\n]*"}"	/* eat up one-line comments */	
	[\t\n]+	/* eat up white space */	
		printf("Unrecognized character: %s\n", yytext);	
	%%		
	int main(int argc, char *argv[])		
	{		
		++argv,argc; /* skip over program name */ if (argc > 0)	
		yyin = fopen(argv[0], "r");	
		else yyin = stdin;	
		yylex();	
	}		

lex(1)	User Commands SunOS	5.5
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the e cution of lex : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .	xe-
EXIT STATUS	 The following exit values are returned: 0 Successful completion. >0 An error occurred. 	
SEE ALSO	<pre>yacc(1), environ(5), regex(5)</pre>	
NOTES	If routines such as yyback() , yywrap() , and yylock() in .l (ell) files are to be extern C functions, the command line to compile a C++ program must define the EXTERN_C_ macro, for example:	_
	CC –D_EXTERN_C file	

NAME	limit, ulimit, unlimit – set or get limitations on the system resources available to the current shell and its descendents
SYNOPSIS	/usr/bin/ulimit [–f] [blocks]
sh	ulimit [-[HS] [a cdfnstv]] ulimit [-[HS]] c d f n s t v]] <i>limit</i>
csh	limit [-h] [resource [limit]] unlimit [-h] [resource]
ksh	ulimit [–HSacdfnstv] [limit]
DESCRIPTION /usr/bin/ulimit	The ulimit utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.
sh	The Bourne shell built-in function, ulimit , prints or sets hard or soft resource limits. These limits are described in getrlimit (2).
	If <i>limit</i> is not present, ulimit prints the specified limits. Any number of limits may be printed at one time. The $-a$ option prints all limits.
	If <i>limit</i> is present, ulimit sets the specified limit to <i>limit</i> . The string unlimited requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see su (1M).
	The $-\mathbf{H}$ option specifies a hard limit. The $-\mathbf{S}$ option specifies a soft limit. If neither option is specified, ulimit will set both limits and print the soft limit.
	The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.
	-c maximum core file size (in 512-byte blocks)
	-d maximum size of data segment or heap (in kbytes)
	-f maximum file size (in 512-byte blocks)
	- n maximum file descriptor plus 1
	-s maximum size of stack segment (in kbytes)
	-t maximum CPU time (in seconds)
	-v maximum size of virtual memory (in kbytes)
csh	The C-shell built-in function, limit , limits the consumption by the current process or any process it spawns, each not to exceed <i>limit</i> on the specified <i>resource</i> . If <i>limit</i> is omitted, print the current limit; if <i>resource</i> is omitted, display all limits. (Run the sysdef (1M) command to obtain the maximum possible limits for your system. The values reported are in

modified 28 Mar 1995

hexidecimal, but can be translated into decimal numbers using the **bc**(1) command).

-h Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

resource is one of:

cputime filesize	Maximum CPU seconds per process. Largest single file allowed; limited to the size of the filesystem. (see df (1M)).
datasize (heaps	ize)
stacksize coredumpsize	Maximum data size (including stack) for the process. This is the size of your virtual memory (see swap(1M)). Maximum stack size for the process. (see swap(1M)). Maximum size of a core dump (file). This limited to the size of the filesystem.
descriptors memorysize	Maximum number of file descriptors. (run sysdef()). Maximum size of virtual memory.

limit is a number, with an optional scaling factor, as follows:

n h	Hours (for cputime).
nk	<i>n</i> kilobytes. This is the default for all but cputime .
n m	<i>n</i> megabytes or minutes (for cputime).
mm:ss	Minutes and seconds (for cputime).

unlimit removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the **limit** command for the list of resource names.

-h Remove corresponding hard limits. Only the privileged user may do this.

- ksh The Korn shell built-in function, ulimit, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value unlimited. The H and S flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the H or S options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless H is specified. When more that one resource is specified, then the limit name and unit is printed before the value.
 - -**a** Lists all of the current resource limits.
 - -c The number of 512-byte blocks on the size of core dumps.
 - -d The number of K-bytes on the size of the data area.
 - **-f** The number of 512-byte blocks on files written by child processes (files of any size may be read).
 - -**n** The number of file descriptors plus 1.
 - **-s** The number of K-bytes on the size of the stack area.
 - -t The number of seconds (CPU time) to be used by each process.

modified 28 Mar 1995

	-v The number of K-bytes for virtual memory.
	If no option is given, – f is assumed.
OPTIONS	The following option is supported by ulimit :
of nons	 -f Set (or report, if no <i>blocks</i> operand is present), the file size limit in blocks. The -f option is also the default case.
OPERANDS	The following operand is supported by ulimit :
	<i>blocks</i> The number of 512-byte blocks to use as the new file size limit.
EXAMPLES /usr/bin/ulimit	To limit the stack size to 512 kilobytes: % ulimit -s 512 % ulimit -a % time(seconds) unlimited file(blocks) 100 data(kbytes) 523256 stack(kbytes) 512 coredump(blocks) 200 nofiles(descriptors) 64 memory(kbytes) unlimited
sh/ksh	To limit the number of file descriptors to 12: \$ ulimit -n 12
	\$ ulimit -atime(seconds)unlimitedfile(blocks)41943data(kbytes)523256stack(kbytes)8192coredump(blocks)200nofiles(descriptors)12vmemory(kbytes)unlimited
csh	To limit the size of a core dump file size to 0 kilobytes: % limit coredumpsize 0 % limit
	cputimeunlimitedfilesizeunlimiteddatasize523256 kbytesstacksize8192 kbytescoredumpsize0 kbytesdescriptors64memorysizeunlimitedTo remove the above limitation for the core file size:

modified 28 Mar 1995

	% unlimit coredumpsize % limit cputime unlimited filesize unlimited datasize 523256 kbytes stacksize 8192 kbytes coredumpsize unlimited descriptors 64 memorysize unlimited
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of ulimit : LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	The following exit values are returned by ulimit:0Successful completion.>0A request for a higher limit was rejected or an error occurred.

NAME	line – read one line
SYNOPSIS	line
AVAILABILITY	SUNWcsu
DESCRIPTION	The line utility copies one line (up to and including a new-line) from the standard input and writes it on the standard output. It returns an exit status of 1 on EOF and always prints at least a new-line. It is often used within shell files to read from the user's termi- nal.
EXIT STATUS	Exit status is:
	0 Successful completion
	>0 End-of-file on input.

lint(1B)	SunOS/BSD Compatibility Package Commands SunOS 5.5		
NAME	lint Congress w	nifon	
NAME	lint – C program ve	rmer	
SYNOPSIS	/usr/ucb/lint [optio	ns]	
AVAILABILITY	SUNWscpu		
DESCRIPTION	/usr/ucb/lint is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link /usr/ccs/bin/ucblint to the C program verifier. /usr/ccs/bin/ucblint is available only with the SPROcc package, whose default location is /opt/SUNWspro. /usr/ucb/lint is identical to /usr/ccs/bin/ucblint, except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The /opt/SUNWspro/man/man1/lint.1 man page is available only with the SPROcc package.		
OPTIONS	/usr/ucb/lint accepts the same options as /usr/ccs/bin/ucblint, with the following excep- tions:		wing excep-
	pr op se in	arch <i>dir</i> for included files whose names do not begin with ior to searching the usual directories. The directories for tions are searched in the order specified. The preprocess arches for #include files in the directory containing <i>source</i> directories named with –I options (if any), then / usr / ucb hally, in / usr / include .	r multiple – I sor first <i>refile</i> , and then
	/u to	dd <i>dir</i> to the list of directories searched for libraries by sr/ccs/bin/ucblint. This option is passed to /usr/ccs/bin/ ries specified with this option are searched before /usr/uc sr/lib.	
	−Y P , dir Cł	nange the default directory used for finding libraries.	
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
FILES	/usr/lint/bin/ld /usr/lib/libc /usr/ucbinclude /usr/ucblib /usr/ucblib/libucb /usr/lib/libsocket /usr/lib/libnsl /usr/lib/libelf /usr/lib/libaio	link editor C library BSD Compatibility directory for header files BSD Compatibility directory for libraries BSD Compatibility C library library containing socket routines library containing network functions library containing routines to process ELF object files library containing asynchronous I/O routines

NAME	listusers – list user login information		
SYNOPSIS	listusers [–g groups] [–l logins]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by /etc/nsswitch.conf.		
OPTIONS	-g groups Lists all user logins belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list.		
	 -l logins Lists the user login or logins specified by logins, sorted by login. Multiple logins can be specified as a comma-separated list. 		
SEE ALSO	nsswitch.conf(4)		
NOTES	A user login is one that has a UID of 100 or greater.		
	The $-\mathbf{l}$ and $-\mathbf{g}$ options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.		

modified 18 Mar 1994

NAME	ln – make hard or symbolic links to files	
SYNOPSIS	/usr/bin/ln [-fns] source_file [target] /usr/bin/ln [-fns] source_file target	
	/usr/xpg4/bin/ln [-fs] source_file [target] /usr/xpg/bin/ln [-fs] source_file target	
AVAILABILITY /usr/bin/ln	SUNWcsu	
/usr/xpg4/bin/ln	SUNWxcu4	
DESCRIPTION	In the first synopsis form, the ln utility will create a new directory entry (link) for the file specified by <i>source_file</i> , at the destination path specified by <i>target</i> . If <i>target</i> is not specified, the link is made in the current directory. This first synopsis form is assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error will result.	
	In the second synopsis form, the ln utility will create a new directory entry for each file specified by a <i>source_file</i> operand, at a destination path in the existing directory named by <i>target</i> .	
	The In utility may be used to create both hard links and symbolic links. A hard link is a pointer to a file and is indistinguishable from the original directory entry. Any changes to a file are effective independent of the name used to reference the file. Hard links may not span file systems and may not refer to directories.	
	In by default creates hard links. <i>source_file</i> is linked to <i>target</i> . If <i>target</i> is a directory, another file named <i>source_file</i> is created in <i>target</i> and linked to the original <i>source_file</i> .	
/usr/bin/ln	If <i>target</i> is a file, its contents are overwritten. If In determines that the mode of <i>target</i> for- bids writing, it will print the mode (see chmod (1)), ask for a response, and read the stan- dard input for one line. If the line begins with y , the link occurs, if permissible; other- wise, the command exits.	
/usr/xpg4/bin/ln	If <i>target</i> is a file and the -f option is not specified, ln will write a diagnostic message to standard error, do nothing more with the current <i>source_file</i> , and go on to any remaining <i>source_files</i> .	
	A symbolic link is an indirect pointer to a file; its directory entry contains the name of the file to which it is linked. Symbolic links may span file systems and may refer to directories.	
OPTIONS	The following options are supported:	
	 -f Link files without questioning the user, even if the mode of <i>target</i> forbids writing. This is the default if the standard input is not a terminal. 	

modified 28 Mar 1995

/usr/bin/ln	optic	e link is an existing file, do not overwrite the contents of the file. The -f on overrides this option. This is the default behavior for /usr/xpg4/bin/ln , is silently ignored.
	–s Crea	te a symbolic link.
	If the tory error exist from who syml does	e –s option is used with two arguments, <i>target</i> may be an existing direc- or a non-existent file. If <i>target</i> already exists and is not a directory, an is returned. <i>source_file</i> may be any path name and need not exist. If it s, it may be a file or directory and may reside on a different file system <i>target</i> . If <i>target</i> is an existing directory, a file is created in directory <i>target</i> se name is <i>source_file</i> or the last component of <i>source_file</i> . This file is a polic link that references <i>source_file</i> . If <i>target</i> not exist, a file with name <i>target</i> is created and it is a symbolic link that ences <i>source_file</i> .
	exist creat <i>sourc</i>	e – s option is used with more than two arguments, <i>target</i> must be an ing directory or an error will be returned. For each <i>source_file</i> , a link is ed in <i>target</i> whose name is the last component of <i>source_file</i> ; each new <i>se_file</i> is a symbolic link to the original <i>source_file</i> . The files and <i>target</i> may be on different file systems.
		for <i>target</i> may be different from those displayed with a -1 listing of the To display the permissions of <i>target</i> use $1s - 1L$. See stat(2) for more
OPERANDS	The following o	perands are supported:
	source_file	A path name of a file to be linked. This can be either a regular or special file. If the $-s$ option is specified, <i>source_file</i> can also be a directory.
	target	The path name of the new directory entry to be created, or of an existing directory in which the new directory entries are to be created.
ENVIRONMENT		or descriptions of the following environment variables that affect the exe- CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	The following ex	xit values are returned:
	0 All the spec	ified files were linked successfully
	>0 An error oc	curred.

lrwxrwxrwx 1 user 7 J

7 Jan 11 23:27 link -> dir

When you **cd**(1) to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is /**usr** and not /**home/user/linktest**.

```
example% pwd
/home/user/linktest
example% ln -s /usr/tmp symlink
example% cd symlink
example% cd ..
example% pwd
/usr
```

C shell user's can avoid any resulting navigation problems by using the **pushd** and **popd** built-in commands instead of **cd**.

NAME	ln – make hard or symbolic links to files
SYNOPSIS	/usr/ucb/ln [–fs] filename [linkname] /usr/ucb/ln [–fs] pathname directory
AVAILABILITY	SUNWscpu
DESCRIPTION	/ usr/ucb/In creates an additional directory entry, called a link, to a file or directory. Any number of links can be assigned to a file. The number of links does not affect other file attributes such as size, protections, data, etc.
	<i>filename</i> is the name of the original file or directory. <i>linkname</i> is the new name to associate with the file or filename. If <i>linkname</i> is omitted, the last component of <i>filename</i> is used as the name of the link.
	If the last argument is the name of a directory, symbolic links are made in that directory for each <i>pathname</i> argument; / usr/ucb/ln uses the last component of each <i>pathname</i> as the name of each link in the named <i>directory</i> .
	A hard link (the default) is a standard directory entry just like the one made when the file was created. Hard links can only be made to existing files. Hard links cannot be made across file systems (disk partitions, mounted file systems). To remove a file, all hard links to it must be removed, including the name by which it was first created; removing the last hard link releases the inode associated with the file.
	A symbolic link, made with the – s option, is a special directory entry that points to another named file. Symbolic links can span file systems and point to directories. In fact, you can create a symbolic link that points to a file that is currently absent from the file system; removing the file that it points to does not affect or alter the symbolic link itself.
	A symbolic link to a directory behaves differently than you might expect in certain cases. While an $ls(1)$ on such a link displays the files in the pointed-to directory, an ' $ls - l$ ' displays information about the link itself:
	example% /usr/ucb/ln –s dir link example% ls link file1 file2 file3 file4 example% ls –l link lrwxrwxrwx 1 user 7 Jan 11 23:27 link → dir
	When you cd (1) to a directory through a symbolic link, you wind up in the pointed-to location within the file system. This means that the parent of the new working directory is not the parent of the symbolic link, but rather, the parent of the pointed-to directory. For instance, in the following case the final working directory is / usr and not / home/user/linktest .
	example% pwd /home/user/linktest example% /usr/ucb/ln –s /var/tmp symlink example% cd symlink

ln(1B)	SunOS/BSD Compatibility Package Commands			
	example% cd example% pwd /usr			
	C shell user's can avoid any resulting navigation problems by using the pushd arbuilt-in commands instead of cd .			
OPTIONS	-f Force a hard link to a directory. This option is only available to the super-user, and should be used with extreme caution.			
	-s Create a symbolic link or links.			
EXAMPLES The commands below illustrate the effects of the different forms of the /us mand: example% /usr/ucb/ln file link example% ls –F file link file link example% /usr/ucb/ln –s file symlink example% ls –F file symlink file symlink@ example% ls –li file link symlink 10 00 00 01		/ usr/ucb/ln com-		
	10606-rw-rr2 user0 Jan 12 00:06 file10606-rw-rr2 user0 Jan 12 00:06 link10607lrwxrwxrwx 1 user4 Jan 12 00:06 symlink \rightarrow fileexample% /usr/ucb/ln -s nonesuch devoidexample% ls -F devoiddevoid@example% cat devoidexample% cat devoiddevoid@example% /usr/ucb/ln -s /proto/bin/* /tmp/binexample% /usr/ucb/ln -s /proto/bin/* /tmp/binexample% ls -F /proto/bin /tmp/bin/proto/bin:x*y*z*/tmp/bin:			
	x@ y@ z@			
SEE ALSO	cp(1), ls(1), mv(1), rm(1), link(2), readlink(2), stat(2), symlink(2)			
NOTES	When the last argument is a directory, simple basenames should not be arguments. If a basename is used, the resulting symbolic link points to example% /usr/ucb/ln -s file /tmp example% ls -l /tmp/file lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file → file example% cat /tmp/file /tmp/file: Too many levels of symbolic links			

modified 11 Mar 1994

To avoid this problem, use full pathnames, or prepend a reference to the **PWD** variable to files in the working directory:

example% rm /tmp/file example% /usr/ucb/ln –s \$PWD/file /tmp lrwxrwxrwx 1 user 4 Jan 12 00:16 /tmp/file → /home/user/subdir/file

modified 11 Mar 1994

NAME	loadfont – display or change font information in the RAM of the video card on an x86 system in text mode
SYNOPSIS	loadfont [-f BDF_file -c codeset] [-m mode] [-d]
AVAILABILITY	x86 SUNWcsu
DESCRIPTION	The loadfont utility allows a user to load and activate a different font into the RAM of the video card used by the console of the Solaris for x86 operating system in text mode. It can also be used to display information about the fonts currently in use. In addition, the – m option can be used to change the size of the characters on the screen; it can also be used to change the number of lines per screen. loadfont will always read from standard output; this will allow a system administrator to use it from a remote terminal. When used without arguments, loadfont displays the different ways the command can be used, as shown in the synopsis.
Options	 -f BDF_file This command reads the contents of BDF_file and subsequently loads the font specified in the file into the RAM of the video card. The file must be in the Binary Distribution Format version 2.1 as developed by Adobe Systems, Inc. (See loadfont(4).) -c codeset codeset is the name of a codeset available for the current font size. This font will be loaded into the RAM of the video card and activated. Use ? to find out the
	 valid <i>codesets</i> available. This option is a shorthand form of -f. -m mode This option will attempt to change the mode of the console as specified. This will result in having a different font size and/or different number of lines and columns on the screen. Use ? to find out the valid modes available. -d This reads the font information from the video RAM and writes it to standard output in a format compatible with the Binary Distribution Format version 2.1 as developed by Adobe Systems, Inc. (See loadfont(4).)
Fonts	 A font is the representation of characters by images. The need to use different fonts can be imposed by: The codeset used to represent the characters internally. The resolution used to display the characters. Each font contains exactly 256 images. All supported fonts are fixed size (constant width and constant height), i.e., each character takes the same amount of space on the screen. When the monitor is not being used in graphics mode, the loadfont utility allows a user to modify the font used by the video card, so different images are displayed on the screen

WARNINGS	When an attempt is made to switch to a mode that the video card does not support, you will get a blank screen. There is nothing wrong with the system; as super-user, simply type in the command to set the mode back, e.g.: loadfont –m V80x25		
NOTES	The default fonts on the system are those of the ISO 8859-1 codeset. The optional IBM DOS 437 codeset is supported <i>only</i> at internationalization level 1. That is, if you choose to download fonts of the optional IBM DOS 437 codeset, there will be no support for non-standard U.S. date, time, currency, numbers, unit, and collation. There will be no support for non-English message and text presentation, and no multi-byte character support. Therefore, non-Windows users should only use IBM DOS 437 codeset in the default C locale.		

modified 31 May 1993

NAME	loadkeys, dumpkeys – load and dump keyboard translation tables		
SYNOPSIS	loadkeys [filename]		
	dumpkeys		
AVAILABILITY	SPARC		
	SUNWcsu		
DESCRIPTION	loadkeys reads the file specified by <i>filename</i> , and modifies the keyboard streams module's translation tables. If no file is specified, and the keyboard is a Type-4 keyboard, a default file for the layout indicated by the DIP switches on the keyboard. The file is in the format specified by keytables (4).		
	If the layout code in the DIP switches on the keyboard has the hexadecimal value 0x <i>dd</i> , the file loaded by loadkeys by default is /usr/share/lib/keytables/layout_ <i>dd</i> . These files specify only the entries that change between the different Type-4 keyboard layouts.		
	dumpkeys writes, to the standard output, the current contents of the keyboard streams module's translation tables, in the format specified by keytables (4).		
FILES	/usr/share/lib/keytables/layout_dd default keytable files		
SEE ALSO	kbd(1), keytables(4), kb(7M)

NAME	locale – get locale-specific information
SYNOPSIS	locale [-a -m] locale [-ck] name
AVAILABILITY	SUNWloc
DESCRIPTION	The locale utility writes information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a <i>public locale</i> is one provided by the implementation that is accessible to the application.
	When locale is invoked without any arguments, it summarizes the current locale environment for each locale category as determined by the settings of the environment variables.
	When invoked with operands, it writes values that have been assigned to the keywords in the locale categories, as follows:
	• Specifying a keyword name selects the named keyword and the category containing that keyword.
	• Specifying a category name selects the named category and all keywords in that category.
OPTIONS	The following options are supported:
	 -a Write information about all available public locales. The available locales include POSIX, representing the POSIX locale.
	 -c Write the names of selected locale categories. The -c option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the -k option.
	 -k Write the names and values of selected keywords. The implementation may omit values for some keywords; see OPERANDS.
	- m Write names of available charmaps; see localedef (1).
OPERANDS	The following operand is supported:
	<i>name</i> The name of a locale category, the name of a keyword in a locale category, or the reserved name charmap . The named category or keyword will be selected for output. If a single <i>name</i> represents both a locale category name and a keyword name in the current locale, the results are unspecified; otherwise, both category and keyword names can be specified as <i>name</i> operands, in any sequence.
EXAMPLES	In the following examples, the assumption is that locale environment variables are set as follows: LANG=locale_x LC_COLLATE=locale_y

modified 1 Feb 1995

1-515

	The command:
	locale
	would result in the following output:
	LANG=locale_x
	LC_CTYPE="locale_x"
	LC_NUMERIC="locale_x"
	LC_TIME="locale_x"
	LC_COLLATE=locale_y
	LC_MONETARY="locale_x"
	LC_MESSAGES="locale_x"
	LC_ALL=
	The command:
	LC_ALL=POSIX locale -ck decimal_point
	would produce:
	LC_NUMERIC
	decimal_point="."
	The following command shows an application of locale to determine whether a user-
	supplied response is affirmative:
	if printf "%s\n" "\$response" grep -Eq "\$(locale yesexpr)"
	then
	affirmative processing goes here
	else
	non-affirmative processing goes here
	fi
ENVIRONMENT	See environ(5) for the descriptions of LANG, LC_ALL, LC_TYPE, LC_MESSAGES, and
	NLSPATH.
	The LANG, LC_*, and NLSPATH environment variables must specify the current locale
	environment to be written out; they will be used if the $-\mathbf{a}$ option is not specified.
	environment to be written out, they will be used if the u option is not specified.
EXIT STATUS	The following exit values are returned:
	0 All the requested information was found and output successfully.
	>0 An error occurred.
SEE ALSO	localedef(1), charmap(5), locale(5)
NOTES	If LC_CTYPE or keywords in the category LC_CTYPE are specified, only the values in the
	codeset 0 are written out.
	If LC_COLLATE or keywords in the category LC_COLLATE are specified, no actual values
	are written out.

modified 1 Feb 1995

NAME	localedef – define	e locale environment			
SYNOPSIS	localedef [-c] [-f charmap] [-i sourcefile] localename				
DESCRIPTION	The localedef utility converts source definitions for locale categories into a format usable by the functions and utilities whose operational behaviour is determined by the setting the locale environment variables; see environ (5).				
	The utility reads source definitions for one or more locale categories belonging to the same locale from the file named in the $-i$ option (if specified) or from standard input.				
	Each category source definition is identified by the corresponding environment variable name and terminated by an END <i>category-name</i> statement. The following categories are supported.				
	LC_CTYPE	Defines character classification and case conversion.			
	LC_COLLATE	Defines collation rules.			
	LC_MONETARY	Defines the format and symbols used in formatting of monetary information.			
	LC_NUMERIC	Defines the decimal delimiter, grouping and grouping symbol for non-monetary numeric editing.			
	LC_TIME	Defines the format and content of date and time information.			
	LC_MESSAGES	Defines the format and values of affirmative and negative responses.			
OPTIONS	The following opt	tions are supported:			
	- c	Create permanent output even if warning messages have been issued.			
		Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. This option must be specified if symbolic names (other than collating symbols defined in a collating-symbol keyword) are used. If the – f option is not present, the default character mapping will be used.			
		The path name of a file containing the source definitions. If this option is not present, source definitions will be read from standard input.			
OPERANDS	The following op	erand is supported:			
	localename I	Identifies the locale. If the name contains one or more slash characters, <i>localename</i> will be interpreted as a path name where the created locale definitions will be stored. This capability may be restricted to users with appropriate privileges. (As a consequence of specifying one <i>localename</i> , although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)			
I					

modified 17 Jul 1995

1-517

	Category	File		Description	
	LC_CTYPE	localename.chrtbl		binary data containing character classification information	
		localename.chrt	bl.c	C language source file, to be used by program- mers as needed	
		localename.char		character mapping file

VIRONMENT	See environ (5) for cution of localede			g environment variables that affect the exe- ES, and NLSPATH.	
EXIT STATUS	The following exi	t values are retur	med:		
	0 No errors occurred and the locales were successfully created.				
	1 Warnings occurred and the locales were successfully created.				
	2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.				
	3 The capability to create new locales is not supported by the implementation.				
	 >3 Warnings or errors occurred and no output was created. 				

modified 17 Jul 1995

If an error is detected, no permanent output will be created.

SEE ALSO locale(1), nl_langinfo(3C), strftime(3C), charmap(5), environ(5), locale(5)

WARNINGS If warnings occur, permanent output will be created if the –**c** option was specified. The following conditions will cause warning messages to be issued:

- If a symbolic name not found in the *charmap* file is used for the descriptions of the LC_CTYPE or LC_COLLATE categories (for other categories, this will be an error conditions).
- If optional keywords not supported by the implementation are present in the source.

User Commands

NAME	logger – add ei	ntries to the system log	
SYNOPSIS	logger [-i] [-f file] [-p priority] [-t tag] [message]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	from the comm line, in which c cated with –f o in which case e	mand provides a method for adding one-line entries to the system log file and line. One or more <i>message</i> arguments can be given on the command case each is logged immediately. If this is unspecified, either the file indi- r the standard input is added to the log. Otherwise, a <i>file</i> can be specified, each line in the file is logged. If neither is specified, logger reads and logs line-by-line basis from the standard input.	
OPTIONS	The following	options are supported:	
	-f file	Use the contents of <i>file</i> as the message to log.	
	—i	Log the process ID of the logger process with each line.	
	- p priority	Enter the message with the specified <i>priority</i> . The message priority can be specified numerically, or as a <i>facility.level</i> pair. For example, ' -p local3.info ' assigns the message priority to the info level in the local3 facility. The default priority is user.notice .	
	–t tag	Mark each line added to the log with the specified <i>tag</i> .	
OPERANDS	The following	operand is supported:	
	message	One of the string arguments whose contents are concatenated together, in the order specified, separated by single space characters.	
EXAMPLES	The following examp	example: le% logger System rebooted	
		ge ' System rebooted ' to the default priority level notice to be treated by other messages to the facility user .	
	The next examp examp	ple: le% logger –p local0.notice –t HOSTIDM –f /dev/idmc	
		file / dev / idmc and logs each line in that file as a message with the tag priority level notice to be treated by syslogd as are other messages to the	
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- er: LC_CTYPE, LC_MESSAGES, and NLSPATH.	
EXIT STATUS	0 Suc	exit values are returned: cessful completion. error occurred.

NAME	login – sign on to the system
SYNOPSIS	login [-p][-d device][-h hostname [terminal]] -r hostname][name[environ]]
AVAILABILITY	SUNWcsu
DESCRIPTION	You use the login command at the beginning of each terminal session to identify yourself to the system. login is invoked by the system when a connection is first established, after the previous user has terminated the login shell by issuing the exit command.
	If login is invoked as a command, it must replace the initial command interpreter. To invoke login in this fashion, type:
	exec login
	from the initial shell.
	login asks for your user name, if it is not supplied as an argument, and your password, if appropriate. Where possible, echoing is turned off while you type your password, so it will not appear on the written record of the session.
	If there are no lowercase characters in the first line of input processed, login assumes the connecting TTY is an uppercase-only terminal. It then sets the port's termio (7I) options to reflect this.
	If you make any mistake in the login procedure, the message:
	Login incorrect
	is printed and a new login prompt will appear. If you make five incorrect login attempts, all five may be logged in / var/adm/loginlog , if it exists. The TTY line will be dropped.
	If password aging is turned on and the password has "aged" (see passwd (1) for more information), the user is forced to changed the password. In this case the / etc/nsswitch.conf file is consulted to determine password repositories (see nsswitch.conf (4)). The password update configurations supported are limited to the following five cases.
	 passwd: files passwd: files nis passwd: files nisplus passwd: compat (==> files nis) passwd: compat (==> files nisplus) passwd_compat: nisplus
	Failure to comply with the configurations will prevent the user from logging onto the system because passwd (1) will fail. If you do not complete the login successfully within a certain period of time, it is likely that you will be silently disconnected.
	After a successful login, accounting files are updated. Device owner, group, and permissions are set according to the contents of the /etc/logindevperm file, and the time you last logged in is printed (see logindevperm (4)).
dified 94 Feb 1005	1 593

modified 24 Feb 1995

The user-ID, group-ID, supplementary group list, and working directory are initialized, and the command interpreter (usually **ksh**) is started.

The basic *environment* is initialized to:

HOME=your-login-directory LOGNAME=your-login-name PATH=/usr/bin: SHELL=last-field-of-passwd-entry MAIL=/var/mail/your-login-name TZ=timezone-specification

For Bourne shell and Korn shell logins, the shell executes /etc/profile and \$HOME/.profile, if it exists. For C shell logins, the shell executes /etc/.login, \$HOME/.cshrc, and \$HOME/.login. The default /etc/profile and /etc/.login files check quotas (see quota(1M)), print /etc/motd, and check for mail. None of the messages are printed if the file \$HOME/.hushlogin exists. The name of the command interpreter is set to – (dash), followed by the last component of the interpreter's path name, for example, –sh.

If the *login-shell* field in the password file (see **passwd**(4)) is empty, then the default command interpreter, /**usr/bin/sh**, is used. If this field is * (asterisk), then the named directory becomes the root directory. At that point **login** is re-executed at the new level, which must have its own root structure.

The environment may be expanded or modified by supplying additional arguments to **login**, either at execution time or when **login** requests your login name. The arguments may take either the form *xxx* or *xxx=yyy*. Arguments without an equal sign are placed in the environment as:

Ln=xxx

where n is a number starting at 0 and is incremented each time a new variable name is required. Variables containing an = are placed in the environment without modification. If they already appear in the environment, then they replace the older values.

There are two exceptions: The variables **PATH** and **SHELL** cannot be changed. This prevents people logged into restricted shell environments, from spawning secondary shells that are not restricted. **login** understands simple single-character quoting conventions. Typing a ' \ ' (backslash) in front of a character quotes it and allows the inclusion of such characters as spaces and tabs.

Alternatively, you can pass the current environment by supplying the $-\mathbf{p}$ flag to **login**. This flag indicates that all currently defined environment variables should be passed, if possible, to the new environment. This option does not bypass any environment variable restrictions mentioned above. Environment variables specified on the login line take precedence, if a variable is passed by both methods.

To enable remote logins by root, edit the /etc/default/login file by inserting a ' # ' (pound-sign) before the CONSOLE=/dev/console entry. See FILES below.

NAME	logname – return user's login name
SYNOPSIS	logname
AVAILABILITY	SUNWesu
DESCRIPTION	The logname utility will write the user's login name to standard output. The login name is the string that would be returned by the getlogin (3C) function. Under the conditions where getlogin() would fail, logname will write a diagnostic message to standard error and exit with a non-zero exit status.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of logname : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	 The following error values are returned: 0 Successful completion. >0 An error occurred.
FILES	/etc/profileenvironment for user at login time/var/adm/utmpuser and accounting information
SEE ALSO	<pre>env(1), login(1), getlogin(3C), utmp(4), environ(5)</pre>

NAME	logout – shell built-in function to exit from a login session
SYNOPSIS csh	logout
DESCRIPTION csh	Terminate a login shell.
SEE ALSO	csh (1), login (1)

modified 15 Apr 1994

look – find words in the system dictionary or lines in a sorted list		
/usr/bin/look [$-d$] [$-f$] [$-tc$] string [filename]		
SUNWesu		
The look command consults a sorted <i>filename</i> and prints all lines that begin with <i>string</i> . If no <i>filename</i> is specified, look uses / usr/share/lib/dict/words with collating sequence - df . look limits the length of a word to search for to 256 characters.		
 -d Dictionary order. Only letters, digits, TAB and SPACE characters are used in comparisons. -f Fold case. Upper case letters are not distinguished from lower case in comparisons. -tc Set termination character. All characters to the right of <i>c</i> in <i>string</i> are ignored. 		
/usr/share/lib/dict/words spelling list		
grep(1), sort(1)		

modified 29 Mar 1994

NAME	lookbib – find references in a bibliographic database			
SYNOPSIS	lookbib database			
AVAILABILITY	SUNWdoc			
DESCRIPTION	A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.			
	lookbib uses an inverted index made by indxbib to find sets of bibliographic references. It reads keywords typed after the '>' prompt on the terminal, and retrieves records con- taining all these keywords. If nothing matches, nothing is returned except another '>' prompt.			
	It is possible to search multiple databases, as long as they have a common index made by indxbib (1). In that case, only the first argument given to indxbib is specified to lookbib .			
	If lookbib does not find the index files (the .i[abc] files), it looks for a reference file with the same name as the argument, without the suffixes. It creates a file with a .ig suffix, suitable for use with fgrep (see grep (1)). lookbib then uses this fgrep file to find references. This method is simpler to use, but the .ig file is slower to use than the .i[abc] files, and does not allow the use of multiple reference files.			
FILES	x.iax.ibx.icindex filesx.igreference file			
SEE ALSO	<pre>addbib(1), grep(1), indxbib(1), refer(1), roffbib(1), sortbib(1)</pre>			
BUGS	Probably all dates should be indexed, since many disciplines refer to literature written in the 1800s or earlier.			

modified 14 Sep 1992

NAME	lorder – find ordering relation for an object or library archive		
SYNOPSIS	lorder filename		
DESCRIPTION	The input is one or more object or library archive <i>filenames</i> (see ar (1)). The standard output is a list of pairs of object file or archive member names; the first file of the pair refers to external identifiers defined in the second. The output may be processed by tsort (1) to find an ordering of a library suitable for one-pass access by ld . Note that the link editor ld is capable of multiple passes over an archive in the portable archive format (see ar (4)) and does not require that lorder be used when building an archive. The usage of the lorder command may, however, allow for a more efficient access of the archive during the link edit process.		
	The following example builds a new library from existing .o files.		
	ar –cr library `lorder *.o tsort `		
FILES	TMPDIR/*symreftemporary filesTMPDIR/*symdeftemporary filesTMPDIRusually /var/tmp but can be redefined by setting the environment variable TMPDIR (see tempnam() in tmpnam(3S))		
SEE ALSO	ar(1), ld(1), tsort(1), tmpnam(3S), ar(4)		
NOTES	lorder will accept as input any object or archive file, regardless of its suffix, provided there is more than one input file. If there is but a single input file, its suffix must be .o. The length of the filename for TMPDIR is limited to whatever sed allows.		

modified 29 Oct 1991

NAME	lp, cancel – send/cancel requests to an LP print service
SYNOPSIS	<pre>lp [-c] [-m] [-p] [-s] [-w] [-d dest] [-f form-name [-d any]] [-H special-handling] [-n number] [-o option] [-P page-list] [-q priority-level] [-S character-set [-d any]] [-S print-wheel [-d any]] [-t title] [-T content-type [-r]] [-y mode-list] [file]</pre>
	lp − i request-ID [− c] [− m] [− p] [− s] [− w] [− d dest] [− f form-name [− d any]] [− H special-handling] [− n number] [− o option] [− P page-list] [− q priority-level] [− S character-set [− d any]] [− S print-wheel [− d any]] [− t title] [− T content-type [− r]] [− y mode-list]
	cancel [request-ID] [printer] cancel –u login-ID-list [printer]
AVAILABILITY	SUNWlpu
DESCRIPTION	The first form of the lp command arranges for the named <i>file(s)</i> and associated information (collectively called a <i>request</i>) to be printed. If no file names are specified on the command line, the standard input is assumed. The standard input may be specified along with a named <i>file</i> (s) on the command line by listing the file name(s) and specifying `-´ (dash) for the standard input. The <i>files</i> will be printed in the order in which they appear on the shell command line.
	The LP print service associates a unique <i>request-ID</i> (with the –i option) with each request and displays it on the standard output. This <i>request-ID</i> can be used later with the –i option when canceling or changing a request, or when determining its status. (See the section on cancel for details about canceling a request, and lpstat (1) for information about checking the status of a print request.)
	The second form of lp is used to change the options for a request. The print request identified by the <i>request-ID</i> is changed according to the printing options specified with this shell command. The printing options available are the same as those with the first form of the lp shell command. If the request has finished printing, the change is rejected. If the request is already printing, it will be stopped and restarted from the beginning (unless the $-P$ option has been given).
	The cancel command allows users to cancel print requests previously sent with the lp command. The first form of cancel permits cancellation of requests based on their <i>request-ID</i> . The second form of cancel permits cancellation of requests based on the <i>login-ID</i> of their owner.
Sending a Print Request	The first form of the lp command is used to send a print request to a particular printer or group of printers.

OPTIONS		lways precede an are available for	y file names, but may be specified in any order. The fol- lp :	
	- c	but will be link the user should been printed in is not specified	f the <i>file</i> before printing. Normally, <i>file</i> will not be copied, ed whenever possible. If the $-c$ option is not given, then l be careful not to remove any <i>file</i> before the request has its entirety. It should also be noted that if the $-c$ option , any changes made to the named <i>file</i> after the request is re it is printed will be reflected in the printed output.	
	− d dest	dest is a printer printer. If dest the first availab then the reques Under certain o tions, and so or (see lpstat (1)). LPDEST (if it is	the printer or class of printers that is to do the printing. If , then the request will be printed only on that specific is a class of printers, then the request will be printed on ole printer that is a member of the class. If <i>dest</i> is any , st will be printed on any printer which can handle it. conditions, (unavailability of printers, file space limita- n) requests for specific destinations may not be accepted By default, <i>dest</i> is taken from the environment variable set). Otherwise, a default destination (if one exists) for ystem is used. Destination names vary between systems	
	- f form-name [-			
		that the form is printer destinat If <i>form-name</i> ha allowed to use When the – d an	st on the form <i>form-name</i> . The LP print service ensures a mounted on the printer. If <i>form-name</i> is requested with a tion that cannot support the form, the request is rejected. s not been defined for the system, or if the user is not the form, the request is rejected (see lpforms (1M)). ny option is given, the request is printed on any printer juested form mounted and can handle all other needs of st.	
	-H special-handling			
			st according to the value of <i>special-handling</i> . Acceptable <i>al-handling</i> are defined below:	
		hold	Do not print the request until notified. If printing has already begun, stop it. Other print requests will go ahead of a held request until it is resumed.	
		resume	Resume a held request. If the request had begun to print when held, it will be the next request printed, unless it is superseded by an immediate request.	

1-533

	immediate	(Available only to LP administrators.) Print the request next. If more than one request is assigned the most recent request is printed next. If a request is currently printing on the desired printer, a hold request must be issued to allow the immediate request to print.
-m		mail(1)) after the files have been printed. By default, no on normal completion of the print request.
– n number	Print <i>number</i> co	pies (default is 1) of the output.
–o option	by specifying the <i>option</i> _{n}), or by specified enclosed in double of the formula of the form	dependent <i>options</i> . Several such <i>options</i> may be collected as $-\mathbf{o}$ keyletter more than once $(-\mathbf{o} \ option_1 - \mathbf{o} \ option_2 \dots - \mathbf{o}$ specifying the $-\mathbf{o}$ keyletter followed by a list of options able quotes (that is, $-\mathbf{o}$ " <i>option</i> ₁ <i>option</i> ₂ <i>option</i> _n "). The ace recognizes the following options:
		not print a banner page with this request. (The adminis- or can disallow this option at any time.)
	nofilebreak	
	ting	not insert a form feed between the files given, if submit- a job to print more than one file.
	A sc num eters the l leng or cc cale (the leng indi	<i>actimal-number</i> at this request with pages <i>scaled-decimal-number</i> lines long. <i>saled-decimal-number</i> is an optionally scaled decimal aber that gives a size in lines, columns, inches, or centim- s, as appropriate. The scale is indicated by appending letter "i" for inches, or the letter "c" for centimeters. For sth or width settings, an unscaled number indicates lines olumns; for line pitch or character pitch settings, an uns- d number indicates lines per inch or characters per inch same as a number scaled with "i"). For example, gth=66 indicates a page length of 66 lines, length=11i cates a page length of 11 inches, and length=27.94c indi- s a page length of 27.94 centimeters.
	This	s option may not be used with the $-\mathbf{f}$ option.
	num num	ecimal-number at this request with page-width set to <i>scaled-decimal- aber</i> columns wide. (See the explanation of <i>scaled-decimal- abers</i> in the discussion of length , above.) This option may be used with the – f option.
	lpi =scaled-decim Prin num	-
	cpi=scaled-decin	

	Print this request with the character pitch set to <i>scaled-decimal-number</i> characters per inch. Character pitch can also be set to pica (representing 10 characters per inch) or elite (representing 12 characters per inch), or it can be compressed (representing as many characters as a printer can handle). There is no standard number of characters per inch for all printers; see the Terminfo database (see ter-minfo (4)) for the default character pitch for your printer.
	This option may not be used with the $-\mathbf{f}$ option.
	<pre>stty=`stty-option-list´</pre>
–P page-list	Print the pages specified in <i>page-list</i> . This option can be used only if there is a filter available to handle it; otherwise, the print request will be rejected.
	The <i>page-list</i> may consist of range(s) of numbers, single page numbers, or a combination of both. The pages will be printed in ascending order.
- p	Enable notification on completion of the print request. Delivery of the notification is dependent on additional software.
- q priority-level	Assign this request <i>priority-level</i> in the printing queue. The values of <i>priority-level</i> range from 0 , the highest priority, to 39 , the lowest priority. If a priority is not specified, the default for the print service is used, as assigned by the system administrator. A priority limit may be assigned to individual users by the system administrator.
- s	Suppress messages from lp such as those that begin with " request id is "
-S character-set	[-d any]
–S print-wheel [–	- d any] Print this request using the specified <i>character-set</i> or <i>print-wheel</i> . If a
	form was requested and it requires a character set or print wheel other than the one specified with the $-S$ option, the request is rejected.
	For printers that take print wheels: if the print wheel specified is not one listed by the administrator as acceptable for the printer specified in this request, the request is rejected unless the print wheel is already mounted on the printer.
	For printers that use selectable or programmable character sets: if the <i>character-set</i> specified is not one defined in the Terminfo database for the printer (see terminfo (4)), or is not an alias defined by the administrator, the request is rejected.

1-535

	l .		
		When the –d any option is used, the request is printed on any printer that has the print wheel mounted or any printer that can select the character set, and that can handle the needs of the request.	
	-t title	Print <i>title</i> on the banner page of the output. If <i>title</i> is not supplied the name of the file is printed on the banner page. Enclose <i>title</i> in quotes if it contains blanks.	
	– T content-type	[_r]	
		Print the request on a printer that can support the specified <i>content-type</i> . If no printer accepts this type directly, a filter will be used to convert the content into an acceptable type. If the – r option is specified, a filter will not be used. If – r is specified, and no printer accepts the <i>content-type</i> directly, the request is rejected. If the <i>content-type</i> is not acceptable to any printer, either directly or with a filter, the request is rejected.	
	$-\mathbf{w}$	Write a message on the user's terminal after the <i>files</i> have been printed. If the user is not logged in, then mail will be sent instead.	
	-y mode-list	Print this request according to the printing modes listed in <i>mode-list</i> . The allowed values for <i>mode-list</i> are locally defined. This option may be used only if there is a filter available to handle it; otherwise, the print request will be rejected.	
Canceling a Print Request	first form allow	mand cancels requests for print jobs made with the lp command. The vs a user to specify one or more <i>request-ID</i> of print jobs to be canceled. he user can specify one or more <i>printer</i> , on which only the currently print-canceled.	
	The second form of cancel permits a user to cancel all of his or her own jobs on all printers. In this form the <i>printer</i> option can be used to restrict the printer(s) on which the user's job(s) will be canceled. Note: In this form, when the <i>printer</i> option is used, all job queued for that printer will be canceled. A printer class is not a valid argument.		
	IDs. The system	special privileges can cancel only requests associated with their own login m administrator can cancel jobs submitted by any user. The <i>login-ID-list</i> ed in quotes if it contains blanks.	
	particular print request is print wheels are avai print wheels ar	at take mountable print wheels or font cartridges, if you do not specify a t wheel or font with the $-S$ option, the one mounted at the time your ed will be used. Use the lpstat $-p$ printer $-l$ command to see which print ilable on a particular printer, or the lpstat $-S$ $-l$ command to find out what e available and on which printers. For printers that have selectable charwill get the standard character set if you don't use the $-S$ option.	

OPERANDS	The following operands are supported by lp :		
	file	A path name of a file to be output. If no <i>file</i> operands are specified, or if a <i>file</i> operand is –, the standard input will be used. If a <i>file</i> operand is used, but the $-c$ option is not specified, the process performing the writing to the output device may have user and group permissions that differ from that of the process invoking lp .	
	The following o	perands are supported by cancel :	
	ID	A request <i>ID</i> , as returned by lp . Specifying a request <i>ID</i> cancels the associated request even if it is currently printing.	
	printer	A printer name (for a complete list of printer names, use lpstat). Speci- fying a printer cancels the request that is currently printing on that printer.	
ENVIRONMENT	RONMENT See environ (5) for descriptions of the following environment variables the cution of lp and cancel : LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPA		
	LPDEST	Determine the output device or destination. If the LPDEST environment variable is not set, the PRINTER environment variable will be used. The -d <i>dest</i> option takes precedence over LPDEST . Results are undefined when -d is not specified and LPDEST contains a value that is not a valid device or destination name.	
	PRINTER	Determine the output device or destination. If the LPDEST and PRINTER environment variables are not set, an unspecified output dev- ice is used. The –d <i>dest</i> option and the LPDEST environment variable takes precedence over PRINTER. Results are undefined when –d is not specified, LPDEST is unset, and PRINTER contains a value that is not a valid device or destination name.	
EXIT STATUS	The following ex	kit values are returned by lp :	
	0	All input files were processed successfully.	
	>0	No output device was available, or an error occurred.	
	The following ex	kit values are returned by cancel :	
	0	Successful completion.	
	>0	An error occurred.

printers and the class itself is accepting requests, then *all* printers in the class will be considered, regardless of their acceptance status.

modified 1 Dec 1994

NAME	lpc – line printer control program
SYNOPSIS	/usr/ucb/lpc [command [parameter]]
AVAILABILITY	SUNWscpu
DESCRIPTION	lpc controls the operation of the printer, or of multiple printers. lpc commands can be used to start or stop a printer, disable or enable a printer's spooling queue, rearrange the order of jobs in a queue, or display the status of each printer—along with its spooling queue and printer daemon.
	With no arguments, lpc runs interactively, prompting with ' lpc >'. If arguments are supplied, lpc interprets the first as a <i>command</i> to execute; each subsequent argument is taken as a <i>parameter</i> for that command. The standard input can be redirected so that lpc reads commands from a file.
USAGE	
Commands	Commands may be abbreviated to an unambiguous substring. Specify the <i>printer</i> parameter by the name of the printer (for example, as lw), not as you would specify it to lpr (1B) or lpq (1B) (not as – Plw). ? [<i>command</i>] help [<i>command</i>]
	Display a short description of each command specified in the argument list, or, if no arguments are given, a list of the recognized commands.
	 abort [all [printer]] Terminate an active spooling daemon on the local host immediately and then disable printing (preventing new daemons from being started by lpr(1B)) for the specified printers. The abort command can only be used by the super-user.
	<pre>clean [all [printer]] Remove all files created in the spool directory by the daemon from the specified printer queue(s) on the local machine. The clean command can only be used by the super-user.</pre>
	disable [all [<i>printer</i>]] Turn the specified printer queues off. This prevents new printer jobs from being entered into the queue by lpr (1B). The disable command can only be used by the super-user.
	down [all [printer]] [message] Turn the specified printer queue off, disable printing and put message in the printer status file. The message does not need to be quoted, and the remaining arguments are treated like echo(1). This is normally used to take a printer down and let others know the reason (lpq(1B) indicates that the printer is down, as does the status command).

1B-539

	<pre>enable [all [printer]] Enable spooling on the local queue for the listed printers, so that lpr(1B) can put new jobs in the spool queue. The enable command can only be used by the super-user.</pre>				
	exit				
	quit Exit from lpc.				
	restart [all [<i>printer</i>]] Attempt to start a new printer daemon. This is useful when some abnormal con- dition causes the daemon to die unexpectedly leaving jobs in the queue. This command can be run by any user.				
	<pre>start [all [printer]] Enable printing and start a spooling daemon for the listed printers. The start command can only be used by the super-user.</pre>				
	<pre>status [all [printer]] Display the status of daemons and queues on the local machine. This command can be run by any user.</pre>				
	<pre>stop [all [printer]] Stop a spooling daemon after the current job completes and disable printing. The stop command can only be used by the super-user.</pre>				
	<pre>topq printer [job#] [user] Move the print job(s) specified by job# or those job(s) belonging to user to the top (head) of the printer queue. The topq command can only be used by the super- user.</pre>				
	up [all [<i>printer</i>]] Enable everything and start a new printer daemon. Undoes the effects of down .				
FILES	/var/spool/lp/* spooling directories				
	/var/spool/lp/system/pstatus printer status information				
SEE ALSO	echo(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), lpsched(1M)				
DIAGNOSTICS	?Ambiguous command The abbreviation you typed matches more than one command.				
	?Invalid command You typed a command or abbreviation that was not recognized.				
	?Privileged command You used a command can be executed only by the super-user.				
	lpc: printer: unknown printer to the print service The printer was not found in the LP database. Usually this is a typing mistake; however, it may indicate that the printer does not exist on the system. Use `lpstat -p´ (see lpstat(1)) or the status command (see Commands above) to dis- cover the reason.				

lpc: error on opening queue to spooler

The connection to **lpsched** on the local machine failed. This usually means the printer server started at boot time has died or is hung. Check to see if the printer spooler daemon /**usr/lib/lp/lpsched** is running.

lpc: Can't send message to LP print service

lpc: Can't receive message from LP print service

These indicate that the LP print service has been stopped. Get help from the system administrator.

lpc: Received unexpected message from LP print service

It is likely there is an error in this software. Get help from system administrator.

lpq(1B)	SunOS/BSD Compatibility Package Commands SunOS 5		SunOS 5.5		
NAME	lpg – display th	ne queue of printer jobs			
SYNOPSIS			terval]][job#][username	e]	
AVAILABILITY	SUNWscpu	1			
DESCRIPTION	lpq displays the contents of a printer queue. It reports the status of jobs specified by <i>job#</i> , or all jobs owned by the user specified by <i>username</i> . lpq reports on all jobs in the default printer queue when invoked with no arguments.				
	For each print job in the queue, lpq reports the user's name, current position, the names of input files comprising the job, the job number (by which it is referred to when using lprm (1B)) and the total size in bytes. Normally, only as much information as will fit on one line is displayed. Jobs are normally queued on a first-in-first-out basis. Filenames comprising a job may be unavailable, such as when lpr is used at the end of a pipeline; in such cases the filename field indicates the standard input.				
		at there is no daemon p nd can be used to resta	resent (that is, due to some r rt a printer daemon.	malfunction), the	
OPTIONS	– P printer	Display information about the queue for the specified <i>printer</i> . In the absence of the –P option, the queue to the printer specified by the PRINTER variable in the environment is used. If the PRINTER variable is not set, and the LPDEST environment variable is not set, the queue for the default printer is used.		specified by the he PRINTER variable is	
	-1	Display queue information in long format; includes the name of the host from which the job originated.			
	+[interval]	Display the spool queue periodically until it empties. This option clears the terminal screen before reporting on the queue. If an <i>interval</i> is sup- plied, lpq sleeps that number of seconds in between reports.			
FILES	/var/spool/lp /var/spool/lp/ti	np/system_name/*-0	spooling directory request files specifying jobs	5	
SEE ALSO	lp (1), lpc (1B), l	pr(1B), lprm(1B), lpsta	t(1), lpsched (1M)		
DIAGNOSTICS	 printer is printing The lpq program queries the spooler LPSCHED about the status of the printer. If the printer is disabled, the superuser can restart the spooler using lpc(1B). printer waiting for auto-retry (offline ?) The daemon could not open the printer device. The printer may be turned offline. This message can also occur if a printer is out of paper, the paper is jammed, and so on. Another possible cause is that a process, such as an output filter, has exclusive use of the device. The only recourse in this case is to kill the offending process and restart the printer with lpc. 				

	waiting for <i>host</i> to come up A daemon is trying to connect to the remote machine named <i>host</i> , in order to
	send the files in the local queue. If the remote machine is up, lpd on the remote machine is probably dead or hung and should be restarted using lpc .
	sending to host
	The files are being transferred to the remote <i>host</i> , or else the local daemon has hung while trying to transfer the files.
	printer disabled reason:
	The printer has been marked as being unavailable with lpc .
	lpq: The LP print service isn't running or can't be reached. The lpsched process overseeing the spooling queue does not exist. This normally occurs only when the daemon has unexpectedly died. You can restart the printer daemon with lpc .
	lpr: printer: unknown printer
	The printer was not found in the System V LP database. Usually this is a typing mistake; however, it may indicate that the printer does not exist on the system. Use ' lpstat - p ' (see lpstat (1)) or ' lpc status ' (see lpc (1B)) to discover the reason.
	lpr: error on opening queue to spooler
	The connection to lpsched on the local machine failed. This usually means the printer server started at boot time has died or is hung. Check if the printer spooler daemon / usr /lib/lpsched is running.
	lpr: Can't send message to LP print service
	lpr: Can't receive message from LP print service
	These indicate that the LP print service has been stopped. Get help from the system administrator.
	lpr: Received unexpected message from LP print service It is likely there is an error in this software. Get help from system administrator.
NOTES	Output formatting is sensitive to the line length of the terminal; this can result in widely-spaced columns.

NAME	lpr – send a job to the printer				
SYNOPSIS	[— i [inder	/usr/ucb/lpr [-P printer] [-# copies] [-C class] [-J job] [-T title] [-i [indent]] [-w cols] [-B] [-m] [-h] [-s] [-filter_option] [filename]			
AVAILABILITY	SUNWscpu				
DESCRIPTION	lpr forwards printer jobs to a spooling area for subsequent printing as facilities become available. Each printer job consists of copies of, or, with – s , complete pathnames of each <i>filename</i> you specify. The spool area is managed by the line printer spooler, lpsched . lpr reads from the standard input if no files are specified.				
OPTIONS	– P printer	Send output to the named <i>printer</i> . In the absence of the $-\mathbf{P}$ option, the queue to the printer specified by the PRINTER variable in the environment is used. If the PRINTER variable is not set, and the LPDEST environment variable is not set, the queue for the default printer is used.			
	-# copies	Produce the number of <i>copies</i> indicated for each named file. For example:			
		lpr –#3 index.c lookup.c			
		produces three copies of index.c , followed by three copies of lookup.c . On the other hand,			
		cat index.c lookup.c lpr –#3			
		generates three copies of the concatenation of the files.			
	-C class	Print <i>class</i> as the job classification on the burst page. For example,			
		lpr –C Operations new.index.c			
		replaces the system name (the name returned by <i>hostname</i>) with Opera - tions on the burst page, and prints the file new.index.c .			
	– J job	Print <i>job</i> as the job name on the burst page. Normally, lpr uses the first file's name.			
	– T title	Use <i>title</i> instead of the file name for the title used by $pr(1)$.			
	- i [indent]	Indent output <i>indent</i> SPACE characters. Eight SPACE characters is the default.			
	–w cols	Use <i>cols</i> as the page width for pr .			
	m	Send mail upon completion.			
	-h	Suppress printing the burst page.			
	- S	Use the full pathnames (not symbolic links) of the files to be printed rather than trying to copy them. This means the data files should not be modified or removed until they have been printed. $-s$ only prevents copies of local files from being made. Jobs from remote hosts are copied			

		anyway. – s only works with named data files; if the lpr command is at the end of a pipeline, the data is copied to the spool.		
	filter_option	The following single letter options notify the line printer spooler that the files are not standard text files. The spooling daemon will use the appropriate filters to print the data accordingly.		
		 -p Use pr to format the files (lpr -p is very much like pr lpr). -l Print control characters and suppress page breaks. -t The files contain troff(1) (cat phototypesetter) binary data. -n The files contain data from ditroff (device independent troff). -d The files contain data from tex (DVI format from Stanford). -g The files contain standard plot data as produced by the plot(1B) routines. -v The files contain a raster image. The printer must support an appropriate imaging model such as PostScript® in order to print the image. -c The files contain data produced by <i>cifplot</i>. -f Interpret the first character of each line as a standard FORTRAN carriage control character. 		
		If no <i>filter_option</i> is given (and the printer can interpret PostScript), the string `%!´ as the first two characters of a file indicates that it contains PostScript commands.		
		These filter options offer a standard user interface, and all options may not be available for, nor applicable to, all printers.		
FILES	/etc/passwd /usr/lib/lp/lpsch /var/spool/lp/tm /var/spool/lp/tm /var/spool/lp/tm	p/*directories used for spoolingp/system/*-0spooler control files		
SEE ALSO	lp (1), lpc (1B) lp	q(1B), lprm(1B), lpstat(1), plot(1B), pr(1), troff(1), lpsched(1M)		
DIAGNOSTICS	<pre>lpr: printer: unknown printer The printer was not found in the LP database. Usually this is a typing mistake; however, it may indicate that the printer does not exist on the system. Use `lpstat -p´ (see lpstat(1)) or `lpc status´ (see lpc(1B)) to discover the reason.</pre>			
	lpr: error on opening queue to spooler The connection to lpsched on the local machine failed. This usually means the printer server started at boot time has died or is hung. Check if the printer spooler daemon / usr/lib/lpsched is running.			
		ter queue is disabled ans the queue was turned off with		
		/usr/etc/lpc disable printer		

to prevent **lpr** from putting files in the queue. This is normally done by the system manager when a printer is going to be down for a long time. The printer can be turned back on by a super-user with **lpc**.

lpr: Can't send message to the LP print service

lpr: Can't receive message from the LP print service

These indicate that the LP print service has been stopped. Get help from the system administrator.

lpr: Received unexpected message from LP print service

It is likely there is an error in this software. Get help from system administrator.

lpr: There is no filter to convert the file content

Use the `lpstat -p -l' command to find a printer that can handle the file type directly, or consult with your system administrator.

lpr: cannot access the file

Make sure file names are valid.

NOTES Ip is the preferred interface.

Command-line options cannot be combined into a single argument as with some other commands. The command:

lpr –fs

is not equivalent to

lpr –f –s

Placing the -s flag first, or writing each option as a separate argument, makes a link as expected.

lpr - p is not precisely equivalent to $pr \mid lpr$. lpr - p puts the current date at the top of each page, rather than the date last modified.

Fonts for **troff**(1) and $T_E X^{\otimes}$ reside on the printer host. It is currently not possible to use local font libraries.

lpr objects to printing binary files.

The -s option, intended to use symbolic links in SunOS, does not use symbolic links in the compatibility package. Instead, the complete path names are used. Also, the copying is avoided only for print jobs that are run from the printer host itself. Jobs added to the queue from a remote host are always copied into the spool area. That is, if the printer does not reside on the host that **lpr** is run from, the spooling system makes a copy the file to print, and places it in the spool area of the printer host, regardless of -s.

NAME	lprm – remove jobs from the printer queue				
SYNOPSIS	/usr/ucb/lprm [–Pprinter] [–] [job #] [username]				
AVAILABILITY	SUNWscpu				
DESCRIPTION	lprm removes a job or jobs from a printer's spooling queue. Since the spool directory is protected from users, using lprm is normally the only method by which a user can remove a job.				
	Without any arguments, lprm deletes the job that is currently active, provided that the user who invoked lprm owns that job.				
	When the super-user specifies a <i>username</i> , lprm removes all jobs belonging to that user.				
	You can remove a specific job by supplying its job number as an argument, which you can obtain using lpq (1B). For example: example% lpq –Phost host is ready and printing				
	Rank Owner Job Files Total Size				
	active wendy 385 standard input 35501 bytes example% lprm –Phost 385				
	lprm reports the names of any files it removes, and is silent if there are no applicable jobs to remove.				
	lprm Sends the request to cancel a job to the print spooler, LPSCHED.				
OPTIONS	–P <i>printer</i> Specify the queue associated with a specific printer. Otherwise the value of the PRINTER variable in the environment is used. If the PRINTER variable is not set, and the LPDEST environment variable is not set, the queue for the default printer is used.				
	 Remove all jobs owned by you. If invoked by the super-user, all jobs in the spool are removed. Job ownership is determined by the user's login name and host name on the machine where the lpr command was executed. 				
FILES	/var/spool/lp/* spooling directories				
SEE ALSO	lp (1), lpc (1B), lpq (1B), lpstat (1), lpsched (1M)				
DIAGNOSTICS	<pre>lprm: printer: unknown printer The printer was not found in the System V LP database. Usually this is a typing mistake; however, it may indicate that the printer does not exist on the system. Use `lpstat -p´ (see lpstat(1)) or `lpc status´ (see lpc(1B)) to discover the reason.</pre>				

	lprm: error on opening queue to spooler The connection to lpsched on the local machine failed. This usually means the printer server started at boot time has died or is hung. Check if the printer spooler daemon / usr/lib/lpsched is running.
	lprm: Can't send message to the LP print service
	lprm: Can't receive message from the LP print service These indicate that the LP print service has been stopped. Get help from the system administrator.
	lprm: Received unexpected message from the LP print service It is likely there is an error in this software. Get help from system administrator
	lprm: Can't cancel request You are not allowed to remove another's request.
NOTES	An active job may be incorrectly identified for removal by an lprm command issued wit

ES An active job may be incorrectly identified for removal by an **lprm** command issued with no arguments. During the interval between an **lpq**(1B) command and the execution of **lprm**, the next job in queue may have become active; that job may be removed unintentionally if it is owned by you. To avoid this, supply **lprm** with the job number to remove when a critical job that you own is next in line.

Only the super-user can remove print jobs submitted from another host.

lp is the preferred interface.

lpstat – print in	formation about the status of the LP print service			
lpstat [−d] [−r] [−R] [−s] [−t] [−a [list]] [−c [list]] [−f [list] [−l]] [−o [list]] [−p [list] [−D] [−l]] [−P] [−S [list] [−l]] [−u [login-ID-list]] [−v [list]]				
SUNWlpu				
The lpstat comr	nand prints information about the current status of the LP print service.			
If no options are given, then lpstat prints the status of all the user's print requests made by lp (see lp (1)). Any arguments that are not <i>options</i> are assumed to be <i>request-IDs</i> as returned by lp . The lpstat command prints the status of such requests. The <i>options</i> may appear in any order and may be repeated and intermixed with other arguments. Some o the keyletters below may be followed by an optional <i>list</i> that can be in one of two forms: list of items separated from one another by a comma, or a list of items separated from one another by spaces enclosed in quotes. For example:				
examp	le% lpstat –u "user1 user2 user3"			
Specifying all after any keyletter that takes <i>list</i> as an argument causes all information relevant to the keyletter to be printed. For example, the command:				
example% lpstat –o all				
prints the status of all output requests.				
The omission of a <i>list</i> following such key letters causes all information relevant to the key letter to be printed. For example, the command:				
exampl	e% lpstat –o			
prints the status of all output requests.				
The following o	ptions are supported:			
- a [list]	Reports whether print destinations are accepting requests. <i>list</i> is a list of intermixed printer names and class names.			
- c [<i>list</i>]	Print name of all classes and their members. <i>list</i> is a list of class names.			
$-\mathbf{d}$	Print the system default destination for output requests.			
-f [list] [-l]	Print a verification that the forms in <i>list</i> are recognized by the LP print service. <i>list</i> is a list of forms; the default is all . The –l option will list the form descriptions.			
- o [<i>list</i>]	Print the status of output requests: <i>list</i> is a list of intermixed printer names, class names, and <i>request-IDs</i> . The keyletter – o may be omitted.			
- p [<i>list</i>] [- D] [-]	I]			
	Print the status of printers. <i>list</i> is a list of printer names. If the $-D$ option is given, a brief description is printed for each printer in <i>list</i> . If the $-I$ option is given, and the printer is on the local machine, a full description of each printer's configuration is given, including the form

lptest (1B)	SunOS/BSD Compatibility Package Commands SunOS	\$ 5.5
NAME	lptest – generate lineprinter ripple pattern	
SYNOPSIS	/usr/ucb/lptest [length [count]]	
AVAILABILITY	SUNWscpu	
DESCRIPTION	lptest writes the traditional "ripple test" pattern on standard output. In 96 lines, this p tern will print all 96 printable ASCII characters in each position. While originally creat to test printers, it is quite useful for testing terminals, driving terminal ports for debug ging purposes, or any other task where a quick supply of random data is needed. The <i>length</i> argument specifies the output line length if the the default length of 79 is in propriate. The <i>count</i> argument specifies the number of output lines to be generated if the default count of 200 is inappropriate.	ed g- ap-
NOTES	if <i>count</i> is to be specified, <i>length</i> must be also be specified. This command is obsolete.	

modified 14 Sep 1992

NAME	ls – list contents of directory		
SYNOPSIS	/usr/bin/ls [-aAbcCdfFgilLmnopqrRstux1] [file] /usr/xpg4/bin/ls [-aAbcCdfFgilLmnopqrRstux1] [file]		
AVAILABILITY /usr/bin/ls	SUNWcsu		
/usr/xpg4/bin/ls	SUNWxcu4		
DESCRIPTION	For each <i>file</i> that is a directory, ls lists the contents of the directory; for each <i>file</i> that is an ordinary file, ls repeats its name and any other information requested. The output is sorted alphabetically by default. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments appear before directories and their contents.		
	There are three major listing formats. The default format for output directed to a termi- nal is multi–column with entries sorted down the columns. The -1 option allows single column output and $-\mathbf{m}$ enables stream output format. In order to determine output for- mats for the $-\mathbf{C}$, $-\mathbf{x}$, and $-\mathbf{m}$ options, ls uses an environment variable, COLUMNS , to determine the number of character positions available on one output line. If this variable is not set, the terminfo (4) database is used to determine the number of columns, based on the environment variable TERM . If this information cannot be obtained, 80 columns are assumed.		
	The mode printed under the –l option consists of ten characters. The first character may be one of the following:		
	 d the entry is a directory; l the entry is a symbolic link; b the entry is a block special file; c the entry is a character special file; p the entry is a fifo (or "named pipe") special file; - the entry is an ordinary file; the entry is a FIFO. 		
	The next 9 characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the file; and the last to all others. Within each set, the three characters indicate permission to read, to write, and to execute the file as a program, respectively. For a directory, "execute" permission is interpreted to mean permission to search the directory for a specified file. The character after permissions is ACL indication. A plus sign is displayed if there is an ACL associated with the file. Nothing is displayed if there are just permissions.		
	ls – l (the long list) prints its output as follows:		
	–rwxrwxrwx+ 1 smith dev 10876 May 16 9:42 part2		
odified 17 Apr 1995	1-553		

modified 17 Apr 1995

ls(1)	User Commands SunOS 5.5	
	Reading from right to left, you see that the current directory holds one file, named part2 . Next, the last time that file's contents were modified was 9:42 A.M. on May 16. The file contains 10,876 characters, or bytes. The owner of the file, or the user, belongs to the group dev (perhaps indicating "development"), and his or her login name is smith . The number, in this case 1 , indicates the number of links to file part2 ; see cp (1). The plus sign indicates that there is an ACL associated with the file. Finally, the dash and letters tell you that user, group, and others have permissions to read, write, and execute part2 . The execute (x) symbol here occupies the third position of the three-character sequence.	
	A – in the third position would have indicated a denial of execution permissions.	
/usr/bin/ls /usr/xpg4/bin/ls	 The permissions are indicated as follows: r the file is readable w the file is writable x the file is executable - the indicated permission is <i>not</i> granted l mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off) L mandatory locking occurs during access (the set-group-ID bit is on and the group execution bit is off) s the set-user-ID or set-group-ID bit is on, and the corresponding user or group execution bit is also on S undefined bit-state (the set-user-ID bit is on and the user execution bit is off) 	
	 t the 1000 (octal) bit, or sticky bit, is on (see chmod(1)), and execution is on T the 1000 bit is turned on, and execution is off (undefined bit-state) 	
	For user and group permissions, the third position is sometimes occupied by a character other than \mathbf{x} or $-$. \mathbf{s} also may occupy this position, referring to the state of the set-ID bit, whether it be the user's or the group's. The ability to assume the same ID as the user during execution is, for example, used during login when you begin as root but need to assume the identity of the user you login as.	
	In the case of the sequence of group permissions, l may occupy the third position. l refers to mandatory file and record locking. This permission describes a file's ability to allow other files to lock its reading or writing permissions during access.	
	For others permissions, the third position may be occupied by t or T . These refer to the state of the sticky bit and execution permissions.	
OPTIONS	- a List all entries, including those that begin with a dot (.), which are normally not listed.	
	-A List all entries, including those that begin with a dot (.), with the exception of the working directory (.) and the parent directory ().	
	- b Force printing of non-printable characters to be in the octal \ddd notation.	
	-c Use time of last modification of the i-node (file created, mode changed, and so forth) for sorting $(-t)$ or printing $(-l \text{ or } -n)$.	
	-C Multi-column output with entries sorted down the columns. This is the default	

modified 17 Apr 1995

output format.

- -d If an argument is a directory, list only its name (not its contents); often used with
 -l to get the status of a directory.
- -f Force each argument to be interpreted as a directory and list the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a; the order is the order in which entries appear in the directory.
- **-F** Put a slash (/) after each filename if the file is a directory, an asterisk (*) if the file is an executable, and an at-sign (@) if the file is a symbolic link.
- -g The same as –l, except that the owner is not printed.
- -i For each file, print the i-node number in the first column of the report.
- -1 List in long format, giving mode, ACL indication, number of links, owner, group, size in bytes, and time of last modification for each file (see above). If the file is a special file, the size field instead contains the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format 'month date year'; files modified within six months show 'month date time.' If the file is a symbolic link, the filename is printed followed by " \rightarrow " and the path name of the referenced file.
- -L If an argument is a symbolic link, list the file or directory the link references rather than the link itself.
- -m Stream output format; files are listed across the page, separated by commas.
- -n The same as -l, except that the owner's UID and group's GID numbers are printed, rather than the associated character strings.
- -**o** The same as -**l**, except that the group is not printed.
- -**p** Put a slash (/) after each filename if the file is a directory.
- -q Force printing of non-printable characters in file names as the character question mark (?).
- -**r** Reverse the order of sort to get reverse alphabetic or oldest first as appropriate.
- -**R** Recursively list subdirectories encountered.
- -s Give size in blocks, including indirect blocks, for each entry.
- -t Sort by time stamp (latest first) instead of by name. The default is the last modification time. (See -u and -c.)
- -u Use time of last access instead of last modification for sorting (with the -t option) or printing (with the -l option).
- -x Multi-column output with entries sorted across rather than down the page.
- -1 Print one entry per line of output.

Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: -C and -1 (one), -c and -u. The last option specified in each pair determines the output format.

modified 17 Apr 1995

ls(1)	User Commands SunOS 5.5
/usr/bin/ls	Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: $-C$ and $-l$ (ell), $-m$ and $-l$ (ell), $-x$ and $-l$ (ell). The $-l$ option overrides the other option specified in each pair.
/usr/xpg4/bin/ls	Specifying more than one of the options in the following mutually exclusive pairs is not considered an error: $-C$ and $-l$ (ell), $-m$ and $-l$ (ell), $-x$ and $-l$ (ell). The last option specified in each pair determines the output format.
OPERANDS	The following operand is supported:
	file A path name of a file to be written. If the file specified is not found, a diagnostic message will be output on standard error.
EXAMPLES	An example of a file's permissions is:
	- r wx rr
	This describes a file that is readable, writable, and executable by the user and readable by the group and others.
	Another example of a file's permissions is:
	-rwsr-xr-x
	This describes a file that is readable, writable, and executable by the user, readable and executable by the group and others, and allows its user-ID to be assumed, during execution, by the user presently executing it.
	Another example of a file's permissions is:
	-rw-rwl
	This describes a file that is readable and writable only by the user and the group and can be locked during access.
	An example of a command line:
	example% ls –a
	This command prints the names of all files in the current directory, including those that begin with a dot (.), which normally do not print.
	Another example of a command line:
	example% ls –aisn
	This command provides information on a ll files, including those that begin with a dot (a), the i -number—the memory address of the i-node associated with the file—printed in the left-hand column (i); the s ize (in blocks) of the files, printed in the column to the right of the i-numbers (s); finally, the report is displayed in the n umeric version of the long list, printing the UID (instead of user name) and GID (instead of group name) numbers associated with the files.
	When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks, is printed.

ls(1B)	SunOS/BSD Compatibility Package Commands SunOS 5	
NAME	ls – list the contents of a directory	
SYNOPSIS	/usr/ucb/ls [-aAcCdfFgilLqrRstu1] filename	
AVAILABILITY	SUNWscpu	
DESCRIPTION	For each <i>filename</i> which is a directory, ls lists the contents of the directory; for each <i>filename</i> which is a file, ls repeats its name and any other information requested. By default, the output is sorted alphabetically. When no argument is given, the current directory is listed. When several arguments are given, the arguments are first sorted appropriately, but file arguments are processed before directories and their contents.	
Permissions Field	The mode printed under the –l option contains 10 characters interpreted as follows. If the first character is: d entry is a directory;	
	 b entry is a block-type special file; c entry is a character-type special file; 	
	l entry is a symbolic link;	
	 p entry is a FIFO (also known as "named pipe") special file; s entry is an AF_UNIX address family socket, or 	
	 entry is a plain file. The next 9 characters are interpreted as three sets of three bits each. The first set refers owner permissions; the next refers to permissions to others in the same user-group; an the last refers to all others. Within each set the three characters indicate permission respectively to read, to write, or to execute the file as a program. For a directory, "execute" permission is interpreted to mean permission to search the directory. The permissions are indicated as follows: 	nd -
	 r the file is readable; w the file is writable; x the file is executable; - the indicated permission is not granted. 	
	The group-execute permission character is given as s if the file has the set-group-id bit set; likewise the owner-execute permission character is given as s if the file has the set-user-id bit set.	
	The last character of the mode (normally x or `-´) is true if the 1000 bit of the mode is of See chmod (1) for the meaning of this mode. The indications of set-ID and 1000 bits of mode are capitalized (S and T respectively) if the corresponding execute permission is <i>not</i> set.	the
	When the sizes of the files in a directory are listed, a total count of blocks, including indirect blocks is printed.	
1B-558	modified 14 Sep 1	1992

OPTIONS	- a	List all entries; in the absence of this option, entries whose names begin with a are <i>not</i> listed (except for the privileged user, for whom ls normally prints
		even files that begin with a $$.).

- -A Same as -a, except that `.´ and `..´ are not listed.
- -c Use time of last edit (or last mode change) for sorting or printing.
- -C Force multi-column output, with entries sorted down the columns; for **ls**, this is the default when output is to a terminal.
- If argument is a directory, list only its name (not its contents); often used with
 -I to get the status of a directory.
- -f Force each argument to be interpreted as a directory and list the name found in each slot. This option turns off -l, -t, -s, and -r, and turns on -a; the order is the order in which entries appear in the directory.
- -F Mark directories with a trailing slash (`/´), executable files with a trailing asterisk (`*´), symbolic links with a trailing at-sign (`@´), and AF_UNIX address family sockets with a trailing equals sign (`=´).
- -g For **ls**, show the group ownership of the file in a long output.
- -i For each file, print the i-node number in the first column of the report.
- -I List in long format, giving mode, number of links, owner, size in bytes, and time of last modification for each file. If the file is a special file the size field will instead contain the major and minor device numbers. If the time of last modification is greater than six months ago, it is shown in the format `month date year'; files modified within six months show `month date time'. If the file is a symbolic link the pathname of the linked-to file is printed preceded by `—>'.
- -L If argument is a symbolic link, list the file or directory the link references rather than the link itself.
- -**q** Display non-graphic characters in filenames as the character ?; for **ls**, this is the default when output is to a terminal.
- -r Reverse the order of sort to get reverse alphabetic or oldest first as appropriate.
- -**R** Recursively list subdirectories encountered.
- -s Give size of each file, including any indirect blocks used to map the file, in kilobytes.
- -t Sort by time modified (latest first) instead of by name.
- $-\mathbf{u}$ Use time of last access instead of last modification for sorting (with the $-\mathbf{t}$ option) and/or printing (with the $-\mathbf{l}$ option).
- -1 Force one entry per line output format; this is the default when output is not to a terminal.

modified 14 Sep 1992

FILES	/etc/group /etc/passwd	to get group ID for ` ls –g ´ to get user ID's for ` ls –l ´ and ` ls –o ´
NOTES	NEWLINE and TAB a	re considered printing characters in filenames.
	The output device is	assumed to be 80 columns wide.
	much different than	used on whether the output is a teletype is undesirable as $\mathbf{s} - \mathbf{s}$ is $\mathbf{s} - \mathbf{s} \mathbf{pr}'$. On the other hand, not doing this setting would make the used ls almost certain losers.
	Unprintable characte	ers in file names may confuse the columnar output options.

SUNWcsu		
SUNWxcu4		
other languages	nd is a macro processor intended as a front end for C, assembler, and s. Each of the argument files is processed in order; if there are no files, or standard input is read. The processed text is written on the standard out-	
Macro calls hav	e the form:	
	g1,arg2,, argn)	
not followed by macro names co	a digit. If the name of the macro. If the name of a defined macro is a (, it is deemed to be a call of that macro with no arguments. Potential possist of alphanumeric characters and underscore (_), where the first a digit.	
Left and right s	ted blanks, TABs, and NEWLINEs are ignored while collecting arguments. ingle quotes are used to quote strings. The value of a quoted string is the of the quotes.	
When a macro name is recognized, its arguments are collected by searching for a match- ing right parenthesis. If fewer arguments are supplied than are in the macro definition, the trailing arguments are taken to be NULL. Macro evaluation proceeds normally during the collection of the arguments, and any commas or right parentheses that happen to turn up within the value of a nested call are as effective as those in the original input text. After argument collection, the value of the macro is pushed back onto the input stream and rescanned.		
The options and	l their effects are as follows:	
- e	Operate interactively. Interrupts are ignored and the output is unbuf- fered.	
- S	Enable line sync output for the C preprocessor (#line \dots)	
– B int	Change the size of the push-back and argument collection buffers from the default of 4,096 .	
–H int	Change the size of the symbol table hash array from the default of 199 . The size should be prime.

modified 27 Jun 1995

	– S int	Change the size of the call stack from the default of 100 slots. Macros take three slots, and non-macro arguments take one.
	– T int	Change the size of the token buffer from the default of 512 bytes.
	To be effective, –U flags:	the above flags must appear before any file names and before any $-\mathbf{D}$ or
	- D name[=val]	Defines <i>name</i> to <i>val</i> or to NULL in <i>val</i> 's absence.
	–U name	Undefines <i>name</i> .
OPERANDS	The following o	perand is supported:
	file	A path name of a text file to be processed. If no <i>file</i> is given, or if it is $-$, the standard input is read.
USAGE		able the following built-in macros. These macros may be redefined, but e the original meaning is lost. Their values are NULL unless otherwise
	changequote	Change quote symbols to the first and second arguments. The symbols may be up to five characters long. changequote without arguments restores the original values (that is, `´).
	changecom	Change left and right comment markers from the default # and NEW- LINE. With no arguments, the comment mechanism is effectively dis- abled. With one argument, the left marker becomes the argument and the right marker becomes NEWLINE. With two arguments, both mark- ers are affected. Comment markers may be up to five characters long.
	decr	Returns the value of its argument decremented by 1.
	define	The second argument is installed as the value of the macro whose name is the first argument. Each occurrence of \$ <i>n</i> in the replacement text, where <i>n</i> is a digit, is replaced by the <i>n</i> -th argument. Argument 0 is the name of the macro; missing arguments are replaced by the null string; \$# is replaced by the number of arguments; \$* is replaced by a list of all the arguments separated by commas; \$@ is like \$*, but each argument is quoted (with the current quotes).
	defn	Returns the quoted definition of its argument(s). It is useful for renam- ing macros, especially built-ins.
	divert	m4 maintains 10 output streams, numbered 0-9. The final output is the concatenation of the streams in numerical order; initially stream 0 is the current stream. The divert macro changes the current output stream to its (digit-string) argument. Output diverted to a stream other than 0 through 9 is discarded.
	divnum	Returns the value of the current output stream.
	dnl	Reads and discards characters up to and including the next NEWLINE.

	dumpdef	Prints current names and definitions, for the named items, or for all if no arguments are given.
	errprint	Prints its argument on the diagnostic output file.
/usr/ccs/bin/m4	eval	Evaluates its argument as an arithmetic expression, using 32-bit signed- integer arithmetic. The following operators are supported: parentheses, unary –, unary +, !, ~, *, /, %, +, –, relationals, bitwise &, , &&, and . Octal and hex numbers may be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
/usr/xpg4/bin/m4	eval	Evaluates its argument as an arithmetic expression, using 32-bit signed- integer arithmetic. The following operators are supported: parentheses, unary –, unary +, !, ~, *, /, %, +, –, <<, >>, relationals, bitwise &, , &&, and . Precedence and associativity are as in C. Octal and hex numbers may also be specified as in C. The second argument specifies the radix for the result; the default is 10. The third argument may be used to specify the minimum number of digits in the result.
	ifdef	If the first argument is defined, the value is the second argument, other- wise the third. If there is no third argument, the value is NULL . The word unix is predefined.
	ifelse	This macro has three or more arguments. If the first argument is the same string as the second, then the value is the third argument. If not, and if there are more than four arguments, the process is repeated with arguments 4, 5, 6 and 7. Otherwise, the value is either the fourth string, or, if it is not present, NULL.
	include	Returns the contents of the file named in the argument.
	incr	Returns the value of its argument incremented by 1. The value of the argument is calculated by interpreting an initial digit-string as a decimal number.
	index	Returns the position in its first argument where the second argument begins (zero origin), or -1 if the second argument does not occur.
	len	Returns the number of characters in its argument.
	m4exit	This macro causes immediate exit from m4 . Argument 1, if given, is the exit code; the default is 0 .
	m4wrap	Argument 1 will be pushed back at final EOF; example: m4wrap(`cleanup()`)
	maketemp	Fills in a string of " X " characters in its argument with the current pro- cess ID.
	popdef	Removes current definition of its argument(s), exposing the previous one, if any.
	pushdef	Like define , but saves any previous definition.

	shift	Returns all but its first argument. The other arguments are quoted and pushed back with commas in between. The quoting nullifies the effect of the extra scan that will subsequently be performed.
	sinclude	This macro is identical to include , except that it says nothing if the file is inaccessible.
	substr	Returns a substring of its first argument. The second argument is a zero origin number selecting the first character; the third argument indicates the length of the substring. A missing third argument is taken to be large enough to extend to the end of the first string.
	syscmd	This macro executes the command given in the first argument. No value is returned.
	sysval	This macro is the return code from the last call to syscmd .
	translit	Transliterates the characters in its first argument from the set given by the second argument to the set given by the third. No abbreviations are permitted.
	traceon	This macro with no arguments, turns on tracing for all macros (includ- ing built-ins). Otherwise, turns on tracing for named macros.
	traceoff	Turns off trace globally and for any macros specified. Macros specifically traced by traceon can be untraced only by specific calls to traceoff .
	undefine	Removes the definition of the macro named in its argument.
	undivert	This macro causes immediate output of text from diversions named as arguments, or all diversions if no argument. Text may be undiverted into another diversion. Undiverting discards the diverted text.
EXAMPLES		f a single m4 input file capable of generating two output files follows. The buld contain lines such as:
		R, 1, do_something) R, 2, do_something)
	The makefile f	or the program might include:
	file1.1	.c : file1.m4 m4 -D VER=1 file1.m4 > file1.1.c
	file1.2	 .c : file1.m4 m4 -D VER=2 file1.m4 > file1.2.c
	The _I I ontion	 can be used to undefine VER . If file1.m4 contains:
	-	R, 1, do_something)
		R , 2, do_something)
		f(VER, do_something)

	then the makefile would contain: file1.0.c : file1.m4 m4 -U VER file1.m4 > file1.0.c
	 file1.1.c : file1.m4 m4 -D VER=1 file1.m4 > file1.1.c
	 file1.2.c : file1.m4 m4 -D VER=2 file1.m4 > file1.2.c
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of m4 : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurredIf the m4exit macro is used, the exit value can be specified by the input file.

NAME	mail, rmail – read mail or send mail to users		
SYNOPSIS Sending mail	<pre>mail [-tw] [-m message_type] recipient rmail [-tw] [-m message_type] recipient</pre>		
Reading mail	mail [-ehpPqr] [-f file]		
Debugging	mail [– x debug_level] [other_mail_options] recipient		
AVAILABILITY	SUNWcsu		
DESCRIPTION	A <i>recipient</i> is usually a user name recognized by login (1). When <i>recipients</i> are named, mail assumes a message is being sent. It reads from the standard input up to an end-of- file (CTRL-D) or, if reading from a terminal device, until it reads a line consisting of just a period. When either of those indicators is received, mail adds the <i>letter</i> to the <i>mailfile</i> for each <i>recipient</i> .		
	A <i>letter</i> is composed of some <i>header lines</i> followed by a blank line followed by the <i>message content</i> . The <i>header lines</i> section of the letter consists of one or more UNIX postmarks:		
	<pre>From sender date_and_time [remote from remote_system_name]</pre>		
	followed by one or more standardized message header lines of the form:		
	keyword-name: [printable text]		
	where <i>keyword-name</i> is comprised of any printable, non-whitespace characters other than colon (`:`). A Content-Length: header line, indicating the number of bytes in the <i>message content</i> will always be present unless the letter consists of only header lines with no message content. A Content-Type: header line that describes the type of the <i>message content</i> (such as text, binary, multipart, etc.) will also be present unless the letter consists of only header lines with no message content. Header lines may be continued on the following line if that line starts with white space.		
OPTIONS Sanding mail	The following command line arguments affect sending mail:		
Sending mail	The following command-line arguments affect sending mail: -m message_type A Message-Type: line is added to the message header with the value of message_type.		
	-t A To: line is added to the message header for each of the intended <i>recipients</i> .		
	-w A letter is sent to a remote recipient without waiting for the completion of the remote transfer program.		
	If a letter is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure. If mail is interrupted during input, the message is saved in the file dead.letter to allow editing and resending. dead.letter is		

	append to (or cr will be appende fails, no dead.le	ed to, thus preserving any previous contents. The initial attempt to reate) dead.letter will be in the current directory. If this fails, dead.letter ed to (or created in) the user's login directory. If the second attempt also etter processing will be done.	
	rmail only permits the sending of mail; uucp (1C) uses rmail as a security precaution. Any application programs that generate mail messages should be sure to invoke rmail rather than mail for message transport and/or delivery.		
	If the local system has the Basic Networking Utilities installed, mail may be sent to a reci- pient on a remote system. There are numerous ways to address mail to recipients on remote systems depending on the transport mechanisms available to the local system. The two most prevalent addressing schemes are UUCP-style and Domain-style.		
	UUCP-style add	ressing Remote recipients are specified by prefixing the recipient name with the remote system name and an exclamation point, such as sysa!user . If csh (1) is the default shell, sysa\!user should be used. A series of system names separated by exclamation points can be used to direct a letter through an extended network (such as sysa!sysb!sysc!user or sysa\!sysb\!sysc\!user).	
	Domain-style a	ddressing Remote recipients are specified by appending an `@´ and domain (and possibly sub-domain) information to the recipient name (such as user@sf.att.com). (The local system administrator should be consulted for details on which addressing conventions are available on the local system.)	
Reading Mail	The following c	ommand-line arguments affect reading mail:	
	-е	Mail is not printed. An exit status of 0 is returned if the user has mail; otherwise, an exit status of 1 is returned.	
	-h	A window of headers are initially displayed rather than the latest mes- sage. The display is followed by the ? prompt.	
	- p	All messages are printed without prompting for disposition.	
	- P	All messages are printed with <i>all</i> header lines displayed, rather than the default selective header line display.	
	- q	mail terminates after interrupts. Normally an interrupt causes only the termination of the message being printed.	
	-r	Messages are printed in first-in, first-out order.	
	-f file	mail uses <i>file</i> (such as mbox) instead of the default <i>mailfile</i> .	
	 mail, unless otherwise influenced by command-line arguments, prints a user's mail messages in last-in, first-out order. The default mode for printing messages is to display only those header lines of immediate interest. These include, but are not limited to, the UNIX From and >From postmarks, From:, Date:, Subject:, and Content-Length: header lines, 		

From and **>From** postmarks, **From**:, **Date**:, **Subject**:, and **Content-Length**: header lines, and any recipient header lines such as **To**:, **Cc**:, **Bcc**:, and so forth. After the header lines

modified 21 Feb 1995

have been displayed, **mail** will display the contents (body) of the message only if it contains no unprintable characters. Otherwise, **mail** will issue a warning statement about the message having binary content and **not** display the content. (This may be overridden via the **p** command. See below.)

For each message, the user is prompted with a ? and a line is read from the standard input. The following commands are available to determine the disposition of the message:

sage.	
#	Print the number of the current message.
-	Print previous message.
<new-line>,+, or n</new-line>	Print the next message.
!command	Escape to the shell to do <i>command</i> .
a	Print message that arrived during the mail session.
d , or dp	Delete the current message and print the next message.
d <i>n</i>	Delete message number <i>n</i> . Do not go on to next message.
dq	Delete message and quit mail .
h	Display a window of headers around current message.
h <i>n</i>	Display a window of headers around message number <i>n</i> .
h a	Display headers of all messages in the user's mailfile.
h d	Display headers of messages scheduled for deletion.
m [persons]	Mail (and delete) the current message to the named <i>persons</i> .
n	Print message number <i>n</i> .
р	Print current message again, overriding any indications of binary (that is, unprintable) content.
Р	Override default brief mode and print current message again, displaying all header lines.
q , or CTRL-D	Put undeleted mail back in the <i>mailfile</i> and quit mail .
r [users]	Reply to the sender, and other <i>users</i> , then delete the message.
s [files]	Save message in the named <i>files</i> (mbox is default) and delete the message.
u [<i>n</i>]	Undelete message number <i>n</i> (default is last read).
w [files]	Save message contents, without any header lines, in the named <i>files</i> (mbox is default) and delete the message.
X	Put all mail back in the <i>mailfile</i> unchanged and exit mail .
y [files]	Same as –w option.
?	Print a command summary.

	When a user log	gs in, the presence of mail, if any, is usually indicated. Also, notification is	
	made if new mail arrives while using mail .		
	The permissions of <i>mailfile</i> may be manipulated using chmod (1) in two ways to alter the function of mail . The other permissions of the file may be read-write (0666), read-only (0664), or neither read nor write (0660) to allow different levels of privacy. If changed to other than the default (mode 0660), the file will be preserved even when empty to perpetuate the desired permissions. (The administrator may override this file preservation using the DEL_EMPTY_MAILFILE option of mailcnfg .)		
	The group ID of the mailfile must be mail to allow new messages to be delivered, and the mailfile must be writable by group mail .		
Debugging	The following c	ommand-line arguments cause mail to provide debugging information:	
	–x debug_level	mail creates a trace file containing debugging information.	
	debugging info lute value of <i>de</i> debugging. If <i>d</i> encountered so debug file will a specification of	auses mail to create a file named / tmp / MLDBG <i>process_id</i> that contains rmation relating to how mail processed the current message. The abso- bug_level controls the verboseness of the debug information. 0 implies no <i>lebug_level</i> is greater than 0 , the debug file will be retained only if mail me problem while processing the message. If <i>debug_level</i> is less than 0 the always be retained. The <i>debug_level</i> specified via – x overrides any DEBUG in / etc/mail/mailcnfg . The information provided by the – x ic and is probably only useful to system administrators.	
	Several forms of notification are available for mail by including one of the following lines in the message header.		
Delivery Notification		• • •	
Delivery Notification		header.	
Delivery Notification	in the message	header. ions: [/options]

NOTES	Solaris Advanced User's Guide The interpretation and resulting action taken because of the header lines described in the Delivery Notifications section above will only occur if this version of mail is installed on the system where the delivery (or failure) happens. Earlier versions of mail may not sup- port any types of delivery notification.		
	Conditions sometimes result in a failure to remove a lock file.		
	After an interrupt, the next message may not be printed; printing may be forced by typ- ing a p .		

NAME	mailcompat – provide SunOS compatibility for Solaris mailbox format
DESCRIPTION	mailcompat is a program to provide SunOS 4. <i>x</i> compatability for the Solaris mailbox for- mat. You would typically run mailcompat to be able to read mail on a workstation run- ning SunOS 4. <i>x</i> when your mail server is running Solaris.
	Enabling mailcompat creates an entry in your .forward file, if it exists. If this file does not exist, mailcompat will create it. Disabling mailcompat will remove the entry from the .forward file, and if this was the only entry, will remove the entire file.
	To execute mailcompat , log onto the Solaris mail server and enter mailcompat on the command line. Answer the queries provided by the program.
EXAMPLES	 The following example enables the mailcompat feature for the user "john". example% mailcompat This program can be used to store your mail in a format that you can read with SunOS 4.X based mail readers To enable the mailcompat feature a ".forward" file is created. Would you like to enable the mailcompat feature? Y Mailcompat feature ENABLED.Run mailcompat with no arguments to remove it example% The following example disables the mailcompat feature for the user "john". example% The following example disables the mailcompat feature for the user "john". example% The following example disables the store your mail in a format that you can read with SunOS 4.X based mail readers You have a .forward file in your home directory containing: " /usr/bin/mailcompat johns" Would you like to remove it and disable the mailcompat feature? y Back to normal reception of mail. example%
FILES	<i>~/.forward</i> list of recipients for forwarding messages

NAME	mailstats – print statistics collect	ed by sendmail
SYNOPSIS	mailstats [–c configfile] [–f stati	sticsfile] file
AVAILABILITY	SUNWcsu	
DESCRIPTION	mailstats prints out the statistics collected by the sendmail (1M) program on mailer usage. These statistics are collected if the file indicated by the S configuration option of sendmail (defined in / etc/mail/sendmail.cf) exists. The default statistics file is / etc/mail/sendmail.st . mailstats first prints the time that the statistics file was created and the last time it was modified. It will then print a table with one row for each mailer specified in the configuration file. The first column is the mailer number, followed by the total number of messages sent from this mailer. The next two columns refer to the number of messages received by sendmail , and the last two columns refer to messages sent by sendmail . The number of messages and their total size (in 1024 byte units) is given. No numbers are printed if no messages were sent (or received) for any mailer. You might want to add an entry to / var/spool/cron/crontabs/root to reinitialize the statis-	
	tics file once a night. Copy / dev / the counters.	null into the statistics file or otherwise truncate it to reset

modified 4 Apr 1995

NAME	mailx, mail, Ma	il – interactive message processing system
SYNOPSIS		
AVAILABILITY	SUNWcsu	
DESCRIPTION	and receiving n below for mails When reading n responding to n modification of Incoming mail i When mails is a messages are re- specific action i called the mbox ENVIRONME dary files name The user can ac sages in the second	es listed above provide a comfortable, flexible environment for sending nail messages electronically. The OPTIONS and USAGE documented a also apply to / usr/ucb/mail and / usr/ucb/Mail , except where noted. mail, mailx provides commands to facilitate saving, deleting, and nessages. When sending mail, mailx allows editing, reviewing and other the message as it is entered. is stored in a standard file for each user, called the mailbox for that user. called to read messages, the mailbox is the default place to find them. As ead, they are marked to be moved to a secondary file for storage, unless is taken, so that the messages need not be seen again. This secondary file is a and is normally located in the user's HOME directory (see MBOX in NT for a description of this file). Messages can be saved in other secon- d by the user. Messages remain in a secondary file until forcibly removed. cess a secondary file by using the – f option of the mailx command. Mes- ondary file can then be read or otherwise processed using the same Com - e primary mailbox . This gives rise within these pages to the notion of a x .
XPG4	 mailx conforms to the XPG4 specification (see xpg4(5)). Incompatibilities exist between the Solaris and XPG4 behavior with respect to the command pairs reply/Reply and followup/Followup and the default values for a number of internal variables. See the Commands and Internal Variables subsections below. To obtain XPG4 behavior, specify the –n option on the command line. See OPTIONS and USAGE below. 	
OPTIONS		nd line options start with a dash (–). Any other arguments are taken to be cipients). If no recipients are specified, mailx attempts to read messages ox .
	- B	Do not buffer standard input or standard output.
	- b <i>bcc</i>	Set the blind carbon copy list to <i>bcc</i> . <i>bcc</i> should be enclosed in quotes if it contains more than one name.
	- c <i>cc</i>	Set the carbon copy list to <i>cc. cc</i> should be enclosed in quotes if it

	contains more than one name.
-d	Turn on debugging output. (Neither particularly interesting nor recommended.)
- e	Test for the presence of mail. mailx prints nothing and exits with a successful return code if there is mail to read.
- F	Record the message in a file named after the first recipient. Overrides the record variable, if set (see mailx Internal Variables).
-f [file]	Read messages from <i>file</i> instead of mailbox . If no <i>file</i> is specified, the mbox is used.
-f [+folder]	Use the file <i>folder</i> in the folder directory (same as the fold er command). The name of this directory is listed in the folder variable.
–H	Print header summary only.
– h number	The number of network "hops" made so far. This is provided for net- work software to avoid infinite delivery loops. This option and its argu- ment are passed to the delivery program.
–I	Include the newsgroup and article-id header lines when printing mail messages. This option requires the –f option to be specified.
—i	Ignore interrupts. See also ignore in mailx Internal Variables .
$-\mathbf{N}$	Do not print initial header summary.
-n	Do not initialize from the system default mailx.rc or Mail.rc file. When this is specified, XPG4 behavior results. See USAGE .
–r address	Use <i>address</i> as the return address when invoking the delivery program. All tilde commands are disabled. This option and its argument is passed to the delivery program.
–s subject	Set the Subject header field to <i>subject. subject</i> should be enclosed in quotes if it contains embedded white space.
– T file	Message-id and article-id header lines are recorded in <i>file</i> after the message is read. This option also sets the $-I$ option.
-t	Scan the input for To: , Cc: , and Bcc: fields. Any recipients on the command line will be ignored.
–U	Convert UUCP-style addresses to internet standards. Overrides the conv environment variable.
–u user	Read <i>user</i> 's mailbox . This is only effective if <i>user</i> 's mailbox is not read protected.
$-\mathbf{V}$	Print the mailx version number and exit.
$-\mathbf{v}$	Pass the $-\mathbf{v}$ flag to sendmail (1M).
_~	Interpret tilde escapes in the input even if not reading from a tty.

OPERANDS	The following operands are supported:
	recipient Addressee of message.
USAGE Starting Mail	At startup time, mailx executes the system startup file / etc/mail/mailx.rc . If invoked as mail or Mail , the system startup file / etc/mail/Mail.rc is used instead.
	The system startup file sets up initial display options and alias lists and assigns values to some mailx internal variables. These variables are flags and valued parameters which are set and cleared using the set and uns et commands. See mailx Internal Variables .
	With the following exceptions, regular commands are legal inside startup files: ! , C opy, e dit, fo llowup, F ollowup, ho ld, m ail, pre serve, r eply, R eply, sh ell, and v isual. An error in the startup file causes the remaining lines in the file to be ignored.
	After executing the system startup file, mailx executes the optional personal startup file \$HOME/.mailrc , wherein the user can override the values of the internal variables as set by the system startup file.
	If the $-n$ option is specified, however, mailx does not execute the system startup file, and the command behavior is XPG4-compliant.
	To execute the system startup file and still retain XPG4-compliant behavior, add the fol- lowing commands to the private startup file and execute mailx without specifying the $-n$ option:
	unset appenddeadletter set replyall set pipeignore
	When reading mail, mailx is in <i>command mode</i> . A header summary of the first several messages is displayed, followed by a prompt indicating mailx can accept regular commands (see Commands below). When sending mail, mailx is in <i>input mode</i> . If no subject is specified on the command line, and the asksub variable is set, a prompt for the subject is printed.
	As the message is typed, mailx reads the message and stores it in a temporary file. Com- mands may be entered by beginning a line with the tilde (~) escape character followed by a single command letter and optional arguments. See Tilde Escapes for a summary of these commands.
Reading Mail	Each message is assigned a sequential number, and there is at any time the notion of a current message, marked by a right angle bracket (>) in the header summary. Many commands take an optional list of messages (<i>message-list</i>) to operate on. In most cases, the current message is set to the highest-numbered message in the list after the command is finished executing.
	The default for <i>message-list</i> is the current message. A <i>message-list</i> is a list of message identifiers separated by spaces, which may include:

	nMessage number nThe current message.^The first undeleted message.\$The last message.*All messages.+The next undeleted messageThe previous undeleted messageThe previous undeleted messageThe previous undeleted messageAll messages from user./stringAll messages of type c, where c is one of:ddeleted messagesnnew messagesoold messagesrread messagesuunread messagesuunread messagesNote that the context of the command determines whether this type of messagespecification makes sense.Other arguments are usually arbitrary strings whose usage depends on the command involved. Filenames, where expected, are expanded using the normal shell conventions (see sh(1)). Special characters are recognized by certain commands and are documented with the commands below.
Sending Mail	Recipients listed on the command line may be of three types: login names, shell com- mands, or alias groups. Login names may be any network address, including mixed net- work addressing. If mail is found to be undeliverable, an attempt is made to return it to the sender's mailbox . If the recipient name begins with a pipe symbol (), the rest of the name is taken to be a shell command to pipe the message through. This provides an automatic interface with any program that reads the standard input, such as lp (1) for recording outgoing mail on paper. Alias groups are set by the a lias command (see Com- mands below) or in a system startup file (for example, \$HOME/.mailrc). Aliases are lists of recipients of any type.
Forwarding Mail	To forward a specific message, include it in a message to the desired recipients with the `f or `m tilde escapes. See Tilde Escapes below. To forward mail automatically, add a comma-separated list of addresses for additional recipients to the .forward file in your home directory. This is different from the format of the alias command, which takes a space-separated list instead. Note: forwarding addresses must be valid, or the messages will "bounce." You cannot, for instance, reroute your mail to a new host by forwarding it to your new address if it is not yet listed in the NIS aliases domain.
Commands	Regular commands are of the form [command] [message-list] [arguments]

In <i>input mode</i> , comma	ands are recognized by the escape character, tilde(~) , and lines not
	are taken as input for the message.
If no command is spe	ecified in <i>command mode</i> , n ext is assumed.
The following is a co	mplete list of mailx commands:
!shell-command	Escape to the shell. See SHELL in ENVIRONMENT.
# comment	NULL command (comment). Useful in mailrc files.
=	Print the current message number.
?	Prints a summary of commands.
a lias <i>alias name</i>	
group alias name	Declare an alias for the given names. The names are substituted when <i>alias</i> is used as a recipient. Useful in the mailrc file. With no arguments, the command displays the list of defined aliases.
alternates <i>name</i>	Declare a list of alternate names for your login. When responding to a message, these names are removed from the list of recipients for the response. With no arguments, print the current list of alter- nate names. See also allnet in mailx Internal Variables .
cd [<i>directory</i>] ch dir [<i>directory</i>]	Change directory. If <i>directory</i> is not specified, \$HOME is used.
copy [file] copy [message-list] file	e Copy messages to the file without marking the messages as saved. Otherwise equivalent to the s ave command.
Copy [message-list]	Save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the mes- sages as saved. Otherwise equivalent to the S ave command.
delete [<i>message-list</i>]	Delete messages from the mailbox . If autoprint is set, the next message after the last one deleted is printed (see mailx Internal Variables).
discard [header-field	.]
ignore [<i>header-field</i>	Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are Status and Received . The fields are included when the message is saved, unless the alwaysignore variable is set. The Mo re, Pa ge, P rint, and Type commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the undi scard and unig nore commands.
dp [message-list] dt [message-list]	Delete the specified messages from the mailbox and print the next message after the last one deleted. Roughly equivalent to a d elete command followed by a p rint command.
ec ho <i>string</i>	Echo the given strings (like echo (1)).

edit [message-list]	Edit the given messages. Each message is placed in a temporary file and the program named by the EDITOR variable is invoked to edit it. (see ENVIRONMENT). Default editor is ed (1).
exit xit	Exit from mailx , without changing the mailbox . No messages are saved in the mbox (see also q uit).
field [<i>message-list</i>] he	ader-file
	Display the value of the header field in the specified message.
file [<i>file</i>] folder [<i>file</i>]	Quit from the current file of messages and read in the specified file. Several special characters are recognized when used as file names:
	 % the current mailbox. % user the mailbox for user. # the previous mail file. & the current mbox. + file The named file in the folder directory (listed in the
	folder variable). With no arguments, print the name of the current mail file, and the number of messages and characters it contains.
folders	Print the names of the files in the directory set by the folder variable (see mailx Internal Variables).
Followup [<i>message</i>]	Respond to a message, recording the response in a file whose name is derived from the author of the message. Overrides the record variable, if set. If the replyall variable is set, the actions of Fo llowup and fo llowup are reversed. (XPG4 specifies that the fo l- lowup and Fo llowup actions are reversed by default, and that the flipr variable is the XPG4 equivalent of the Solaris replyall vari- able.) See also the followup, Save , and Copy commands and out- folder in mailx Internal Variables .
followup [message-lis	<i>t</i>]
	Respond to the first message in the <i>message-list</i> , sending the mes- sage to the author of each message in the <i>message-list</i> . The subject line is taken from the first message and the response is recorded in a file whose name is derived from the author of the first message. If the replyall variable is set, the actions of followup and Followup are reversed. (XPG4 specifies that the followup and Followup actions are reversed by default, and that the flipr variable is the XPG4 equivalent of the Solaris replyall variable.) See also the Fol- lowup, Save , and Copy commands and outfolder in mailx Inter- nal Variables .
from [<i>message-list</i>]	Print the header summary for the specified messages. If no mes- sages are specified, print the header summary for the current

	message.
group alias name	
a lias alias name	Declare an alias for the given names. The names are substituted when <i>alias</i> is used as a recipient. Useful in the mailrc file.
headers [<i>message</i>]	Print the page of headers which includes the message specified. The screen variable sets the number of headers per page (see mailx Internal Variables). See also the z command.
help	Print a summary of commands.
hold [<i>message-list</i>] preserve [<i>message-list</i>]] Hold the specified messages in the mailbox .
if s r t mail-commands	
el se <i>mail-commands</i>	
endif	Conditional execution, where <i>s</i> executes following <i>mail-commands</i> , up to an el se or en dif, if the program is in <i>send</i> mode, <i>r</i> causes the <i>mail-commands</i> to be executed only in <i>receive</i> mode, and t causes the <i>mail-commands</i> to be executed only if mailx is being run from a terminal. Useful in the mailrc file.
inc	Incorporate messages that arrive while you are reading the system mailbox. The new messages are added to the message list in the current mail session. This command does not commit changes made during the session, and prior messages are not renumbered.
ignore [header-field	
discard [header-field	-
	Suppress printing of the specified header fields when displaying messages on the screen. Examples of header fields to ignore are Status and Cc . All fields are included when the message is saved. The Mo re, Pa ge, P rint and T ype commands override this command. If no header is specified, the current list of header fields being ignored is printed. See also the undi scard and unig nore commands.
list	Print all commands available. No explanation is given.
load [message] file	
	The specified message is replaced by the message in the named file. <i>file</i> should contain a single mail message including mail headers (as saved by the s ave command).
m ail <i>recipient</i>	Mail a message to the specified recipients.
Mail recipient	Mail a message to the specified recipients, and record it in a file whose name is derived from the author of the message. Overrides the record variable, if set. See also the Save and Copy commands and outfolder in mailx Internal Variables .

mbox [<i>message-list</i>]	Arrange for the given messages to end up in the standard mbox save file when mailx terminates normally. See MBOX in ENVIRONMENT for a description of this file. See also the ex it and q uit commands.
mo re [<i>message-list</i>] pa ge [<i>message-list</i>]	Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default com- mand is pg (1) or if the bsdcompat variable is set, the default is more (1). See ENVIRONMENT . Same as the p rint and t ype com- mands.
Mo re [<i>message-list</i>] Pa ge [<i>message-list</i>]	Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ig nore command. Same as the P rint and T ype commands.
new [message-list] New [message-list] unread [message-list] Unread [message-list]	
······	Take a message list and mark each message as <i>not</i> having been read.
next [<i>message</i>]	Go to the next message matching <i>message</i> . If message is not supplied, this command finds the next message that was not deleted or saved. A <i>message-list</i> may be specified, but in this case the first valid message in the list is the only one used. This is useful for jumping to the next message from a specific user, since the name would be taken as a command in the absence of a real command. See the discussion of <i>message-list</i> above for a description of possible message specifications.
pi pe [<i>message-list</i>] [<i>sh</i> [<i>message-list</i>] [<i>shell-c</i>	
	Pipe the message through the given <i>shell-command</i> . The message is treated as if it were read. If no arguments are given, the current message is piped through the command specified by the value of the cmd variable. If the page variable is set, a form feed character is inserted after each message (see mailx Internal Variables).
pre serve [<i>message-list</i>] ho ld [<i>message-list</i>]	
print [<i>message-list</i>] type [<i>message-list</i>]	Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default com- mand is pg (1) or if the bsdcompat variable is set, the default is

	more (1). See ENVIRONMENT . Same as the mo re and pa ge commands.
P rint [<i>message-list</i>] Type [<i>message-list</i>]	Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ig nore command. Same as the Mo re and Pa ge commands.
put [file] put [message-list] file	Save the specified message in the given file. Use the same conven- tions as the p rint command for which header fields are ignored.
Pu t [<i>file</i>]	i o
Put [<i>message-list</i>] file	Save the specified message in the given file. Overrides suppression of fields by the ig nore command.
quit	Exit from mailx , storing messages that were read in mbox and unread messages in the mailbox . Messages that have been explicitly saved in a file are deleted unless the keepsave variable is set.
reply [<i>message-list</i>] respond [<i>message-list</i>]	
replysender [message	
	Send a response to the author of each message in the <i>message-list</i> . The subject line is taken from the first message. If record is set to a file, a copy of the reply is added to that file. If the replyall variable is set, the actions of R eply/ R espond and reply/respond are reversed. (XPG4 specifies that the actions of R eply/ R espond and reply/respond are reversed by default, and that the flipr variable is the XPG4 equivalent of the Solaris replyall variable.) The replys ender command is not affected by the replyall variable, but sends each reply only to the sender of each message.
R eply [<i>message</i>]	
Respond [<i>message</i>] replyall [<i>message</i>]	Reply to the specified message, including all other recipients of that message. If the variable record is set to a file, a copy of the reply added to that file. If the replyall variable is set, the actions of R eply/ R espond and reply/respond are reversed. (XPG4 specifies that the actions of R eply/ R espond and reply/respond are reversed by default, and that the flipr variable is the XPG4 equivalent of the Solaris replyall variable.) The replyall command is not affected by the replyall variable, but always sends the reply to all recipients of the message.
retain	Add the list of header fields named to the <i>retained list</i> . Only the header fields in the retain list are shown on your terminal when you print a message. All other header fields are suppressed. The set of retained fields specified by the retain command overrides any list of ignored fields specified by the ig nore command. The

	Type and P rint commands can be used to print a message in its entirety. If ret ain is executed with no arguments, it lists the current set of retained fields.
Save [message-list]	Save the specified messages in a file whose name is derived from the author of the first message. The name of the file is taken to be the author's name with all network addressing stripped off. See also the Copy, followup, and Followup commands and outfolder in mailx Internal Variables.
save [file]	
save [message-list] file	Save the specified messages in the given file. The file is created if it does not exist. The file defaults to mbox . The message is deleted from the mailbox when mailx terminates unless keepsave is set (see also mailx Internal Variables and the exit and quit commands).
set	
set variable	
set variable=string set variable=number	Define a variable. To agaign a value to variable concrete the variable
set variable=number	Define a <i>variable</i> . To assign a <i>value</i> to <i>variable</i> , separate the variable name from the value by an `=´ (there must be no space before or after the `=´). A variable may be given a null, string, or numeric <i>value</i> . To embed SPACE characters within a <i>value</i> enclose it in quotes.
	With no arguments, se t displays all defined variables and any values they might have. See mailx Internal Variables for a description of all predefined mail variables.
shell	Invoke an interactive shell. See also SHELL in ENVIRONMENT.
size [message-list]	Print the size in characters of the specified messages.
source file	Read commands from the given file and return to command mode.
top [message-list]	Print the top few lines of the specified messages. If the toplines variable is set, it is taken as the number of lines to print (see mailx Internal Variables). The default is 5.
touch [message-list]	Touch the specified messages. If any message in <i>message-list</i> is not specifically saved in a file, it is placed in the mbox , or the file specified in the MBOX environment variable, upon normal termination. See ex it and q uit.
Type [<i>message-list</i>] Print [<i>message-list</i>]	Print the specified messages on the screen, including all header fields. Overrides suppression of fields by the ig nore command.
type [<i>message-list</i>] print [<i>message-list</i>]	Print the specified messages. If crt is set, the messages longer than the number of lines specified by the crt variable are paged through the command specified by the PAGER variable. The default

		command is pg (1) See ENVIRONMENT .
	una lias [<i>alias</i>]	
	ung roup [<i>alias</i>]	Remove the definitions of the specified aliases.
	undelete [<i>message-list</i>]	Restore the specified deleted messages. Will only restore messages deleted in the current mail session. If autoprint is set, the last message of those restored is printed (see mailx Internal Variables).
	undiscard [header-field unignore [header-field.	
	0	Remove the specified header fields from the list being ignored. If no header fields are specified, all header fields are removed from the list being ignored.
	unretain [header-field]
		Remove the specified header fields from the list being retained. If no header fields are specified, all header fields are removed from the list being retained.
	unr ead [<i>message-list</i>] Unread [<i>message-list</i>]	
		Same as the ne w command.
	unset variable	Erase the specified variables. If the variable was imported from the environment (that is, an environment variable or exported shell variable), it cannot be unset from within mailx .
	version	Print the current version and release date of the mailx utility.
	visual [<i>message-list</i>]	Edit the given messages with a screen editor. Each messages is placed in a temporary file and the program named by the VISUAL variable is invoked to edit it. (see ENVIRONMENT). Note that the default visual editor is vi .
	write [<i>message-list</i>] file	Write the given messages on the specified file, minus the header and trailing blank line. Otherwise equivalent to the s ave com- mand.
	xit	
	exit	Exit from mailx , without changing the mailbox . No messages are saved in the mbox (see also q uit).
	z[+ -]	Scroll the header display forward or backward one screen–full. The number of headers displayed is set by the screen variable (see mailx Internal Variables).
Tilde Escapes	may be entered only fr (~). See escape in mai	cape commands can be used when composing mail to send. These rom <i>input mode</i> , by beginning a line with the tilde escape character Ix Internal Variables for changing this special character. The e entered as text by typing it twice.
I		

"!shell-command	Escape to the shell. If present, run <i>shell-command</i> .
~.	Simulate end of file (terminate message input).
~ :mail-command ~_ mail-command	Perform the command-level request. Valid only when sending a mes- sage while reading mail.
~?	Print a summary of tilde escapes.
~A	Insert the autograph string Sign into the message (see mailx Internal Variables).
~a	Insert the autograph string sign into the message (see mailx Internal Variables).
~b name	Add the <i>names</i> to the blind carbon copy (Bcc) list. This is like the carbon copy (Cc) list, except that the names in the Bcc list are not shown in the header of the mail message.
°c name	Add the <i>names</i> to the carbon copy (Cc) list.
~d	Read in the dead-letter file. See DEAD in ENVIRONMENT for a description of this file.
~e	Invoke the editor on the partial message. See also EDITOR in ENVIRONMENT .
~f [message-list]	Forward the specified message, or the current message being read. Valid only when sending a message while reading mail. The messages are inserted into the message without alteration (as opposed to the m escape).
~F [message-list]	Forward the specified message, or the current message being read, including all header fields. Overrides the suppression of fields by the ig nore command.
~h	Prompt for Subject line and To , Cc , and Bcc lists. If the field is displayed with an initial value, it may be edited as if you had just typed it.
~i variable	Insert the value of the named variable into the text of the message. For example, ~A is equivalent to `~i Sign . ´ Environment variables set and exported in the shell are also accessible by ~i .
~m [message-list]	Insert the listed messages, or the current message being read into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the indentprefix variable is inserted as the leftmost characters of each line. If indentprefix is not set, a TAB character is inserted into each line.
~M [message-list]	Insert the listed messages, or the current message being read, including the header fields, into the letter. Valid only when sending a message while reading mail. The text of the message is shifted to the right, and the string contained in the indentprefix variable is inserted as the left- most characters of each line. If indentprefix is not set, a TAB character is

		inserted into each line. Overrides the suppression of fields by the ig nore command.
	ĩр	Print the message being entered.
	~q	Quit from input mode by simulating an interrupt. If the body of the message is not null, the partial message is saved in dead-letter . See DEAD in ENVIRONMENT for a description of this file.
	~R	Mark message for return receipt.
	~r file ~< file	
	~< ! shell-comman	nd
		Read in the specified file. If the argument begins with an exclamation point (!), the rest of the string is taken as an arbitrary shell command and is executed, with the standard output inserted into the message.
	s string	Set the subject line to <i>string</i> .
	~t name	Add the given <i>names</i> to the To list.
	~v	Invoke a preferred screen editor on the partial message. The default visual editor is vi (1). See also VISUAL in ENVIRONMENT .
	~w file	Write the message into the given file, without the header.
	ĩx	Exit as with ~q except the message is not saved in dead-letter .
	~ shell-command	1
		Pipe the body of the message through the given <i>shell-command</i> . If the <i>shell-command</i> returns a successful exit status, the output of the command replaces the message.
mailx Internal Variables	execution environmay be used to	ariables are internal mailx variables. They may be imported from the onment or set using the se t command at any time. The uns et command erase variables. The default values correspond to the Solaris values. er, the XPG4 default values will be noted.
	allnet	All network names whose last component (login name) match are treated as identical. This causes the <i>message-list</i> message specifications to behave similarly. Disabled by default. See also the alt ernates command and the metoo variable.
	alwaysignore	Ignore header fields with ig nore everywhere, not just during p rint or type. Affects the s ave, S ave, c opy, C opy, to p, pi pe, and w rite commands, and the ~m and ~f tilde escapes. Enabled by default.
	append	Upon termination, append messages to the end of the mbox file instead of prepending them. Although disabled by default, append is set in the global startup file (which can be suppressed with the – n command line option).
	appenddeadlet	
		Append to the deadletter file rather than overwrite it. Although disabled

	v	, appenddeadletter is set in the global startup file (which can ssed with the $-\mathbf{n}$ command line option).
askbcc		r the Bcc list after the Subject is entered if it is not specified on and line with the –b option. Disabled by default.
askcc	-	r the Cc list after the Subject is entered if it is not specified on and line with the $-c$ option. Disabled by default.
asksub		r subject if it is not specified on the command line with the – s nabled by default.
autoinc	arrive. The the common set in	cally incorporate new messages into the current session as they is has an affect similar to issuing the inc command every time and prompt is displayed. Disabled by default, but autoinc is default system startup file for mailx ; it is not set for mail or / usr/ucb/Mail .
autoprint		tomatic printing of messages after d elete and u ndelete com- isabled by default.
bang		e special-casing of exclamation points (!) in shell escape com- s as in vi (1). Disabled by default.
bsdcompat		atically if mailx is invoked as mail or Mail . Causes mailx to ail/Mail.rc as the system startup file. Changes the default nore (1).
cmd=shell-comm	nand	
	Set the det	fault command for the pi pe command. No default value.
conv =conversion	i Convert u either:	ucp addresses to the specified address style, which can be
	internet	This requires a mail delivery program conforming to the RFC822 standard for electronic mail addressing.
	optimize	Remove loops in uucp (1C) address paths (typically gen- erated by the r eply command). No rerouting is performed; mail has no knowledge of UUCP routes or connections.
		n is disabled by default. See also sendmail (1M) and the –U -line option.
crt[=number]	specified b	ages having more than <i>number</i> lines through the command by the value of the PAGER variable (pg (1) or more (1) by if <i>number</i> is not specified, the current window size is used. by default.
debug	Enable ver Disabled b	rbose diagnostics for debugging. Messages are not delivered. by default.
dot	end-of-file	riod on a line by itself, or EOF during input from a terminal as \mathbf{e} . Disabled by default, but dot is set in the global startup file \mathbf{n} be suppressed with the $-\mathbf{n}$ command line option).

flipr	Reverse the effect of the fo llowup/ Fo llowup and r eply/ R eply com- mand pairs. If both flipr and replyall are set, the effect is as if neither was set.
escape=c	Substitute <i>c</i> for the $$ escape character. Takes effect with next message sent.
folder=directory	The directory for saving standard mail files. User-specified file names beginning with a plus (+) are expanded by preceding the file name with this directory name to obtain the real file name. If <i>directory</i> does not start with a slash (/), SHOME is prepended to it. There is no default for the folder variable. See also outfolder below.
header	Enable printing of the header summary when entering mailx . Enabled by default.
hold	Preserve all messages that are read in the mailbox instead of putting them in the standard mbox save file. Disabled by default.
ignore	Ignore interrupts while entering messages. Handy for noisy dial-up lines. Disabled by default.
ignoreeof	Ignore end-of-file during message input. Input must be terminated by a period (.) on a line by itself or by the ~. command. See also dot above. Disabled by default.
indentprefix=st	<i>ring</i> When indentprefix is set, <i>string</i> is used to mark indented lines from messages included with ~m. The default is a TAB character.
keep	When the mailbox is empty, truncate it to zero length instead of remov- ing it. Disabled by default.
<pre>iprompt=string</pre>	The specified prompt string is displayed before each line on input is requested when sending a message.
keepsave	Keep messages that have been saved in other files in the mailbox instead of deleting them. Disabled by default.
makeremote	When replying to all recipients of a message, if an address does not include a machine name, it is assumed to be relative to the sender of the message. Normally not needed when dealing with hosts that support RFC822.
metoo	If your login appears as a recipient, do not delete it from the list. Dis- abled by default.
mustbang	Force all mail addresses to be in bang format.
onehop	When responding to a message that was originally sent to several reci- pients, the other recipient addresses are normally forced to be relative to the originating author's machine for the response. This flag disables alteration of the recipients' addresses, improving efficiency in a network where all machines can send directly to all other machines (that is, one hop away). Disabled by default.

outfolder	Locate the files used to record outgoing messages in the directory specified by the folder variable unless the path name is absolute. Disabled by default. See folder above and the S ave, C opy, fo llowup, and F ollowup commands.
page	Used with the pi pe command to insert a form feed after each message sent through the pipe. Disabled by default.
pipeignore	Omit ignored header when outputting to the pipe command. Although disabled by default, pipeignore is set in the global startup file (which can be suppressed with the – n command line option). unset . The XPG4 default is set .
postmark	Your "real name" to be included in the From line of messages you send. By default this is derived from the comment field in your passwd (4) file entry.
prompt =string	Set the <i>command mode</i> prompt to <i>string</i> . Default is "? ", unless the bsdcompat variable is set, then the default is "&".
quiet	Refrain from printing the opening message and version when entering mailx . Disabled by default.
record=file	Record all outgoing mail in <i>file</i> . Disabled by default. See also outfolder above.
replyall	Reverse the effect of the r eply and R eply and fo llowup and Fo llowup commands. Although set by default, replayall is unset in the global startup file (which can be suppressed with the – n command line option). See flipr .
save	Enable saving of messages in dead-letter on interrupt or delivery error. See DEAD for a description of this file. Enabled by default.
screen=number	Sets the number of lines in a screen-full of headers for the h eaders com- mand. <i>number</i> must be a positive number.
	The default is set according to baud rate or window size. With a baud rate less than 1200 , <i>number</i> defaults to 5 , if baud rate is exactly 1200 , it defaults to 10 . If you are in a window, <i>number</i> defaults to the default window size minus 4. Otherwise, the default is 20 .
sendmail=shell	
	Alternate command for delivering messages. Note: in addition to the expected list of recipients, mail also passes the – i and – m , flags to the command. Since these flags are not appropriate to other commands, you may have to use a shell script that strips them from the arguments list before invoking the desired command. Default is / usr/bin/rmail .
sendwait	Wait for background mailer to finish before returning. Disabled by default.
showname	Causes the message header display to show the sender's real name (if known) rather than their mail address. Disabled by default, but

		showname is set in the / etc/mail/mailx.rc system startup file for mailx .
	showto	When displaying the header summary and the message is from you, print the recipient's name instead of the author's name.
	sign=string	The variable inserted into the text of a message when the ~a (autograph) command is given. No default (see also ~i in Tilde Escapes).
	Sign=string	The variable inserted into the text of a message when the A command is given. No default (see also i in Tilde Escapes).
	toplines=numb	er
		The number of lines of header to print with the to p command. Default is 5 .
	verbose	Invoke sendmail (1M) with the -v flag.
	translate	The name of a program to translate mail addresses. The program receives mail addresses as arguments. The program produces, on the standard output, lines containing the following data, in this order:
		• the postmark for the sender (see the postmark variable)
		• translated mail addresses, one per line, corresponding to the program's arguments. Each translated address will replace the corresponding address in the mail message being sent.
		• a line containing only "y" or "n". if the line contains "y" the user will be asked to confirm that the message should be sent.
		The translate program will be invoked for each mail message to be sent. If the program exits with a non-zero exit status, or fails to produce enough output, the message is not sent.
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- : HOME, LANG, LC_CTYPE, LC_TIME, LC_MESSAGES, NLSPATH, and
	DEAD	The name of the file in which to save partial letters in case of untimely interrupt. Default is \$HOME/dead.letter .
	EDITOR	The command to run when the edit or \tilde{e} command is used. Default is $ed(1)$.
	LISTER	The command (and options) to use when listing the contents of the folder directory. The default is $ls(1)$.
	MAIL	The name of the initial mailbox file to read (in lieu of the standard sys- tem mailbox). The default is / var/mail / <i>username</i> .
	MAILRC	The name of the startup file. Default is \$HOME/.mailrc .
	MAILX_HEAD	The specified string is included at the beginning of the body of each message that is sent.
	MAILX_TAIL	The specified string is included at the end of the body of each message that is sent.

	МВОХ	command over	e file to save messages which have been read. The ex it rides this function, as does saving the message explicitly Default is \$HOME/mbox .
	PAGER	used to specify	o use as a filter for paginating output. This can also be the options to be used. Default is pg (1), or if the able is set, the default is more (1). See mailx Internal
	SHELL	The name of a p	preferred command interpreter. Default is sh (1).
	VISUAL	The name of a p	preferred screen editor. Default is vi (1).
EXIT STATUS	When the – e op	otion is specified,	the following exit values are returned:
	0	Mail was found	
	>0	Mail was not fo	und or an error occurred.
	Otherwise, the	following exit val	ues are returned:
			n; note that this status implies that all messages were ssurances that any of them were actually <i>delivered</i>
	>0 an e	error occurred	
FILES	\$HOME/.mailro \$HOME/mbox \$HOME/.Maillo /etc/mail/mailx /etc/mail/Mail. /tmp/R[emqsx] /usr/share/lib/r	ock a.rc rc *	personal startup file secondary storage file lock file to prevent multiple writers of system mailbox optional global startup file for mailx only BSD compatibility system-wide startup file for / usr/ucb/mail and / usr/ucb/Mail temporary files help message files
	/var/mail/*		post office directory

	mailx does not	lock your record	file. So, if you use a record file and send two or more rom the messages may be interleaved in the record file.

The format for the **alias** command is a space-separated list of recipients, while the format for an alias in either the **.forward** or **/etc/aliases** is a comma-separated list.

To read mail on a workstation running SunOS 4.*x* when your mail server is running Solaris, first execute the **mailcompat**(1) program.

NAME	make – maintain, update, and regenerate related programs and files
SYNOPSIS	/usr/ccs/bin/make [-d] [-dd] [-D] [-DD] [-e] [-i] [-k] [-n] [-p] [-P] [-q] [-r] [-s] [-S] [-t] [-V] [-f makefile] [-K statefile] [target] [macro=value]
AVAILABILITY	SUNWsprot
DESCRIPTION	make executes a list of shell commands associated with each <i>target</i> , typically to create or update a file of the same name. <i>makefile</i> contains entries that describe how to bring a target up to date with respect to those on which it depends, which are called <i>dependencies</i> . Since each dependency is a target, it may have dependencies of its own. Targets, dependencies, and sub-dependencies comprise a tree structure that make traces when deciding whether or not to rebuild a <i>target</i> .
	make recursively checks each <i>target</i> against its dependencies, beginning with the first target entry in <i>makefile</i> if no <i>target</i> argument is supplied on the command line. If, after processing all of its dependencies, a target file is found either to be missing, or to be older than any of its dependencies, make rebuilds it. Optionally with this version of make , a target can be treated as out-of-date when the commands used to generate it have changed since the last time the target was built.
	To build a given target, make executes the list of commands, called a <i>rule</i> . This rule may be listed explicitly in the target's makefile entry, or it may be supplied implicitly by make .
	Except when in POSIX mode, when no <i>makefile</i> is specified with a $-f$ option:
	 If there is a file named makefile in the working directory, make uses that file. If, however, there is an SCCS history file (SCCS/s.makefile) which is newer, make attempts to retrieve and use the most recent version.
	• In the absence of the above file(s), if a file named Makefile is present in the working directory, make attempts to use it. If there is an SCCS history file (SCCS/s.Makefile) that is newer, make attempts to retrieve and use the most recent version.
	In POSIX mode, when no <i>makefile</i> is specified with a $-f$ option, make tries the following files in sequence:
	 ./makefile, ./Makefile s.makefile, SCCS/s.makefile s.Makefile, SCCS/s.Makefile
	If no <i>target</i> is specified on the command line, make uses the first target defined in <i>makefile</i> .
	If a <i>target</i> has no makefile entry, or if its entry has no rule, make attempts to derive a rule by each of the following methods, in turn, until a suitable rule is found. (Each method is described under USAGE below.)
	Pattern matching rules.
	• Implicit rules, read in from a user-supplied makefile.

		ndard implicit rules (also known as suffix rules), typically read in from the / usr/share/lib/make/make.rules .
	file	CS retrieval. make retrieves the most recent version from the SCCS history (if any). See the description of the .SCCS_GET: special-function target for ails.
		e rule from the .DEFAULT: target entry, if there is such an entry in the kefile.
		nakefile entry for a <i>target</i> , if no rule can be derived for building it, and if no ne is present, make issues an error message and halts.
OPTIONS	The following	options are supported:
	-d	Display the reasons why make chooses to rebuild a target; make displays any and all dependencies that are newer. In addition, make displays options read in from the MAKEFLAGS environment variable.
	-dd	Display the dependency check and processing in vast detail.
	$-\mathbf{D}$	Display the text of the makefiles read in.
	-DD	Display the text of the makefiles, make.rules file, the state file, and all hidden-dependency reports.
	- e	Environment variables override assignments within makefiles.
	−f makefile	Use the description file <i>makefile</i> . A '-' as the <i>makefile</i> argument denotes the standard input. The contents of <i>makefile</i> , when present, override the standard set of implicit rules and predefined macros. When more than one '- f <i>makefile</i> ' argument pair appears, make uses the concatenation of those files, in order of appearance.
	- i	Ignore error codes returned by commands. Equivalent to the special-function target '.IGNORE:'.
	- k	When a nonzero error status is returned by a rule, or when make cannot find a rule, abandon work on the current target, but continue with other dependency branches that do not depend on it.
	-K statefile	Use the state file <i>statefile</i> . A '-' as the <i>statefile</i> argument denotes the stan- dard input. The contents of <i>statefile</i> , when present, override the stan- dard set of implicit rules and predefined macros. When more than one '-K <i>statefile</i> ' argument pair appears, make uses the concatenation of those files, in order of appearance. (See also .KEEP_STATE and .KEEP_STATE_FILE in the Special-Functions Targets section).
	-n	No execution mode. Print commands, but do not execute them. Even lines beginning with an @ are printed. However, if a command line con- tains a reference to the \$(MAKE) macro, that line is always executed (see the discussion of MAKEFLAGS in Reading Makefiles and the Environ- ment). When .POSIX is in effect, lines beginning with a "+" are exe- cuted.

1S-595

- p	Print out the complete set of macro definitions and target descriptions.
- P	Merely report dependencies, rather than building them.

- Merely report dependencies, rather than building them.
- Question mode. **make** returns a zero or nonzero status code depending on whether or not the target file is up to date. When **.POSIX** is in effect, lines beginning with a "+" are executed.
- -r Do not read in the default makefile /usr/share/lib/make/make.rules.
- -s Silent mode. Do not print command lines before executing them. Equivalent to the special-function target **.SILENT**:.
- -S Undo the effect of the -k option. Stop processing when a non-zero exit status is returned by a command.
- Touch the target files (bringing them up to date) rather than performing their rules. This can be dangerous when files are maintained by more than one person. When the .KEEP_STATE: target appears in the makefile, this option updates the state file just as if the rules had been performed. When .POSIX is in effect, lines beginning with a "+" are executed.
- -V Puts **make** into SysV mode. Refer to **sysV-make**(1) for respective details.

OPERANDS The following operands are supported:

target Target names, as defined in USAGE.

macro=value

-q

Macro definition. This definition overrides any regular definition for the specified macro within the makefile itself, or in the environment. However, this definition can still be overridden by conditional macro assignments.

USAGE Refer to **make** in *Programming Utilities Guide* for tutorial information.

Reading MakefilesWhen make first starts, it reads the MAKEFLAGS environment variable to obtain any the
following options specified present in its value: -d, -D, -e, -i, -k, -n, -p, -q, -r, -s, -S,
or -t. Due to the implementation of POSIX.2 standardization, the MAKEFLAGS values
will contain a leading '—' character. make then reads the command line for additional
options, which also take effect.

Next, **make** reads in a default makefile that typically contains predefined macro definitions, target entries for implicit rules, and additional rules, such as the rule for retrieving SCCS files. If present, **make** uses the file **make.rules** in the current directory; otherwise it reads the file /**usr/share/lib/make/make.rules**, which contains the standard definitions and rules. Use the directive:

include /usr/share/lib/make/make.rules

in your local **make.rules** file to include them.

	Next, make imports variables from the environment (unless the $-e$ option is in effect),
	and treats them as defined macros. Because make uses the most recent definition it encounters, a macro definition in the makefile normally overrides an environment vari- able of the same name. When $-\mathbf{e}$ is in effect, however, environment variables are read in <i>after</i> all makefiles have been read. In that case, the environment variables take pre- cedence over definitions in the makefile.
	Next, make reads any makefiles you specify with –f , or one of makefile or Makefile as described above and then the state file, in the local directory if it exists. If the makefile contains a .KEEP_STATE_FILE target, then it reads the state file that follows the target. Refer to special target .KEEP_STATE_FILE for details.
	Next, (after reading the environment if –e is in effect), make reads in any macro definitions supplied as command line arguments. These override macro definitions in the makefile and the environment both, but only for the make command itself.
	make exports environment variables, using the most recently defined value. Macro definitions supplied on the command line are not normally exported, unless the macro is also an environment variable.
	make does not export macros defined in the makefile. If an environment variable is set, and a macro with the same name is defined on the command line, make exports its value as defined on the command line. Unless – e is in effect, macro definitions within the makefile take precedence over those imported from the environment.
	The macros MAKEFLAGS, MAKE, SHELL, HOST_ARCH, HOST_MACH, and TARGET_MACH are special cases. See Special-Purpose Macros , below for details.
Makefile Target	A target entry has the following format:
Entries	target [: ::] [dependency] [; command] [command]
	The first line contains the name of a target, or a space-separated list of target names, ter- minated with a colon or double colon. If a list of targets is given, this is equivalent to having a separate entry of the same form for each target. The colon(s) may be followed by a <i>dependency</i> , or a dependency list. make checks this list before building the target. The dependency list may be terminated with a semicolon (;), which in turn can be fol- lowed by a single Bourne shell command. Subsequent lines in the target entry begin with a TAB, and contain Bourne shell commands. These commands comprise the rule for building the target.
	Shell commands may be continued across input lines by escaping the NEWLINE with a backslash (\). The continuing line must also start with a TAB.
	To rebuild a target, make expands macros, strips off initial TAB characters and either exe- cutes the command directly (if it contains no shell metacharacters), or passes each com- mand line to a Bourne shell for execution.

1S-597

	The first line that does not begin with a TAB or '#' begins another target or macro definition.		
Special Characters Global	#	Start a comment. The comment ends at the next NEWLINE. If the '#' fol- lows the TAB in a command line, that line is passed to the shell (which also treats '#' as the start of a comment).	
	include filename	If the word include appears as the first seven letters of a line and is fol- lowed by a SPACE or TAB, the string that follows is taken as a filename to interpolate at that line. include files can be nested to a depth of no more than about 16. If <i>filename</i> is a macro reference, it is expanded.	
Targets and Dependencies	:	Target list terminator. Words following the colon are added to the dependency list for the target or targets. If a target is named in more than one colon-terminated target entry, the dependencies for all its entries are added to form that target's complete dependency list.	
	::	Target terminator for alternate dependencies. When used in place of a ':' the double-colon allows a target to be checked and updated with respect to alternate dependency lists. When the target is out-of-date with respect to dependencies listed in the first alternate, it is built according to the rule for that entry. When out-of-date with respect to dependencies in another alternate, it is built according the rule in that other entry. Implicit rules do not apply to double-colon targets; you must supply a rule for each entry. If no dependencies are specified, the rule is always performed.	
	target [+ target	.]: Target group. The rule in the target entry builds all the indicated targets as a group. It is normally performed only once per make run, but is checked for command dependencies every time a target in the group is encountered in the dependency scan.	
	%	Pattern matching wild card metacharacter. Like the '*' shell wild card, '%' matches any string of zero or more characters in a target name or dependency, in the target portion of a conditional macro definition, or within a pattern replacement macro reference. Note that only one '%' can appear in a target, dependency-name, or pattern-replacement macro reference.	
	./pathname	make ignores the leading './' characters from targets with names given as pathnames relative to "dot," the working directory.	
Macros	=	Macro definition. The word to the left of this character is the macro name; words to the right comprise its value. Leading and trailing white space characters are stripped from the value. A word break following the = is implied.	
	\$	Macro reference. The following character, or the parenthesized or	

		bracketed string, is interpreted as a macro reference: make expands the reference (including the \$) by replacing it with the macro's value.	
	() {}	Macro-reference name delimiters. A parenthesized or bracketed word appended to a \$ is taken as the name of the macro being referred to. Without the delimiters, make recognizes only the first character as the macro name.	
	\$\$	A reference to the dollar-sign macro, the value of which is the character '\$'. Used to pass variable expressions beginning with \$ to the shell, to refer to environment variables which are expanded by the shell, or to delay processing of dynamic macros within the dependency list of a target, until that target is actually processed.	
	\ \$	Escaped dollar-sign character. Interpreted as a literal dollar sign within a rule.	
	+=	When used in place of '=', appends a string to a macro definition (must be surrounded by white space, unlike '=').	
	:=	Conditional macro assignment. When preceded by a list of targets with explicit target entries, the macro definition that follows takes effect when processing only those targets, and their dependencies.	
	:sh =	Define the value of a macro to be the output of a command (see Command Substitutions , below).	
	:sh	In a macro reference, execute the command stored in the macro, and replace the reference with the output of that command (see Command Substitutions).	
Rules	+	make will always execute the commands preceded by a "+", even when -n is specified.	
	_	make ignores any nonzero error code returned by a command line for which the first non-TAB character is a '-'. This character is not passed to the shell as part of the command line. make normally terminates when a command returns nonzero status, unless the $-i$ or $-k$ options, or the .IGNORE : special-function target is in effect.	
	@	If the first non-TAB character is a @, make does not print the command line before executing it. This character is not passed to the shell.	
	?	Escape command-dependency checking. Command lines starting with this character are not subject to command dependency checking.	
	!	Force command-dependency checking. Command-dependency check- ing is applied to command lines for which it would otherwise be suppressed. This checking is normally suppressed for lines that contain references to the '?' dynamic macro (for example, ' \$?').	
		When any combination of '+', '-', '@', '?', or '!' appear as the first charac- ters after the TAB, all that are present apply. None are passed to the	

1S-599

		shell.
Special-Function	When incorporated in a makefile, the following target names perform special-functions:	
Targets	.DEFAULT:	If it has an entry in the makefile, the rule for this target is used to process a target when there is no other entry for it, no rule for building it, and no SCCS history file from which to retrieve a current version. make ignores any dependencies for this target.
	.DONE:	If defined in the makefile, make processes this target and its dependencies after all other targets are built. This target is also performed when make halts with an error, unless the .FAILED target is defined.
	.FAILED:	This target, along with its dependencies, is performed instead of .DONE when defined in the makefile and make halts with an error.
	.GET_POSIX:	This target contains the rule for retrieving the current version of an SCCS file from its history file in the current working directory. make uses this rule when it is running in POSIX mode.
	.IGNORE:	Ignore errors. When this target appears in the makefile, make ignores non-zero error codes returned from commands. When used under POSIX mode, .IGNORE could be followed by target names only, for which the errors will be ignored.
	.INIT:	If defined in the makefile, this target and its dependencies are built before any other targets are processed.
	.KEEP_STATE:	If this target is in effect, make updates the state file, .make.state , in the current directory. This target also activates command dependencies, and hidden dependency checks. If either the .KEEP_STATE : target appears in the makefile, or the environment variable KEEP_STATE is set (" setenv KEEP_STATE "), make will rebuild everything in order to collect dependency information, even if all the targets were up to date due to previous make runs. (See also the ENVIRONMENT section.) This target has no effect if used under POSIX mode.
	.KEEP_STATE_F	
		This target has no effect if used under POSIX mode. This target implies .KEEP_STATE. If the target is followed by a filename, make uses it as the state file. If the target is followed by a directory name, make looks for a .make.state in that directory. If the target is not followed by any name, make looks for .make.state file in the current working directory.
.MAKE_VERSION:		DN:
		A target-entry of the form:
		.MAKE_VERSION: VERSION- <i>number</i>
		enables version checking. If the version of make differs from the version indicated, make issues a warning message.
	.NO_PARALLEL	: Currently, this target has no effect, it is, however, reserved for future
		Currently, this target has no effect, it is, nowever, reserved for future
000		

	.PARALLEL:	Currently of no effect, but reserved for future use.
	.POSIX:	This target enables the POSIX compliant mode.
	.PRECIOUS:	List of files not to delete. make does not remove any of the files listed as dependencies for this target when interrupted. make normally removes the current target when it receives an interrupt. When used under POSIX mode, if the target is not followed by a list of files, all the file are assumed precious.
	.SCCS_GET:	This target contains the rule for retrieving the current version of an SCCS file from its history file. To suppress automatic retrieval, add an entry for this target with an empty rule to your makefile.
	.SCCS_GET_PO	SIX:
		This target contains the rule for retrieving the current version of an SCCS file from its history file. make uses this rule when it is running in POSIX mode.
	.SILENT:	Run silently. When this target appears in the makefile, make does not echo commands before executing them. When used in POSIX mode, it could be followed by target names, and only those will be executed silently.
	.SUFFIXES:	The suffixes list for selecting implicit rules (see The Suffixes List).
	.WAIT:	Currently of no effect, but reserved for future use.
Clearing Special Targets	In this version of make , you can clear the definition of the following special targets by supplying entries for them with no dependencies and no rule: .DEFAULT, .SCCS_GET, and .SUFFIXES	
Command Dependencies	When the .KEEP_STATE : target is effective, make checks the command for building a target against the state file. If the command has changed since the last make run, make rebuilds the target.	
Hidden Dependencies	When the .KEEP_STATE : target is effective, make reads reports from cpp (1) and other compilation processors for any "hidden" files, such as #include files. If the target is out of date with respect to any of these files, make rebuilds it.	
Macros	Entries of the form	
	macro=value	
	up to a comme	<i>macro</i> is the name of the macro, and <i>value</i> , which consists of all characters nt character or unescaped NEWLINE, is the value. make strips both lead- g white space in accepting the value.
	Subsequent references to the macro, of the forms: \$ (<i>name</i>) or \$ { <i>name</i> } are replaced by <i>value</i> . The parentheses or brackets can be omitted in a reference to a macro with a single-character name.	

make(1S)	SunOS Specific Commands	SunOS 5.5
	Macro references can contain references to other macros, in which case nested are expanded first.	references
Suffix Replacement Macro References	Substitutions within macros can be made as follows: \$(name:string1=string2)	
	where <i>string1</i> is either a suffix, or a word to be replaced in the macro definition <i>string2</i> is the replacement suffix or word. Words in a macro value are separate SPACE, TAB, and escaped NEWLINE characters.	
Pattern Replacement Macro References	Pattern matching replacements can also be applied to macros, with a reference form:	e of the
	\$(name: op%os= np%ns)	
	where <i>op</i> is the existing (old) prefix and <i>os</i> is the existing (old) suffix, <i>np</i> and <i>ns</i> new prefix and new suffix, respectively, and the pattern matched by % (a strin more characters), is carried forward from the value being replaced. For example,	g of zero or
	PROGRAM=fabricate DEBUG= \$(PROGRAM:%=tmp/%–g)	
	sets the value of DEBUG to tmp/fabricate –g.	
	Note that pattern replacement macro references cannot be used in the dependent a pattern matching rule; the % characters are not evaluated independently. All number of % metacharacters can appear after the equal-sign.	
Appending to a Macro	Words can be appended to macro values as follows:	
	macro += word	
Special-Purpose Macros	When the MAKEFLAGS variable is present in the environment, make takes optit, in combination with options entered on the command line. make retains the bined value as the MAKEFLAGS macro, and exports it automatically to each conshell it invokes.	is com-
	Note that flags passed by way of MAKEFLAGS are only displayed when the – o options are in effect.	l , or – dd
	The MAKE macro is another special case. It has the value make by default, and porarily overrides the –n option for any line in which it is referred to. This all invocations of make written as:	
	\$(MAKE)	
	to run recursively, with the $-n$ flag in effect for all commands but make . This use ' make $-n$ ' to test an entire hierarchy of makefiles.	lets you
	For compatibility with the 4.2 BSD make , the MFLAGS macro is set from the M variable by prepending a '–'. MFLAGS is not exported automatically.	AKEFLAGS
	The SHELL macro, when set to a single-word value such as /usr/bin/csh, indicaname of an alternate shell to use. The default is /bin/sh. Note that make exect mands that contain no shell metacharacters itself. Built-in commands, such as	utes com-
1S-602	modified	l 18 Jul 1995

	C shell, are not recognized unless the command line includes a metacharacter (for instance, a semicolon). This macro is neither imported from, nor exported to the environment, regardless of $-e$. To be sure it is set properly, you must define this macro within every makefile that requires it.		
	The following n	nacros are provided for use with cross-compilation:	
	HOST_ARCH	The machine architecture of the host system. By default, this is the output of the arch (1) command prepended with '—'. Under normal circumstances, this value should never be altered by the user.	
	HOST_MACH	The machine architecture of the host system. By default, this is the output of the mach (1), prepended with '—'. Under normal circumstances, this value should never be altered by the user.	
	TARGET_ARCH	The machine architecture of the target system. By default, the output of mach , prepended with '—'.	
Dynamic Macros		al dynamically maintained macros that are useful as abbreviations within shown here as references; if you were to define them, make would sime definition.	
	\$ *	The basename of the current target, derived as if selected for use with an implicit rule.	
	\$<	The name of a dependency file, derived as if selected for use with an implicit rule.	
	\$@	The name of the current target. This is the only dynamic macro whose value is strictly determined when used in a dependency list. (In which case it takes the form ' \$\$ @'.)	
	\$?	The list of dependencies that are newer than the target. Command- dependency checking is automatically suppressed for lines that contain this macro, just as if the command had been prefixed with a '?'. See the description of '?', under Makefile Special Tokens , above. You can force this check with the ! command-line prefix.	
	\$%	The name of the library member being processed. (See Library Mainte-nance , below.)	
	additional ' \$ ' ch implicit rules (a	⁶ ^(a) dynamic macro within a dependency list, precede the reference with an naracter (as in, ' \$\$ ^(a)). Because make assigns \$ < and \$ * as it would for according to the suffixes list and the directory contents), they may be n used within explicit target entries.	
	the strings they resulting name	an be modified to apply either to the filename part, or the directory part of stand for, by adding an upper case F or D , respectively (and enclosing the in parentheses or braces). Thus, ' (OD) ' refers to the directory part of the ere is no directory part, '.' is assigned. (OD) refers to the filename part.	

1S-603

Conditional Macro	A macro definition of the form:
Definitions	target-list := macro = value
	indicates that when processing any of the targets listed and their dependencies, macro is to be set to the value supplied. Note that if a conditional macro is referred to in a dependency list, the \$ must be delayed (use \$\$ instead). Also, target-list may contain a % pattern, in which case the macro will be conditionally defined for all targets encountered that match the pattern. A pattern replacement reference can be used within the value. You can temporarily append to a macro's value with a conditional definition of the form: target-list := macro += value
Predefined Macros	make supplies the macros shown in the table that follows for compilers and their options, host architectures, and other commands. Unless these macros are read in as environment variables, their values are not exported by make . If you run make with any of these set in the environment, it is a good idea to add commentary to the makefile to indicate what value each is expected to take. If –r is in effect, make does not read the default makefile (./make.rules or /usr/share/lib/make/make.rules) in which these macro definitions are supplied.

	List			
Implicit Rules	When a target has no entry in the makefile, make attempts to determine its class (if any) and apply the rule for that class. An implicit rule describes how to build any target of a given class, from an associated dependency file. The class of a target can be determined either by a pattern, or by a suffix; the corresponding dependency file (with the same basename) from which such a target might be built. In addition to a predefined set of implicit rules, make allows you to define your own, either by pattern, or by suffix.			
Pattern Matching Rules	A target entry of the form: tp % <i>ts</i> : <i>dp</i> % <i>ds</i> <i>rule</i>			
	is a pattern matching rule, in which tp is a target prefix, ts is a target suffix, dp is a dependency prefix, and ds is a dependency suffix (any of which may be null). The '%' stands for a basename of zero or more characters that is matched in the target, and is used to construct the name of a dependency. When make encounters a match in its search for an implicit rule, it uses the rule in that target entry to build the target from the dependency file. Pattern-matching implicit rules typically make use of the $@$ and $$<$ dynamic macros as placeholders for the target and dependency names. Other, regular dependencies may occur in the dependency list; however, none of the regular dependencies may contain '%'. An entry of the form: tp %ts: [dependency] dp %ds [dependency] rule			

is a valid pattern matching rule.

Suffix Rules

When no pattern matching rule applies, **make** checks the target name to see if it ends with a suffix in the known suffixes list. If so, **make** checks for any suffix rules, as well as a dependency file with same root and another recognized suffix, from which to build it.

The target entry for a suffix rule takes the form:

DsTs: rule

where *Ts* is the suffix of the target, *Ds* is the suffix of the dependency file, and *rule* is the rule for building a target in the class. Both *Ds* and *Ts* must appear in the suffixes list. (A suffix need not begin with a '.' to be recognized.)

A suffix rule with only one suffix describes how to build a target having a null (or no) suffix from a dependency file with the indicated suffix. For instance, the **.c** rule could be used to build an executable program named **file** from a C source file named **'file.c'**. If a target with a null suffix has an explicit dependency, **make** omits the search for a suffix rule.

	/usr/sha		set of implicit rules from the file ules , unless – r is in effect, or there is a make.rules file in the include that file.	
The Suffixes List			he list of dependencies for the '.SUFFIXES :' special-function	
	target. The default list is contained in the SUFFIXES macro (See <i>Table of Predefined Macros</i> for the standard list of suffixes). You can define additional .SUFFIXES : targets; a .SUF -			
	FIXES target with no dependencies clears the list of suffixes. Order is significant within			
	tanget with no dependencies clears the list of summes, order is significant within			

1S-614

	the list; make selects a rule that corresponds to the target's suffix and the first dependency-file suffix found in the list. To place suffixes at the head of the list, clear the list and replace it with the new suffixes, followed by the default list:
	.SUFFIXES: .SUFFIXES: <i>suffixes</i> \$(SUFFIXES)
	A tilde ($$) indicates that if a dependency file with the indicated suffix (minus the $$) is under SCCS its most recent version should be retrieved, if necessary, before the target is processed.
Library Maintenance	A target name of the form:
·	lib(member)
	refers to a member, or a space-separated list of members, in an ar (1) library.
	The dependency of the library member on the corresponding file must be given as an explicit entry in the makefile. This can be handled by a pattern matching rule of the form:
	<i>lib(%.s)</i> : %. <i>s</i>
	where <i>.s</i> is the suffix of the member; this suffix is typically <i>.o</i> for object libraries.
	A target name of the form
	lib((symbol))
	refers to the member of a randomized object library that defines the entry point named <i>symbol</i> .
Command Execution	Command lines are executed one at a time, <i>each by its own process or shell.</i> Shell commands, notably cd , are ineffectual across an unescaped NEWLINE in the makefile. A line is printed (after macro expansion) just before being executed. This is suppressed if it starts with a '@', if there is a '. SILENT :' entry in the makefile, or if make is run with the -s option. Although the -n option specifies printing without execution, lines containing the macro \$(MAKE) are executed regardless, and lines containing the @ special character are printed. The -t (touch) option updates the modification date of a file without executing any rules. This can be dangerous when sources are maintained by more than one person. make invokes the shell with the -e (exit-on-errors) argument. Thus, with semicolon-separated command sequences, execution of the later commands depends on the success of the former. This behavior can be overridden by starting the command line with a '-', or by writing a shell script that returns a non-zero status only as it finds appropriate.
Bourne Shell	To use the Bourne shell if control structure for branching, use a command line of the
Constructs	form:
	if expression ; \ then command ; \
	else command ; \; \
	fi
11C 1 10 T 1 1005	10.015

1S-615

make(1S)	SunOS Specific Commands	SunOS 5.5
	Although composed of several input lines, the escaped NEWLINE characters in make treats them all as one (shell) command line.	isure that
	To use the Bourne shell for control structure for loops, use a command line of	the form:
	for var in list ; \ do command; \	
	done	
	To refer to a shell variable, use a double-dollar-sign (\$\$). This prevents expand dollar-sign by make .	sion of the
Command Substitutions	To incorporate the standard output of a shell command in a macro, use a define form:	uition of the
	MACRO :sh =command	
	The command is executed only once, standard error output is discarded, and is characters are replaced with SPACEs. If the command has a non-zero exit status halts with an error.	
	To capture the output of a shell command in a macro reference, use a reference form:	e of the
	\$(MACRO :sh)	
	where <i>MACRO</i> is the name of a macro containing a valid Bourne shell commar this case, the command is executed whenever the reference is evaluated. As w command substitutions, the reference is replaced with the standard output of mand. If the command has a non-zero exit status, make halts with an error.	ith shell/
Signals	INT, SIGTERM, and QUIT signals received from the keyboard halt make and r target file being processed unless that target is in the dependency list for .PRE	
EXAMPLES	This makefile says that pgm depends on two files a.o and b.o , and that they in depend on their corresponding source files (a.c and b.c) along with a common	
	pgm: a.o b.o \$(LINK.c) –o \$@ a.o b.o	
	a.o: incl.h a.c cc –c a.c	
	b.o: incl.h b.c cc –c b.c	
	The following makefile uses implicit rules to express the same dependencies:	
	pgm: a.o b.o cc a.o b.o –o pgm a.o b.o: incl.h	

ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of make : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
	KEEP_STATE		
	This environment variable has the same effect as the .KEEP_STATE : special-function target. It enables command dependencies, hidden dependencies and writing of the state file.		
	USE_SVR4_MAKE		
	This environment variable causes make to invoke the generic System V ver- sion of make (/ usr/ccs/lib/svr4.make). See sysV-make (1).		
	MAKEFLAGS		
	This variable is interpreted as a character string representing a series of option characters to be used as the default options. The implementation will accept both of the following formats (but need not accept them when intermixed):		
	1. The characters are option letters without the leading hyphens or blank character separation used on a command line.		
	2. The characters are formatted in a manner similar to a portion of the make command line: options are preceded by hyphens and blank-character-separated. The <i>macro=name</i> macro definition operands can also be included. The difference between the contents of MAKEFLAGS and the command line is that the contents of the variable will not be subjected to the word expansions (see wordexp (3C)) associated with parsing the command line values.		
	When the command-line options $-\mathbf{f}$ or $-\mathbf{p}$ are used, they will take effect regardless of whether they also appear in MAKEFLAGS. If they otherwise appear in MAKEFLAGS, the result is undefined.		
	The MAKEFLAGS variable will be accessed from the environment before the makefile is read. At that time, all of the options (except $-f$ and $-p$) and command-line macros not already included in MAKEFLAGS are added to the MAKEFLAGS macro. The MAKEFLAGS macro will be passed into the environment as an environment variable for all child processes. If the MAKEFLAGS macro is subsequently set by the makefile, it replaces the MAKEFLAGS variable currently found in the environment.		
EXIT STATUS	When the $-\mathbf{q}$ option is specified, the make utility will exit with one of the following values:		
	0 Successful completion.		
	1 The target was not up-to-date.		
	>1 An error occurred.		
	When the $-\mathbf{q}$ option is not specified, the make utility will exit with one of the following values:		
	0 successful completion		
	>0 an error occurred

DIAGNOSTICS	 Solaris Advanced User's Guide Programming Utilities Guide Don't know how to make target 'target' There is no makefile entry for target, and none of make's implicit rules apply (there is no dependency file with a suffix in the suffixes list, or the target's suffix is not in the list). **** target removed. make was interrupted while building target. Rather than leaving a partially-completed version that is newer than its dependencies, make removes the file named target. **** target not removed. make was interrupted while building target and target was not present in the directory. **** target could not be removed, reason make was interrupted while building target, which was not removed for the indicated reason. Read of include file 'file' failed The makefile indicated in an include directive was not found, or was inaccessible. Loop detected when expanding macro value 'macro' A reference to the macro being defined was found in the definition. Could not write state file 'file' You used the .KEEP_STATE: target, but do not have write permission on the stat file. **** Error code n The previous shell command returned a nonzero error code. 	

***	signal	message

The previous shell command was aborted due to a signal. If '- **core dumped**' appears after the message, a **core** file was created.

Conditional macro conflict encountered

Displayed only when -d is in effect, this message indicates that two or more parallel targets currently being processed depend on a target which is built differently for each by virtue of conditional macros. Since the target cannot simultaneously satisfy both dependency relationships, it is conflicted.

BUGS Some commands return nonzero status inappropriately; to overcome this difficulty, prefix the offending command line in the rule with a '-'.

Filenames with the characters '=', ':', or '@', do not work.

You cannot build **file.o** from **lib(file.o**).

Options supplied by **MAKEFLAGS** should be reported for nested **make** commands. Use the **-d** option to find out what options the nested command picks up from **MAKEFLAGS**.

This version of **make** is incompatible in certain respects with previous versions:

- The –**d** option output is much briefer in this version. –**dd** now produces the equivalent voluminous output.
- make attempts to derive values for the dynamic macros '\$*', '\$<', and '\$?', while processing explicit targets. It uses the same method as for implicit rules; in some cases this can lead either to unexpected values, or to an empty value being assigned. (Actually, this was true for earlier versions as well, even though the documentation stated otherwise.)
- make no longer searches for SCCS history "(s.)" files.
- Suffix replacement in macro references are now applied after the macro is expanded.

There is no guarantee that makefiles created for this version of **make** will work with earlier versions.

If there is no **make.rules** file in the current directory, and the file /usr/share/lib/make/make.rules is missing, make stops before processing any targets. To force **make** to run anyway, create an empty **make.rules** file in the current directory.

Once a dependency is made, **make** assumes the dependency file is present for the remainder of the run. If a rule subsequently removes that file and future targets depend on its existence, unexpected errors may result.

When hidden dependency checking is in effect, the **\$?** macro's value includes the names of hidden dependencies. This can lead to improper filename arguments to commands when **\$?** is used in a rule.

Pattern replacement macro references cannot be used in the dependency list of a pattern matching rule.

Unlike previous versions, this version of **make** strips a leading './' from the value of the '**\$**@' dynamic macro.

With automatic SCCS retrieval, this version of **make** does not support tilde suffix rules.

The only dynamic macro whose value is strictly determined when used in a dependency list is \$@ (takes the form '\$\$@').

make invokes the shell with the –**e** argument. This cannot be inferred from the syntax of the rule alone.

NAME	man – finc	l and display reference manual pages	
SYNOPSIS	man [–] [–adFlrt] [–M path] [–T macro-package] [–s section] name man [–M path] –k keyword man [–M path] –f file		
AVAILABILITY	SUNWdoc		
DESCRIPTION	The man command displays information from the reference manuals. It displays complete manual pages that you select by <i>name</i> , or one-line summaries selected either by <i>keyword</i> (– k), or by the name of an associated file (– f). If no manual page is located, man prints an error message.		
Location of Manual Pages	The reference page sources are typically located in the /usr/share/man/man* or /usr/man/man* directories, with each directory corresponding to a section of the manual. Since these directories are optionally installed, they may not reside on your host; you may have to mount /usr/share/man from a host on which they do reside. If there are preformatted, up-to-date versions in the corresponding cat* or fmt* directories, man simply displays or prints those versions. If the preformatted version of interest is out of date or missing, man reformats it prior to display and will store the preformatted version if cat? or fmt? is writable. The windex database is not updated. See catman(1M). If directories for the preformatted versions are not provided, man reformats a page whenever it is requested; it uses a temporary file to store the formatted text during display.		
	If the standard output is not a terminal, or if the '–' flag is given, man pipes its output through cat (1); otherwise, man pipes its output through more (1) to handle paging and underlining on the screen.		
OPTIONS	The follow	ving options are supported:	
	- a	Show all manual pages matching <i>name</i> within the MANPATH search path. Manual pages are displayed in the order found.	
	-d	Debug. Displays what a section-specifier evaluates to, method used for searching, and paths searched by man .	
	-f file	man attempts to locate manual pages related to any of the given <i>files</i> . It strips the leading path name components from each <i>file</i> , and then prints one-line summaries containing the resulting basename or names. This option also uses the windex database.	
	- F	Force man to search all directories specified by MANPATH or the man.cf file, rather than using the windex lookup database. This is useful if the database is not up to date. If the windex database does not exist, this option is assumed.	
	– k keyword		
		Print out one-line summaries from the windex database (table of contents) that contain any of the given <i>keywords</i> . The windex database is created using catman (1M).	

	_ l	List all manual pages found matching <i>name</i> within the search path.
	-M path	Specify an alternate search path for manual pages. <i>path</i> is a colon-separated list of directories that contain manual page directory subtrees. For example, if <i>path</i> is / usr/share/man:/usr/local/man , man searches for <i>name</i> in the standard location, and then / usr/local/man . When used with the - k or - f options, the - M option must appear first. Each directory in the <i>path</i> is assumed to contain subdirectories of the form man *, one for each section. This option overrides the MANPATH environment variable.
	- r	Reformat the manual page, but do not display it. This replaces the $mant$ <i>name</i> combination.
	-s section	
		Specify sections of the manual for man to search. The directories searched for <i>name</i> is limited to those specified by <i>section</i> . <i>section</i> can be a digit (perhaps followed by one or more letters), a word (for example: local, new, old, public), or a letter. To specify multiple sections, separate each section with a comma. This option overrides the MANPATH environment variable and the man.cf file. See Search Paths below for an explanation of how man conducts its search.
	-t	man arranges for the specified manual pages to be troff ed to a suitable raster output device (see troff (1). If both the – and –t flags are given, man updates the troff ed versions of each named <i>name</i> (if necessary), but does not display them.
	-T macro-	package
		Format manual pages using <i>macro-package</i> rather than the standard – man macros defined in / usr/share/lib/tmac/an . See Search Path under USAGE for a complete explanation of the default search path order.
OPERANDS	The follov	wing operand is supported:
	name	A keyword or the name of a standard utility.
USAGE Manual Page Sections	major sect typically of for the sec descriptio	the reference manuals are organized into <i>sections</i> . A section name consists of a tion name, typically a single digit, optionally followed by a subsection name, one or more letters. An unadorned major section name acts as an abbreviation ction of the same name along with all of its subsections. Each section contains ons apropos to a particular reference category, with subsections refining these ns. See the intro manual pages for an explanation of the classification used in se.
Search Path	tions. ma	arching for a given <i>name</i> , man constructs a list of candidate directories and sec- in searches for <i>name</i> in the directories specified by the MANPATH environment If this variable is not set, /usr/share/man is searched by default.

	Within the manual page directories, man confines its search to the sections specified in the following order:				
	 sections specified on the command line with the -s option 				
	• sections embedded in the MANPATH environment variable				
	 <i>sections</i> specified in the man.cf file for each directory specified in the MAN- PATH environment variable 				
	If none of the above exist, man searches each directory in the manual page path, and displays the first matching manual page found.				
	The man.cf file has the following format:				
	MANSECTS=section[,section]				
	Lines beginning with '#' and blank lines are considered comments, and are ignored. Each directory specified in MANPATH can contain a manual page configuration file, specifying the default search order for that directory.				
Formatting Manual Pages	Manual pages are troff (1) or nroff (1) source files prepared with the –man macro package. Please refer to man (5) for more information.				
Preprocessing Manual Pages	When formatting a manual page, man examines the first line to determine whether it requires special processing. If the first line is a string of the form: X = X				
	where X is separated from the '"' by a single SPACE and consists of any combination of characters in the following list, man pipes its input to troff (1) or nroff (1) through the corresponding preprocessors.				
	e eqn(1), or neqn for nroff r refer(1) t tbl(1) v vgrind(1)				
	If eqn or neqn is invoked, it will automatically read the file / usr/pub/eqnchar (see eqnchar (5)). If nroff (1) is invoked, col (1) is automatically used.				
Referring to Other Manual Pages	If the first line of the manual page is a reference to another manual page entry fitting the pattern:				
	.so man*/ sourcefile				
	man processes the indicated file in place of the current one. The reference must be expressed as a path name relative to the root of the manual page directory subtree.				
	When the second or any subsequent line starts with .so , man ignores it; troff (1) or nroff (1) processes the request in the usual manner.				
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of man : LC_CTYPE , LC_MESSAGES , and NLSPATH .				
	MANPATH A colon-separated list of directories; each directory can be followed by a				

1-623

man(1)	User Commands			SunOS 5.5
		/usr/share/mar	ted list of sections. If set, its value as the default directory search pa ection search path. The $-\mathbf{M}$ and $-\mathbf{s}$ es.)	th, and the man.cf file
PAGER A program to use for interactively delivering If not set, 'more –s' (see more(1)) is used.			n 's output to the screen.	
	TCAT	The name of th	e program to use to display troff e	d manual pages.
	TROFF	The name of th troff (1) is used	e formatter to use when the –t flag	g is given. If not set,

SEE ALSO	apropos(1), cat(1), col(1), eqn(1), more(1), nroff(1), refer(1), tbl(1), troff(1), vgrind(1), whatis(1), catman(1M), environ(5), eqnchar(5), man(5)			
NOTES	Because troff is not 8-bit clean, man has not been made 8-bit clean.			
	The -f and -k options use the / usr/share/man/windex database, which is created by catman (1M).			
BUGS	 The manual is supposed to be reproducible either on a phototypesetter or on an ASCII to minal. However, on a terminal some information (indicated by font changes, for instance) is lost. Some dumb terminals cannot process the vertical motions produced by the e (see eqn(1 preprocessing flag. To prevent garbled output on these terminals, when you use e also use t, to invoke col(1) implicitly. This workaround has the disadvantage of eliminating superscripts and subscripts — even on those terminals that can display them. CTRL-Q will clear a terminal that gets confused by eqn(1) output. 			
			when you use e also antage of eliminating	

NAME	mconnect – connect to SMTP mail server socket
SYNOPSIS	mconnect [-p port] [-r] [hostname]
AVAILABILITY	SUNWcsu
DESCRIPTION	mconnect opens a connection to the mail server on a given host, so that it can be tested independently of all other mail software. If no host is given, the connection is made to the local host. Servers expect to speak the Simple Mail Transfer Protocol (SMTP) on this connection. Exit by typing the quit command. Typing EOF sends an end of file to the server. An interrupt closes the connection immediately and exits.
OPTIONS	-p port Specify the port number instead of the default SMTP port (number 25) as the next argument.
	 -r "Raw" mode: disable the default line buffering and input handling. This produces an effect similar to telnet to port number 25.
FILES	/ etc/mail/sendmail.hf help file for SMTP commands

NAME	mcs – manipulate the comment section of an object file		
SYNOPSIS	mcs [–a s	string] $[-c] [-d] [-n name] [-p] [-V] filename$	
DESCRIPTION	The mcs command is used to manipulate a section, by default the .comment section, in an ELF object file. It is used to add to, delete, print, and compress the contents of a section in an ELF object file, and only print the contents of a section in a COFF object file. mcs must be given one or more of the options described below. It applies each of the options in order to each file.		
OPTIONS	– a string	Append <i>string</i> to the comment section of the ELF object files. If <i>string</i> contains embedded blanks, it must be enclosed in quotation marks.	
	- c	Compress the contents of the comment section of the ELF object files. All duplicate entries are removed. The ordering of the remaining entries is not disturbed.	
	-d	Delete the contents of the comment section from the ELF object files. The sec- tion header for the comment section is also removed.	
	-n name	Specify the name of the comment section to access if other than .comment . By default, mcs deals with the section named .comment . This option can be used to specify another section.	
	- p	Print the contents of the comment section on the standard output. Each sec- tion printed is tagged by the name of the file from which it was extracted, using the format <i>filename[member_name</i>]: for archive files; and <i>filename</i> : for other files.	
	$-\mathbf{V}$	Print, on standard error, the version number of mcs .	
	For examp of each EI	It file is an archive (see ar (4)), the archive is treated as a set of individual files. ple, if the -a option is specified, the string is appended to the comment section LF object file in the archive; if the archive member is not an ELF object file, then inchanged.	
	only the – cuting the	executed on an archive file the archive symbol table will be removed, unless p option has been specified. The archive symbol table must be restored by exe- ar command with the -s option before the archive can be linked by the ld com- cs will produce appropriate warning messages when this situation arises.	
EXAMPLES		ving example: xample% mcs –p <i>filename</i>	
	prints file	name's comment section.	
	The next example: example% mcs –a string filename		
	appends s	string to filename's comment section.

NAME	mesg – permit or deny messages
SYNOPSIS	mesg $[-n -y n y]$
AVAILABILITY	SUNWcsu
DESCRIPTION	The mesg utility will control whether other users are allowed to send messages via write , talk (1) or other utilities to a terminal device. The terminal device affected is determined by searching for the first terminal in the sequence of devices associated with standard input, standard output and standard error, respectively. With no arguments, mesg reports the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.
OPTIONS	The following options are supported:
	$-\mathbf{n} \mid \mathbf{n}$ Deny permission to other users to send message to the terminal. See write(1).
	$-\mathbf{y} \mid \mathbf{y}$ Grant permission to other users to send messages to the terminal.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of mesg : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	0 if messages are receivable
	1 if messages are not receivable
	2 on error.
FILES	/ dev/tty * terminal devices
SEE ALSO	talk(1), write(1), environ(5)

NAME	message – puts its arguments on FMLI message line		
SYNOPSIS	message [-t] [-b [<i>num</i>]] [-o] [-w] [<i>string</i>] message [-f] [-b [<i>num</i>]] [-o] [-w] [<i>string</i>] message [-p] [-b [<i>num</i>]] [-o] [-w] [<i>string</i>]		
DESCRIPTION	The message command puts <i>string</i> out on the FMLI message line. If there is no string, the <i>stdin</i> input to message will be used. The output of message has a duration (length of time it remains on the message line). The default duration is "transient": it or one of two other durations can be requested with the mutually-exclusive options below. Messages displayed with message - p will replace (change the value of) any message currently displayed or stored via use of the permanentmsg descriptor. Likewise, message - f will replace any message currently displayed or stored via use of the framemsg descriptor. If more than one message in a frame definition file is specified with the - p option, the last one specified will be the permanent duration message. The <i>string</i> argument should always be the last argument.		
OPTIONS	t f	Explicitly defines a message to have transient duration. Transient messages remain on the message line only until the user presses another key or a CHECKWORLD occurs. The descriptors itemmsg , fieldmsg , invalidmsg , choicemsg , the default-if-not-defined value of oninterrupt , and FMLI generated error messages (that is, from syntax errors) also output transient duration messages. Transient messages take precedence over both frame messages and permanent messages. Defines a message to have "frame" duration. Frame messages remain on the message line as long as the frame in which they are defined is current. The	
		descriptor framemsg also outputs a frame duration message. Frame mes- sages take precedence over permanent messages.	
	- p	Defines a message to have "permanent" duration. Permanent messages remain on the message line for the length of the FMLI session, unless expli- citly replaced by another permanent message or temporarily superseded by a transient message or frame message. A permanent message is not affected by navigating away from, or by closing, the frame which generated the per- manent message. The descriptor permanentmsg also outputs a permanent duration message.	
	- b [num]	Rings the terminal bell <i>num</i> times, where <i>num</i> is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen will flash <i>num</i> times instead, if possible.	
	-0	Forces message to duplicate its message to <i>stdout</i> .	
	- W	Turns on the working indicator.	

modified 5 Jul 1990

1F-629

EXAMPLES	When a value entered in a field is invalid, ring the bell 3 times and then display Invalid Entry: Try again! on the message line:			
	invalidmsg=`message –b 3 "Invalid Entry: Try again!"`			
	Display a message that tells the user what is being done:			
	done=`message EDITOR has been set in your environment` close			
	Display a message on the message line and <i>stdout</i> for each field in a form (a pseudo-"field duration" message).			
	fieldmsg="`message -o -f "Enter a filename."`"			
	Display a blank transient message (effect is to "remove" a permanent or frame duration message).			
	done=`message ""` nop			
SEE ALSO	sleep(1)			
NOTES	If message is coded more than once on a single line, it may appear that only the right- most instance is interpreted and displayed. Use sleep (1) between uses of message in this case, to display multiple messages.			
	message - f should not be used in a stand-alone backquoted expression or with the init descriptor because the frame is not yet current when these are evaluated.			
	In cases where `message -f " <i>string</i> "` is part of a stand-alone backquoted expression, the context for evaluation of the expression is the previously current frame. The previously current frame can be the frame that issued the open command for the frame containing the backquoted expression, or it can be a frame given as an argument when fmli was invoked. That is, the previously current frame is the one whose frame message will be modified.			
	Permanent duration messages are displayed when the user navigates to the command line.			

modified 5 Jul 1990

NAME	mkdir – make directories		
SYNOPSIS	mkdir $[-\mathbf{m} \mod e] [-\mathbf{p}] \dim \ldots$		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The mkdir command creates the named directories in mode 777 (possibly altered by the file mode creation mask umask (1)).		
	Standard entries in a directory (for instance, the files ".", for the directory itself, and "", for its parent) are made automatically. mkdir cannot create these entries by name. Creation of a directory requires write permission in the parent directory.		
	The owner-ID and group-ID of the new directories are set to the process's effective user-ID and group-ID, respectively. mkdir calls the mkdir (2) system call.		
setgid and mkdir	To change the setgid bit on a newly created directory, you must use chmod g+s or chmod g-s after executing mkdir .		
	The setgid bit setting is inherited from the parent directory.		
OPTIONS	The following options are supported:		
	-m <i>mode</i> This option allows users to specify the mode to be used for new directories. Choices for modes can be found in chmod (1).		
	- p With this option, mkdir creates <i>dir</i> by creating all the non-existing parent directories first. The mode given to intermediate directories will be the difference between 777 and the bits set in the file mode creation mask. The difference, however, must be at least 300 (write and execute permission for the user).		
OPERANDS	The following operand is supported:		
	<i>dir</i> A path name of a directory to be created.		
EXAMPLES	The following example: example% mkdir -p ltr/jd/jan		
	creates the subdirectory structure ltr/jd/jan .		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of mkdir : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	 The following exit values are returned: All the specified directories were created successfully or the -p option was specified and all the specified directories now exist. 		
	>0 An error occurred.		

1-631

NAME	mkmsgs – create message files for use by gettxt		
SYNOPSIS	mkmsgs [–o] [–i locale] inputstrings msgfile		
AVAILABILITY	SUNWloc		
DESCRIPTION	The mkmsgs utility is used to create a file of text strings that can be accessed using the text retrieval tools (see gettxt (1), srchtxt (1), exstr (1), and gettxt (3C)). It will take as input a file of text strings for a particular geographic locale (see setlocale (3C)) and create a file of text strings in a format that can be retrieved by both gettxt (1) and gettxt (3C). By using the –i option, you can install the created file under the / usr/lib/locale / <i>locale</i> /LC_MESSAGES directory (<i>locale</i> corresponds to the language in which the text strings are written).		
	<i>inputstrings</i> is the name of the file that contains the original text strings. <i>msgfile</i> is the name of the output file where mkmsgs writes the strings in a format that is readable by gettxt (1) and gettxt (3C). The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either $\ 0$ (null) or the ASCII code for / (slash) or : (colon).		
	The input file contains a set of text strings for the particular geographic locale. Text strings are separated by a newline character. Nongraphic characters must be represented as alphabetic escape sequences. Messages are transformed and copied sequentially from <i>inputstrings</i> to <i>msgfile</i> . To generate an empty message in <i>msgfile</i> , leave an empty line at the correct place in <i>inputstrings</i> .		
	added only the correct	be changed simply by editing the file <i>inputstrings</i> . New strings must be y at the end of the file; then a new <i>msgfile</i> file must be created and installed in place. If this procedure is not followed, the retrieval function will retrieve the ng and software compatibility will be broken.	
OPTIONS	-0	Overwrite <i>msgfile</i> , if it exists.	
	−i locale	Install <i>msgfile</i> in the / usr/lib/locale / <i>locale</i> / LC_MESSAGES directory. Only someone who is super-user or a member of group bin can create or overwrite files in this directory. Directories under / usr/lib/locale will be created if they do not exist.	
EXAMPLES	The follow	ing example shows an input message source file C.str :	
		le %s:\t cannot be opened\n s: Bad directory\n	
	WI	ite error\n	

modified 26 Jul 1994

1-633

The following command uses the input strings from **C.str** to create text strings in the appropriate format in the file **UX** in the current directory:

example% mkmsgs C.str UX

The following command uses the input strings from **FR.str** to create text strings in the appropriate format in the file **UX** in the directory /**usr/lib/locale/fr/LC_MESSAGES**.

example% mkmsgs –i fr FR.str UX

These text strings would be accessed if you had set the environment variable LC_MESSAGES=fr and then invoked one of the text retrieval tools listed at the beginning of the DESCRIPTION section.

FILES /usr/lib/locale/locale/LC_MESSAGES/* message files created by mkmsgs

NAME	mkstr - create an error message file by massaging C source files		
SYNOPSIS	/usr/ucb/mkstr [–] messagefile prefix filename		
AVAILABILITY	SUNWscpu		
AVAILABILITY DESCRIPTION	<pre>SUNWscpu mkstr creates files of error messages. You can use mkstr to make programs with large numbers of error diagnostics much smaller, and to reduce system overhead in running the program — as the error messages do not have to be constantly swapped in and out. mkstr processes each of the specified <i>filenames</i>, placing a massaged version of the input file in a file with a name consisting of the specified <i>prefix</i> and the original source file name. A typical example of using mkstr would be: mkstr pistrings processed *.c This command would cause all the error messages from the C source files in the current directory to be placed in the file pistrings and processed copies of the source for these files to be placed in files whose names are prefixed with <i>processed</i>. To process the error messages in the source to the message file, mkstr keys on the string 'error(" in the input stream. Each time it occurs, the C string starting at the ''' is placed in the message file followed by a null character and a NEWLINE character; the null char- acter makes it possible to sensibly cat the error message file to see its contents. The mas- saged copy of the input file then contains a lseek pointer into the file which can be used to retrieve the message, that is:</pre>

NAME	more, page – browse or page through a text file		
SYNOPSIS	<pre>/usr/bin/more [-cdflrsuw] [-lines] [+linenumber] [+/pattern] [filename] /usr/bin/page [-cdflrsuw] [-lines] [+linenumber] [+/pattern] [filename] /usr/xpg4/bin/more [-cdeisu] [-nnumber] [-pcommand] [-ttagstring] [filename] /usr/xpg4/bin/more [-cdeisu] [-nnumber] [+command] [-ttagstring] [filename]</pre>		
AVAILABILITY /usr/bin/more /usr/bin/page	SUNWcsu		
/usr/xpg4/bin/more	SUNWxcu4		
DESCRIPTION	more is a filter that displays the contents of a text file on the terminal, one screenful at a time. It normally pauses after each screenful. / usr/bin/more then prints More and / usr/xpg4/bin/more then prints <i>filename</i> at the bottom of the screen. If more is reading from a file rather than a pipe, the percentage of characters displayed so far is also shown.		
	more scrolls up to display one more line in response to a RETURN character; it displays another screenful in response to a SPACE character. Other commands are listed below.		
	page clears the screen before displaying the next screenful of text; it only provides a one- line overlap between screens.		
	more sets the terminal to NOECHO mode, so that the output can be continuous. Commands that you type do not normally show up on your terminal, except for the / and ! commands.		
	/usr/bin/more exits after displaying the last specified file. /usr/xpg4/bin/more prom for a command at the last line of the last specified file.		
	If the standard output is not a terminal, more acts just like cat (1), except that a header is printed before each file in a series.		
OPTIONS	The following options are available in both versions of more :		
	 -c Clear before displaying. Redraws the screen instead of scrolling for faster displays. This option is ignored if the terminal does not have the ability to clear to the end of a line. 		
	-d Display error messages rather than ringing the terminal bell if an unrecognized command is used. This is helpful for inexperienced users.		
	-s Squeeze. Replace multiple blank lines with a single blank line. This is helpful when viewing nroff (1) output on the screen.		
/usr/bin/more	The following options are available only in / usr/bin/more :		
	 -f Do not fold long lines. This is useful when lines contain nonprinting characters or escape sequences, such as those generated when nroff(1) output is piped through ul(1). 		

1-637

	_1	Do not treat FORMFEED characters (CTRL-L) as page breaks. If –l is not used, more pauses to accept commands after any line containing a [^] L character (CTRL-L). Also, if a file begins with a FORMFEED, the screen is cleared before the file is printed.		
	- r	Normally, more ignores control characters that it does not interpret in some way. The $-\mathbf{r}$ option causes these to be displayed as C where C stands for any such control character.		
	- u	Suppress generation of underlining escape sequences. Normally, more handles underlining, such as that produced by nroff (1), in a manner appropriate to the terminal. If the terminal can perform underlining or has a stand-out mode, more supplies appropriate escape sequences as called for in the text file.		
	-w	Normally, more exits when it comes to the end of its input. With – w , however, more prompts and waits for any key to be struck before exiting.		
	-lines	Display the indicated number of <i>lines</i> in each screenful, rather than the default (the number of lines in the terminal screen less two).		
	+linenumber	Start up at <i>linenumber</i> .		
	+/pattern	Start up two lines above the line containing the regular expression <i>pat-</i> <i>tern</i> . Note: Unlike editors, this construct should <i>not</i> end with a '/.' If it does, then the trailing slash is taken as a character in the search pattern.		
/usr/xpg4/bin/more	The following o	The following options are available only in / usr/xpg4/bin/more :		
	- e	Exit immediately after writing the last line of the last file in the argument list.		
	-i	Perform pattern matching in searches without regard to case.		
	– n number			
		Specify the number of lines per screenful. The <i>number</i> argument is a positive decimal integer. The –n option overrides any values obtained from the environment.		
	-p command	For each file examined, initially execute the more command in the <i>command</i> argument. If the command is a positioning command, such as a line number or a regular expression search, set the current position to represent the final results of the command, without writing any intermediate lines of the file. For example, the two commands: more -p 1000j file		
		more -p 1000G file are equivalent and start the display with the current position at line 1000, bypassing the lines that j would write and scroll off the screen if it had been issued during the file examination. If the positioning com- mand is unsuccessful, the first line in the file will be the current position.		
	-t tagstring	Write the screenful of the file containing the tag named by the <i>tagstring</i>		

SunOS 5.5		User Commands	more(1)
		argument. See the ctags (1) utility.	
	–u	Treat a backspace character as a printable control character, d a ^H (CTRL-H), suppressing backspacing and the special hand produces underlined or standout-mode text on some terminal Also, do not ignore a carriage-return character at the end of a	ling that types.
		-t <i>tagstring</i> and $-p$ <i>command</i> (or the obsolescent <i>+command</i>) options <i>tring</i> is processed first.	are given,
USAGE			
Environment		the terminal's terminfo (4) entry to determine its display characterist	
	page throu	s in the environment variable MORE for any preset options. For instaugh files using the $-c$ mode by default, set the value of this variable to command sequence to set up this environment variable is placed in the file).	o –c. (Nor-
Commands	 The commands take effect immediately. It is not necessary to type a carriage unless the command requires a <i>filename, command, tagstring,</i> or <i>pattern.</i> Up to when the command character itself is given, the user may type the line kill ch cancel the numerical argument being formed. In addition, the user may type character to redisplay the 'More(xx%)' or <i>filename</i> message. In the following commands, <i>i</i> is a numerical argument (1 by default). 		he time racter to
	<i>i</i> SPACE	Display another screenful, or <i>i</i> more lines if <i>i</i> is specified.	
	<i>i</i> RETURN	Display another line, or <i>i</i> more lines, if specified.	
	íb í B	(CTRL-B) Skip back <i>i</i> screenfuls and then print a screenful.	
	id î D	(CTRL-D) Scroll forward one half screenful or <i>i</i> more lines. If <i>i</i> is specount becomes the default for subsequent d and u commands.	ecified, the
	if	Skip <i>i</i> screens full and then print a screenful.	
	h	Help. Give a description of all the more commands.	
	^L	(CTRL-L) Refresh.	
	in	Search for the <i>i</i> th occurrence of the last <i>pattern</i> entered.	
	q		
	Q	Exit from more .	
	is	Skip <i>i</i> lines and then print a screenful.	
	v	Drop into the vi editor at the current line of the current file.	1 6
	iz	Same as SPACE, except that <i>i</i> , if present, becomes the new default nu lines per screenful.	imber of
	=	Display the current line number.	
	i/pattern	Search forward for the <i>i</i> th occurrence of the regular expression <i>patt</i>	ern.

	1	
		Display the screenful starting two lines before the line that contains the <i>i</i> th match for the regular expression <i>pattern</i> , or the end of a pipe, whichever comes first. If more is displaying a file and there is no match, its position in the file remains unchanged. Regular expressions can be edited using erase and kill characters. Erasing back past the first column cancels the search command.
	!command	Invoke a shell to execute <i>command</i> . The characters % and !, when used within <i>command</i> are replaced with the current filename and the previous shell command, respectively. If there is no current filename, % is not expanded. Prepend a backslash to these characters to escape expansion.
	:f	Display the current filename and line number.
	<i>i</i> :n	Skip to the <i>i</i> th next filename given in the command line, or to the last filename in the list if <i>i</i> is out of range.
	<i>i</i> :p	Skip to the <i>i</i> th previous filename given in the command line, or to the first filename if <i>i</i> is out of range. If given while more is positioned within a file, go to the beginning of the file. If more is reading from a pipe, more simply rings the terminal bell.
	:q :Q	Exit from more (same as q or Q).
/usr/bin/more	The follow	ving commands are available only in / usr/bin/more :
		Single quote. Go to the point from which the last search started. If no search has been performed in the current file, go to the beginning of the file.
		Dot. Repeat the previous command.
	^\	Halt a partial display of text. more stops sending output, and displays the usual More prompt. Some output is lost as a result.
/usr/xpg4/bin/more	The follow	ving commands are available only in / usr/xpg4/bin/more :
	î F	(CTRL-F) Skip <i>i</i> screens full and print a screenful. (Same as <i>i</i> f .)
	^G	(CTRL-G) Display the current line number (same as =).
	ig	Go to line number <i>i</i> with the default of the first line in the file.
	iG	Go to line number <i>i</i> with the default of the Last line in the file.
	ij	Display another line, or <i>i</i> more lines, if specified. (Same as <i>i</i> RETURN.)
	ik	Scroll backwards one or <i>i</i> lines, if specified.
	m letter	Mark the current position with the name <i>letter</i> .
	Ν	Reverse direction of search.
	r	Refresh the screen.
	R	Refresh the screen, discarding any buffered input.
	iu ĩ U	(CTRL-U) Scroll backwards one half a screen of <i>i</i> lines, if specified. If <i>i</i> is

		specified, the count becomes the new default for subsequent ${\bf d}$ and ${\bf u}$ commands.	
	ZZ	Exit from more (same as q).	
		Examine (display) a new file. If no <i>filename</i> is specified, the current file is redisplayed.	
		Go to the tag named by the <i>tagstring</i> argument and scroll/rewrite the screen with the tagged line in the current position. See the ctags utility.	
	'letter	Return to the position that was previously marked with the name <i>letter</i> .	
		Return to the position from which the last move of more than a screenful was made. Defaults to the beginning of the file.	
		Search backward in the file for the <i>i</i> th line containing the <i>pattern</i> . The <i>!</i> specifies to search backward for the <i>i</i> th line that does not contain the <i>pattern</i> .	
	i/!pattern ![command]	Search forward in the file for the <i>i</i> th line that does not contain the pattern.	
		Invoke a shell or the specified command.	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of more : LC_COLLATE , LC_CTYPE , LC_MESSAGES , NLSPATH , and TERM .		
/usr/xpg4/bin/more	The following environment variables also affect the execution of /usr/xpg4/bin/more:		
	COLUMNS	Override the system selected horizontal screen size.	
	EDITOR	Used by the v command to select an editor.	
	LINES	Override the system selected vertical screen size. The $-n$ option has precedence over LINES in determining the number of lines in a screen.	
	MORE	A string specifying options as described in the OPTIONS section, above. As in a command line, The options must be separated by blank characters and each option specification must start with a –. Any command line options are processed after those specified in MORE as though the command line were:	
		more \$MORE options operands	
FILES	/usr/lib/mo	bre.help help file for /usr/bin/more and /usr/bin/page only.	
SEE ALSO	cat(1), csh(environ(5)	1), ctags(1), man(1), nroff(1), script(1), sh(1), ul(1), environ(4), terminfo(4),	
NOTES /usr/bin/more	Skipping backwards is too slow on large files.		
/usr/xpg4/bin/more	Will not behave correctly if the terminal is not set up correctly.		

NAME	msgfmt – create a message object from a message file		
SYNOPSIS	msgfmt [–v] [–o output-file] filename.po		
AVAILABILITY	SUNWloc		
DESCRIPTION	msgfmt creates message object files from portable object files (<i>filename.po</i>), without changing the portable object files.		
	The .po file contains messages displayed to users by system commands or by application programs. .po files can be edited, and the messages in them can be rewritten in any language supported by the system.		
	The xgettext (1) command can be used to create .po files from script or programs.		
Portable Object Files	Formats for all .po files are the same. Each .po file contains one or more lines, with each line containing either a comment or a statement. Comments start the line with a hash mark (#) and end with the newline character. All comments are ignored. The format of a statement is:		
	directive value		
	Each directive starts at the beginning of the line and is separated from <i>value</i> by white space (such as one or more space or tab characters). <i>value</i> consists of one or more quoted strings separated by white space. Use any of the following types of directives: domain <i>domainname</i> msgid <i>message_identifier</i> msgstr <i>message_string</i>		
	The behavior of the domain directive is affected by the options used. See OPTIONS for the behavior when the -0 option is specified. If the -0 option is not specified, the behavior of the domain directive is as follows:		
	• All <i>msgids</i> from the beginning of each .po file to the first domain directive are put into a default message object file, messages.mo .		
	• When msgfmt encounters a domain <i>domainname</i> directive in the .po file, all following <i>msgids</i> until the next domain directive are put into the message object file <i>domainname</i> . mo .		
	• Duplicate <i>msgids</i> are defined in the scope of each domain. That is, a <i>msgid</i> is considered a duplicate only if the identical <i>msgid</i> exists in the same domain.		
	All duplicate <i>msgids</i> are ignored.		
	The msgid directive specifies the value of a message identifier associated with the direc- tive that follows it. The <i>message_identifier</i> string identifies a target string to be used at retrieval time. Each statement containing a msgid directive must be followed by a state- ment containing a msgstr directive.		
	The msgstr directive specifies the target string associated with the <i>message_identifier</i> string declared in the immediately preceding msgid directive.		

modified 30 Sep 1992

	cal tab, \ b for b	s can contain the escape sequences n for newline, t for tab, v for verti- ackspace, r for carriage return, f for formfeed, h for backslash, $"$ for ddd for octal bit pattern, and xDD for hexadecimal bit pattern.
OPTIONS	$-\mathbf{v}$	Verbose. List duplicate message identifiers. Message strings are not redefined.
	– o output-file	Specify output file name as <i>output-file</i> . All domain directives and duplicate <i>msgids</i> in the .po file are ignored.
EXAMPLES	exampl # defau msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr # domair msgid msgstr The following c error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error_domair error error_domair error error_domair error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error error e	<pre>module1.po and module2.po are portable message objects files. le% cat module1.po lt domain "messages.mo" "msg 1" "msg 1 translation" a "help_domain" "help 2" "help 2" "help 2 translation" a "error_domain" "error 3" "error 3 translation" le% cat module2.po ltd domain "messages.mo" "mesg 4" "mesg 4 translation" a "error_domain" "error 5" "error 5 translation" a "window_domain" "window 6" "window 6 translation" ommand will produce the output files, messages.mo, help_domain.mo, ain.mo. le% msgfmt module1.po ommand will produce the output files, messages.mo, help_domain.mo, and window_domain.mo. le% msgfmt module1.po module2.po</pre>

	exampl	e% msgfmt –o hello.mo module1.po module2.po

modified 30 Sep 1992

Install message object files in /usr/lib/locale/locale/LC_MESSAGES/domain.mo where *locale* is the message locale as set by setlocale(3C), and *domain* is text domain as set by textdomain(). The /usr/lib/locale portion can optionally be changed by calling bindtextdomain(). See gettext(3I).

SEE ALSO xgettext(1), gettext(3I)

NOTES Neither **msgfmt** nor any **gettext**(3I) routine imposes a limit on the total length of a message. However, each line in the ***.po** file is limited to **MAX_INPUT** (512) bytes.

Installing message catalogs under the C locale is pointless, since they are ignored for the sake of efficiency.

modified 30 Sep 1992

NAME	mt – magnetic tape control			
SYNOPSIS	mt [–f tapen	ame] command [count]		
AVAILABILITY	SUNWcsu			
DESCRIPTION	mt sends commands to a magnetic tape drive. If <i>tapename</i> is not specified, the environment variable TAPE is used. If TAPE does not exist, mt uses the device / dev/rmt/0 . <i>tapename</i> refers to a raw tape device. By default, mt performs the requested operation once; multiple operations may be performed by specifying <i>count</i> .			
		e <i>commands</i> are listed below. Only as many characters as are required to ntify a <i>command</i> need be specified.		
		0 exit status when the operation(s) were successful, 1 if the command was d or if mt was unable to open the specified tape drive, and 2 if an operation		
mt Commands	eof, weof	Write <i>count</i> EOF marks at the current position on the tape.		
	fsf	Forward space over <i>count</i> EOF marks. The tape is positioned on the first block of the file.		
	fsr	Forward space <i>count</i> records.		
	bsf Back space over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.			
	bsr Back space <i>count</i> records.			
	nbsf Back space <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count+1</i> bsf 's followed by one fsf .			
	asf	Absolute space to <i>count</i> file number. This is equivalent to a rewind followed by a fsf <i>count</i> .		
	For the following commands, <i>count</i> is ignored:			
	eom Space to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.			
	rewind Rewind the tape.			
	offline, rewoffl			
	Rewind the tape and, if appropriate, take the drive unit off-line by unload- ing the tape. It cycles through all four tapes.			
	status	Print status information about the tape unit.		
	retension	Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.		
	erase	Erase the entire tape.

/dev/rmt/* magnetic tape interface /dev/rmt/*b /dev/rmt/*bn /dev/rmt/*c /dev/rmt/*cb /dev/rmt/*cb /dev/rmt/*ch /dev/rmt/*hb /dev/rmt/*hb /dev/rmt/*hb /dev/rmt/*lb /dev/rmt/*lb /dev/rmt/*ln /dev/rmt/*ln /dev/rmt/*n /dev/rmt/*mb /dev/rmt/*mb /dev/rmt/*mb /dev/rmt/*u /dev/rmt/*u
tar(1), tcopy(1), ar(4), environ(4), mtio(7I), st(7D)
 Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page. mt is architecture sensitive. Heterogeneous operation (that is, Sun3 to Sun4 or visa versa) is not supported.

modified 5 Apr 1995

NAME	mv – move files		
SYNOPSIS	/usr/bin/mv [-fi] source target_file /usr/bin/mv [-fi] source target_dir		
	/usr/xpg4/bin/mv [-fi] source target_file /usr/xpg4/bin/mv [-fi] source target_dir		
AVAILABILITY /usr/bin/mv	SUNWcsu		
/usr/xpg4/bin/mv	SUNWxcu4		
DESCRIPTION	The two sets of synopses reflect the difference between / usr/bin/mv and / usr/xpg4/bin/mv when both the –f and the –i options are specified (see OPTIONS below). Each set of synopses contains two forms.		
	In the first synopsis form, the mv utility moves the file named by the <i>source</i> operand to the destination specified by the <i>target_file</i> . <i>source</i> and <i>target_file</i> may not have the same name. If <i>target_file</i> does not exist, mv creates a file named <i>target_file</i> . If <i>target_file</i> exists, its contents are overwritten. This first synopsis form is assumed when the final operand does not name an existing directory.		
	In the second synopsis form, mv moves each file named by a <i>source</i> operand to a destina- tion file in the existing directory named by the <i>target_dir</i> operand. The destination path for each <i>source</i> is the concatenation of the target directory, a single slash character (/), and the last path name component of the <i>source</i> . This second form is assumed when the final operand names an existing directory.		
	If mv determines that the mode of <i>target_file</i> forbids writing, it will print the mode (see chmod (2)), ask for a response, and read the standard input for one line. If the line begins with y , the mv occurs, if permissible; otherwise, the command exits. Note that the mode displayed may not fully represent the access permission if <i>target</i> is associated with an ACL. When the parent directory of <i>source</i> is writable and has the sticky bit set, one or more of the following conditions must be true:		
	 the user must own the file the user must own the directory the file must be writable by the user the user must be a privileged user 		
	If <i>source</i> is a directory, <i>target_dir</i> must be a directory in the same physical file system. <i>target_dir</i> and <i>source</i> do not have to share the same parent directory.		
	If <i>source</i> is a file and <i>target_file</i> is a link to another file with links, the other links remain and <i>target_file</i> becomes a new file.		
OPTIONS	mv will move the file(s) without prompting even if it is writing over an existing <i>target</i>. Note that this is the default if the standard input is not a terminal.		
	-i mv will prompt for confirmation whenever the move would overwrite an

A nawk <i>pro</i> - ence of patterns and corresponding actions. The string specifying <i>program</i> ed in single quotes (') to protect it from interpretation by the shell. The ttern - action statements can be specified in the command line as <i>program</i> ore, file(s) specified by the - f <i>progfile</i> option. When input is read that ern, the action associated with the pattern is performed.	
Input is interpreted as a sequence of records. By default, a record is a line, but this can be changed by using the RS built-in variable. Each record of input is matched to each pattern in the <i>program</i> . For each pattern matched, the associated action is executed.		
field is a string and/or tabs) ca nawk utility de \$0 refers to the	ty interprets each input record as a sequence of fields where, by default, a of non-blank characters. This default white-space field delimiter (blanks an be changed by using the FS built-in variable or the $-F$ <i>ERE</i> option. The enotes the first field in a record \$1 , the second \$2 , and so forth. The symbol entire record; setting any other field causes the reevaluation of \$0 . D resets the values of all fields and the NF built-in variable.	
The following	options are supported:	
– F ERE	Define the input field separator to be the extended regular expression <i>ERE</i> , before any input is read (can be a character).	
−f progfile	Specifies the pathname of the file <i>progfile</i> containing a nawk program. If multiple instances of this option are specified, the concatenation of the files specified as <i>progfile</i> in the order specified is the nawk program. The nawk program can alternatively be specified in the command line as a single argument.	
–v assignment	The <i>assignment</i> argument must be in the same form as an <i>assignment</i> operand. The assignment is of the form <i>var=value</i> , where <i>var</i> is the name of one of the variables described below. The specified assignment occurs before executing the nawk program, including the actions associated with BEGIN patterns (if any). Multiple occurrences of this option can be specified.	
	/usr/bin/nawk /usr/xpg4/bin/a [argumen SUNWesu SUNWxcu4 The /usr/bin/na programming gram is a seque must be enclos sequence of pa or in one, or m matches a patte Input is interpro- changed by usi tern in the prog The nawk utilifield is a string and/or tabs) ca nawk utility do S0 refers to the Assigning to S0 The following -F ERE -f progfile	

OPERANDS	The followin	g operands are	supported:		
	program	If no – f option is specified, the first operand to nawk is the text of the nawk program. The application supplies the <i>program</i> operand as a single argument to nawk . If the text does not end in a newline character, nawk interprets the text as if it did.			
	argument	Either of the	Either of the following two types of <i>argument</i> can be intermixed:		
		file	A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no <i>file</i> operands are specified, or if a <i>file</i> operand is –, the standard input is used.		
		assignment	An operand that begins with an underscore or alphabetic character from the portable character set, followed by a sequence of underscores, digits and alphabetics from the portable character set, followed by the = character specifies a variable assignment rather than a pathname. The characters before the = represent the name of a nawk variable; if that name is a nawk reserved word the behavior is undefined. The characters following the equal sign is interpreted as if they appeared in the nawk program preceded and followed by a double-quote (") character, as a STRING token , except that if the last character is an unescaped backslash, it is interpreted as a literal backslash rather than as the first character of the sequence " .}S 1 3 "\" " "" "" "" "" "" The variable is assigned the value of that STRING token. If the value is considered a <i>numeric</i> string, the variable is assigned its numeric value. Each such variable assignment is performed just before the processing of the following <i>file</i> , if any. Thus, an assignment before the first <i>file</i> argument is executed after the BEGIN actions (if any), while an assignments are executed before processing the standard input.		
INPUT FILES	Input files to	the nawk prog	ram from any of the following sources:		
	 any file operands or their equivalents, achieved by modifying the nawk variable ARGV and ARGC 				
	• standard input in the absence of any <i>file</i> operands				
	• arguments to the getline function				
	or not, for th	ese files, implei	the variable RS is set to a value other than a newline character mentations support records terminated with the specified bytes and may support longer records.		

An **nawk** program is composed of pairs of the form:

If -f *progfile* is specified, the files named by each of the *progfile* option-arguments must be text files containing an **nawk** program.
The standard input are used only if no *file* operands are specified, or if a *file* operand is -.

EXTENDED DESCRIPTION

pattern { action }

Either the pattern or the action (including the enclosing brace characters) can be omitted. Pattern-action statements are separated by a semicolon or by a newline.

A missing pattern matches any record of input, and a missing action is equivalent to an action that writes the matched record of input to standard output.

Execution of the **nawk** program starts by first executing the actions associated with all **BEGIN** patterns in the order they occur in the program. Then each *file* operand (or standard input if no files were specified) is processed by reading data from the file until a record separator is seen (a newline character by default), splitting the current record into fields using the current value of **FS**, evaluating each pattern in the program in the order of occurrence, and executing the action associated with each pattern that matches the current record. The action for a matching pattern is executed before evaluating subsequent patterns. Last, the actions associated with all **END** patterns is executed in the order they occur in the program.

Expressions in nawkExpressions describe computations used in *patterns* and *actions*. In the following table,
valid expression operations are given in groups from highest precedence first to lowest
precedence last, with equal-precedence operators grouped between horizontal lines. In
expression evaluation, where the grammar is formally ambiguous, higher precedence
operators are evaluated before lower precedence operators. In this table *expr, expr1*,
expr2, and *expr3* represent any expression, while *lvalue* represents any entity that can be
assigned to (that is, on the left side of an assignment operator).

Name	Type of Result	Associativity

Each expression has either a string value, a numeric value or both. Except as stated for specific contexts, the value of an expression is implicitly converted to the type needed for the context in which it is used. A string value is converted to a numeric value by the equivalent of the following calls:

setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);

A numeric value that is exactly equal to the value of an integer is converted to a string by the equivalent of a call to the **sprintf** function with the string %**d** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value is converted to a string by the equivalent of a call to the **sprintf** function with the value of the variable **CONVFMT** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. The result of the conversion is unspecified if the value of **CONVFMT** is not a floating-point format specification. This document specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to it, or can force it to be treated as a string by concatenating the null string ("") to it.

A string value is considered to be a *numeric string* in the following case:

- 1. Any leading and trailing blank characters is ignored.
- 2. If the first unignored character is a + or -, it is ignored.
- 3. If the remaining unignored characters would be lexically recognized as a **NUMBER** token, the string is considered a *numeric string*.

If a – character is ignored in the above steps, the numeric value of the *numeric string* is the negation of the numeric value of the recognized **NUMBER** token. Otherwise the numeric value of the *numeric string* is the numeric value of the recognized **NUMBER** token. Whether or not a string is a *numeric string* is relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero is treated as false and any other value is treated as true. Otherwise, a string value of the null string is treated as false and any other value is treated as true. A Boolean context is one of the following:

- the first subexpression of a conditional expression.
- an expression operated on by logical NOT, logical AND, or logical OR.
- the second expression of a **for** statement.
- the expression of an **if** statement.
- the expression of the **while** clause in either a **while** or **do** ... **while** statement.
- an expression used as a pattern (as in Overall Program Structure).

The **nawk** language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They are initially empty, and their sizes changes dynamically. The subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an *lvalue* and as an expression, as described in the grammar. Unsubscripted array names are used in only the following contexts:

- a parameter in a function definition or function call.
- the NAME token following any use of the keyword in.

A valid array *index* consists of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because **nawk** arrays are really one dimensional, such a comma-separated list is converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the **SUBSEP** variable. Thus, the following two index operations are equivalent:

var[expr1, expr2, ... exprn] var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]

A multi-dimensioned *index* used with the **in** operator must be put in parentheses. The **in** operator, which tests for the existence of a particular array element, does not create the element if it does not exist. Any other reference to a non-existent array element automatically creates it.

Variables and Special Variables	Variables can be used in an nawk program by referencing them. With the exception of function parameters, they are not explicitly declared. Uninitialized scalar variables and array elements have both a numeric value of zero and a string value of the empty string. Field variables are designated by a \$ followed by a number or numerical expression. The effect of the field number <i>expression</i> evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables are created by assigning a value to them. References to non-existent fields (that is, fields after \$NF) produce the null string. However, assigning to a non-existent field (for example, \$(NF+2) = 5) increases the value of NF , create any intervening fields with the null string as their values and cause the value of \$0 to be recomputed, with the fields being separated by the value of OFS . Each field variable has a string value when created. If the string, with any occurrence of the decimal-point character from the current locale changed to a period character, is considered a <i>numeric string</i> (see Expressions in nawk above), the field variable also has the numeric value of the <i>numeric string</i> .	
		tions support the following other special variables that are set by nawk :
	ARGC ARGV	The number of elements in the ARGV array. An array of command line arguments, excluding options and the <i>program</i>
	AKGV	argument, numbered from zero to ARGC –1.
		The arguments in ARGV can be modified or added to; ARGC can be altered. As each input file ends, nawk treats the next non-null element of ARGV , up to the current value of ARGC -1, inclusive, as the name of the next input file. Setting an element of ARGV to null means that it is not treated as an input file. The name – indicates the standard input. If an argument matches the format of an <i>assignment</i> operand, this argument is treated as an assignment rather than a <i>file</i> argument.
/usr/xcu4/bin/awk	CONVFM	The printf format for converting numbers to strings (except for output statements, where OFMT is used); % .6g by default.
	ENVIRON	The variable ENVIRON is an array representing the value of the environ- ment. The indices of the array are strings consisting of the names of the environment variables, and the value of each array element is a string con- sisting of the value of that variable. If the value of an environment variable is considered a <i>numeric string</i> , the array element also has its numeric value.
		In all cases where nawk behavior is affected by environment variables (including the environment of any commands that nawk executes via the system function or via pipeline redirections with the print statement, the printf statement, or the getline function), the environment used is the environment at the time nawk began executing; it is implementation- dependent whether any modification of ENVIRON affects this environment.
	FILENAME	A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value is the name of the last input file processed.

	FNR	The ordinal number of the current record in the current file. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed in the last file processed.
	FS	Input field separator regular expression; a space character by default.
	NF	The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a getline function without a <i>var</i> argument is exe- cuted previously. Inside an END action, NF retains the value it had for the last record read, unless a subsequent, redirected, getline function without a <i>var</i> argument is performed prior to entering the END action.
	NR	The ordinal number of the current record from the start of input. Inside a BEGIN action the value is zero. Inside an END action the value is the number of the last record processed.
	OFMT	The printf format for converting numbers to strings in output statements "" "%.6g" by default. The result of the conversion is unspecified if the value of OFMT is not a floating-point format specification.
	OFS	The print statement output field separator; a space character by default.
	ORS	The print output record separator; a newline character by default.
	LENGTH	The length of the string matched by the match function.
	RS	The first character of the string value of RS is the input record separator; a newline character by default. If RS contains more than one character, the results are unspecified. If RS is null, then records are separated by sequences of one or more blank lines: leading or trailing blank lines do not produce empty records at the beginning or end of input, and the field separator is always newline, no matter what the value of FS .
	RSTART	The starting position of the string matched by the match function, number- ing from 1. This is always equivalent to the return value of the match func- tion.
	SUBSEP	The subscript separator string for multi-dimensional arrays; the default value is implementation-dependent.
Regular Expressions	except that it within the El ing table. Th sions. Note stants can co	ility makes use of the extended regular expression notation (see regex (5)) allows the use of C-language conventions to escape special characters REs, namely $ a, b, f, n, r, t, v$, and those specified in the follownese escape sequences are recognized both inside and outside bracket exprestibility needs need not be separated by newline characters and string conntain newline characters, so even the \n sequence is valid in nawk EREs. In character within the regular expression requires escaping as shown in the

Escape Sequence	Description	Meaning
\"	Backslash quotation-mark	Quotation-mark character
V	Backslash slash	Slash character
\ddd	A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NULL character), the behavior is undefined.	The character encoded by the one-, two- or three-digit octal integer. Multi-byte characters require multi- ple, concatenated escape sequences, including the leading \setminus for each byte.
\c	A backslash character followed by any character not described in this table or special characters ($ \a,$ $b, \f, \n, \r, \t, \v)$.	Undefined

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, ~ and !~. These operators interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the ~ expression evaluates to the value 1, and the !~ expression evaluates to the value 0. If the regular expression does not match the string, the ~ expression evaluates to the value 1. If the right-hand operand is any expression other than the lexical token ERE, the string value of the expression is interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions also are applied in the determining the value of a string literal (the lexical token STRING), and is applied a second time when a string literal is used in this context.

When an **ERE** token appears as an expression in any context other than as the right-hand of the ~ or !~ operator or as one of the built-in function arguments described below, the value of the resulting expression is the equivalent of:

\$0~/ere/

The *ere* argument to the **gsub**, **match**, **sub** functions, and the *fs* argument to the **split** function (see **String Functions**) is interpreted as extended regular expressions. These can be either **ERE** tokens or arbitrary expressions, and are interpreted in the same manner as the right-hand side of the ~ or !~ operator.

An extended regular expression can be used to separate fields by using the –**F** *ERE* option or by assigning a string containing the expression to the built-in variable **FS**. The default value of the **FS** variable is a single space character. The following describes **FS** behavior:

- 1. If **FS** is a single character:
 - a. If **FS** is the space character, skip leading and trailing blank characters; fields are delimited by sets of one or more blank characters.
 - b. Otherwise, if **FS** is any other character *c*, fields are delimited by each single occurrence of *c*.

	 Otherwise, the string value of FS is considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression delimits fields.
	Except in the gsub , match , split , and sub built-in functions, regular expression matching is based on input records; that is, record separator characters (the first character of the value of the variable RS , a newline character by default) cannot be embedded in the expression, and no expression matches the record separator character. If the record separator is not a newline character, newline characters embedded in the expression can be matched. In those four built-in functions, regular expression matching are based on text strings. So, any character (including the newline character and the record separator) can be embedded in the pattern and an appropriate pattern will match any character. However, in all nawk regular expression matching, the use of one or more NUL charac- ters in the pattern, input record or text string produces undefined results.
Patterns	A <i>pattern</i> is any valid <i>expression</i> , a range specified by two expressions separated by comma, or one of the two special patterns BEGIN or END .
Special Patterns	The nawk utility recognizes two special patterns, BEGIN and END . Each BEGIN pattern is matched once and its associated action executed before the first record of input is read (except possibly by use of the getline function in a prior BEGIN action) and before command line assignment is done. Each END pattern is matched once and its associated action executed after the last record of input has been read. These two patterns have associated actions.
	BEGIN and END do not combine with other patterns. Multiple BEGIN and END patterns are allowed. The actions associated with the BEGIN patterns are executed in the order specified in the program, as are the END actions. An END pattern can precede a BEGIN pattern in a program.
	If an nawk program consists of only actions with the pattern BEGIN , and the BEGIN action contains no getline function, nawk exits without reading its input when the last statement in the last BEGIN action is executed. If an nawk program consists of only actions with the pattern END or only actions with the patterns BEGIN and END , the input is read before the statements in the END actions are executed.
Expression Patterns	An expression pattern is evaluated as if it were an expression in a Boolean context. If the result is true, the pattern is considered to match, and the associated action (if any) is executed. If the result is false, the action is not executed.
Pattern Ranges	A pattern range consists of two expressions separated by a comma. In this case, the action is performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.
Actions	An action is a sequence of statements. A statement may be one of the following:

	<pre>if (expression) statement [else statement] while (expression) statement do statement while (expression) for (expression ; expression) statement for (var in array) statement delete array[subscript] #delete an array element break continue { [statement] } expression # commonly variable = expression print [expression-list] [>expression] printf format [, expression-list] [>expression] next # skip remaining patterns on this input line exit [expr] # skip the rest of the input; exit status is expression</pre>
	return [expr] Any single statement can be replaced by a statement list enclosed in braces. The state- ments are terminated by newline characters or semicolons, and are executed sequentially in the order that they appear.
	The next statement causes all further processing of the current input record to be aban- doned. The behavior is undefined if a next statement appears or is invoked in a BEGIN or END action.
	The exit statement invokes all END actions in the order in which they occur in the pro- gram source and then terminate the program without reading further input. An exit statement inside an END action terminates the program without further execution of END actions. If an expression is specified in an exit statement, its numeric value is the exit status of nawk , unless subsequent errors are encountered or a subsequent exit statement with an expression is executed.
Output Statements	Both print and printf statements write to standard output by default. The output is writ- ten to the location specified by <i>output_redirection</i> if one is supplied, as follows:
	> expression >> expression expression
	In all cases, the <i>expression</i> is evaluated to produce a string that is used as a full pathname to write into (for > or >>) or as a command to be executed (for). Using the first two forms, if the file of that name is not currently open, it is opened, creating it if necessary and using the first form, truncating the file. The output then is appended to the file. As long as the file remains open, subsequent calls in which <i>expression</i> evaluates to the same string value simply appends output to the file. The file remains open until the close function, which is called with an expression that evaluates to the same string value. The third form writes output onto a stream piped to the input of a command. The stream is created if no stream is currently open with the value of <i>expression</i> as its command name. The stream created is equivalent to one created by a call to the popen (3S) function
	with the value of <i>expression</i> as the <i>command</i> argument and a value of w as the <i>mode</i>

argument. As long as the stream remains open, subsequent calls in which *expression* evaluates to the same string value writes output to the existing stream. The stream will remain open until the **close** function is called with an expression that evaluates to the same string value. At that time, the stream is closed as if by a call to the **pclose** function.

These output statements take a comma-separated list of *expression s* referred in the grammar by the non-terminal symbols **expr_list**, **print_expr_list** or **print_expr_list_opt**. This list is referred to here as the *expression list*, and each member is referred to as an *expression argument*.

The **print** statement writes the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable **OFS** above), and terminated by the output record separator (see variable **ORS** above). All expression arguments is taken as strings, being converted if necessary; with the exception that the **printf** format in **OFMT** is used instead of the value in **CONVFMT**. An empty expression list stands for the whole input record (\$0).

The **printf** statement produces output based on a notation similar to the File Format Notation used to describe file formats in this document Output is produced as specified with the first expression argument as the string **format** and subsequent expression arguments as the strings **arg1** to **argn**, inclusive, with the following exceptions:

1. The *format* is an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The space character in the *for-mat* string, in any context other than a *flag* of a conversion specification, is treated as an ordinary character that is copied to the output.

2. If the character set contains a Δ character and that character appears in the *format* string, it is treated as an ordinary character that is copied to the output.

3. The *escape sequences* beginning with a backslash character is treated as sequences of ordinary characters that are copied to the output. Note that these same sequences is interpreted lexically by **nawk** when they appear in literal strings, but they is not treated specially by the **printf** statement.

4. A *field width* or *precision* can be specified as the * character instead of a digit string. In this case the next argument from the expression list is fetched and its numeric value taken as the field width or precision.

5. The implementation does not precede or follow output from the **d** or **u** conversion specifications with blank characters not specified by the *format* string.

6. The implementation does not precede output from the **o** conversion specification with leading zeros not specified by the *format* string.

7. For the **c** conversion specification: if the argument has a numeric value, the character whose encoding is that value is output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value will be output; if the string does not contain any characters the behavior is undefined.

	8. For each conversion specification that consumes an argument, the next expression argument will be evaluated. With the exception of the c conversion, the value will be conversion to the appropriate type for the conversion specification		
	converted to the appropriate type for the conversion specification.9. If there are insufficient expression arguments to satisfy all the conversion		
	specifications in the <i>format</i> string, the behavior is undefined.		
	10. If any character sequence in the <i>format</i> string begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.		
	Both print and p	rintf can output at least {LINE_MAX} bytes.	
Functions	The nawk langua and general.	age has a variety of built-in functions: arithmetic, string, input/output	
Arithmetic Functions	The arithmetic functions, except for int , are based on the ISO C standard. The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [] brackets), such use is undefined.		
	atan2(y,x)	Return arctangent of y/x .	
	$\cos(x)$	Return cosine of <i>x</i> , where <i>x</i> is in radians.	
	sin(x)	Return sine of <i>x</i> , where <i>x</i> is in radians.	
	exp(x)	Return the exponential function of <i>x</i> .	
	$\log(x)$	Return the natural logarithm of <i>x</i> .	
	sqrt(x)	Return the square root of <i>x</i> .	
	int (<i>x</i>)	Truncate its argument to an integer. It will be truncated toward 0 when $x > 0$.	
	rand()	Return a random number n , such that $0 \le n < 1$.	
	<pre>srand([expr])</pre>	Set the seed value for rand to <i>expr</i> or use the time of day if <i>expr</i> is omitted. The previous seed value will be returned.	
String Functions	The string functions in the following list shall be supported. Although the grammar per- mits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the [] brackets), such use is undefined.		
	gsub(ere, repl[, in		
		Behave like sub (see below), except that it will replace all occurrences of the regular expression (like the ed utility global substitute) in \$0 or in the <i>in</i> argument, when specified.	
	index(s, t)	Return the position, in characters, numbering from 1, in string <i>s</i> where string <i>t</i> first occurs, or zero if it does not occur at all.	
	<pre>length[([s])]</pre>	Return the length, in characters, of its argument taken as a string, or of	

1-660

	the whole record, \$0 , if there is no argument.
match(s, ere)	Return the position, in characters, numbering from 1, in string <i>s</i> where the extended regular expression <i>ere</i> occurs, or zero if it does not occur at all. RSTART will be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH will be set to the length of the matched string, –1 if no match is found.
split (<i>s</i> , <i>a</i> [, <i>fs</i>])	Split the string <i>s</i> into array elements $a[1]$, $a[2]$,, $a[n]$, and return <i>n</i> . The separation will be done with the extended regular expression <i>fs</i> or with the field separator FS if <i>fs</i> is not given. Each array element will have a string value when created. If the string assigned to any array element, with any occurrence of the decimal-point character from the current locale changed to a period character, would be considered a <i>numeric string</i> ; the array element will also have the numeric value of the <i>numeric string</i> . The effect of a null string as the value of <i>fs</i> is unspecified.
sprintf (<i>fmt</i> , <i>expr</i> ,	Format the expressions according to the printf format given by <i>fmt</i> and return the resulting string.
<pre>sub(ere, repl[, in])</pre>	
	Substitute the string <i>repl</i> in place of the first instance of the extended regular expression <i>ERE</i> in string <i>in</i> and return the number of substitutions. An ampersand (&) appearing in the string <i>repl</i> will be replaced by the string from <i>in</i> that matches the regular expression. For each occurrence of backslash (\) encountered when scanning the string <i>repl</i> from beginning to end, the next character is taken literally and loses its special meaning (for example, \& will be interpreted as a literal ampersand character). Except for & and it is unspecified what the special meaning of any such character is. If <i>in</i> is specified and it is not an <i>lvalue</i> the behavior is undefined. If <i>in</i> is omitted, nawk will substitute in the current record (\$0).
substr (<i>s</i> , <i>m</i> [, <i>n</i>])	Return the at most <i>n</i> -character substring of <i>s</i> that begins at position <i>m</i> , numbering from 1. If <i>n</i> is missing, the length of the substring will be limited by the length of the string <i>s</i> .
tolower(s)	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is an upper-case letter specified to have a tolower mapping by the LC_CTYPE category of the current locale will be replaced in the returned string by the lower-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.
toupper(s)	Return a string based on the string <i>s</i> . Each character in <i>s</i> that is a lower-case letter specified to have a toupper mapping by the LC_CTYPE category of the current locale will be replaced in the returned string by the upper-case letter specified by the mapping. Other characters in <i>s</i> will be unchanged in the returned string.

User-defined The nawk language also provides user-defined functions. Su Functions as: function name(args,) { statements }	uch functions can be defined
A function can be referred to anywhere in an nawk program; precede its definition. The scope of a function will be global.	
Function arguments can be either scalars or arrays; the behave name is passed as an argument that the function uses as a scal is passed as an argument that the function uses as an array. If passed by value if scalar and by reference if array name. Arg to the function; all other variable names will be global. The scalar as both an argument name and as the name of a function or a same name must not be used both as a variable name with gl of a function. The same name must not be used within the sa variable and as an array.	alar, or if a scalar expression Function arguments will be gument names will be local same name will not be used a special nawk variable. The lobal scope and as the name
The number of parameters in the function definition need not parameters in the function call. Excess formal parameters can If fewer arguments are supplied in a function call than are in extra parameters that are used in the function body as scalars string value of the null string and a numeric value of zero, an are used in the function body as arrays will be initialized as e ments are supplied in a function call than are in the function undefined.	n be used as local variables. the function definition, the s will be initialized with a nd the extra parameters that empty arrays. If more argu-
When invoking a function, no white space can be placed betw the opening parenthesis. Function calls can be nested and rec upon functions. Upon return from any nested or recursive fu of the calling function's parameters will be unchanged, excep passed by reference. The return statement can be used to retu- statement appears outside of a function definition, the behavior	cursive calls can be made unction call, the values of all ot for array parameters urn a value. If a return
In the function definition, newline characters are optional befafter the closing brace. Function definitions can appear anywa <i>pattern-action</i> pair is allowed.	

USAGE The **index**, **length**, **match**, and **substr** functions should not be confused with similar functions in the ISO C standard; the **nawk** versions deal with characters, while the ISO C standard deals with bytes.

> Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

EXAMPLES The **nawk** program specified in the command line is most easily specified within singlequotes (for example, '*program*') for applications using **sh**, because **nawk** programs commonly contain characters that are special to the shell, including double-quotes. In the cases where a **nawk** program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\'' { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with **quote:**.

The following are examples of simple **nawk** programs:

- Write to the standard output all input lines for which field 3 is greater than 5:
 \$3 > 5
- 2. Write every tenth line:

(NR % 10) == 0

3. Write any line with a substring matching the regular expression:

```
/(G | D)(2[0-9][[:alpha:]]*)/
```

4. Print any line with a substring containing a G or D, followed by a sequence of digits and characters. This example uses character classes **digit** and **alpha** to match language-independent digit and alphabetic characters respectively:

/(G | D)([[:digit:][:alpha:]]*)/

5. Write any line in which the second field matches the regular expression and the fourth field does not:

\$2 ~ /xyz/ && \$4 !~ /xyz/

6. Write any line in which the second field contains a backslash:

\$2~/\\/

7. Write any line in which the second field contains a backslash. Note that backslash escapes are interpreted twice, once in lexical processing of the string and once in processing the regular expression:

\$2~"\\\\"

8. Write the second to the last and the last field in each line. Separate the fields by a colon:

```
{OFS=":";print $(NF-1), $NF}
    Write the line number and number of fields in each line. The three strings
9.
    representing the line number, the colon and the number of fields are con-
    catenated and that string is written to standard output:
         {print NR ":" NF}
10. Write lines longer than 72 characters:
         {length($0) > 72}
11. Write first two fields in opposite order separated by the OFS:
         { print $2, $1 }
12. Same, with input fields separated by comma or space and tab characters, or both:
         BEGIN { FS = ",[t]* | [ t]+" }
                   { print $2, $1 }
13. Add up first column, print sum and average:
                \{s += \$1\}
         END
                {print "sum is ", s, " average is", s/NR}
14. Write fields in reverse order, one per line (many lines out for each line in):
         { for (i = NF; i > 0; --i) print $i }
15. Write all lines between occurrences of the strings start and stop:
         /start/, /stop/
16. Write all lines whose first field is different from the previous one:
         $1 != prev { print; prev = $1 }
17. Simulate echo:
         BEGIN {
                  for (i = 1; i < ARGC; ++i)
                        printf "%s%s", ARGV[i], i==ARGC-1?"\n":""
         }
18. Write the path prefixes contained in the PATH environment variable, one per line:
         BEGIN {
                  n = split (ENVIRON["PATH"], path, ":")
                  for (i = 1; i <= n; ++i)
                        print path[i]
         }
19. If there is a file named input containing page headers of the form:
         Page#
    and a file named program that contains:
                  /Page/{ $2 = n++; }
                  { print }
    then the command line:
```

NAME	newform – change the format of a text file		
SYNOPSIS	newform [-s] [-itabspec] [-otabspec] [-bn] [-en] [-pn] [-an] [-f] [-cchar] [-ln] [filename]		
AVAILABILITY	SUNWesu		
DESCRIPTION	 newform reads lines from the named <i>filenames</i>, or the standard input if no input file is named, and reproduces the lines on the standard output. Lines are reformatted in accordance with command line options in effect. Except for -s, command line options may appear in any order, may be repeated, and may be intermingled with the optional <i>filenames</i>. Command line options are processed in the order specified. This means that option sequences like "-e15 -l60" will yield results different from "-l60 -e15". Options are applied to all <i>filenames</i> on the command line. 		
OPTIONS	− S	Shears off leading characters on each line up to the first tab and places up to 8 of the sheared characters at the end of the line. If more than 8 characters (not counting the first tab) are sheared, the eighth character is replaced by a * and any characters to the right of it are discarded. The first tab is always discarded.	
		An error message and program exit will occur if this option is used on a file without a tab on each line. The characters sheared off are saved internally until all other options specified are applied to that line. The characters are then added at the end of the processed line.	
	For example, to convert a file with leading digits, one or more t on each line, to a file beginning with the text, all tabs after the fi to spaces, padded with spaces out to column 72 (or truncated to and the leading digits placed starting at column 73, the comman newform - s - i - l - a - e <i>file-name</i>		
	-itabspec	Input tab specification: expands tabs to spaces, according to the tab specifications given. <i>Tabspec</i> recognizes all tab specification forms described in tabs (1). In addition, <i>tabspec</i> may be —, in which newform assumes that the tab specification is to be found in the first line read from the standard input (see fspec (4)). If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8 . A <i>tabspec</i> of -0 expects no tabs; if any are found, they are treated as -1 .	
	– o tabspec	Output tab specification: replaces spaces by tabs, according to the tab specifications given. The tab specifications are the same as for $-itabspec$. If no <i>tabspec</i> is given, <i>tabspec</i> defaults to -8 . A <i>tabspec</i> of -0 means that no spaces will be converted to tabs on output.	
	- b n	Truncate <i>n</i> characters from the beginning of the line when the line length is greater than the effective line length (see $-ln$). Default is to truncate the number of characters necessary to obtain the effective line length. The default value is used when $-\mathbf{b}$ with no <i>n</i> is used. This option can be used to delete the	

modified 14 Sep 1992

		sequence numbers from a COBOL program as follows: newform –l1 –b7 <i>file-name</i>	
	- e n	Same as $-bn$ except that characters are truncated from the end of the line.	
	- p n	Prefix <i>n</i> characters (see – <i>cchar</i>) to the beginning of a line when the line length is less than the effective line length. Default is to prefix the number of characters necessary to obtain the effective line length.	
	- a n	Same as $-\mathbf{p}n$ except characters are appended to the end of a line.	
	-f	Write the tab specification format line on the standard output before any other lines are output. The tab specification format line which is printed will correspond to the format specified in the <i>last</i> – o option. If no – o option is specified, the line which is printed will contain the default specification of – 8 .	
	–cchar	Change the prefix/append character to <i>char</i> . Default character for <i>char</i> is a space.	
	-ln	Set the effective line length to <i>n</i> characters. If <i>n</i> is not entered, $-\mathbf{l}$ defaults to 72. The default line length without the $-\mathbf{l}$ option is 80 characters. Note: Tabs and backspaces are considered to be one character (use $-\mathbf{i}$ to expand tabs to spaces).	
		The $-\mathbf{l1}$ must be used to set the effective line length shorter than any existing line in the file so that the $-\mathbf{b}$ option is activated.	
SEE ALSO	csplit(1),	tabs(1), fspec(4)	
DIAGNOSTICS	All diagn	ostics are fatal.	
	usage:		
	newform was called with a bad option. "not –s format"		
		here was no tab on one line.	
	"can't op		
		elf-explanatory. line too long "	
	А	line exceeds 512 characters after being expanded in the internal work buffer.	
	"tabspec		
		A tab specification is incorrectly formatted, or specified tab stops are not ascend- ng.	
		indirection illegal"	
		<i>tabspec</i> read from a file (or standard input) may not contain a <i>tabspec</i> referenc- ng another file (or standard input).	
		al execution	
	1 – for an	y error	

modified 14 Sep 1992

NOTES newform normally only keeps track of physical characters; however, for the –i and –o options, **newform** will keep track of backspaces in order to line up tabs in the appropriate logical columns.

newform will not prompt the user if a *tabspec* is to be read from the standard input (by use of -i— or -o—).

If the $-\mathbf{f}$ option is used, and the last $-\mathbf{o}$ option specified was $-\mathbf{o}--$, and was preceded by either a $-\mathbf{o}--$ or a $-\mathbf{i}--$, the tab specification format line will be incorrect.

modified 14 Sep 1992

NAME	newgrp – log in to a new group			
SYNOPSIS Command	/ usr/bin/newgrp [– – l] [group]			
sh Built-in	newgrp [argument]			
ksh Built-in	<pre>† newgrp [argument]</pre>			
AVAILABILITY	SUNWcsu			
DESCRIPTION Command	The newgrp command logs a user into a new group by changing a user's real and effec- tive group ID. The user remains logged in and the current directory is unchanged. The execution of newgrp always replaces the current shell with a new shell, even if the com- mand terminates with an error (unknown group).			
	Any variable that is not exported is reset to null or its default value. Exported variables retain their values. System variables (such as PS1 , PS2 , PATH , MAIL , and HOME), are reset to default values unless they have been exported by the system or the user. For example, when a user has a primary prompt string (PS1) other than \$ (default) and has not exported PS1 , the user's PS1 will be set to the default prompt string \$, even if newgrp terminates with an error. Note that the shell command export (see sh (1) and set (1)) is the method to export variables so that they retain their assigned value when invoking new shells.			
	With no operands and options, newgrp changes the user's group IDs (real and effective) back to the group specified in the user's password file entry. This is a way to exit the effect of an earlier newgrp command.			
	A password is demanded if the group has a password and the user is not listed in /etc/group as being a member of that group. The only way to create a password for a group is to use passwd(1), then cut and paste the password from /etc/shadow to /etc/group. Group passwords are antiquated and not often used.			
sh Built-in	Equivalent to exec newgrp <i>argument</i> where <i>argument</i> represents the options and/or operand of the newgrp command.			
ksh Built-in	Equivalent to exec / bin / newgrp <i>argument</i> where <i>argument</i> represents the options and/or operand of the newgrp command.			
	 On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort. 			

modified 1 Feb 1995

	assignn means	following a command preceded by <i>††</i> that are in the format of a variable nent, are expanded with the same rules as a variable assignment. This that tilde substitution is performed after the = sign and word splitting and ne generation are not performed.
OPTIONS	The following option is supported:	
	- l	
	_	change the environment to what would be expected if the user actually logged in again as a member of the new group.
OPERANDS	The following o	perand is supported:
	group	A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs will be set. If <i>group</i> is a non-negative numeric string and exists in the group database as a group name (see getgrnam (3C)), the numeric group ID associated with that group name will be used as the group ID.
	argument	\mathbf{sh} and \mathbf{ksh} only. Options and/or operand of the \mathbf{newgrp} command.
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- rp: LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	group identifica shell. Otherwis	eeds in creating a new shell execution environment, whether or not the ation was changed successfully, the exit status will be the exit status of the se, the following exit value is returned:
	>0	An error occurred.

NAME	news – print news items
SYNOPSIS	news [–a] [–n] [–s] [<i>items</i>]
AVAILABILITY	SUNWesu
DESCRIPTION	news is used to keep the user informed of current events. By convention, these events are described by files in the directory / var/news .
	When invoked without arguments, news prints the contents of all current files in / var/news , most recent first, with each preceded by an appropriate header. news stores the "currency" time as the modification date of a file named .news_time in the user's home directory (the identity of this directory is determined by the environment variable \$HOME); only files more recent than this currency time are considered "current."
OPTIONS	-a news prints all items, regardless of currency. In this case, the stored time is not changed.
	 n news reports the names of the current items without printing their contents, and without changing the stored time.
	-s news reports how many current items exist, without printing their names or contents, and without changing the stored time. It is useful to include such an invocation of news in one's .profile file, or in the system's /etc/profile.
	All other arguments are assumed to be specific news items that are to be printed.
	If a <i>delete</i> is typed during the printing of a news item, printing stops and the next item is started. Another <i>delete</i> within one second of the first causes the program to terminate.
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of news for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how news behaves.
	LC_CTYPE Determines how news handles characters. When LC_CTYPE is set to a valid value, news can display and handle text and filenames containing valid charac- ters for that locale. news can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. news can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

NAME	nice – run a command at a different priority
SYNOPSIS command	/usr/bin/nice [–increment –n increment] command [arguments]
csh Builtin	nice [-/+increment] [command]
AVAILABILITY	SUNWcsu
DESCRIPTION	/ usr/bin/nice executes <i>command</i> with a lower CPU scheduling priority. The priocntl (1) command is a more general interface to scheduler functions.
	The invoking process (generally the user's shell) must be in a scheduling class that supports the / usr/bin/nice command.
	nice is also a csh built-in command which behaves differently than the command version. See $csh(1)$ for description.
OPTIONS	The following options are supported:
	 <i>-increment</i> <i>n increment</i> If the <i>increment</i> argument (in the range 1–19) is given, it is used; if not, an increment of 10 is assumed.
	The super-user may run commands with priority higher than normal by using a negative increment, for example, —10. A negative increment assigned by an unprivileged user is ignored.
	If the csh is used, the syntax on this man page does not apply, unless / usr/bin/nice is invoked at the beginning of the command line. Instead, refer to csh (1) for a different nice syntax.
OPERANDS	The following operands are supported:
	<i>command</i> The name of a command that is to be invoked. If <i>command</i> operand names any of the special built-in utilities (see shell_builtins (1)), the results are undefined.
	<i>argument</i> Any string to be supplied as an argument when invoking <i>command</i> .
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of nice : LC_CTYPE , LC_MESSAGES , PATH , and NLSPATH .
EXIT STATUS	If <i>command</i> is invoked, the exit status of nice will be the exit status of <i>command</i> ; otherwise, nice will exit with one of the following values:
	1-125 An error occurred in the nice utility.
	126 <i>command</i> was found but could not be invoked.
	127 <i>command</i> could not be found.

modified 17 Feb 1995

SEE ALSO	csh(1), nohup(1), priocntl(1), shell_builtins(1), nice(2), environ(5)
NOTES	An <i>increment</i> larger than 19 is equivalent to 19 .

modified 17 Feb 1995

NAME	nis+, NIS+, nis – a new version of the network information name service
DESCRIPTION	NIS+ is a new version of the network information nameservice. This version differs in several significant ways from version 2, which is referred to as NIS or YP in earlier releases. Specific areas of enhancement include the ability to scale to larger networks, security, and the administration of the service.
	The man pages for NIS+ are broken up into three basic categories. Those in section 1 are the user commands that are most often executed from a shell script or directly from the command line. Section 1M man pages describe utility commands that can be used by the network administrator to administer the service itself. The NIS+ programming API is described by man pages in section 3N.
	All commands and functions that use NIS version 2 are prefixed by the letters yp as in ypmatch (1), ypcat (1), yp_match (3N), and yp_first (3N). Commands and functions that use the new replacement software NIS+ are prefixed by the letters nis as in nismatch (1), nischown (1), nis_list (3N), and nis_add_entry (3N). A complete list of NIS+ commands is in the LIST OF COMMANDS section.
	This man page introduces the NIS+ terminology. It also describes the NIS+ namespace, authentication, and authorization policies.
NIS+ NAMESPACE	The naming model of NIS+ is based upon a tree structure. Each node in the tree corresponds to an NIS+ object. There are six types of NIS+ objects: <i>directory</i> , <i>table</i> , <i>group</i> , <i>link</i> , <i>entry</i> , and <i>private</i> .
NIS+ Directory Object	Each NIS+ namespace will have at least one NIS+ directory object. An NIS+ directory is like a UNIX file system directory which contains other NIS+ objects including NIS+ direc- tories. The NIS+ directory that forms the root of the NIS+ namespace is called the root directory. There are two special NIS+ directories: org_dir and groups_dir . The org_dir directory consists of all the system-wide administration tables, such as passwd , hosts , and mail_aliases . The groups_dir directory consists of NIS+ group objects which are used for access control. The collection of org_dir , groups_dir and their parent directory is referred to as an NIS+ domain. NIS+ directories can be arranged in a tree-like struc- ture so that the NIS+ namespace can match the organizational or administrative hierar- chy.
NIS+ Table Object	NIS+ tables (not files), contained within NIS+ directories, store the actual information about some particular type. For example, the hosts system table stores information about the IP address of the hosts in that domain. NIS+ tables are multicolumn and the tables can be searched through any of the searchable columns. Each table object defines the schema for its table. The NIS+ tables consist of NIS+ entry objects. For each entry in the NIS+ table, there is an NIS+ entry object. NIS+ entry objects conform to the schema defined by the NIS+ table object.

nis+(1)	User Commands	SunOS 5.5	
NIS+ Group Object	NIS+ group objects are used for access control at group granularity. NIS+ gro contained within the groups_dir directory of a domain, contain a list of all the cipals within a certain NIS+ group. An NIS+ principal is a user or a machine NIS+ requests.	e NIS+ prin-	
NIS+ Link Object	NIS+ link objects are like UNIX symbolic file-system links—they are typically shortcuts in the NIS+ namespace.	inks—they are typically used for	
	Refer to nis_objects (3N) for more information about the NIS+ objects.		
NIS+ NAMES	The NIS+ service defines two forms of names, <i>simple</i> names and <i>indexed</i> name names are used by the service to identify NIS+ objects contained within the N namespace. Indexed names are used to identify NIS+ entries contained withit tables. Furthermore, entries within NIS+ tables are returned to the caller as N of type <i>entry</i> . NIS+ objects are implemented as a union structure which is des the file <rpcsvc nis_object.x=""></rpcsvc> . The differences between the various types and ings of the components of these objects are described in nis_objects (3N).	IS+ n NIS+ IIS+ objects scribed in	
Simple Names	Simple names consist of a series of labels that are separated by the '.'(dot) cha label is composed of printable characters from the ISO Latin 1 set. Each label any nonzero length, provided that the fully qualified name is fewer than NIS_MAXNAMELEN octets including the separating dots. (See < rpcsvc/nis.h > actual value of NIS_MAXNAMELEN in the current release.) Labels that contai characters (see Grammar) must be quoted.	can be of for the	
	The NIS+ namespace is organized as a singly rooted tree. Simple names iden within this tree. These names are constructed such that the leftmost label in a identifies the leaf node and all of the labels to the right of the leaf identify that parent node. The parent node is referred to as the leaf's <i>directory</i> . This is a nattory and should not be confused with a file system directory.	name t object's	
	For example, the name <i>example.simple.name.</i> is a simple name with three labels <i>example</i> is the leaf node in this name, the directory of this leaf is <i>simple.name.</i> witself is a simple name. The leaf of which is <i>simple</i> and its directory is simply <i>n</i>	vhich by	
	The function nis_leaf_of (3N) returns the first label of a simple name. The fur nis_domain_of (3N) returns the name of the directory that contains the leaf. I of these two functions can break a simple name into each of its label components	terative use	
	The name '.' (dot) is reserved to name the <i>global root</i> of the namespace. For sy are connected to the Internet, this global root will be served by a Domain Nam When an NIS+ server is serving a root directory whose name is not '.' (dot) this is referred to as a <i>local root</i> .	ne Service.	
	NIS+ names are said to be <i>fully qualified</i> when the name includes all of the labe ing all of the directories, up to the global root. Names without the trailing dot <i>partially</i> qualified.		

modified 4 May 1994

SunOS 5.5	User Commands nis+ (
Indexed Names	Indexed names are compound names that are composed of a search criterion and a si ple name. The search criterion component is used to select entries from a table; the si ple name component is used to identify the NIS+ table that is to be searched. The sear criterion is a series of column names and their desired values enclosed in bracket '[]' characters. These criteria take the following form:	m-
	[column_name=value, column_name=value,]	
	A search criterion is combined with a simple name to form an indexed name by con- catenating the two parts, separated by a ','(comma) character as follows.	
	[search-criterion], table. directory.	
	When multiple column name/value pairs are present in the search criterion, only those entries in the table that have the appropriate value in all columns specified are returned. When no column name/value pairs are specified in the search criterion, [], <i>all</i> entries the table are returned.	ed.
Grammar	The following text represents a context-free grammar that defines the set of legal NIS- names. The terminals in this grammar are the characters '.' (dot), '[' (open bracket), '] (close bracket), ',' (comma), '=' (equals) and whitespace. Angle brackets ('<' and '>'), which delineate non-terminals, are not part of the grammar. The character ' ' (vertica bar) is used to separate alternate productions and should be read as ''this production this production''. name ::= . <simple name=""> <indexed name=""> simple name ::= <string>. <string>.<simple name=""> indexed name ::= <search criterion="">,<simple name=""> search criterion ::= [<attribute list="">]</attribute></simple></search></simple></string></string></indexed></simple>	, 1
	statch children ist ::= { <attribute ist="">} attribute ::= <attribute> <attribute>,<attribute list=""> attribute ::= <string> string ::= ISO Latin 1 character set except the character '/' (slash). The initial character may not be a terminal character or the characters '@' (at), '+' (plus), or ('-') hyphen.</string></attribute></attribute></attribute></attribute>	
	Terminals that appear in strings must be quoted with '"' (double quote). The '"' chara may be quoted by quoting it with itself '""'.	cter
Name Expansion	The NIS+ service only accepts fully qualified names. However, since such names may unwieldy, the NIS+ commands in section 1 employ a set of standard expansion rules will attempt to fully qualify a partially qualified name. This expansion is actually dor by the NIS+ library function nis_getnames (3N) which generates a list of names using default NIS+ directory search path or the NIS_PATH environment variable. The defau NIS+ directory search path includes all the names in its path. nis_getnames() is invo by the functions nis_lookup (3N) and nis_list (3N) when the EXPAND_NAME flag is u	that ne ; the ult ked

The NIS PATH environment variable contains an ordered list of simple names. The names are separated by the ':' (colon) character. If any name in the list contains colons, the colon should be quoted as described in the Grammar section. When the list is exhausted, the resolution function returns the error NIS NOTFOUND. This may mask the fact that the name existed but a server for it was unreachable. If the name presented to the list or lookup interface is fully qualified, the **EXPAND** NAME flag is ignored.

In the list of names from the NIS_PATH environment variable, the '\$' (dollar sign) character is treated specially. Simple names that end with the label '\$' have this character replaced by the default directory (see **nis_local_directory**(3N)). Using "\$" as a name in this list results in this name being replaced by the list of directories between the default directory and the global root that contain at least two labels.

Below is an example of this expansion. Given the default directory of some.long.domain.name., and the NIS_PATH variable set to fred.bar.:org dir.\$:\$. This path is initially broken up into the list:

- 1 fred.bar.
- 2 org_dir.\$ Ś
- 3

The dollar sign in the second component is replaced by the default directory. The dollar sign in the third component is replaced with the names of the directories between the default directory and the global root that have at least two labels in them. The effective path value becomes:

- 1 fred.bar.
- 2a org_dir.some.long.domain.name.
- 3a some.long.domain.name.
- 3b long.domain.name.
- 3c domain.name.

Each of these simple names is appended to the partially qualified name that was passed to the nis_lookup(3N) or nis_list(3N) interface. Each is tried in turn until NIS_SUCCESS is returned or the list is exhausted.

If the NIS_PATH variable is not set, the path "\$" is used.

The library function nis_getnames(3N) can be called from user programs to generate the list of names that would be attempted. The program nisdefaults(1) with the -s option can also be used to show the fully expanded path.

Concatenation Path Normally all the entries for a certain type of information are stored within the table itself. However, there are times when it is desirable for the table to point to other tables where entries can be found. For example, you may want to store all the IP addresses in the host table for their own domain, and yet want to be able to resolve hosts in some other domain without explicitly specifying the new domain name. NIS+ provides a mechanism for concatenating different but related tables with a "NIS+ Concatenation Path". With a concatenation path, you can create a sort of flat namespace from a hierarchical

modified 4 May 1994

	structure. You can also create a table with no entries and just point the hosts or any other table to its parent domain. Note that with such a setup, you are moving the administrative burden of managing the tables to the parent domain. The concatenation path will slow down the request response time because more tables and more servers are searched. It will also decrease the availability if all the servers are incapacitated for a particular directory in the table path.
	The NIS+ Concatenation Path is also referred to as the "table path". This path is set up at table creation time through nistbladm (1). You can specify more than one table to be concatenated and they will be searched in the given order. Note that the NIS+ client libraries, by default, will not follow the concatenation path set in site-specific tables. Refer to nis_list (3N) for more details.
Namespaces	The NIS+ service defines two additional <i>disjoint</i> namespaces for its own use. These namespaces are the NIS+ <i>Principal</i> namespace, and the NIS+ <i>Group</i> namespace. The names associated with the group and principal namespaces are syntactically identical to simple names. However, the information they represent <i>cannot</i> be obtained by directly presenting these names to the NIS+ interfaces. Instead, special interfaces are defined to map these names into NIS+ names so that they may then be resolved.
Principal Names	NIS+ principal names are used to uniquely identify users and machines that are making NIS+ requests. These names have the form:
	<i>principal.domain</i> Here <i>domain</i> is the fully qualified name of an NIS+ directory where the named principal's credentials can be found. See Directories and Domains for more information on
	domains. Note that in this name, <i>principal</i> , is not a leaf in the NIS+ namespace.
	Credentials are used to map the identity of a host or user from one context such as a pro- cess UID into the NIS+ context. They are stored as records in an NIS+ table named <i>cred</i> , which always appears in the <i>org_dir</i> subdirectory of the directory named in the principal name.
	This mapping can be expressed as a replacement function:
	principal.domain ->[cname=principal.domain],cred.org_dir.domain
	This latter name is an NIS+ name that can be presented to the nis_list (3N) interface for resolution. NIS+ principal names are administered using the nisaddcred (1M) command.
	The <i>cred</i> table contains five columns named <i>cname</i> , <i>auth_name</i> , <i>auth_type</i> , <i>public_data</i> , and <i>private_data</i> . There is one record in this table for each identity mapping for an NIS+ principal. The current service supports two such mappings:
	LOCAL This mapping is used to map from the UID of a given process to the NIS+ prin- cipal name associated with that UID. If no mapping exists, the name <i>nobody</i> is returned. When the effective UID of the process is 0 (for example, the super- user), the NIS+ name associated with the host is returned. Note that UIDs are sensitive to the context of the machine on which the process is executing.
	DES This mapping is used to map to and from a Secure RPC "netname" into an NIS+ principal name. See secure_rpc (3N) for more information on netnames.
	1 001

	Note that since netnames contain the notion of a domain, they span NIS+ direc- tories.
	The NIS+ client library function nis_local_principal (3N) uses the <i>cred.org_dir</i> table to map the UNIX notion of an identity, a process' UID, into an NIS+ principal name. Shell programs can use the program nisdefaults (1) with the - p switch to return this information.
	Mapping from UIDs to an NIS+ principal name is accomplished by constructing a query of the form:
	[auth_type=LOCAL, auth_name=uid],cred.org_dir.default-domain.
	This query will return a record containing the NIS+ principal name associated with this UID, in the machine's default domain.
	The NIS+ service uses the DES mapping to map the names associated with Secure RPC requests into NIS+ principal names. RPC requests that use Secure RPC include the <i>net-name</i> of the client making the request in the RPC header. This netname has the form:
	unix.UID@domain
	The service constructs a query using this name of the form:
	[auth_type=DES, auth_name=netname],cred.org_dir.domain.
	where the domain part is extracted from the netname rather than using the default domain. This query is used to look up the mapping of this netname into an NIS+ principal name in the domain where it was created.
	This mechanism of mapping UID and netnames into an NIS+ principal name guarantees that a client of the NIS+ service has only one principal name. This principal name is used as the basis for authorization which is described below. All objects in the NIS+ namespace and all entries in NIS+ tables must have an owner specified for them. This owner field always contains an NIS+ principal name.
Group Names	Like NIS+ principal names, NIS+ group names take the form: group_name .domain
	All objects in the NIS+ namespace and all entries in NIS+ tables may optionally have a <i>group owner</i> specified for them. This group owner field, when filled in, always contains the fully qualified NIS+ group name.
	The NIS+ client library defines several interfaces (nis_groups (3N)) for dealing with NIS+ groups. These interfaces internally map NIS+ group names into an NIS+ simple name which identifies the NIS+ group object associated with that group name. This mapping can be shown as follows:
	group.domain -> group.groups_dir.domain
	This mapping eliminates collisions between NIS+ group names and NIS+ directory names. For example, without this mapping, a directory with the name <i>engineering.foo.com.</i> , would make it impossible to have a group named <i>engineering.foo.com.</i> . This is due to the restric- tion that within the NIS+ namespace, a name unambiguously identifies a single object. With this mapping, the NIS+ <i>group</i> name <i>engineering.foo.com.</i> maps to the NIS+ <i>object</i> name <i>engineering.groups_dir.foo.com.</i>

NIS+ SECURITYThe contents of a group object is a list of NIS+ principal names, and the names of other NIS+ groups. See nis_groups(3N) for a more complete description of their use.NIS+ SECURITYNIS- defines a security model to control access to information managed by the service. The service defines access rights that are selectively granted to individual clients or groups of clients. Principal names and group names are used to define clients and groups are associated with NIS+ domains as defined below. The security model also uses the notion of a class of principals called <i>nobody</i> , which con- tains all clients, whether or not they have authenticated.Directories and DomainsSome directories within the NIS+ namespace are referred to as NIS+ Domains. Domains are those NIS+ directories that contain the subdirectories groups. dir and arg_dir. Further, the subdirectory org_dir should contain the table named crid. NIS+ Group names and NIS+ Principal names always include the NIS+ domain name after their first label.AuthenticationThe NIS+ name service uses Secure RPC for the integrity of the NIS+ service. This requires that users of the service and their machines must have a Secure RPC key pair associated with them. This key is initially guenrated with her name service that will not be savailable to untrusted machines or users on the network. In addition to the Secure RPC key, users need a mapping of their UID into an NIS+ principal name. This mapping is created by the system administrator using the niselient(1M) or niseldered(1M) command. Users that will be using machines in several NIS+ domain. For the purposes of NIS+ and Secure RPC, the home domain is defined to be the one where your Secure RPC key pair is local credential entry in each of those domains. This credential should be created with the NIS+ principal name of the user in the	SunOS 5.5	User Commands	nis+(1)			
The service defines access rights that are selectively granted to individual clients or groups of clients that may be granted or denied access to NIS+ information. These princi- pals and groups are associated with NIS+ domains as defined below.The security model also uses the notion of a class of principals called nobody, which con- tains all clients, whether or not they have authenticated themselves to the service. The class world includes any client who has been authenticated themselves to the service. The class world includes any client who has been authenticated.Directories and DomainsSome directories within the NIS+ namespace are referred to as NIS+ Domains. 		ing read access on the parent object conveys read access to all of the				

	modify	This right grants modification access to an existing object. Read access is not required for modification. However, in many applications, one will need to read an object before modifying it. Such modify operations will fail unless read access is also granted.			
	create	This right gives a client permission to create new objects where one had not previously existed. It is only used in conjunction with directory and table objects. Having create access for a table allows a client to add additional entries to the table. Having create access for a directory allows a client to add new objects to an NIS+ directory.			
	destroy	This right gives a client permission to destroy or remove an existing object or entry. When a client attempts to destroy an entry or object by removing it, the service first checks to see if the table or directory containing that object grants the client destroy access. If it does, the operation proceeds, if the containing object does not grant this right then the object itself is checked to see if it grants this right to the client. If the object grants the right, then the operation proceeds; otherwise the request is rejected.			
	Each of these rights may be granted to any one of four different categories.				
	owner	A right may be granted to the <i>owner</i> of an object. The owner is the NIS+ princi- pal identified in the owner field. The owner can be changed with the nischown (1) command. Note that if the owner does not have modification access rights to the object, the owner cannot change any access rights to the object, unless the owner has modification access rights to its parent object.			
	group own	er			
		A right may be granted to the <i>group owner</i> of an object. This grants the right to any principal that is identified as a member of the group associated with the object. The group owner may be changed with the nischgrp (1) command. The object owner need not be a member of this group.			
	world	A right may be granted to everyone in the <i>world</i> . This grants the right to all clients who have authenticated themselves with the service.			
	nobody	A right may be granted to the <i>nobody</i> principal. This has the effect of granting the right to any client that makes a request of the service, regardless of whether they are authenticated or not.			
	subdirecto <i>nobody</i> pri process of other table	for bootstrapping reasons, directory objects that are NIS+ domains, the <i>org_dir</i> ory and the <i>cred</i> table within that subdirectory must have <i>read</i> access to the ncipal. This makes navigation of the namespace possible when a client is in the flocating its credentials. Granting this access does not allow the contents of es within <i>org_dir</i> to be read (such as the entries in the password table) unless the f gives "real" access rights to the <i>nobody</i> principal.			
Directory Authorization	These righ This struc	I capabilities are provided for granting access rights to clients for directories. Its are contained within the <i>object access rights</i> (OAR) structure of the directory. Iture allows the NIS+ service to grant rights that are not granted by the directory be granted for objects contained by the directory of a specific type.			

	An example of this capability is a directory object which does not grant create access to all clients, but does grant create access in the OAR structure for <i>group</i> type objects to clients who are members of the NIS+ group associated with the directory. In this example the only objects that could be created as children of the directory would have to be of the type <i>group</i> .
	Another example is a directory object that grants create access only to the owner of the directory, and then additionally grants create access through the OAR structure for objects of type <i>table</i> , <i>link</i> , <i>group</i> , and <i>private</i> to any member of the directory's group. This has the effect of giving nearly complete create access to the group with the exception of creating subdirectories. This restricts the creation of new NIS+ domains because creating a domain requires creating both a <i>groups_dir</i> and <i>org_dir</i> subdirectory.
	Note that there is currently no command line interface to set or change the OAR of the directory object.
Table Authorization	As with directories, additional capabilities are provided for granting access to entries within tables. Rights granted to a client by the access rights field in a table object apply to the table object and all of the entry objects "contained" by that table. If an access right is not granted by the table object, it may be granted by an entry within the table. This holds for all rights except <i>create</i> .
	For example, a table may not grant read access to a client performing a nis_list (3N) operation on the table. However, the access rights field of entries within that table may grant read access to the client. Note that access rights in an entry are granted to the owner and group owner of the <i>entry</i> and not the owner or group of the table. When the list operation is performed, all entries that the client has read access to are returned. Those entries that do not grant read access are not returned. If none of the entries that match the search criterion grant read access to the client making the request, no entries are returned and the result status contains the NIS_NOTFOUND error code.
	Access rights that are granted by the rights field in an entry are granted for the entire entry. However, in the table object an additional set of access rights is maintained for each column in the table. These rights apply to the equivalent column in the entry. The rights are used to grant access when neither the table nor the entry itself grant access. The access rights in a column specification apply to the owner and group owner of the entry rather than the owner and group owner of the table object.
	When a read operation is performed, if read access is not granted by the table and is not granted by the entry but <i>is</i> granted by the access rights in a column, that entry is returned with the correct values in all columns that are readable and the string *NP * (No Permission) in columns where read access is not granted.
	As an example, consider a client that has performed a list operation on a table that does not grant read access to that client. Each entry object that satisfied the search criterion specified by the client is examined to see if it grants read access to the client. If it does, it is included in the returned result. If it does not, then each column is checked to see if it grants read access to the client. If any columns grant read access to the client, data in those columns is returned. Columns that do not grant read access have their contents replaced by the string *NP *. If none of the columns grant read access, then the entry is

1-685

	not returned.	
LIST OF COMMANDS	The following lists all com	nands and programming functions related to NIS+:
NIS+ User Commands	nisaddent(1M)	add /etc files and NIS maps into their corresponding NIS+ tables
Communus	niscat(1)	display NIS+ tables and objects
	nischgrp(1)	change the group owner of a NIS+ object
	nischmod(1)	change access rights on a NIS+ object
	nischown(1)	change the owner of a NIS+ object
	nischttl(1)	change the time to live value of a NIS+ object
	nisdefaults(1)	display NIS+ default values
	niserror(1)	display NIS+ error messages
	nisgrep(1)	utilities for searching NIS+ tables
	nisgrpadm(1)	NIS+ group administration command
	nisln(1)	symbolically link NIS+ objects
	nisls(1)	list the contents of a NIS+ directory
	nismatch(1)	utilities for searching NIS+ tables
	nismkdir(1)	create NIS+ directories
	nispasswd(1)	change NIS+ password information
	nisrm(1)	remove NIS+ objects from the namespace
	nisrmdir(1)	remove NIS+ directories
	nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file
	nistbladm(1)	NIS+ table administration command
	nistest(1)	return the state of the NIS+ namespace using a condi- tional expression
NIS+ Administrative	aliasadm(1M)	manipulate the NIS+ aliases map
Commands	nis_cachemgr(1M)	NIS+ utility to cache location information about NIS+ servers
	nisaddcred(1M)	create NIS+ credentials
	nisaddent(1M)	create NIS+ tables from corresponding /etc files or NIS maps
	nisclient(1M)	initialize NIS+ credentials for NIS+ principals
	nisd(1M)	NIS+ service daemon
	nisd_resolv(1M)	NIS+ service daemon
	nisinit(1M)	NIS+ client and server initialization utility
	nislog(1M)	display the contents of the NIS+ transaction log
	nisping(1M)	send ping to NIS+ servers
	nispopulate(1M)	populate the NIS+ tables in a NIS+ domain
	nisserver(1M)	set up NIS+ servers
	nissetup(1M)	initialize a NIS+ domain
	nisshowcache(1M)	NIS+ utility to print out the contents of the shared cache file

Describes how to make the transition from NIS to NIS+ Solaris Advanced User's Guide

Describes the **admintool**(1M) window interface for modifying the data in NIS+ tables

NAME	niscat – display NIS+ tables and objects				
SYNOPSIS	niscat [–AhLMv] tablename niscat [–ALMP] –o name				
AVAILABILITY	SUNWnisu				
DESCRIPTION	In the first synopsis, niscat displays the contents of the NIS+ tables named by <i>tablename</i> . In the second synopsis, it displays the internal representation of the NIS+ objects named by <i>name</i> .				
OPTIONS	- A		y the data v concatenat		all of the data in tables in the initial
	-h	the '#'	(hash) char		ying the table. The header consists of e name of each column. The column rator character.
	-L Follow links. When this option is specified, if <i>tablename</i> or <i>name</i> names a LINK type object, the link is followed and the object or table named by the link is displayed.				
	-M Master server only. This option specifies that the request should be sent to the master server of the named data. This guarantees that the most up-to-date information is seen at the possible expense of increasing the load on the master server and increasing the possibility of the NIS+ server being unavailable or busy for updates.				
	- P	low the	e concatena	tion path of a table i	n specifies that the request should fol- f the initial search is unsuccessful. This dexed name for <i>name</i> and the -0 option.
	 -v Display binary data directly. This option displays columns containing binary data on the standard output. Without this option binary data is displayed as the string *BINARY*. 				
	–o name	indexe display	d name (see	e nismatch (1)), then ption is used to disp	the named NIS+ object(s). If <i>name</i> is an each of the matching entry objects is lay access rights and other attributes of
EXAMPLES			-	ntents of the hosts ta	ble.
	# cl cr	kample% cname ient1 unchy unchy	5 niscat –h name client1 crunchy softy	hosts.org_dir addr 129.144.201.100 129.144.201.44 129.144.201.44	comment Joe Smith Jane Smith

modified 18 Oct 1994

	The string *NP * is returned in those fields where the user has insufficient access rights.
	Display the passwd.org_dir on the standard output.
	example% niscat passwd.org_dir
	Display the contents of table frodo and the contents of all tables in its concatenation path.
	example% niscat –A frodo
	Display the entries in the table groups.org_dir as NIS+ objects. Note that the brackets are protected from the shell by single quotes.
	example% niscat –o '[]groups.org_dir'
	Display the table object of the passwd.org_dir table.
	example% niscat –o passwd.org_dir
	The previous example displays the passwd table object and not the passwd table. The table object include information such as the number of columns, column type, searchable or not searchable separator, access rights, and other defaults.
	Display the directory object for org_dir , which includes information such as the access rights and replica information.
	example% niscat –o org_dir
ENVIRONMENT	NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults (1)).
EXIT CODES	niscat returns 0 on success and 1 on failure.
SEE ALSO	nis+(1), nismatch(1), nistbladm(1), nisdefaults(1), nis_objects(3N), nis_tables(3N)
NOTES	Columns without values in the table are displayed by two adjacent separator characters.

modified 18 Oct 1994

NAME	nischgrp – change the group owner of a NIS+ object				
SYNOPSIS	nischgrp [–AfLP] group name				
AVAILABILITY	SUNWnisu				
DESCRIPTION	nischgrp changes the group owner of the NIS+ objects or entries specified by <i>name</i> to the specified NIS+ <i>group</i> . Entries are specified using indexed names (see nismatch (1)). If <i>group</i> is not a fully qualified NIS+ group name, it will be resolved using the directory search path (see nisdefaults (1)).				
	The only restriction on changing an object's group owner is that you must have r permissions for the object.				
	This command v	vill fail if the master NIS+ server is not running.			
OPTIONS		all entries in all tables in the concatenation path that match the search cri- pecified in <i>name</i> . This option implies the $-\mathbf{P}$ switch.			
	– f Force the	e operation and fail silently if it does not succeed.			
		inks and change the group owner of the linked object or entries rather group owner of the link itself.			
	sense wl	he concatenation path within a named table. This option only makes nen either <i>name</i> is an indexed name or the $-L$ switch is also specified and ed object is a link pointing to entries.			
EXAMPLES	The following two examples show how to change the group owner of an object to a group in a different domain, and how to change it to a group in the local domain, respectively.				
	example	% nischgrp newgroup.remote.domain. object % nischgrp my-buds object			
	This example shows how to change the group owner for a password entry.				
	example% nischgrp admins '[uid=99],passwd.org_dir'				
	In the previous example, admins is a NIS+ group in the same domain.				
		Imples change the group owner of the object or entries pointed to by a up owner of all entries in the hobbies table.			
		% nischgrp –L my-buds linkname % nischgrp my-buds '[],hobbies'			
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).			

EXIT CODES	nischgrp returns 0 on success and 1 on failure.
SEE ALSO	${\bf nis+(1),nischmod(1),nischown(1),nisdefaults(1),nisgrpadm(1),nis_objects(3N)}$
NOTES	The NIS+ server will check the validity of the group name prior to effecting the modification.

NAME	nischmod – change access rights on a NIS+ object				
SYNOPSIS	nischmod [–AfLP] mode name				
AVAILABILITY	SUNWnisu				
DESCRIPTION	nischmod changes the access rights (mode) of the NIS+ objects or entries specified by <i>name</i> to <i>mode</i> . Entries are specified using indexed names (see nismatch (1)). Only principals with modify access to an object may change its mode.				
	<i>mode</i> has the following form:				
	rights [, rights]				
	<i>rights</i> has the form:				
	[who] op permission [op permission]				
	who is a combination of:				
	n Nobody's permissions.				
	o Owner's permissions.				
	g Group's permissions.w World's permissions.				
	a All, or owg.				
	If <i>who</i> is omitted, the default is a .				
	op is one of:				
	 For the permission. To revoke the permission. 				
	= To set the permissions explicitly.				
	permission is any combination of:				
	r Read.				
	m Modify.				
	c Create. d Destroy.				
	u Desuby.				
OPTIONS	-A Modify all entries in all tables in the concatenation path that match the search criteria specified in <i>name</i> . This option implies the – P switch.				
	- f Force the operation and fail silently if it does not succeed.				
	-L Follow links and change the permission of the linked object or entries rather than the permission of the link itself.				
	- P Follow the concatenation path within a named table. This option is only applicable when either <i>name</i> is an indexed name or the – L switch is also specified and the named object is a link pointing to an entry.				

EXAMPLES	This example gives everyone read access to an object. (i.e., access for owner, group, and all).				
	example%	nischmod a+r object			
	(nobody).	This example denies create and modify privileges to group and unauthenticated clients (nobody). example% nischmod gn–cm <i>object</i>			
	-	In this example, a complex set of permissions are set for an object.			
	example%	example% nischmod o=rmcd,g=rm,w=rc,n=r <i>object</i>			
	This example sets the permissions of an entry in the password table so that the group owner can modify them.				
	example% nischmod g+m '[uid=55],passwd.org_dir'				
	The next example changes the permissions of a linked object. example% nischmod –L w+mr <i>linkname</i>				
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).			
EXIT CODES	nischmod returns 0 on success and 1 on failure.				
SEE ALSO	<pre>chmod(1), nis+(1), nischgrp(1), nischown(1), nisdefaults(1), nis_objects(3N)</pre>				
NOTES	Unlike the system o	chmod (1) command, this command does not accept an octal notation.			

NAME	nischown – change the owner of a NIS+ object			
SYNOPSIS	nischown [–AfLP] owner name			
AVAILABILITY	SUNWnisu			
DESCRIPTION	nischown changes the owner of the NIS+ objects or entries specified by <i>name</i> to <i>owner</i> . Entries are specified using indexed names (see nismatch (1)). If <i>owner</i> is not a fully qualified NIS+ principal name (see nisaddcred (1M)), the default domain (see nisde- faults (1)) will be appended to it.			
	sions for the object.	on changing an object's owner is that you must have modify permis- Note: If you are the current owner of an object and you change own- t be able to regain ownership unless you have modify access to the		
	The command will fail if the master NIS+ server is not running.			
OPTIONS	•	entries in all tables in the concatenation path that match the search crited in <i>name</i> . It implies the $-\mathbf{P}$ option.		
	- f Force the operation and fail silently if it does not succeed.			
	 -L Follow links and change the owner of the linked object or entries rather the owner of the link itself. -P Follow the concatenation path within a named table. This option is only n ingful when either <i>name</i> is an indexed name or the -L option is also specific the named object is a link pointing to entries. 			
EXAMPLES	APLES The following two examples show how to change the owner of an object to a principal in a different domain, and to change it to a principal in the local domain, respectively. example% nischown bob.remote.domain. object example% nischown skippy objectThe next example shows how to change the owner of an entry in the passwd table.			
	example%	nischown bob.remote.domain. '[uid=99],passwd.org_dir'		
	This example shows how to change the object or entries pointed to by a link. example% nischown –L skippy linkname			
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).		

modified 25 Jan 1993

EXIT CODES	nischown returns 0 on success and 1 on failure.
SEE ALSO	nis+(1), nischgrp(1), nischmod(1), nischttl(1), nisdefaults(1), nisaddcred(1M), nis_objects(3N)
NOTES	The NIS+ server will check the validity of the name before making the modification.

modified 25 Jan 1993

NAME	nischttl – change the time to live value of a NIS+ object				
SYNOPSIS	nischttl [–AfLP] time name				
AVAILABILITY	SUNWnisu				
DESCRIPTION	nischttl changes the time to live value (ttl) of the NIS+ objects or entries specified by <i>name</i> to <i>time</i> . Entries are specified using indexed names (see nismatch (1)).				
	The time to live value is used by object caches to expire objects within their cache. When an object is read into the cache, this value is added to the current time in seconds yielding the time when the cached object would expire. The object may be returned from the cache until the current time is earlier than the calculated expiration time. When the expiration time has been reached, the object will be flushed from the cache.				
	The time to live <i>time</i> may be specified in seconds or in days, hours, minutes, seconds for- mat. The latter format uses a suffix letter of d , h , m , or s to identify the units of time. See the examples below for usage.				
	The command will fail if the master NIS+ server is not running.				
OPTIONS	-A Modify all tables in the concatenation path that match the search criterion specified in <i>name</i> . This option implies the – P switch.				
	- f Force the operation and fail silently if it does not succeed.				
	-L Follow links and change the time to live of the linked object or entries rather than the time to live of the link itself.				
	-P Follow the concatenation path within a named table. This option only makes sense when either <i>name</i> is an indexed name or the -L switch is also specified and the named object is a link pointing to entries.				
EXAMPLES	The following example shows how to change the ttl of an object using the seconds format and the days, hours, minutes, seconds format. The ttl of the second object is set to 1 day and 12 hours.				
	example% nischttl 184000 object example% nischttl 1d12h object				
	This example shows how to change the ttl for a password entry.				
	example% nischttl 1h30m '[uid=99],passwd.org_dir'				
	The next two examples change the ttl of the object or entries pointed to by a link, and the ttl of all entries in the hobbies table.				
	example% nischttl –L 12h linkname example% nischttl 3600 '[],hobbies				
ENVIRONMENT	NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).				

1-698

EXIT CODES	nischttl returns 0 on success and 1 on failure.					
SEE ALSO	<pre>nis+(1), nischgrp(1), nischmod(1), nischown(1), nisdefaults(1), nis_objects(3N)</pre>					
NOTES	Setting a high ttl value allows objects to stay persistent in caches for a longer period of time and can improve performance. However, when an object changes, in the worst case, the number of seconds in this attribute must pass before that change is visible to all clients. Setting a ttl value of 0 means that the object should not be cached at all.					
	A high ttl value is a week, a low value is less than a minute. Password entries should have ttl values of about 12 hours (easily allows one password change per day), entries in the RPC table can have ttl values of several weeks (this information is effectively unchanging).					
	Only directory and group objects are cached in this implementation.					

NAME	nisdefaults – display NIS+ default values			
SYNOPSIS	nisdefaults [–adghprstv]			
AVAILABILITY	SUNWnisu			
DESCRIPTION	nisdefaults prints the default values that are returned by calls to the NIS+ local name functions (see nis_local_names (3N)). With no options specified, all defaults will be printed in a verbose format. With options, only that option is displayed in a terse form suitable for shell scripts. See the example below.			
OPTIONS	 -a Print all defaults in a terse format. -d Print the default domain name. -g Print the default group name. -h Print the default host name. -p Print the default principal name. -r Print the default access rights with which new objects will be created. -s Print the default directory search path. -t Print the default time to live value. -v Print the defaults in a verbose format. This prepends an identifying string to the output. 			
EXAMPLES	The following prints the NIS+ defaults for a root process on machine example in the foo.bar . domain. example# nisdefaults Principal Name : example.foo.bar . Domain Name : foo.bar. Host Name : example.foo.bar. Group Name : Access Rights :rmcdrr Time to live : 12:00:00 Search Path : foo.bar. This example sets a variable in a shell script to the default domain. DOMAIN='nisdefaults -d' This example prints out the default time to live in a verbose format. example% nisdefaults -tv Time to live : 12:00:00 This example prints out the time to live in the terse format: example% nisdefaults -t 43200			

ENVIRONMENT	Several environment variables affect the defaults associated with a process.			
	NIS_DEFAULTS	S This variable contains a defaults string that will override the NIS+ stan- dard defaults. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the gen- eric object properties. All of the legal tokens are described below.		
		<pre>ttl=time This token sets the default time to live for objects that are created. The value time is specified in the format as defined by the nischttl(1) command. The default value is 12 hours.</pre>		
		owner = <i>ownername</i> This token specifies that the NIS+ principal <i>ownername</i> should own created objects. The default for this value is the principal who is executing the command.		
		group =groupname This token specifies that the group groupname should be the group owner for created objects. The default is NULL.		
		access=rightsThis token specifies the set of access rights that are to be granted for created objects. The value rights is specified in the format as defined by the nischmod(1) command. The default value is $rmcdrr$.		
	NIS_GROUP	This variable contains the name of the local NIS+ group. If the name is not fully qualified, the default domain will be appended to it.		
	NIS_PATH	This variable overrides the default NIS+ directory search path. It con- tains an ordered list of directories separated by ':' (colon) characters. The '\$' (dollar sign) character is treated specially. Directory names that end in '\$' have the default domain appended to them, and a '\$' by itself is replaced by the list of directories between the default domain and the global root that are at least two levels deep. The default NIS+ directory search path is '\$'.		
		Refer to the Name Expansion subsection in nis +(1) for more details.		
SEE ALSO	nis+(1), nis_loca	al_names(3N)		

1-701

NAME	niserror – display NIS+ error messages
SYNOPSIS	niserror error-num
AVAILABILITY	SUNWnisu
DESCRIPTION	niserror prints the NIS+ error associated with status value <i>error-num</i> on the standard output. It is used by shell scripts to translate NIS+ error numbers that are returned into text messages.
EXAMPLES	The following example prints the error associated with the error number 20 : example% niserror 20 Not Found, no such name
SEE ALSO	nis+(1), nis_error(3N)

NAME	nisgrpadm – NIS+ group administration command				
SYNOPSIS	nisgrpadm –a –r –t] [–s] group principal				
		$padm - c \mid -d \mid -l \mid -M \mid [-M] \mid -s \mid group$			
AVAILABILITY	SUNWnisu				
DESCRIPTION	and th nisgrj princi The n occup object	padm is used to administer NIS+ groups. This command administers both groups ne groups' membership lists. nisgrpadm can create, destroy, or list NIS+ groups. padm can be used to administer a group's membership list. It can add or delete ipals to the group, or test principals for membership in the group. ames of NIS+ groups are syntactically similar to names of NIS+ objects but they by a separate namespace. A group named "a.b.c.d." is represented by a NIS+ group named "a.groups_dir.b.c.d."; the functions described here all expect the name of			
		roup, not the name of the corresponding group object.			
		are three types of group members:			
		n <i>explicit</i> member is just a NIS+ principal-name, for example "wickedwitch.west.oz."			
	 An <i>implicit</i> ("domain") member, written "*.west.oz.", means that all principals in the given domain belong to this member. No other forms of wildcarding are allowed: "wickedwitch.*.oz." is invalid, as is "wickedwitch.west.*.". Note that principals in subdomains of the given domain are <i>not</i> included. A <i>recursive</i> ("group") member, written "@cowards.oz.", refers to another group; all principals that belong to that group are considered to belong here. Any member may be made <i>negative</i> by prefixing it with a minus sign ('-'). A group m thus contain explicit, implicit, recursive, negative explicit, negative implicit, and negative members. 				
	A principal is considered to belong to a group if it belongs to at least one non-negative group member of the group and belongs to no negative group members.				
OPTIONS	-a	Add the list of NIS+ principals specified to <i>group</i> . The principal name should be fully qualified.			
	- c	Create <i>group</i> in the NIS+ namespace. The NIS+ group name should be fully qualified.			
	-d	Destroy (remove) <i>group</i> from the namespace.			
	-l	List the membership list of the specified group. (See $-M$.)			
	- M	Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy. Note that the $-\mathbf{M}$ flag is applicable only with the $-\mathbf{I}$ flag.			
	- r	Remove the list of principals specified from <i>group</i> . The principal name should be fully qualified.			

modified 25 Feb 1993

1-703

	 -s Work silently. Results are returned using the exit status of the command. This status can be translated into a text string using the niserror(1) command. -t Display whether the principals specified are members in <i>group</i>. 			
EXAMPLES Administering Groups	This example shows how to create a group in the foo.com. domain. example% nisgrpadm –c my_buds.foo.com. This example shows how to remove the group from the current domain.			
	example% nisgrpadm –d freds_group			
Administering Members	This example shows how one would add two principals, bob and betty to the group my_buds.foo.com .			
	example%	nisgrpadm –a my_buds.foo.com. bob.bar.com. betty.foo.com.		
	This example shows how to remove betty from freds_group .			
	example% nisgrpadm –r freds_group betty.foo.com.			
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ group name is not fully qualified, each directory specified will be searched until the group is found (see nisdefaults (1)).		
SEE ALSO	<pre>nis+(1), nischgrp(1), nisdefaults(1), niserror(1), nis_groups(3N)</pre>			
DIAGNOSTICS	NIS_SUCCESS	On success, this command returns an exit status of 0 .		
	NIS_PERMISSION	When you do not have the needed access right to change the group, the command returns this error.		
	NIS_NOTFOUND	This is returned when the group does not exist.		
	NIS_TRYAGAIN	This error is returned when the server for the group's domain is currently checkpointing or otherwise in a read-only state. The com- mand should be retried at a later date.		
	NIS_MODERROR	This error is returned when the group was modified by someone else during the execution of the command. Reissue the command and optionally recheck the group's membership list.		
NOTES	Principal names <i>mu</i> tions <i>except</i> create.	<i>ust</i> be fully qualified, whereas groups can be abbreviated on all opera-		

modified 25 Feb 1993

NAME	nisln – symbolically link NIS+ objects			
SYNOPSIS	nisln [–L] [–D defaults] name linkname			
AVAILABILITY	SUNWnisu			
DESCRIPTION	The nisln command links a NIS+ object named <i>name</i> to a NIS+ name <i>linkname</i> . If <i>name</i> is an indexed name (see nismatch (1)), the link points to entries within a NIS+ table. Clients wishing to look up information in the name service can use the FOLLOW_LINKS flag to force the client library to follow links to the name they point to. Further, all of the NIS+ administration commands accept the –L switch indicating they should follow links (see nis_names (3N) for a description of the FOLLOW_LINKS flag).			
OPTIONS	-L	When present, this option specifies that this command should follow links. If <i>name</i> is itself a link, then this command will follow it to the linked object that it points to. The new link will point to that linked object rather than to <i>name</i> . Specify a different set of defaults to be used for the creation of the link object. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.		
	– D defaults			
		ttl= <i>time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the nischttl (1) command. The default is 12 hours.	
		owner=ownername	This token specifies that the NIS+ principal <i>owner-name</i> should own the created object. The default for this value is the the principal who is executing the command.	
		group =groupname	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL .	
		access=rights	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the nisch-mod (1) command. The default value is $\mathbf{rmcdr}\mathbf{r}$.	

1-705

In this example we create a link in the domain foo.com . named hosts that points to the object hosts.bar.com .		
example% nisln hosts.bar.com. hosts.foo.com.		
In this example we in <i>eng.sun.com</i> .	make a link <i>example.sun.com</i> . that points to an entry in the hosts table	
example%	nisln '[name=example],hosts.eng.sun.com.' example.sun.com.	
NIS_PATH	If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).	
nisln returns 0 on success and 1 on failure.		
nisdefaults(1), nismatch(1), nisrm(1), nistbladm(1), nis_names(3N), nis_tables(3N)		
linked object may b the link will become to the client. When the link will be follo (see nis_tables (3N)	ink, nisln verifies that the linked object exists. Once created, the e deleted or replaced and the link will not be affected. At that time e invalid and attempts to follow it will return NIS_LINKNAMEERROR the path attribute in tables specifies a link rather than another table, owed if the flag FOLLOW_LINKS was present in the call to nis_list()) and ignored if the flag is not present. If the flag is present and the lid, a warning is sent to the system logger and the link is ignored.

NAME	nisls – list the contents of a NIS+ directory		
SYNOPSIS	nisls [–dglLmMR] [name]		
AVAILABILITY	SUNWnisu		
DESCRIPTION	For each <i>name</i> that is a NIS+ directory, nisls lists the contents of the directory. For each <i>name</i> that is a NIS+ object other than a directory, nisls simply echos the name. If no <i>name</i> is specified, the first directory in the search path (see nisdefaults (1)) is listed.		
OPTIONS	-d Treat NIS+ directories like other NIS+ objects, rather than listing their contents.		
	-g Display group owner instead of owner when listing in long format.		
	-l List in long format. This option displays additional information about the objects such as their type, creation time, owner, and access rights.		
	The access rights are listed in the following order in long mode: nobody, owner, group owner, and world.		
	-L This option specifies that links are to be followed. If <i>name</i> actually points to a link, it is followed to the linked object.		
	-m Display modification time instead of creation time when listing in long format.		
	-M Master only. This specifies that information is to be returned from the master server of the named object. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.		
	- R List directories recursively. This option will reiterate the list for each subdirectory found in the process of listing each <i>name</i> .		
ENVIRONMENT	NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).		
EXIT CODES	nisls returns 0 on success and 1 on failure.		
SEE ALSO	nisdefaults(1), nisgrpadm(1), nismatch(1), nistbladm(1), nis_objects(3N)		

NAME	nismat	tch, nisgrep – utilities for searching NIS+ tables	
SYNOPSIS	nisma nisma	tch [–AchMoPv] key tablename tch [–AchMoPv] colname=key tablename tch [–AchMoPv] indexedname p [–AchMov] keypat tablename	
	nisgre	p [- AchMov] colname=keypat tablename	
AVAILABILITY	SUNW	√nisu	
DESCRIPTION	nismatch and nisgrep can be used to search NIS+ tables. The command nisgrep differs from the nismatch command in its ability to accept regular expressions <i>keypat</i> for the search criteria rather than simple text matches.		
	Because nisgrep uses a callback function, it is not constrained to searching only those columns that are specifically made searchable at the time of table creation. This makes it more flexible, but slower, than nismatch .		
	In nismatch , the server does the searching; wheareas in nisgrep , the server returns all the readable entries and then the client does the pattern-matching.		
	In both commands, the parameter <i>tablename</i> is the NIS+ name of the table to be searched. If only one key or key pattern is specified without the column name, then it is applied searching the first column. Specific named columns can be searched by using the <i>colname=key</i> syntax. When multiple columns are searched, only entries that match in all columns are returned. This is the equivalent of a logical join operation.		
	nismatch accepts an additional form of search criteria, <i>indexedname</i> , which is a NIS+ indexed name of the form:		
		[colname=value,],tablename	
OPTIONS	- A	All data. Return the data within the table and all of the data in tables in the initial table's concatenation path.	
	- c	Print only a count of the number of entries that matched the search criteria.	
	-h	Display a header line before the matching entries that contains the names of the table's columns	
	- M	Master server only. Send the lookup to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.	
	-0	Display the internal representation of the matching NIS+ object(s).	
	- P	Follow concatenation path. Specify that the lookup should follow the concatena- tion path of a table if the initial search is unsuccessful.	
	- v	Verbose. Do not suppress the output of binary data when displaying matching entries. Without this option binary data is displayed as the string *BINARY *.	
	I		

modified 21 Feb 1993

RETURN VALUES	0 Successfully matches some entries.		
	1 Successfully searches the table and no matches are found.		
	2 An error condition occurs. An error message is also printed.		
EXAMPLES	 S This example searches a table named passwd in the org_dir subdirectory of the zotz.com. domain. It returns the entry that has the username of skippy. In this example, all the work is done on the server. example% nismatch name=skippy passwd.org_dir.zotz.com. 		
	This example is similar to the one above except that it uses nisgrep to find all users in the table named passwd that are using either ksh (1) or csh (1).		
	example% nisgrep 'shell=[ck]sh' passwd.org_dir.zotz.com.		
ENVIRONMENT	NIS_PATH If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults (1)).		
SEE ALSO	niscat(1), nisdefaults(1), nisls(1), nistbladm(1), nis_objects(3N)		
DIAGNOSTICS	No memory An attempt to allocate some memory for the search failed.		
	 tablename is not a table The object with the name tablename was not a table object. Can't compile regular expression The regular expression in keypat was malformed. 		
	column not found: <i>colname</i> The column named <i>colname</i> does not exist in the table named <i>tablename</i> .

NAME	nismkdir – create NIS+ directories		
SYNOPSIS	nismkdir [–D defaults] [–m hostname] [–s hostname] dirname		
AVAILABILITY	SUNWnisu		
DESCRIPTION	The nismkdir command creates new NIS+ subdirectories within an existing domain. It can also be used to create replicated directories. Without options, this command will create a subdirectory with the same master and the replicas as its parent directory. It is advisable to use nisserver (1M) to create an NIS+ domain which consists of the specified directory along with the org_dir and group_dir subdirectories. The two primary aspects that are controlled when making a directory are its access rights, and its degree of replication. <i>dirname</i> is the fully qualified NIS+ name of the directory that has to be created.		
OPTIONS	- D defaults - m hostname	Specify a different set of defaults to be used when creating new directories. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below. ttl=time This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the nischttl (1) command. The default value is 12h (12 hours). owner=ownername This token specifies that the NIS+ principal ownername should own the created object. The default for this value is the principal who is executing the command. group=groupname This token specifies that the group groupname should be the group owner for the object that is created. The default value is NULL. access=rights This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the nischmod (1) command. The default value is	

modified 17 Jan 1995

		Specify that the host <i>hostname</i> will be a replica for an existing directory named <i>dirname.</i>	
RETURN VALUES	This command returns 0 if successful and 1 otherwise.		
EXAMPLES	To create a new directory bar under the foo.com . domain that shares the same master and replicas as the foo.com . directory one would use the command:		
	example	% nismkdir bar.foo.com.	
	To create a new directory <i>bar.foo.com.</i> that is not replicated under the foo.com. domain one would use the command:		
	example% nismkdir –m myhost.foo.com. bar.foo.com.		
	To add a replica server of the <i>bar.foo.com</i> . directory, one would use the command:		
	example% nismkdir –s replica.foo.com. bar.foo.com.		
ENVIRONMENT	NIS_DEFAULTS	This variable contains a defaults string that will override the NIS+ standard defaults. If the $-\mathbf{D}$ switch is used those values will then override both the NIS_DEFAULTS variable and the standard defaults.	
	NIS_PATH	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found (see nisdefaults (1)).	
SEE ALSO	nis+(1), nischmod(1), nisdefaults(1), nisls(1), nisrmdir(1), nisserver(1M)		
NOTES	A host that serves a NIS+ directory <i>must be</i> a NIS+ client in a directory above the one it is serving. The exceptions to this rule are the root NIS+ servers which are both clients and servers of the same NIS+ directory. When the host's default domain is different from the default domain on the client where the command is executed, the hostname supplied as an argument to the –s or –m options must be fully qualified.		
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	
	the command is e	executed, the hostname supplied as an argument to the -s or -m options	

modified 17 Jan 1995

NAME	nispasswd – change NIS+ password information	
SYNOPSIS	nispasswd [–ghs] [–D domainname] [username]	
	nispasswd –a	
	nispasswd –D domainname [–d [username]]	
	nispasswd [-l] [-f] [-n min] [-x max] [-w warn] [-D domainname] username	
AVAILABILITY	SUNWnisu	
DESCRIPTION	nispasswd changes a password, gecos (finger) field (-g option), home directory (-h option), or login shell (-s option) associated with the <i>username</i> (invoker by default) in the NIS+ passwd table.	
	Additionally, the command can be used to view or modify aging information associated with the user specified if the invoker has the right NIS+ privileges.	
	nispasswd uses secure RPC to communicate with the NIS+ server, and therefore, never sends unencrypted passwords over the communication medium.	
	nispasswd does not read or modify the local password information stored in the /etc/passwd and /etc/shadow files.	
	When used to change a password, nispasswd prompts non-privileged users for their old password. It then prompts for the new password twice to forestall typing mistakes. When the old password is entered, nispasswd checks to see if it has "aged" sufficiently. If "aging" is insufficient, nispasswd terminates; see getspnam (3C).	
	The old password is used to decrypt the username's secret key. If the password does not decrypt the secret key, nispasswd prompts for the old secure-RPC password. It uses this password to decrypt the secret key. If this fails, it gives the user one more chance. The old password is also used to ensure that the new password differs from the old by at least three characters. Assuming aging is sufficient, a check is made to ensure that the new password meets construction requirements described below. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical, the cycle of prompting for the new password is repeated twice. The new password is used to re-encrypt the user's secret key. Hence, it also becomes their secure-RPC password.	
	Passwords must be constructed to meet the following requirements:	
	• Each password must have at least six characters. Only the first eight characters are significant.	
	• Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" refers to all upper or lower case letters.	

modified 24 Oct 1994

	circ	h password must differ from the user's login <i>username</i> and any reverse or ular shift of that login <i>username</i> . For comparison purposes, an upper case er and its corresponding lower case letter are equivalent.	
	com	w passwords must differ from the old by at least three characters. For parison purposes, an upper case letter and its corresponding lower case er are equivalent.	
	Network administrators, who own the NIS+ password table, may change any password attributes if they establish their credentials (see keylogin (1)) before invoking nispasswd . Hence, nispasswd does not prompt these privileged-users for the old password and they are not forced to comply with password aging and password construction requirements.		
	Any user may use the – d option to display password attributes for his or her own login name. The format of the display will be:		
	username status mm/dd/yy min max warn		
	or, if passwore	d aging information is not present,	
	userna	ame status	
	where		
	username	The login ID of the user.	
		The password status of <i>username</i> : "PS" stands for password exists or locked, "LK" stands for locked, and "NP" stands for no password.	
		The date password was last changed for <i>username</i> . (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and, therefore, may differ by as much as a day in other time zones.)	
		The minimum number of days required between password changes for <i>username</i> .	
	max	The maximum number of days the password is valid for <i>username</i> .	
		The number of days relative to <i>max</i> before the password expires that the <i>username</i> will be warned.	
OPTIONS	-g	Change the gecos (finger) information.	
	_h	Change the home directory.	
	- s	Change the login shell. By default, only the NIS+ administrator can change the login shell. User will be prompted for the new login shell.	
	- a	Show the password attributes for all entries. This will show only the entries in the NIS+ passwd table in the local domain that the invoker is authorized to "read".	
	-d [username]	Display password attributes for the caller or the user specified if the invoker has the right privileges.	
	-1	Locks the password entry for <i>username</i> . Subsequently, login (1) would disallow logins with this NIS+ password entry.	
	-f	Force the user to change password at the next login by expiring the

NAME	nisrm – remove NIS+ objects from the namespace	
SYNOPSIS	nisrm [–if] name	
AVAILABILITY	SUNWnisu	
DESCRIPTION	The nisrm command removes NIS+ objects named <i>name</i> from the NIS+ namespace. This command will fail if the NIS+ master server is not running.	
OPTIONS	-i Interactive mode. Like the system rm(1) command the nisrm command will ask for confirmation prior to removing an object. If the name specified by <i>name</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected objects.	
	 -f Force. The removal is attempted, and if it fails for permission reasons, a nisch-mod(1) is attempted and the removal retried. If the command fails, it fails silently. 	
EXAMPLES	Remove the objects <i>foo</i> , <i>bar</i> , and <i>baz</i> from the namespace.	
	example% nisrm foo bar baz	
ENVIRONMENT	NIS_PATH If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).	
EXIT CODES	nisrm returns 0 on success and 1 on failure.	
SEE ALSO	<pre>nis+(1), nischmod(1), nisdefaults(1), nisrmdir(1), nistbladm(1), rm(1)</pre>	
NOTES	This command will not remove directories (see nisrmdir (1)) nor will it remove non- empty tables (see nistbladm (1)).	

modified 25 Feb 1993

NAME	nisrmdir – remove NIS+ directories		
SYNOPSIS	nisrmdir [–if] [–s hostname] dirname		
AVAILABILITY	SUNWnisu		
DESCRIPTION	 nisrmdir deletes existing NIS+ subdirectories. It can remove a directory outright, or simply remove replicas from serving a directory. This command modifies the object that describes the directory <i>dirname</i>, and then notifies each replica to remove the directory named <i>dirname</i>. If the notification of any of the 		
	affected replicas fails, the directory object is returned to its original state unless the $-\mathbf{f}$ option is present.		
	This command will fail if the NIS+ master server is not running.		
OPTIONS	 –i Interactive mode. Like the system rm(1) command the nisrmdir command will ask for confirmation prior to removing a directory. If the name specified by <i>dirname</i> is a non-fully qualified name this option is forced on. This prevents the removal of unexpected directories. 		
	 -f Force the command to succeed even though it may not be able to contact the affected replicas. This option should be used when a replica is known to be down and will not be able to respond to the removal notification. When the replica is finally rebooted it will read the updated directory object, note that it is no longer a replica for that directory, and stop responding to lookups on that directory. Cleanup of the files that held the now removed directory can be accomplished manually by removing the appropriate files in the /var/nis directory (see nisfiles(4) for more information). 		
	-s <i>hostname</i> Specify that the host <i>hostname</i> should be removed as a replica for the directory named <i>dirname</i> . If this option is not present <i>all</i> replicas and the master server for a directory are removed and the directory is removed from the namespace.		
RETURN VALUES	This command returns 0 if it is successful, and 1 otherwise.		
EXAMPLES	To remove a directory bar under the foo.com . domain, one would use the command: example% nisrmdir bar.foo.com .		
	To remove a replica that is serving directory bar.foo.com. one would use the command:		
	example% nisrmdir –s replica.foo.com. bar.foo.com.		
	To force the removal of directory bar.foo.com . from the namespace, one would use the command:		

	example% nisrmdir –f bar.foo.com.		
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the director is found (see nisdefaults (1)).	ory

NAME	nistbladm – NIS+ table administration command		
SYNOPSIS	nistbladm – a – A [– D defaults] colname=value tablename		
	nistbladm –a –A [–D defaults] indexedname		
	nistbladm – c [– D defaults] [– p path] [– s sep] type colname=[flags][,access] tablename		
	nistbladm –d <i>tablename</i>		
	nistbladm –e –E colname=value indexedname		
	nistbladm –m colname=value indexedname		
	nistbladm –r –R [colname=value] tablename		
	nistbladm –r –R indexedname		
	nistbladm –u [–p path] [–s sep] [–t type] [colname=access] tablename		
AVAILABILITY	SUNWnisu		
DESCRIPTION	The nistbladm command is used to administer NIS+ tables. There are five primary operations that it performs: creating and deleting tables, adding entries to, modifying entries within, and removing entries from tables.		
	Though NIS+ does not place restrictions on the size of tables or entries, the size of data has an impact on the performance and the disk space requirements of the NIS+ server. NIS+ is not designed to store huge pieces of data, such as files; instead pointer to files should be stored in NIS+.		
	NIS+ design is optimized to support 10,000 objects with a total size of 10M bytes. If the requirements exceed the above, it is suggested that the domain hierarchy be created, or the data stored in the tables be pointers to the actual data, instead of the data itself.		
	When creating tables, a table type, <i>type</i> , and a list of column definitions must be provided.		
	<i>type</i> is a string that is stored in the table and later used by the service to verify that entries being added to it are of the correct type.		
	Syntax for column definitions is:		
	colname=[flags][,access]		
	flags is a combination of:		
	S Searchable. Specifies that searches can be done on the column's values (see nismatch (1)).		
	I Case-insensitive (only makes sense in combination with S). Specifies		
	that searches should ignore case.C Crypt. Specifies that the column's values should be encrypted.		
	B Binary data (does not make sense in combination with S). If not set, the column's values are expected to be null terminated ASCII strings.		
I			

modified 11 May 1995

- X XDR encoded data (only makes sense in combination with **B**).
- *access* is specified in the format as defined by the **nischmod**(1) command.

When manipulating entries, this command takes two forms of entry name. The first uses a series of space separated *colname=value* pairs that specify column values in the entry. The second is a NIS+ indexed name, *indexedname*, of the form:

[colname=value, ...],tablename

OPTIONS -

IS -a | A Add entries to a NIS+ table. The difference between the lowercase 'a' and the uppercase 'A' is in the treatment of preexisting entries. The entry's contents are specified by the *column=value* pairs on the command line. Note: Values for *all* columns must be specified when adding entries to a table.

Normally, NIS+ reports an error if an attempt is made to add an entry to a table that would overwrite an entry that already exists. This prevents multiple parties from adding duplicate entries and having one of them get overwritten. If you wish to force the add, the uppercase 'A' specifies that the entry is to be added, even if it already exists. This is analogous to a modify operation on the entry.

- -c Create a table named *tablename* in the namespace. The table that is created must have at least one column and at least one column must be searchable.
- -d tablename

Destroy the table named *tablename*. The table that is being destroyed must be empty. The table's contents can be deleted with the $-\mathbf{R}$ option below.

 $-\mathbf{e} \mid \mathbf{E}$ Edit the entry in the table that is specified by *indexdname*. *indexdname* must uniquely identify a single entry. It is possible to edit the value in a column that would change the indexed name of an entry.

The change (*colname=value*) may affect other entries in the table if the change results in an entry whose indexed name is different from *indexedname* and which matches that of another existing entry. In this case, the -e option will fail and an error will be reported. The -E option will force the replacement of the existing entry by the new entry (effectively removing two old entries and adding a new one).

- -m A synonym for –E. This option has been superseded by the –E option.
- $-\mathbf{r} \mid \mathbf{R}$ Remove entries from a table. The entry is specified by either a series of *column=value* pairs on the command line, or an indexed name that is specified as *entryname*. The difference between the interpretation of the lowercase 'r' versus the uppercase 'R' is in the treatment of non-unique entry specifications. Normally the NIS+ server will disallow an attempt to remove an entry when the search criterion specified for that entry resolves to more than one entry in the table. However, it is sometimes desirable to remove more than one entry, as when you are attempting to remove all of the entries from a table. In this case, using the uppercase 'R' will force the NIS+ server to remove all entries matching the passed search criterion. If that criterion is null and no column values specified, then all entries in the table will be removed.

modified 11 May 1995

	 -u Update attributes of a table. This allows the concatenation path (-p), separation character (specified with the (-s)), column access rights, and table type string (-t) of a table to be changed. Neither the number of columns, nor the columns that are searchable may be changed. 			
	-D defaults			
	When creating objects, this option specifies a different set of defaults to be us during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.			
	ttl = <i>time</i> This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the nischttl (1) command. The default value is 12 hours.			
	owner=ownername			
	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. Normally this value is the same as the principal who is executing the command.			
	group=groupname			
	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default value is NULL.			
	access=rights			
	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the nischmod (1) command. The default value is $\mathbf{rmcdr}\mathbf{r}$.			
	-p path When creating or updating a table, this option specifies the table's search path. When a nis_list() function is invoked, the user can specify the flag FOLLOW_PATH to tell the client library to continue searching tables in the table's path if the search criteria used does not yield any entries. The path consists of an ordered list of table names, separated by colons. The names in the path must be fully qualified.			
	-s <i>sep</i> When creating or updating a table, this option specifies the table's separator character. The separator character is used by niscat (1) when displaying tables on the standard output. Its purpose is to separate column data when the table is in ASCII form. The default value is a space.			
	-t <i>type</i> When updating a table, this option specifies the table's type string.			
RETURN VALUES	This command returns 0 on success and 1 on failure.			
EXAMPLES	This example creates a table named hobbies in the directory foo.com . of the type hobby_tbl with two searchable columns, name and hobby . example% nistbladm –c hobby_tbl name=S,a+r,o+m hobby=S,a+r hobbies.foo.com .			

modified 11 May 1995

	The column name has read access for all (that is, owner , group , and world) and modify access for only the owner. The column hobby is readable by all, but not modifiable by anyone.			
	In this example, if the access rights had not been specified, the tables access rights would have come from either the standard defaults or the NIS_DEFAULTS variable (see below).			
	To add entries to this table:			
	example% nistbladm –a name=bob hobby=skiing hobbies.foo.com. example% nistbladm –a name=sue hobby=skiing hobbies.foo.com. example% nistbladm –a name=ted hobby=swimming hobbies.foo.com.			
	To add the concatenation path:			
	example%	nistbladm –u –p hobbies.bar.com.:hobbies.baz.com. hobbies		
	To delete the skiers	s from our list:		
	example%	nistbladm –R hobby=skiing hobbies.foo.com.		
	Note: The use of the – r option would fail because there are two entries with the value of skiing .			
	To create a table with a column that is named with no flags set, you supply only the name and the equals (=) sign as follows.			
	example% nistbladm -c notes_tbl name=S,a+r,o+m note= notes.foo.com.			
	This example created a table, named <i>notes.foo.com.</i> , of type <i>notes_tbl</i> with two columns name and note . The note column is not searchable.			
	When entering data for columns in the form of a <i>value</i> string, it is essential characters be protected by single or double quotes. These are the character comma (,), left bracket (]), right bracket (]), and space (). These characters NIS+ within an indexed name. These characters are protected by enclosing value in double quote (") characters as follows.			
	example%	nistbladm –a fullname="Joe User" nickname=Joe nicknames		
	If there is any doub quotes.	ot about how the string will be parsed, it is better to enclose it in		
ENVIRONMENT	NIS_DEFAULTS	This variable contains a defaults string that will be override the NIS+ standard defaults. If the – D switch is used those values will then override both the NIS_DEFAULTS variable and the standard defaults.		
	NIS_PATH	If this variable is set, and the NIS+ table name is not fully qualified, each directory specified will be searched until the table is found (see nisdefaults (1)).		
SEE ALSO	nis+(1), niscat(1), r	nischmod(1), nischown(1), nisdefaults(1), nismatch(1), nissetup(1M)		
WARNINGS	To modify one of the entries, say, for example, from "bob" to "robert": example% nistbladm -m name=robert [name=bob],hobbies			

modified 11 May 1995

Note that "**[name=bob],hobbies**" is an indexed name, and that the characters '[' (open bracket) and ']' (close bracket) are interpreted by the shell. When typing entry names in the form of NIS+ indexed names, the name must be protected by using single quotes. It is possible to specify a set of defaults such that you cannot read or modify the table object later.

modified 11 May 1995

NAME	nistest – return the state of the NIS+ namespace using a conditional expression		
SYNOPSIS	nistest [–	ALMP] [–a rights –t type] object	
	nistest [–	ALMP] [–a rights] indexedname	
AVAILABILITY	SUNWnis	u	
DESCRIPTION	nistest provides a way for shell scripts and other programs to test for the existence, type, and access rights of objects and entries. Entries are named using indexed names (see nismatch (1)).		
OPTIONS	- A	All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned. This option is only valid when using indexed names or following links.	
	–L	Follow links. If the object named by <i>object</i> or the tablename component of <i>indexedname</i> names a LINK type object, the link is followed when this switch is present.	
	- M	Master server only. This option specifies that the lookup should be sent to the master server of the named data. This guarantees that the most up to date information is seen at the possible expense that the master server may be busy.	
	- P	Follow concatenation path. This option specifies that the lookup should fol- low the concatenation path of a table if the initial search is unsuccessful. This option is only valid when using indexed names or following links.	
	– a rights	This option is used to verify that the current process has the desired or required access rights on the named object or entries. The access rights are specified in the same way as the nischmod (1) command.	
	-t type	This option tests the type of <i>object</i> . The value of <i>type</i> can be one of the following:	
		G Return true if the object is a group object.	
		D Return true if the object is a directory object.	
		T Return true if the object is a table object.	
		L Return true if the object is a link object.	
		P Return true if the object is a private object.	
RETURN VALUES	0	Success.	
	1	Failure due to object not present, not of specified type and/or no such access.	
	2	Failure due to illegal usage.	

modified 25 Sep 1992

EXAMPLES	When testing for access rights, nistest returns success (0) if the specified rights are granted to the current user. Thus testing for access rights		
	example% nistest –a w=mr skippy.domain		
	-		
	skippy.domain.	enticated NIS+ clients have read and modify access to the object named	
		on a particular entry in a table can be accomplished using the indexed following example tests to see if an entry in the password table can be	
	example%	6 nistest –a o=m '[uid=99],passwd.org_dir'	
ENVIRONMENT	NIS_PATH	If this variable is set, and the NIS+ name is not fully qualified, each directory specified will be searched until the object is found (see nis-defaults (1)).

modified 25 Sep 1992

NAME	nl – line numbering filter		
SYNOPSIS	/usr/bin/nl [$-\mathbf{p}$] [$-\mathbf{b}[type]$] [$-\mathbf{d}[delim]$] [$-\mathbf{f}[type]$] [$-\mathbf{h}[type]$] [$-\mathbf{i}[incr]$] [$-\mathbf{l}[num]$] [$-\mathbf{n}[format]$] [$-\mathbf{s}[sep]$] [$-\mathbf{w}[width]$] [$-\mathbf{v}[startnum]$] [file]		
	/usr/xpg4/bin/nl[-p][-b type][-d delim][-f type][-h type][-i incr] [-l num][-n format][-s sep][-w width][-v startnum][file]		
AVAILABILITY /usr/bin/nl	SUNWesu		
/usr/xpg4/bin/nl	SUNWxcu4		
DESCRIPTION	The nl command reads lines from the named <i>file</i> , or the standard input if no <i>file</i> is named, and reproduces the lines on the standard output. Lines are numbered on the left in accordance with the command options in effect.		
	nl views the text it reads in terms of logical pages. Line numbering is reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer. For example, –bt (the default) numbers non-blank lines in the body section and does not number any lines in the header and footer sections.		
	The start of logical page sections are signaled by input lines containing nothing but the following delimiter character(s):		
	Line contents Start of		
	\:\:\: header \:\: body		
	$\:\$ body $\:$ footer		
	Unless optioned otherwise, nl assumes the text being read is in a single logical page body.		
OPTIONS	Command options may appear in any order and may be intermingled with an optional file name. Only one file may be named. The specified default is used when the option is not entered on the command line. / usr/xpg4/bin/nl options require option arguments. A SPACE character <i>may</i> separate options from option arguments. / usr/bin/nl options <i>may</i> have option arguments. If option-arguments of / usr/bin/nl options are not specified, these options result in the default. The supported options are:		
	-btype Specifies which logical page body lines are to be numbered. Recognized <i>types</i> and their meanings are:		
	a number all lines		
	t number all non-empty lines.		
	nno line numberingpexpnumber only lines that contain the regular expressionspecified in exp; see NOTES below.		

		Default <i>type</i> for logical page body is t (text lines numbered).
	-ftype	Same as – b <i>type</i> except for footer. Default <i>type</i> for logical page footer is n (no lines numbered).
	-d <i>delim</i>	The two delimiter characters specifying the start of a logical page section may be changed from the default characters (\backslash :) to two user-specified characters. If only one character is entered, the second character remains the default character (:). No space should appear between the $-\mathbf{d}$ and the delimiter characters. To enter a backslash, use two backslashes.
	-htype	Same as $-btype$ except for header. Default <i>type</i> for logical page header is n (no lines numbered).
	- i incr	<i>incr</i> is the increment value used to number logical page lines. Default <i>incr</i> is 1 .
	–lnum	<i>num</i> is the number of blank lines to be considered as one. For example, $-l2$ results in only the second adjacent blank being numbered (if the appropriate $-ha$, $-ba$, and/or $-fa$ option is set). Default <i>num</i> is 1 .
	- n format	format is the line numbering format. Recognized values are:
		 ln left justified, leading zeroes suppressed rn right justified, leading zeroes suppressed rz right justified, leading zeroes kept
		Default <i>format</i> is rn (right justified).
	- p	Do not restart numbering at logical page delimiters.
	-ssep	<i>sep</i> is the character(s) used in separating the line number and the corresponding text line. Default <i>sep</i> is a TAB.
	-vstartnum	<i>startnum</i> is the initial value used to number logical page lines. Default <i>startnum</i> is 1 .
	- w width	<i>width</i> is the number of characters to be used for the line number. Default <i>width</i> is 6 .
OPERANDS	The following operand is supported:	
	file	A path name of a text file to be line-numbered.
EXAMPLES	The command:	
	exa	nple% nl –v10 –i10 –d!+ filename1
		irst line of the page body to be numbered 10 , the second line of the page abered 20 , the third 30 , and so forth. The logical page delimiters are !+.
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.
FILES	/usr/lib/locale/locale/LC_COLLATE/CollTable collation table generated by localedef /usr/lib/locale/locale/LC_COLLATE/coll.so shared object containing string transformation library routines
SEE ALSO	<pre>pr(1), environ(5), regex(5), regexp(5)</pre>
NOTES	Internationalized Regular Expressions are used in the POSIX and "C" locales. In other locales, Internationalized Regular Expressions are used if the following two conditions are met:
	 /usr/lib/locale/locale/LC_COLLATE/CollTable is present
	 /usr/lib/locale/locale/LC_COLLATE/coll.so is not present;
	otherwise, Simple Regular Expressions are used.
	Internationalized Regular Expressions are explained on regex (5). Simple Regular Expressions are explained on regexp (5).

NAME	nm – print name list of an object file		
SYNOPSIS	/usr/ccs/bin/nm [–AChlnPprRsTuVv] [–efox] [–g –u] [–t format] file /usr/xpg4/bin/nm [–AChlnPprRsTuVv] [–efox] [–g –u] [–t format] file		
AVAILABILITY /usr/ccs/bin/nm	SUNWbtool		
/usr/xpg4/bin/nm	SUNWxcu4		
DESCRIPTION	The nm command displays the symbol table of each ELF object file that is specified by <i>file</i> . If no symbolic information is available for a valid input file, the nm utility will report that fact, but not consider it an error condition.		
OPTIONS	The output of nm may be controlled using the following options: -A Write the full path name or library name of an object on each line. -C Demangle C++ symbol names before printing them out. -e See NOTES below. -f See NOTES below. -g Write only external (global) symbol information. -h Do not display the output heading data. -l Distinguish between WEAK and GLOBAL symbols by appending a * to the key letter for WEAK symbols. -n Sort external symbols by name before they are printed. -o Print the value and size of a symbol in octal instead of decimal. (equivalent to -t o). -p Produce easy to parse, terse output. Each symbol name is preceded by its value (blanks if undefined) and one of the letters: A absolute symbol B bss (uninitialized data space) symbol C data object symbol F file symbol. N symbol has no type S section symbol T text symbol U undefined If the symbol's binding attribute is: LOCAL the key letter is hour eace		
	LOCALthe key letter is lower caseWEAKthe key letter is upper case; if the -l modifier is specified, the upper case key letter is followed by a *		

		GLOBAL the key let	ter is upper case.
	- P	Write information in put .	a portable output format, as specified in Standard Out -
	-r	Prepend the name of	the object file or archive to each output line.
	- R		e (if present), followed by the object file and symbol n is also specified, this option is ignored.
	— s	Print section name in	stead of section index.
	−t format		alue in the specified format. The format is dependent on sed as the <i>format</i> option-argument:
		o The offset is v	written in decimal (default). written in octal. written in hexadecimal.
	$-\mathbf{T}$	See NOTES below.	
/usr/ccs/bin/nm /usr/xpg4/bin/nm	u u	Print undefined symbols Print long listing for e	ools only. each undefined symbol. See OUTPUT below.
	- v	Sort external symbols	by value before they are printed.
	$-\mathbf{V}$	Print the version of the	ne nm command executing on the standard error output.
	- x	Print the value and si (equivalent to $-\mathbf{t} \mathbf{x}$).	ze of a symbol in hexadecimal instead of decimal
	where in t and – o and	may be used in any order, either singly or in combination, and may appear any- the command line. When conflicting options are specified (such as $-\mathbf{v}$ and $-\mathbf{n}$; nd $-\mathbf{x}$) the first is taken and the second ignored with a warning message to the $\mathbf{e} - \mathbf{R}$ for exception.)	
OPERANDS	The follow	wing operand is supported:	
	file	A path name of an object file, executable file or object-file library.	
OUTPUT Standard Output	For each s	symbol, the following information will be printed:	
	Index	The index of the sym	bol. (The index appears in brackets.)
	Value	The value of the syml	ool is one of the following:
		• alignment constrain	defined symbols in a relocatable file nts for symbols whose section index is SHN_COMMON a executable and dynamic library files.
	Size	The size in bytes of th	e associated object.
	Туре	A symbol is of one of	the following types:
		NOTYPE OBJECT FUNC SECTION	no type was specified a data object such as an array or variable a function or other executable code a section symbol

	FILE	name of the source file.		
Bind	The symbol's binding attributes.			
	LOCAL symbols	have a scope limited to the object file containing their definition		
	GLOBAL symbols WEAK symbols	are visible to all object files being combined are essentially global symbols with a lower precedence than GLOBAL .		
Other	A field reserved for	future use, currently containing 0 .		
Shndx	Except for three special values, this is the section header table index in relation to which the symbol is defined. The following special values exist:			
	ABS	indicates the symbol's value will not change through		
	COMMON	relocation indicates an unallocated block and the value provides alignment constraints		
	UNDEF	indicates an undefined symbol.		
Name	The name of the sym	ıbol		
Object N				
70.1 D	-	ect or library if – A is specified.		
portable		previous information is displayed using the following ions differ depending on whether –t d , –t o or –t x was		
-		<library name="" object="">, name, type, value, size</library>		
"	'%s%s %s %o %o∖n", <	library/object name>, name, type, value, size		
		library/object name>, name, type, value, size		
	ibrary/object name> is fo			
•	If –A is not specified,	library/object name> is an empty string.		
		the corresponding <i>file</i> operand does not name a library:		
"%s: ", file				
 If -A is specified and the corresponding <i>file</i> operand names a library. In this case, <<i>object file</i>> names the object file in the library containing the symbol being described: "%s[%s]: ", <i>file</i>, <<i>object file</i>> 				
If –A is not specified, then if more than one <i>file</i> operand is specified or if only one <i>file</i> operand is specified and it names a library, nm will write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:				
•	If the corresponding	file operand does not name a library:		
	"%s:\ n ", <i>file</i>			
•		<i>file</i> operand names a library; in this case, <i><object file=""></object></i> is the e library containing the following symbols:		
		modified 11 Apr 1995		

SunOS 5.5	User Commands nm (1)	1
	"%s[%s]:\n", <i>file</i> , <i><object file=""></object></i> If − P is specified, but − t is not, the format is as if − t x had been specified.	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of nm : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.	
SEE ALSO	ar(1), as(1), dump(1), ld(1), a.out(4), ar(4), environ(5)	
NOTES	The following options are obsolete because of changes to the object file format and will be deleted in a future release.	
	$-\mathbf{e}$ Print only external and static symbols. The symbol table now contains only static and external symbols. Automatic symbols no longer appear in the symbol table. They do appear in the debugging information produced by \mathbf{cc} – \mathbf{g} , which may be examined using $\mathbf{dump}(1)$.	
	-f Produce full output. Redundant symbols (such as .text, .data, and so forth). which existed previously do not exist and producing full output will be ident- ical to the default output.	
	-T By default, nm prints the entire name of the symbols listed. Since symbol names have been moved to the last column, the problem of overflow is removed and it is no longer necessary to truncate the symbol name.	

NAME	nohup – run a o	nohup – run a command immune to hangups			
SYNOPSIS		o command [arguments] aohup command [arguments]			
AVAILABILITY /usr/bin/nohup	SUNWcsu				
/usr/xpg4/bin/nohup	SUNWxcu4				
DESCRIPTION		ity invokes the named <i>command</i> with the arguments supplied. When the bked, nohup arranges for the SIGHUP signal to be ignored by the process.			
	user wants to lo SIGHUP signals background job	used when it is known that <i>command</i> will take a long time to run and the ogout of the terminal; when a shell exits, the system sends its children s, which by default cause them to be killed. All stopped, running, and so will ignore SIGHUP and continue running, if their invocation is pre- bhup command or if the process programmatically has chosen to ignore			
/usr/bin/nohup		y / usr/bin/nohup are immune to SIGHUP (hangup) and SIGQUIT (quit)			
/usr/xpg4/bin/nohup	•	signals. Processes run by / usr/xpg4/bin/nohup are immune to SIGHUP .			
		t arrange to make processes immune to a SIGTERM (terminate) signal, so ange to be immune to SIGTERM or the shell makes them immune to will receive it.			
	\$HOME/nohup see chmod(1)).	not writable in the current directory, output is redirected to .out . If a file is created, the file will have read and write permission (600 , If the standard error is a terminal, it is redirected to the standard output, not redirected. The priority of the process run by nohup is not altered.			
OPERANDS	The following o	operands are supported:			
	command	The name of a command that is to be invoked. If the <i>command</i> operand names any of the special shell_builtins (1) utilities, the results are undefined.			
	arguments	Any string to be supplied as an argument when invoking the <i>command</i> operand.			
EXAMPLES		desirable to apply nohup to pipelines or lists of commands. This can be lacing pipelines and command lists in a single file, called a shell script. sue:			
	-	le\$ nohup sh file			
		applies to everything in <i>file</i> . If the shell script <i>file</i> is to be executed often, o type sh can be eliminated by giving <i>file</i> execute permission.

NAME	nroff – format documents for display or line-printer				
SYNOPSIS	nroff	[-ehiq] [-m name] [-	•nN] [–opagelist] [–raN] [–sN] [–Tname]		
AVAILABILITY	SUNW	Vdoc			
DESCRIPTION	nroff	formats text in the nam	ned <i>files</i> for typewriter-like devices. See also troff (1).		
	If no fi	ile argument is present	, nroff reads the standard input. An argument consisting of e corresponding to the standard input.		
OPTIONS	Option	ns may appear in any c	order so long as they appear <i>before</i> the files.		
	- e	Produce equally-spa	ced words in adjusted lines, using full terminal resolution.		
	-h		racters during horizontal spacing to speed output and reduce ant. TAB settings are assumed to be every 8 nominal charac-		
	— i	Read the standard in	put after the input files are exhausted.		
	$-\mathbf{q}$	Invoke the simultane	eous input-output mode of the rd request.		
	- m nar				
		Prepend the macro file / usr/share/lib/tmac/tmac .name to the input files.			
		$-\mathbf{n}N$ Number first generated page N .			
	–opage	–opagelist Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range <i>N</i> – <i>M</i> means pages <i>N</i> through <i>M</i> ; an initial – <i>N</i> means from the beginning to page <i>N</i> ; and a final <i>N</i> – means from <i>N</i> to the end.			
	-raN	Set register a (one-ch	aracter) to N.		
	- s N		nroff will halt prior to every <i>N</i> pages (default <i>N</i> =1) to allow inging, and will resume upon receipt of a NEWLINE.		
	- T nan	1e			
		Prepare output for a	device of the specified <i>name</i> . Known <i>names</i> are:		
		37	Teletype Corporation Model 37 terminal — this is the default.		
		lp tn300	GE Any line printer or terminal without half-line capabil- ity.		
		300	DASI-300.		
		300-12 2005	DASI-300 — 12-pitch.		
		300S 300S-12	DASI-300S. DASI-300S.		
		382	DASI-3005. DASI-382 (fancy DTC 382).		
		450	DASI-450 (Diablo Hyterm).		
	450-12 DASI-450 (Diablo Hyterm) — 12-pitch.				
		832	AJ 832.		

modified 25 Feb 1994

EXAMPLE	The following command: example% nroff –s4 –m formats users.guide using the –n	e users.guide me macro package, and stopping every 4 pages.
FILES	/var/tmp/trtmp* /usr/share/lib/tmac/tmac.*	temporary file standard macro files
	/usr/share/lib/nterm/*	terminal driving tables for nroff
	/usr/share/lib/nterm/README	index to terminal description files

NOTES		naking nroff 8 -bit clean would require rewriting the some nroff syntax is based on ASCII only and does not ences.

modified 25 Feb 1994

NAME	od – octal dump
SYNOPSIS	<pre>/usr/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string] [-] [file] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-] [file] [offset_string] /usr/xpg4/bin/od [-bcCDdFfOoSsvXx] [-A address_base] [-j skip] [-N count] [-t type_string] [-] [file]</pre>
AVAILABILITY /usr/bin/od	SUNWtoo
/usr/xpg4/bin/od	SUNWxcu4
DESCRIPTION	The od command copies sequentially each input file to standard output and transforming the input data according to the output types specified by the -t or -bcCDdFfOoSsvXx options. If no output type is specified, the default output is as if -t o2 had been specified. Multiple types can be specified by using multiple -bcCDdFfOoSstvXx options. Output lines are written for each type specified in the order in which the types are specified. If no <i>file</i> is specified, the standard input is used. The [offset_string] operand is mutually exclusive from the -A , -j , -N , and -t options. For the purposes of this description, the following terms are used: word refers to a 16-bit unit, independent of the word size of the machine refers to a 32-bit unit refers to a 64-bit unit.
OPTIONS	The following options are supported:
	 -A address_base Specify the input offset base. The address_base option-argument must be a character. The characters d, o and x specify that the offset base will be written in decimal, octal or hexadecimal, respectively. The character n specifies that the offset will not be written. Unless -A n is specified, the output line will be preceded by the input offset, cumulative across input files, of the next byte to be written. In addition, the offset of the byte following the last byte written will be displayed after all the input data has been processed. Without the -A address_base option and the [offset_string] operand, the input offset base is displayed in octal. -b Interpret bytes in octal. This is equivalent to -t o1.
/usr/bin/od	-c Display single-byte characters. Certain non-graphic characters appear as C-
, csr/bh/od	Ianguage escapes: null \0 backspace \b form-feed \f

1-736

		return tab others appear as echo "hello worl	\n \r \t 3-digit octal numbers. For example: d" od -c l o world \n
/usr/xpg4/bin/od	- c	setting of the LC_ ten in the area co sequence ** is wi character, as an i	s single-byte or multibyte characters according to the current CTYPE locale category. Printable multibyte characters are writ- rresponding to the first byte of the character; the two character ritten in the area corresponding to each remaining byte in the ndication that the character is continued. Non-graphic charac- ame as they would using the $-\mathbf{C}$ option.
	- C	setting of the LC_ ten in the area co sequence ** are v	Single-byte or multibyte characters according to the current CTYPE locale category. Printable multibyte characters are writ- rresponding to the first byte of the character; two character written in the area corresponding to each remaining byte in the ndication that the character is continued. Certain non-graphic r as C escapes:
		backspace formfeed newline return	\0 \b \f \n \r \t
		Other non-printa byte in the charac	ble characters appear as one three-digit octal number for each cter.
	$-\mathbf{d}$	Interpret words i	n unsigned decimal. This is equivalent to – t u2 .
	- D	Interpret long wo	ords in unsigned decimal. This is equivalent to -t u4 .
	-f	Interpret long wo	ords in floating point. This is equivalent to -t f4 .
	$-\mathbf{F}$	Interpret double	long words in extended precision. This is equivalent to $-t f8$.
	–j skip	read or seek past bined input is no	ytes from the beginning of the input. The od command will the first <i>skip</i> bytes in the concatenated input files. If the com- t at least <i>skip</i> bytes long, the od command will write a diagnos- undard error and exit with a non-zero exit status.
		leading 0x or 0X , with a leading 0 , the character b , k 512 , 1024 or 1048	<i>ip</i> option-argument is interpreted as a decimal number. With a the offset is interpreted as a hexadecimal number; otherwise, the offset will be interpreted as an octal number. Appending a or m to offset will cause it to be interpreted as a multiple of 576 bytes, respectively. If the <i>skip</i> number is hexadecimal, any nsidered to be the final hexadecimal digit. The address is

displayed starting at **0000000**, and its base is not implied by the base of the *skip* option-argument.

-N count

Format no more than *count* bytes of input. By default, *count* is interpreted as a decimal number. With a leading 0x or 0X, *count* is interpreted as a hexadecimal number; otherwise, with a leading 0, it is interpreted as an octal number. If *count* bytes of input (after successfully skipping, if -j *skip* is specified) are not available, it will not be considered an error; the **od** command will format the input that is available. The base of the address displayed is not implied by the base of the *count* option-argument.

- -o Interpret words in octal. This is equivalent to -t o2.
- -O Interpret long words in unsigned octal. This is equivalent to -t o4.
- -s Interpret words in signed decimal. This is equivalent to -t d2.
- -S Interpret long words in signed decimal. This is equivalent to -t d4.

-t type_string

Specify one or more output types. The *type_string* option-argument must be a string specifying the types to be used when writing the input data. The string must consist of the type specification characters:

a *Named character.* Interpret bytes as named characters. Only the least significant seven bits of each byte will be used for this type specification. Bytes with the values listed in the following table will be written using the corresponding names for those characters.

Value	Name	Value	Name	Value	Name	Value	Name
\000	nul	∖001	soh	∖002	stx	∖003	etx
\004	eot	∖005	enq	\006	ack	∖007	bel
\010	bs	∖011	ht	∖012	lf	∖013	vt
∖014	ff	∖015	cr	∖016	SO	∖017	si
∖020	dle	∖021	dc1	∖022	dc2	∖023	dc3
∖024	dc4	∖025	nak	∖026	syn	∖027	etb
\030	can	∖031	em	∖032	sub	∖033	esc
∖034	fs	∖035	gs	∖036	rs	∖037	us
∖040	sp	\177	del				

Named Characters in od

Character. Interpret bytes as single-byte or multibyte characters specified by the current setting of the LC_CTYPE locale category. Printable multibyte characters are written in the area corresponding to the first byte of the character; the two character sequence ** is written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. Certain non-graphic characters appear as C escapes: \0, \a, \b, \f, \n, \r, \t, \v. Other non-printable characters appear as one three-digit octal number for each byte in the character.

SunOS 5.5	User Commands	od (1)
	The type specification characters d , f , o , u and x can be follow unsigned decimal integer that specifies the number of bytes t by each instance of the output type.	
	f <i>Floating point</i> . Can be followed by an optional F , D or I conversion should be applied to an item of type float , d ble , respectively.	
	d, o, u and x Signed decimal, octal, unsigned decimal, and hexadecimal, a be followed by an optional C, S, I or L indicating that the should be applied to an item of type char, short, int or D	ne conversion
	Multiple types can be concatenated within the same <i>type_strin</i> options can be specified. Output lines are written for each ty order in which the type specification characters are specified.	pe specified in the
	 -v Show all input data (verbose). Without the -v option, all gro that would be identical to the immediately preceding output byte offsets), will be replaced with a line containing only an a 	line (except for
	$-\mathbf{x}$ Interpret words in hex. This is equivalent to $-\mathbf{t} \mathbf{x} 2$.	
	-X Interpret long words in hex. This is equivalent to -t x4.	
OPERANDS	The following operands are supported:	
	 Use the standard input in addition to any f When this operand is not given, the standa only if no <i>file</i> operands are specified. 	
/usr/bin/od	<i>file</i> A path name of a file to be read. If no <i>file</i> o specified, the standard input will be used. more than two operands, none of the –A, – is specified, and <i>any</i> of the following are training of the following are	If there are no j, –N or –t options
	1. the first character of the last operand	d is a plus sign (+)
	2. the first character of the second open	rand is numeric
	3. the first character of the second oper second character of the second oper hexadecimal character or digit	
	4. the second operand is named " x "	
	5. the second operand is named "." then the corresponding operand is assume operand rather than a file operand.	d to be an offset
	Without the – N count option, the display c end-of-file is reached.	ontinues until an

/usr/xpg4/bin/od	file	Same as / usr/bin/od , except only one of the first two condi- tions must be true.
/usr/bin/od	[+] [0] offset [.] [b B] [+] [0] [offset] [.] [+] [0x x] [offset] [+] [0x x] offset [B]	The <i>offset_string</i> operand specifies the byte offset in the file where dumping is to commence. The offset is interpreted in octal bytes by default. If <i>offset</i> begins with " 0 ", it is interpreted in octal. If <i>offset</i> begins with " x " or " 0x ", it is interpreted in hexadecimal and any appended " b " is considered to be the final hexadecimal digit. If "." is appended, the offset is inter- preted in decimal. If " b " or " B " is appended, the offset is inter- preted in units of 512 bytes. If the <i>file</i> argument is omitted, the <i>offset</i> argument must be preceded by a plus sign (+). The address is displayed starting at the given offset. The radix of the address will be the same as the radix of the offset, if specified, otherwise it will be octal. Decimal overrides octal, and it is an error to specify both hexadecimal and decimal conversions in the same offset operand.
/usr/xpg4/bin/od	<pre>[+] [0] offset [.] [b B] + [offset] [.] [+][0x] [offset] [+][0x] offset [B] +x [offset] +xoffset [B]</pre>	Description of <i>offset_string</i> is the same as for / usr/bin/od .
ENVIRONMENT		criptions of the following environment variables that affect the exe- E, LC_MESSAGES, LC_NUMERIC, and NLSPATH.
EXIT STATUS		ies are returned: Successful completion. An error occurred.

NAME	pack, pcat, unpack – compress and expand files			
SYNOPSIS	pack [- f] [-] <i>file</i>			
	pcat file			
	unpack file			
AVAILABILITY	SUNWesu			
DESCRIPTION				
pack	The pack command attempts to store the specified files in a compressed form. Wherever possible (and useful), each input file <i>file</i> is replaced by a packed file <i>file</i> .z with the same access modes, access and modified dates, and owner as those of <i>file</i> . If pack is successful, <i>file</i> will be removed.			
	The amount of compression obtained depends on the size of the input file and the charac- ter frequency distribution. Because a decoding tree forms the first part of each .z file, it is usually not worthwhile to pack files smaller than three blocks, unless the character fre- quency distribution is very skewed, which may occur with printer plots or pictures.			
	Typically, text files are reduced to 60-75% of their original size. Load modules, which use a larger character set and have a more uniform distribution of characters, show little compression, the packed versions being about 90% of the original size.			
	pack returns a value that is the number of files that it failed to compress.			
	No packing will occur if:			
	• the file appears to be already packed			
	 the file name has more than {NAME_MAX} - 2 bytes the file has links 			
	• the file is a directory			
	• the file cannot be opened			
	the file is emptyno disk storage blocks will be saved by packing			
	 a file called <i>file.z</i> already exists 			
	• the <i>.z</i> file cannot be created			
	• an I/O error occurred during processing.			
	The last segment of the file name must contain no more than {NAME_MAX} - 2 bytes to allow space for the appended .z extension. Directories cannot be compressed.			
pcat	The pcat command does for packed files what cat (1) does for ordinary files, except that pcat cannot be used as a filter. The specified files are unpacked and written to the standard output.			
	pcat returns the number of files it was unable to unpack. Failure may occur if:			
	 the file cannot be opened; the file does not appear to be the output of pack. 			

modified 1 Feb 1995

unpack	The unpack command expands files created by pack . For each <i>file</i> specified in the command, a search is made for a file called <i>file.z</i> (or just <i>file</i> , if <i>file</i> ends in .z). If this file appears to be a packed file, it is replaced by its expanded version. The new file has the suffix stripped from its name, and has the same access modes, access and modification dates, and owner as those of the packed file.			
	unpack returns a value that is the number of files it was unable to unpack. Failure may occur for the same reasons that it may in pcat , as well as for the following:			
	 a file with the "unpacked" name already exists; the unpacked file cannot be created. the filename (excluding of the .z extension) has more than {NAME_MAX} bytes 			
OPTIONS	The following options are supported by pack :			
	 -f Forces packing of <i>file</i>. This is useful for causing an entire directory to be packed even if some of the files will not benefit. Packed files can be restored to their original form using unpack or pcat. 			
OPERANDS	The following operands are supported:			
	<i>file</i> A path name of a file to be packed, unpacked, or pcated; <i>file</i> can include or omit the .z suffix.			
	 pack uses Huffman (minimum redundancy) codes on a byte-by-byte basis. If the – argument is used, an internal flag is set that causes the number of times each byte is used, its relative frequency, and the code for the byte to be printed on the standard output. Additional occurrences of – in place of <i>file</i> will cause the internal flag to be set and reset. 			
EXAMPLES	To view a packed file named file.z use:			
	example% pcat file.z			
	or just:			
	example% pcat file			
	To make an unpacked copy, say nnn , of a packed file named file.z (without destroying file.z) use the command:			
	example% pcat file >nnn			
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of pack , pcat , and unpack : LC_CTYPE , LC_MESSAGES , and NLSPATH .			
EXIT STATUS	The following exit values are returned:			
	 0 Successful completion. >0 An error occurred. The number of files the command failed to pack/unpack is returned.

AVAILABILITY	SUNWcsu
DESCRIPTION	 The passwd command changes the password or lists password attributes associated with the user's login <i>name</i>. Additionally, privileged users may use passwd to install or change passwords and attributes associated with any login <i>name</i>. When used to change a password, passwd prompts everyone for their old password, if any. It then prompts for the new password twice. When the old password is entered, passwd checks to see if it has "aged" sufficiently. If "aging" is insufficient, passwd terminates; see pwconv(1M), nistbladm(1), and shadow(4) for additional information. The pwconv command creates and updates /etc/shadow with information from /etc/passwd. pwconv relies on a special value of 'x' in the password field of /etc/passwd. This value of 'x' indicates that the password for the user is already in /etc/shadow and should not be modified. If aging is sufficient, a check is made to ensure that the new password meets construction requirements. When the new password is entered a second time, the two copies of the new password are compared. If the two copies are not identical the cycle of prompting for the new password must have at least six characters. Only the first eight characters are significant. PASSLENGTH is found in /etc/default/passwd and is set to 6. Each password must contain at least two alphabetic characters and at least one numeric or special character. In this case, "alphabetic" refers to all upper or lower case letters. Each password must differ from the user's login <i>name</i> and any reverse or circular shift of that login <i>name</i>. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

modified 24 Oct 1994

• New passwords must differ from the old by at least three characters. For comparison purposes, an upper case letter and its corresponding lower case letter are equivalent.

If all requirements are met, by default, the **passwd** command will consult /**etc/nsswitch.conf** to determine in which repositories to perform password update. It searches the **passwd** and **passwd_compat** entries. The sources (repositories) associated with these entries will be updated. However, the password update configurations supported are limited to the following 5 cases. Failure to comply with the configurations will prevent users from logging onto the system.

- passwd: files
- passwd: files nis
- passwd: files nisplus
- passwd: compat (==> files nis)
- passwd: compat (==> files nisplus)
- passwd_compat: nisplus

Network administrators, who own the NIS+ password table, may change any password attributes.

In **files** case, super-users (for instance, real and effective uid equal to zero, see **id**(1M) and **su**(1M)) may change any password; hence, **passwd** does not prompt privileged users for the old password. Privileged users are not forced to comply with password aging and password construction requirements. A privileged user can create a null password by entering a carriage return in response to the prompt for a new password. (This differs from **passwd** –d because the "password" prompt will still be displayed.)

Any user may use the -s option to show password attributes for his or her own login *name*. Provided they are using the -r **nisplus** argument. Otherwise the -s argument is restricted to the super-user.

The format of the display will be:

name status mm/dd/yy min max warn

or, if password aging information is not present,

name status

where

name The login ID of the user.

status The password status of *name*: **PS** stands for passworded or locked, **LK** stands for locked, and **NP** stands for no password.

mm/dd/yy

The date password was last changed for *name*. (Note that all password aging dates are determined using Greenwich Mean Time (Universal Time) and, therefore, may differ by as much as a day in other time zones.)

min The minimum number of days required between password changes for *name*. **MINWEEKS** is found in /etc/default/passwd and is set to NULL.

modified 24 Oct 1994

	max warn	The maximum number of days the password is valid for <i>name</i> . MAXWEEKS is found in /etc/default/passwd and is set to NULL. The number of days relative to <i>max</i> before the password expires and the <i>name</i> will be warned.
OPTIONS	- r	Specifies the repository to which an operation is applied. The supported repositories are files , nis , or nisplus .
	- e	Change the login shell.
	-g	Change the gecos (finger) information.
	-h	Change the home directory.
	–D domainname	Consult the passwd.org_dir table in <i>domainname</i> . If this option is not specified, the default <i>domainname</i> returned by nis_local_directory (3N) will be used. This domain name is the same as that returned by domainname (1M).
	−s name	Show password attributes for the login <i>name</i> . For the nisplus repository, this works for everyone. However for the files repository, this only works for the super-user. It does not work at all for the nis repository which does not support password aging.
	-a	Show password attributes for all entries. Use only with the -s option; <i>name</i> must not be provided. For nisplus repository, this will show only the entries in the NIS+ passwd table in the local domain that the invoker is authorized to "read". For the files repository, this is restricted to the super-user.
Privileged User	Only a privilege	d user can use the following options:
Options	- f	Force the user to change password at the next login by expiring the password for <i>name</i> .
	- l	Locks password entry for name.
	− n min	Set minimum field for <i>name</i> . The <i>min</i> field contains the minimum number of days between password changes for <i>name</i> . If <i>min</i> is greater than <i>max</i> , the user may not change the password. Always use this option with the $-\mathbf{x}$ option, unless <i>max</i> is set to -1 (aging turned off). In that case, <i>min</i> need not be set.
	-w warn	Set warn field for <i>name</i> . The <i>warn</i> field contains the number of days before the password expires and the user is warned.
	-x max	Set maximum field for <i>name</i> . The <i>max</i> field contains the number of days that the password is valid for <i>name</i> . The aging for <i>name</i> will be turned off immediately if <i>max</i> is set to -1 . If it is set to 0 , then the user is forced to change the password at the next login session and aging is turned off.
	-d	Deletes password for <i>name</i> . The login <i>name</i> will not be prompted for password. It is only applicable to the files repository.

modified 24 Oct 1994

ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE,LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, theoperational behavior of passwd for each corresponding locale category is determined bythe value of the LANG environment variable. If LC_ALL is set, its contents are used tooverride both the LANG and the other LC_* variables. If none of the above variables is setin the environment, the "C" (U.S. style) locale determines how passwd behaves.LC_CTYPEDetermines how passwd can display and handle text and filenames contain-			
	ir E ca 1,	ng valid characters fo xtended Unix Code an be 1, 2, or 3 bytes	or that locale. passwd can display and handle (EUC) characters where any individual character wide. passwd can also handle EUC characters of widths. In the "C" locale, only characters from ISO	
	T fc sa	his includes the lang orm of affirmative ar	nostic and informative messages are presented. guage and style of the messages, and the correct ad negative responses. In the "C" locale, the mes- the default form found in the program itself (in sh).	
EXIT STATUS	 The passwd command exits with one of the following values: success. Permission denied. Invalid combination of options. Unexpected failure. Password file unchanged. Unexpected failure. Password file(s) missing. Password file(s) busy. Try again later. Invalid argument to option. 			
FILES	/etc/oshadow /etc/passwd /etc/shadow /etc/default/passw		rd file. an be set for the following flags in swd . For example: MAXWEEKS=26	
		MAXWEEKS	Maximum time period that password is valid.	
		MINWEEKS	Minimum time period before the password can be changed.	
		PASSLENGTH	Minimum length of password, in characters.	
		WARNWEEKS	Time period until warning of date of password's ensuing expiration.

modified 24 Oct 1994

NOTES The **passwd** command replaces the **nispasswd** and **yppasswd** commands and should be used in their place.

modified 24 Oct 1994

NAME	paste – merge corresponding or subsequent lines of files				
SYNOPSIS	paste [-s] [-d list] file				
AVAILABILITY	SUNWesu				
DESCRIPTION	The paste utility will concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.				
	The default operation of paste will concatenate the corresponding lines of the input files. The NEWLINE character of every line except the line from the last input file will be replaced with a TAB character.				
	If an EOF (end-of-file) condition is detected on one or more input files, but not all input files, paste will behave as though empty lines were read from the files on which EOF was detected, unless the $-s$ option is specified.				
OPTIONS	The following options are supported:				
	 -d <i>list</i> Unless a backslash character (\) appears in <i>list</i>, each character in <i>list</i> is an element specifying a delimiter character. If a backslash character appears in <i>list</i>, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default TAB character, to replace the NEWLINE character of the input lines. The elements in <i>list</i> are used circularly; that is, when the list is exhausted the first element from the list is reused. 				
	When the $-\mathbf{s}$ option is specified:				
	• The last newline character in a file will not be modified.				
	• The delimiter will be reset to the first element of list after each <i>file</i> operand is processed.				
	When the option is not specified:				
	• The NEWLINE characters in the file specified by the last <i>file</i> will not be modified.				
	• The delimiter will be reset to the first element of list each time a line is processed from each file.				
	If a backslash character appears in <i>list</i> , it and the character following it will be used to represent the following delimiter characters:				
	 Newline character. Tab character. Backslash character. Empty string (not a null character). If \0 is immediately followed by the character x, the character X, or any character defined by the LC_CTYPE digit keyword, the results are unspecified.

	For each patched file, a reject file may also be created as noted in the absence of a $-\mathbf{r}$ option, the name of this file will be formed by .rej to the original filename.		
Patchfile Format	The patch file must contain zero or more lines of header informat more patches. Each patch must contain zero or more lines of file the format produced by diff – c , and one or more sets of diff out tomarily called hunks.	ename identification in	
	patch recognizes the following expression in the header informa	ition:	
	Index: <i>pathname</i> The file to be patched is named <i>path</i>	name.	
	If all lines (including headers) within a patch begin with the sam blank characters, patch will remove this sequence before proceed if the type of difference is context, patch recognizes the following	ding. Within each patch,	
	*** filename timestamp The patches arose from filename.		
	filename timestamp The patches should be applied to file	ename.	
	Each hunk within a patch must be the diff output to change a lir nal file. The line numbers for successive hunks within a patch m order.		
Filename	If no <i>file</i> operand is specified, patch performs the following steps	s to obtain a path name:	
Determination	 If the patch contains the strings *** and, patch strip beginning of each path name (depending on the presence option), then tests for the existence of both files in the cu tory specified with the -d option). 	e or value of the – p	
	2. If both files exist, patch assumes that no path name can listep. If the header information contains a line with the s components from the beginning of the path name (dependent of the existence of this file in the current directory (or d the - d option).	string Index: , patch strips nding on – p), then tests	

	 If an SCCS directory exists in the current directory, patch will attempt to perform a get -e SCCS/s.filename command to retrieve an editable version of the file. If no path name can be obtained by applying the previous steps, or if the path names obtained do not exist, patch will write a prompt to standard output and request a filename interactively from standard input.
Patch Application	If the $-c$, $-e$ or $-n$ option is present, patch will interpret information within each hunk as a context difference, an ed difference or a normal difference, respectively. In the absence of any of these options, patch determines the type of difference based on the format of information within the hunk.
	For each hunk, patch begins to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, patch scans both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.
	If no such place is found and it is a context difference, then another scan will take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context will be ignored and another scan will be made. Implementations may search more extensively for installation locations.
	If no location can be found, patch will append the hunk to the reject file. The rejected hunk will be written in context-difference format regardless of the format of the patch file. If the input was a normal or ed - style difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they will reflect the approximate locations for the failed hunks in the new file rather than the old one.
	If the type of patch is an ed diff, the implementation may accomplish the patching by invoking the ed command.
EXIT STATUS	 The following exit values are returned: 0 Successful completion. 1 One or more lines were written to a reject file. >1 An error occurred.

NAME	pathchk – check path names		
SYNOPSIS	pathchk [–p] path		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The pathchk command will check that one or more path names are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation will result). More extensive portability checks are provided by the – p option.		
	By default, pathchk will check each component of each <i>path</i> operand based on the under- lying file system. A diagnostic will be written for each <i>path</i> operand that:		
	 is longer than PATH_MAX bytes. 		
	 contains any component longer than NAME_MAX bytes in its containing directory 		
	 contains any component in a directory that is not searchable 		
	 contains any character in any component that is not valid in its containing directory. 		
	The format of the diagnostic message is not specified, but will indicate the error detected and the corresponding <i>path</i> operand.		
	It will not be considered an error if one or more components of a <i>path</i> operand do not exist as long as a file matching the path name specified by the missing components could be created that does not violate any of the checks specified above.		
OPTIONS	The following option is supported:		
	 -p Instead of performing checks based on the underlying file system, write a diagnostic for each <i>path</i> operand that: 		
	 is longer than _POSIX_PATH_MAX bytes 		
	 contains any component longer than _POSIX_NAME_MAX bytes 		
	 contains any character in any component that is not in the portable filename character set. 		
OPERANDS	The following operand is supported:		
	path A path to be checked.		

modified 1 Feb 1995

EXAMPLES To verify that all paths in an imported data interchange archive are legitimate and unambiguous on the current system: pax –f archive | sed –e '/ == .*/s///' | xargs pathchk if [\$? -eq 0] then pax -r -f archive else echo Investigate problems before importing files. exit 1 fi To verify that all files in the current directory hierarchy could be moved to any system conforming to the X/Open specification that also supports the pax(1) command: find . - print | xargs pathchk - p if [\$? -eq 0] then pax -w -f archive. else echo Portable archive cannot be created. exit 1 fi To verify that a user-supplied path names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file: case \$- in *C*) reset="";; reset="set +C" *) set -C:: esac test -r "\$path" && pathchk "\$path.out" && rm "\$path.out" > "\$path.out" if [\$? -ne 0]; then printf "%s: %s not found or %s.out fails \ creation checks.\n" \$0 "\$path" "\$path" Sreset # reset the noclobber option in case a trap # on EXIT depends on it exit 1 fi Sreset PROCESSING < "\$path" > "\$path.out" The following assumptions are made in this example: 1. **PROCESSING** represents the code that will be used by the application to use **\$path** once it is verified that **\$path.out** will work as intended.

modified 1 Feb 1995

	The state of the noclobber option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The reset variable is used in this example to restore the initial state.)	
	Note the usage of:	
	rm "\$path.out" > "\$path.out"a.The pathchk command has already verified, at this point, that \$path.outwill not be truncated.	
	b. With the noclobber option set, the shell will verify that \$path.out does not already exist before invoking rm .	
	c. If the shell succeeded in creating \$path.out , rm will remove it so that the application can create the file again in the PROCESSING step.	
	 d. If the PROCESSING step wants the file to exist already when it is invoked, the: rm "Spath.out" > "Spath.out" 	
	should be replaced with: > "\$path.out"	
	which will verify that the file did not already exist, but leave Spath.out in place for use by PROCESSING .	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of pathchk : LC_CTYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	The following exit values are returned:	
	0 All <i>path</i> operands passed all of the checks.	
	>0 An error occurred.

NAME	pathconv – search FMLI criteria for filename		
SYNOPSIS	pathconv [–f] [–v alias] pathconv [–t] [–l] [–n <i>num</i>] [–v string]		
DESCRIPTION	The pathconv function converts an alias to its pathname. By default, it takes the alias as a string from the standard input.		
OPTIONS	 -f If -f is specified, the full path will be returned (this is the default). -t If -t is specified, pathconv will truncate a pathname specified in <i>string</i> in a format suitable for display as a frame title. This format is a shortened version of the full pathname, created by deleting components of the path from the middle of the string until it is under DISPLAYW — 6 characters in length, and then inserting ellipses () between the remaining pieces. Ellipses are also used to show truncation at the ends of the strings if necessary, unless the -l option is given. -l If -l is specified, < and > will be used instead of ellipses () to indicate truncation at the ends of the string generated by the -t option. Using -l allows display of the longest possible string while still notifying users it has been truncated. -nnum If -n is specified, <i>num</i> is the maximum length of the string (in characters) generated by the -t option. The argument <i>num</i> can be any integer from 1 to 255. -valias string If the -v option is used, then alias or string can be specified when pathconv is called. The argument alias must be an alias defined in the <i>alias_file</i> named when fmli was invoked. The argument <i>string</i> can only be used with the -t option and must be a pathname. 		
EXAMPLES	Here is a menu descriptor that uses pathconv to construct the menu title. It searches for MYPATH in the <i>alias_file</i> named when fmli was invoked: menu=`pathconv –v MYPATH/ls` where there is a line in <i>alias_file</i> that defines MYPATH . For example, MYPATH=\$HOME/bin:/usr/bin . Here is a menu descriptor that takes <i>alias</i> from the standard input. menu=`echo MYPATH/ls pathconv`

NAME	pax – portable archive interchange		
SYNOPSIS	<pre>pax [-cdnv] [-f archive] [-s replstr] [pattern] pax -r [-cdiknuv] [-f archive] [-o options] [-p string] [-s replstr] [pattern] pax -w [-dituvX] [-b blocksize] [-a] [-f archive] [-o options] [-s replstr] [-x format] [file] pax -r -w [-diklntuvX] [-p string] [-s replstr] [file] directory</pre>		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The pax command reads, writes and writes lists of the members of archive files and copy directory hierarchies. A variety of archive formats are supported; see the $-\mathbf{x}$ format option.		
Modes of Operations	directory hierarchies. A variety of archive formats are supported; see the – x <i>format</i>		

		one of the files to be copied, the results are unspecified. It is an error if <i>ectory</i> doesn't to exist, is not writable by the user, or is not a directory.
		y modes, if intermediate directories are necessary to extract an archive will perform actions equivalent to the mkdir (2) function, called with the iments:
	• the i	intermediate directory used as the <i>path</i> argument
		octal value of 777 or rwx (read, write, and execute permissions) as the <i>mode</i> ument (see chmod (1)).
	member, pax v	d <i>pattern</i> or <i>file</i> operands are not matched by at least one file or archive will write a diagnostic message to standard error for each one that did not t with a non-zero exit status.
	The supported archive format	l archive formats are automatically detected on input. The default output t is tar (1).
	these files can	archive format supports the specification of linked files, it is an error if not be linked when the archive is extracted. Any of the various names in at represent a file can be used to select the file for extraction.
OPTIONS	The following	options are supported:
	- r	Read an archive file from standard input.
	-w	Write files to the standard output in the specified archive format.
	-a	Append files to the end of the archive. This option will not work for some archive devices, such as 1/4-inch streaming tapes and 8mm tapes.
	-b blocksize	Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking is automatically determined on input. Portable applications must not specify a <i>blocksize</i> value larger than 32256 . Default blocking when creating archives depends on the archive format. (See the – x option below.)
	- c	Match all file or archive members except those specified by the <i>pattern</i> or <i>file</i> operands.
	-d	Cause files of type directory being copied or archived or archive members of type directory being extracted to match only the file or archive member itself and not the file hierarchy rooted at the file.
	-f archive	Specify the path name of the input or output archive, overriding the default standard input (in list or read modes) or standard output (write mode).
	- i	Interactively rename files or archive members. For each archive member matching a <i>pattern</i> operand or file matching a <i>file</i> operand, a prompt will be written to the file / dev/tty . The prompt will contain the name of the file or archive member. A line will then be read from / dev/tty . If this line is blank, the file or archive member will be skipped.

	If this line consists of a single period, the file or archive member will be processed with no modification to its name. Otherwise, its name will be replaced with the contents of the line. The pax command will immediately exit with a non-zero exit status if end-of-file is encountered when reading a response or if / dev / tty cannot be opened for reading and writing.
- k	Prevent the overwriting of existing files.
-1	Link files. In copy mode, hard links will be made between the source and destination file hierarchies whenever possible.
- n	Select the first archive member that matches each <i>pattern</i> operand. No more than one archive member will be matched for each pattern (although members of type directory will still match the file hierarchy rooted at that file).
–o options	Reserved for special format-specific options.
- p string	Specify one or more file characteristic options (privileges). The <i>string</i> option-argument must be a string specifying file characteristics to be retained or discarded on extraction. The string consists of the specification characters a , e , m , o and p . Multiple characteristics can be concatenated within the same string and multiple – p options can be specified. The meaning of the specification characters are as follows:
	a Do not preserve file access times.
	e Preserve the user ID, group ID, file mode bits, access time, and modification time.
	m Do not preserve file modification times.
	• Preserve the user ID and group ID.
	p Preserve the file mode bits. Other, implementation-dependent file-mode attributes may be preserved.
	In the preceding list, "preserve" indicates that an attribute stored in the archive will be given to the extracted file, subject to the permissions of the invoking process; otherwise, the attribute will be determined as part of the normal file creation action.
	If neither the e nor the o specification character is specified, or the user ID and group ID are not preserved for any reason, pax will not set the setuid and setgid bits of the file mode.
	If the preservation of any of these items fails for any reason, pax will write a diagnostic message to standard error. Failure to preserve these items will affect the final exit status, but will not cause the extracted file to be deleted.
	If file-characteristic letters in any of the <i>string</i> option-arguments are duplicated or conflict with each other, the ones given last will take precedence. For example, if $-\mathbf{p}$ eme is specified, file modification times will

	be preserve	ed.	
−s replstr	according t ed(1) s (sub the regex(5)	or archive member names named by <i>pattern</i> or <i>file</i> operands o the substitution expression <i>replstr</i> , which is based on the ostitution) command, using the regular expression syntax on) manual page. The concepts of "address" and "line" are s in the context of the pax command, and must not be sup- format is:	
	−s / ol	ld/new/ [gp]	
	ampersand	h ed, <i>old</i> is a basic regular expression and <i>new</i> can contain an (&) or a n backreference, where <i>n</i> is a digit. The <i>old</i> string nitted to contain newline characters.	
	Any non-null character can be used as a delimiter (/ shown here). Mul- tiple – s expressions can be specified; the expressions will be applied in the order specified, terminating with the first successful substitution. The optional trailing g is as defined in the ed command. The optional trailing p causes successful substitutions to be written to standard error. File or archive member names that substitute to the empty string are ignored when reading and writing archives.		
-t		access times of the archived files to be the same as they were g read by pax .	
- u	Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name.		
	read mode	an archive member with the same name as a file in the file system will be extracted if the archive member is newer than the file.	
	write mode	an archive file member with the same name as a file in the file system will be superseded if the file is newer than the archive member.	
	copy mode	the file in the destination hierarchy will be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.	
$-\mathbf{v}$		e, produce a verbose table of contents (see Standard Output). write archive member path names to standard error (see rror).	
- x format	Specify the following f	output archive format. The pax command recognizes the ormats:	
	-	The extended cpio interchange format; see the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 5120 . Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512 .	

		ustar	The extended tar interchange format; see the IEEE 1003.1(1990) specifications. The default <i>blocksize</i> for this format for character special archive files is 10240 . Implementations support all <i>blocksize</i> values less than or equal to 32256 that are multiples of 512 .
			Any attempt to append to an archive file in a format different from the existing archive format will cause pax to exit immediately with a non-zero exit status.
	- X		versing the file hierarchy specified by a path name, pax will not nto directories that have a different device ID (st_dev , see
	–v) interact as f user-specified p and –i options	ollows. In p attern opera will modify	in the names of files or archive members $(-c, -i, -n, -s, -u \text{ and})$ read mode, the archive members are selected based on the ands as modified by the $-c, -n$ and $-u$ options. Then, any $-s$, in that order, the names of the selected files. The $-v$ option from these modifications.
	by the – n and –	u options.	selected based on the user-specified path names as modified Then, any $-s$ and $-i$ options will, in that order, modify the s. The $-v$ option will write names resulting from these
			ns are specified, pax does not consider a file selected unless it iich it is compared.
OPERANDS	The following c	perands ar	e supported:
	directory	The destin	nation directory path name for copy mode.
	file	A path na	me of a file to be copied or archived.
	pattern	pattern m fnmatch(matching one or more path names of archive members. A ust conform to the pattern matching notation found on the 5) manual page. The default, if no <i>pattern</i> is specified, is to nembers in the archive.
OUTPUT			
Standard Output			pecified, the standard output will be the archive formatted (See $-\mathbf{x}$ format.)
	dard output us	ing the follo	
		' <pathname< th=""><th></th></pathname<>	
	· ·		in list mode, the table of contents of the selected archive standard output using the following formats:
	For path names	representii	ng hard links to previous members of the archive:

	"%s∆==∆	% s\n " < <i>ls –l listing>, linkname</i>
	For all other path	names:
	<pathnam< p=""></pathnam<>	e> "%s\n" <ls-l listing=""></ls-l>
	writing path nam underlying archiv	g> is the format specified by the ls command with the – l option. When es in this format, it is unspecified what is written for fields for which the re format does not have the correct information, although the correct character-separated fields will be written.
	In list mode, stan	dard output will not be buffered more than a line at a time.
Standard Error		n read, write or copy modes, pax will write the path names it processes ror output using the following format:
	member, and will	will be written as soon as processing is begun on the file or archive be flushed to standard error. The trailing newline character, which will will be written when the file has been read or written.
		specified, and the replacement string has a trailing p , substitutions will dard error in the following format:
	input archive for	odes of pax , optional messages of unspecified format concerning the nat and volume number, the number of files, blocks, volumes and ell as other diagnostic messages may be written to standard error.
		both standard output and standard error, it is unspecified how non- ers in path names or linknames are written.
ERRORS	writing an archiv option is specified exit status will be	te a file or a link when reading an archive or cannot find a file when e, or cannot preserve the user ID, group ID or file mode when the -p l, a diagnostic message will be written to standard error and a non-zero returned, but processing will continue. In the case where pax cannot ile, pax will not, by default, create a second copy of the file.
	pax may have on have extracted a f file the user want	f a file from an archive is prematurely terminated by a signal or error, y partially extracted the file or (if the $-n$ option was not specified) may ile of the same name as that specified by the user, but which is not the ed. Additionally, the file modes of extracted directories may have addine read, write, execute mask set as well as incorrect modification and
USAGE	and cpio (1) imple opposed ways. T which future file	s) option was invented to reconcile differences between historical $tar(1)$ mentations. In particular, the two utilities use $-m$ in diametrically he $-p$ option also provides a consistent means of extending the ways in attributes can be addressed, such as for enhanced security systems or e files. Although it may seem complex, there are really two modes that nonly used:
	-	'Preserve everything''. This would be used by the historical superuser, comeone with all the appropriate privileges, to preserve all aspects of he files as they are recorded in the archive. The e flag is the sum of o

	–р р	and p , and other implementation-dependent attributes. "Preserve" the file mode bits. This would be used by the user with reg- ular privileges who wished to preserve aspects of the file other than the ownership. The file times are preserved by default, but two other flags are offered to disable these and use the time of extraction.
EXAMPLES	The following c	ommand:
	exampl	e pax –w –f /dev/rmt/1m .
		ents of the current directory to tape drive 1, medium density (assuming m V device naming procedures. The historical BSD device name would be
	The following c	ommands:
	exampl	e% mkdir newdir example% pax –rw olddir newdir
	copy the olddir	directory hierarchy to newdir .
		e pax –r –s `,^//*usr//*,,` –f a.pax re a.pax , with all files rooted in / usr in the archive extracted relative to the y.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the cution of pax : LC_CTYPE , LC_MESSAGES , LC_TIME , and NLSPATH .	
	LC_COLLATE	Determine the locale for the behaviour of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the <i>pattern</i> operand, the basic regular expression for the –s option, and the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.
EXIT STATUS	The following e	xit values are returned:
	-	iles were processed successfully.
	>0 An e	error occurred.

NAME	pcmapkeys – set keyboard extended map and scancode translation for the PC console in text mode
SYNOPSIS	pcmapkeys [-f mapfile -n -g -d -e]
AVAILABILITY	x86 SUNWcsu
DESCRIPTION	pcmapkeys is a utility that permits a user to activate character mapping on input and output and keyboard extended mapping on the PC console in text mode. The keyboard extended mapping consists of the support for the deadkey and compose key sequences.
Consistent Keyboard-Display Mapping	 The original UNIX operating system was written to support the ASCII codeset. ASCII is one of many standards to represent a number of characters internally as certain numbers. Typical for ASCII is that it supports 128 different characters, each represented by a single byte of which the 8th bit is not used. Many UNIX system applications, including the shell, took advantage of this. Starting with UNIX System V Release 3.1, most of these applications have been modified to properly support characters represented as a byte with the 8th bit set as well. This means that now 256 characters can be supported at the same time. However, a consistent coding convention needs to be applied. In the IBM PC world, an 8-bit coding referred to as IBM extended ASCII has been used for several years; MS-DOS users are quite familiar with that. In heterogeneous UNIX system environments, a different codeset, called ISO 8859, has been promoted. In both codesets, characters found in the ASCII codeset are represented in the same way. The other 128 characters are encoded differently, however, and some characters found in one codeset will be missing in the other. The Solaris for x86 system supports both codesets; actually, it supports any 8-bit one byte codeset. To be able to use characters from the French, German, Finnish, and other alphabets, there are systems available on the market that generate 7-bit codes but display the abovementioned characters on the screen instead of the ones found on a U.S. console. On the keyboard there are enequal number of keys, but there are different characters on the key caps. Others may support 256 different characters at a time but use their own proprietary codesets. For example, if you are using the Solaris for x86 system with a console and a French keyboard and you do not use pcmapkeys to map the French keyboard tables, then if you edit a file and use the French character <i>é</i> in text, the actual code generated is ASCII 123, which is the code normally used for t
	Output mapping

On output, any byte can be mapped to either a byte or a string. In the above example, 130 would be mapped back to 123 to properly display the character on the screen. If the connected device is a printer that does not support the *é* character, it could be mapped to the string '**e BACKSPACE**'.

Deadkeys

On typewriters, keys can be found that behave slightly differently than all the others, because when you press them, the printing wheel of the typewriter does not move. Ctrl ([^]) and the grave accent ([^]) are such characters. When [^] is followed by an *e*, the letter *è* is generated. This is called a deadkey or a non-spacing character. Solaris for x86 supports the use of deadkeys. Typically, the [^] character, the [^] character, and the umlaut character are used as deadkeys.

Compose sequences

Characters can also be generated using a compose sequence. A dedicated character called the "compose character" followed by two other keystrokes will generate a single character. As an example, COMPOSE followed by the plus and the minus sign could generate the plus/minus sign (±). Compose sequences can also be used as an alternative for deadkeys, e.g., "COMPOSE [^] e" instead of "[^] e."

Numeric compose sequences

Compose sequence characters that are not present on the keyboard and cannot be intuitively composed by some key sequence, for example, graphics characters, can be generated by pressing the compose key followed by three digits.

Toggle key

An optional toggle key can be defined to temporarily disable the current mapping from within an application. This can be useful when, for example, a German programmer wants easy access to the curly braces and the brackets. Use of the toggle key is analogous to the use of the $-\mathbf{d}$ and $-\mathbf{e}$ command line options.

Scancode MappingThe keyboards of the console and some other peripherals such as SunRiver workstations
behave differently than those of regular terminals. They generate what are called *scan-
codes* and you will also find a number of keys on these keyboards, such as the Alt key,
that are not found on regular terminals. Scancodes generated by PC keyboards typically
represent the location of the key on the keyboard. The keyboard driver has to properly
translate these scancodes. The different national variants of a PC keyboard not only have
non-English characters printed on some of the keycaps, but the order of some of the keys
is different as well. Without changing the scancode translation, a French user would type
A and see Q on his screen. Several status keys can influence the translated code as well.
The keyboard driver, and thus the **pcmapkeys** program, makes a distinction between two
sets of key combinations that can be translated.

Function keys

Up to 60 key combinations are recognized as function keys. The first 12 are the 12 function keys of a 101-key PC-keyboard (the first 10 on an 84-key keyboard).

If you do not know whether you have an 84- or 101-key keyboard, you can use the following scheme to determine which type you have:

If your keyboard has arrow keys that are separate from the ones on the numeric keypad, then you have a 101-key keyboard.

If the arrow keys on your keyboard are located on the numeric keypad only, then you have an 84-key keyboard.

F13 to F24 are the same keys used in combination with Shift, F25 to F36 when used with Ctrl, and F37 to F48 when used with Ctrl and Shift together. F49 to F60 are the keys on the numeric keypad, in the following order:

Each of these function keys can be given a string as a value. The total length of all strings should not exceed 512 characters.

Regular keys

Scancodes generated by all keys on the PC keyboard can be translated in a different way as well. For each key, a different translation can be specified for each of the following four cases:

1. The key is pressed.

2. The key and the Shift key are pressed simultaneously.

3. The key and the Alt key are pressed simultaneously.

4. The key, the Shift, and the Alt keys are pressed simultaneously.

For each of these cases, the scancode can be translated into one of the following:

a single byte a single byte preceded by ESC N a single byte preceded by ESC O a single byte preceded by ESC [

Internally, special bits are set to indicate that an escape sequence needs to be generated. Other bits are used to indicate whether the translated code should be influenced by some special keys.

Num Lock

If the Num Lock bit is set, the regular and Shift values are swapped, as are the Alt and Shift Alt values, whenever the Num Lock LED is on. By default, only the keys on the numeric keypad have this bit set. That is why these keys generate 7,

8, 9, etc. when the Num Lock LED is on, which is the same value that would be produced if Shift were used with these keys.

Caps Lock

This has the same effect as the Num Lock key. By default, this bit is set for all letters and not set for punctuation signs.

Ctrl When a key is translated into a single byte (no escape sequence) and this bit is set, the corresponding control character will be generated when the Ctrl key is pressed simultaneously. This is equally valid for the Shift, Alt, and Shift Alt combination. When this bit is not used, the Ctrl key combination will not generate anything.

mapfile This section describes the layout of a *mapfile* that is read by the **pcmapkeys** program.

A *mapfile* is a text file that consists of several **sections**. A sharp sign (#) can be used to include comments. Everything following the # until the end of the line will be ignored by the **pcmapkeys** program. Inside a line, C-style comments can be used as well. The beginning of each section is indicated by a *keyword*. Spaces and tabs are silently ignored and can be used at all times to improve readability. All but one section, the one that defines the *compose character*, can be left out. The order in which the different sections should appear is predefined. Here is the list of keywords in the order they should appear:

input: toggle: dead: compose: output: scancodes:

Characters can be described in several different ways. ASCII characters can be described by putting them between single quotes. For example:

'a' '{'

Between single quotes, control characters can be listed by using a circumflex sign before the character that needs to be quoted. For example:

`^x'

When a backslash ($\)$ is used, what follows will be interpreted as a decimal, octal (leading zero), or hexadecimal (leading x or X) representation of the character, although in this case the use of single quotes is not mandatory. For example:

'**x88**'

is the same as:

0x88 (zero needed when not quoted)

and:

'**\007**'

is the same as:

007

When strings are needed, a list of character representations should be used. Quoted strings will be supported in the future.

The following paragraphs describe what goes in each section.

Input section

The input section describes which input characters should be mapped into a single byte. A very small sample input section could be:

input:

'A' 'B' # map A into B on input

'#' 0x9c # map sharp sign into pound sign

Toggle section

The toggle section is a one-line section that defines which key is to toggle between mapping and no mapping. For example:

toggle:

'^y' # ctrl y is the toggle key

Deadkey section

The deadkey section defines which keys should be treated as deadkeys. A **dead:** keyword followed by the specification of the character appears in this section for each deadkey. The subsequent lines describe what key should be generated for each key following the deadkey. A deadkey followed by a key not described in this part of the *mapfile* will not generate any key and a beep tone will be produced on the terminal. For example:

dead:	,~,	# circumflex is a deadkey
,,	,~,	# circumflex followed by space generates circumflex
'e'	0x88	# circumflex followed by e generates e circumflex
dead:	,",	# double quote used as a deadkey
,,	,,,,	# double quote space generates double quote
'a'	0x84	# double quote a generates an umlaut

Compose section

The first line of this section describes what the compose character is. That line should always be present in the *mapfile*. Subsequent lines consist of three character representations indicating each time that the third character needs to be generated on input when the compose character is followed by the first two. Compose sequences with the same first character should be grouped together. For example:

compose: '^x'

,",	`е'	0x89	# e with umlaut is generated when typing ^x " e
,",	'a'	0x84	# a with umlaut
'e'	, , ,	0x89	# e with umlaut is generated when typing ^x e "
'a'	,",	0x84	# a with umlaut

The following example would give the wrong result. All lines starting with the same character specification should be grouped together.

compose:	`^X
compose.	

,",	`е'	0x89	# e with umlaut is generated when typing `x " e
'e'	,,,,	0x89	# e with umlaut is generated when typing `x e "
,",	'a'	0x84	# a with umlaut
'a'	,",	0x84	# a with umlaut

Output section

This section describes the mapping on output, either single byte to single byte, or single byte to string. A string is specified as a series of character specifications. For example:

output:	
0x82 '{'	# map e with accent to { to display e with accent
`^u` '(''K''I''L'''L'')'	<pre># print (KILL) when kill character is used</pre>

Scancodes section

This section will only have an effect when your terminal is a scancode device. No error message will be produced if this section is in your *mapfile* when not needed, because the **pcmapkeys** program will find out whether the terminal is a scancode device or not. The lines in this section can have two different formats. One format will be used to describe what the values of the function keys must be. The other format describes the translation of scancodes into a byte or an escape sequence. No specific order is required.

Function keys

Here is an example of a line defining a string for a function key:

F13 'd''a''t''e''0 # Shift F1 is the date command

The numbering convention of the function keys is described in a previous section. Currently, the use of quoted strings such as " $date \ n$ " is not supported.

Scancodes

Specifying how to translate a scancode is a more complex task. The general format of such a line is:

scancode normal shift alt shiftalt flags

scancode should list the hexadecimal representation of a scancode generated by a key (unquoted). How keys correspond with scancodes can be found in **keyboard**(7D).

normal, **shift**, **alt** and **shiftalt** are character representations in one of the formats described throughout this document, optionally followed by one of the following special keywords:

| C This indicates that the key is influenced by the Ctrl key.

| N This indicates that Esc N should preceed the specified character.

| O This indicates that Esc O should preceed the specified character.

| [This indicates that Esc [should preceed the specified character.

The **normal** field defines how the scancode is translated when no other key is pressed, the **shift** field defines the translation for when the Shift key is used simultaneously, the **alt** field specifies what to do when the Alt key is pressed together with this and the **shiftalt** field contains the information on what to generate when both the Shift and Alt keys are

	active translat optional. This whether or no sample line th 0x10 'q' C '' If the normal	must be filled in. When no translation is requested (that is, the current tion does not need to be changed) a dash (–) can be used. The sixth field is is field can contain the special keyword CAPS or NUM or both, to indicate of the Caps Lock key or Num Lock key status have any effect. Here is a nat describes the default translation for the ' Q ' key: $\mathbf{Q}' \mathbf{C}'\mathbf{q}' \mathbf{N}'\mathbf{Q}' \mathbf{N}'CAPS$ or shift field is filled out for a scancode that represents a function key, a bry message will be produced and that translation information will be
	A more detail	ed example of a scancodes section is:
	<pre># left square # control shif 0x1a '[' C '{ # 9 on numer</pre>)' '9' N '9' N NUM
	More complet tory.	te examples of <i>mapfile</i> s can be found in the / usr/share/lib/keyboards direc-
OPTIONS	-f mapfile	Installs the contents of the file <i>mapfile</i> and sets the corresponding map- ping as supported by the console driver. The layout of the <i>mapfile</i> and the supported functionality are described below.
	-n	Disables and dismantles the current keyboard extended mapping. The $-f$ option must be used to re-install the keyboard extended mapping.
	-g	Displays the current mappings and keyboard extended mapping (if one is installed) in hex values (see / usr/include/sys/emap.h). This option is mainly used for debugging purposes.
	− d and − e	- d temporarily disables the compose key and deadkey sequences if the keyboard extended mapping is installed. The keyboard extended mapping can be enabled again by using the – e option (or it can be reinstalled by using the – f option).
FILES	/usr/share/lib	/ keyboards/8859 /* sample mapfiles to be used in conjunction with ISO-8859-1 fonts (see loadfont (1))
	/usr/share/lib	/ keyboards/437 /* sample mapfiles to be used in conjunction with IBM 437 fonts (see loadfont (1))

modified 11 Jul 1994

SEE ALSO loadfont(1)

NOTES

The default keyboard mappings on the system are those of the ISO 8859-1 codeset. The optional IBM DOS 437 codeset is supported *only* at internationalization level 1. That is, if you choose to download keyboard mappings of the optional IBM DOS 437 codeset, there will be no support for non-standard U.S. date, time, currency, numbers, unit, and collation. There will be no support for non-English message and text presentation, and no multi-byte character support. Therefore, non-Windows users should only use IBM DOS 437 codeset in the default C locale.

NAME	pg – files perus	sal filter for CRTs
SYNOPSIS	pg [–number]	[- p string][- cefnrs][+linenumber][+/pattern/][filename]
AVAILABILITY	SUNWcsu	
DESCRIPTION		nd is a filter that allows the examination of <i>filenames</i> one screenful at a time e user types a RETURN, another page is displayed; other possibilities are
		is different from previous paginators in that it allows you to back up and ing that has already passed. The method for doing this is explained below.
		erminal attributes, pg scans the terminfo (4) data base for the terminal type e environment variable TERM . If TERM is not defined, the terminal type ned.
OPTIONS	-number	An integer specifying the size (in lines) of the window that pg is to use instead of the default. (On a terminal containing 24 lines, the default window size is 23).
	– p string	pg uses <i>string</i> as the prompt. If the prompt string contains a % d , the first occurrence of % d in the prompt will be replaced by the current page number when the prompt is issued. The default prompt string is ":".
	- c	Home the cursor and clear the screen before displaying each page. This option is ignored if clear_screen is not defined for this terminal type in the terminfo (4) data base.
	- e	pg does <i>not</i> pause at the end of each file.
	-f	Normally, pg splits lines longer than the screen width, but some sequences of characters in the text being displayed (for instance, escape sequences for underlining) generate undesirable results. The – f option inhibits pg from splitting lines.
	-n	Normally, commands must be terminated by a <i><newline></newline></i> character. This option causes an automatic end of command as soon as a command letter is entered.
	-r	Restricted mode. The shell escape is disallowed. pg prints an error message but does not exit.
	- S	pg prints all messages and prompts in the standard output mode (usu- ally inverse video).
	+linenumber	Start up at <i>linenumber</i> .
	+/pattern/	Start up at the first line containing the regular expression pattern.

OPERANDS	The following operands are supported:		
	filename	A path name of a text file to be displayed. If no <i>filename</i> is given, or if it is –, the standard input is read.	
USAGE Commands		that may be typed when pg pauses can be divided into three categories: urther perusal, those that search, and those that modify the perusal	
	signed number <i>address</i> is interp <i>address</i> specifies specifies an add	t cause further perusal normally take a preceding <i>address</i> , an optionally indicating the point from which further text should be displayed. This preted in either pages or lines depending on the command. A signed is a point relative to the current page or line, and an unsigned <i>address</i> dress relative to the beginning of the file. Each command has a default used if none is provided.	
	The perusal cor	nmands and their defaults are as follows:	
	(+1)< <i>newline</i> > o		
		This causes one page to be displayed. The address is specified in pages.	
	(+1) l	With a relative address this causes pg to simulate scrolling the screen, forward or backward, the number of lines specified. With an absolute address this command prints a screenful beginning at the specified line.	
	(+1) d or ^D	Simulates scrolling half a screen forward or backward.	
	if	Skip <i>i</i> screens of text.	
	iz	Same as < <i>newline</i> > except that <i>i</i> , if present, becomes the new default number of lines per screenful.	
	The following p	perusal commands take no <i>address</i> .	
	. or ^L	Typing a single period causes the current page of text to be redisplayed.	
	\$	Displays the last windowful in the file. Use with caution when the input is a pipe.	
	ular expression	commands are available for searching for text patterns in the text. The reg- s are described on the regexp (5) manual page. They must always be ter- <i>newline</i> >, even if the $-n$ option is specified.	
	i/pattern/	Search forward for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately after the current page and continues to the end of the current file, without wrap-around.	
	î patternî î?pattern?	Search backwards for the <i>i</i> th (default <i>i</i> =1) occurrence of <i>pattern</i> . Searching begins immediately before the current page and continues to the beginning of the current file, without wrap-around. The ^ notation is useful for Adds 100 terminals which will not properly handle the ?.	

	After searching, pg will normally display the line found at the top of the screen. This can be modified by appending m or b to the search command to leave the line found in the middle or at the bottom of the window from now on. The suffix t can be used to restore the original situation.	
	The user of pg can modify the environment of perusal with the following commands:	
	in	Begin perusing the <i>i</i> th next file in the command line. The <i>i</i> is an unsigned number, default value is 1.
	ip	Begin perusing the <i>i</i> th previous file in the command line. <i>i</i> is an unsigned number, default is 1.
	iw	Display another window of text. If <i>i</i> is present, set the window size to <i>i</i> .
	s filename	Save the input in the named file. Only the current file being perused is saved. The white space between the s and <i>filename</i> is optional. This command must always be terminated by a <i><newline></newline></i> , even if the <i>-n</i> option is specified.
	h	Help by displaying an abbreviated summary of available commands.
	${f q}$ or ${f Q}$	Quit pg .
	!command	<i>Command</i> is passed to the shell, whose name is taken from the SHELL environment variable. If this is not available, the default shell is used. This command must always be terminated by a <i><newline></newline></i> , even if the <i>-n</i> option is specified.
	mally CTRL-\) o display the pron manner. Unfort	en output is being sent to the terminal, the user can hit the quit key (nor- r the interrupt (break) key. This causes pg to stop sending output, and npt. The user may then enter one of the above commands in the normal unately, some output is lost when this is done, because any characters erminal's output queue are flushed when the quit signal occurs.
		output is not a terminal, then pg acts just like cat (1), except that a header e each file (if there is more than one).
EXAMPLES	The following co	ommand line uses pg to read the system news:
	0	e% news pg –p "(Page %d):"
ENVIRONMENT		or descriptions of the following environment variables that affect the exeCTYPE, LC_MESSAGES, and NLSPATH.
	The following e	nvironment variables affect the execution of pg :
	COLUMNS	Determine the horizontal screen size. If unset or NULL, use the value of TERM , the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.
	LINES	Determine the number of lines to be displayed on the screen. If unset or NULL, use the value of TERM, the window size, baud rate, or some combination of these, to indicate the terminal type for the screen size calculation.

g(1)	User Commands		SunOS 5.5
	SHELL	Determine the name of the command interpreter execu mand.	ted for a !com-
	TERM	Determine terminal attributes. Optionally attempt to se dependent database, keyed on the value of the TERM er able. If no information is available, a terminal incapabl addressable movement is assumed.	nvironment vari-
EXIT STATUS	The following	g exit values are returned:	
	0 Successfu	ul completion.	
	>0 An error	occurred.	
FILES	/tmp/pg* /usr/share/lib	temporary file when input is from a pipe p/terminfo/?/* terminal information database	
SEE ALSO	cat(1), grep(1), more(1), terminfo(4), environ(5), regexp(5)	
NOTES	minating exec and place the being read fro the pipeline. The terminal If terminal tak When using p	g for terminal input, pg responds to BREAK, CTRL-C, and C cution. Between prompts, however, these signals interrupt is user in prompt mode. These should be used with caution om a pipe, since an interrupt is likely to terminate the other /, ^, or ? may be omitted from the searching commands. bs are not set every eight positions, undesirable results may pg as a filter with another command that changes the terminate as may not be restored correctly.	pg 's current task when input is commands in y occur.

NAME	pkginfo – display software package information		
SYNOPSIS	[–c catego pkginfo [–d de	-x -l][-p -i][-r][-a arch][-v version] ry1, [category2 [,]]] [pkginst [, pkginst [,]]] vice][-R root_path][-q -x -l][-a arch][-v version] ry1 , [category2 [,]]] [pkginst [, pkginst [,]]]	
AVAILABILITY	SUNWcsu		
DESCRIPTION		ys information about software packages which are installed on the system ynopsis) or which reside on a particular device or directory (with the s).	
		tes a package by its instance. An instance can be the package abbreviation tance (for example, inst.1 or inst.beta). All instances of package can be st. *.	
	Remember that "*" is a special character to some shells and may need to be escaped.		
	For C-Shell users, the "*" character must be surrounded by single quotes ('), or preceded by a backslash ().		
	•	s, pkginfo lists the primary category, package instance, and the names of nstalled and partially installed packages. It displays one line for each d.	
OPTIONS	The – p and – i o	ptions are meaningless if used in conjunction with the $-\mathbf{d}$ option.	
	The options – q ,	- x , and - l are mutually exclusive.	
	- q	Do not list any information. Used from a program to check whether or not a package has been installed.	
	- x	Designate an extracted listing of package information. The listing con- tains the package abbreviation, package name, package architecture (if available) and package version (if available).	
	- l	Specify long format, which includes all available information about the designated package(s).	
	$-\mathbf{p}$	Display information for partially installed packages only.	
	— i	Display information for fully installed packages only.	
	- r	List the installation base for relocatable packages.	
	- a arch	Specify the architecture of the package as <i>arch</i> .	
	−v version	Specify the version of the package as <i>version</i> . All compatible versions can be requested by preceding the version name with a tilde (~). Multiple white spaces are replaced with a single white space during version comparison.	
	-c category	Display packages that match the category category. Categories are	

modified 9 May 1995

		defined in the category field of the pkginfo file. If more than one category is supplied, the package needs to match only one category in the list. The match is not case specific.
	-d device	Defines a device, <i>device</i> , on which the software resides. <i>device</i> can be an absolute directory pathname or the identifiers for tape, floppy disk, removable disk, and so forth. The special token spool may be used to indicate the default installation spool directory (/ var/spool/pkg).
	- R root_path	Defines the full path name of a subdirectory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> .
SEE ALSO	pkgtrans(1), pl	kgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M)

modified 9 May 1995

NAME	pkgmk – produce an installable package		
SYNOPSIS	pkgmk [–o] [–a arch] [–b basdir] [–d device] [–f prototype] [–l limit] [–p pstamp] [–r rootpath] [–v version] [variable=value] [pkginst]		
DESCRIPTION	pkgmk produces an installable package to be used as input to the pkgadd command. The package contents will be in directory structure format.		
	The command uses the package prototype file as input and creates a pkgmap file. The contents for each entry in the prototype file is copied to the appropriate output location. Information concerning the contents (checksum, file size, modification date) is computed and stored in the pkgmap file, along with attribute information specified in the prototype file.		
OPTIONS	-0	Overwrite the same instance, package instance will be overwritten if it already exists.	
	– a arch	Override the architecture information provided in the pkginfo file with <i>arch</i> .	
	– b basdir	Prepend the indicated <i>basedir</i> to locate relocatable objects on the source machine.	
	-d device	Create the package on <i>device</i> . <i>device</i> can be an absolute directory path- name or the identifiers for a floppy disk or removable disk (for example, / dev/diskette). The default device is the installation spool directory (/ var/spool/pkg).	
	-f prototype	Use the file prototype as input to the command. The default prototype filename is [Pp]rototype .	
	–1 limit	Specify the maximum size in 512 byte blocks of the output device as <i>limit.</i> By default, if the output file is a directory or a mountable device, pkgmk will employ the df command to dynamically calculate the amount of available space on the output device. This option is useful in conjunction with pkgtrans to create package with datastream format.	
	– p pstamp	Override the production stamp definition in the pkginfo file with <i>pstamp</i> .	
	– r rootpath	Ignore destination paths in the prototype file. Instead, use the indicated <i>rootpath</i> with the source pathname appended to locate objects on the source machine.	
	–v version	Override the version information provided in the pkginfo file with <i>ver-</i> <i>sion</i> .	
	variable=value	Place the indicated variable in the packaging environment. (See proto-type (4) for definitions of packaging variables.)	
	pkginst	Specifies the package by its instance. An instance can be the package abbreviation or a specific instance (for example, inst.1).	

modified 5 Jul 1990

SEE ALSO | pkgparam(1), pkgproto(1), pkgtrans(1)

NOTES Architecture information is provided on the command line with the **–a** option or in the **prototype** file. If no architecture information is supplied, **pkgmk** uses the output of **uname –m**.

Version information is provided on the command line with the -v option or in the **proto-type** file. If no version information is supplied, a default based on the current date will be provided.

Command line definitions for both architecture and version override the **prototype** definitions.

NAME	pkgparam – di	splays package parameter values	
SYNOPSIS	pkgparam [–v] [–R root_path] [–d device] pkginst [param] pkgparam –f filename [–v] [param]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	pkgparam displays the value associated with the parameter or parameters requested on the command line. The values are located in either the pkginfo file for <i>pkginst</i> or from the specific file named with the –f option.		
	One parameter value is shown per line. Only the value of a parameter is given unless the $-v$ option is used. With this option, the output of the command is in this format:		
	parameter1='value1' parameter2='value2' parameter3='value3'		
	If no parameters are specified on the command line, values for all parameters associated with the package are shown.		
OPTIONS	Options and ar	guments for this command are:	
	$-\mathbf{v}$	Verbose mode. Display name of parameter and its value.	
	– R root_path	Defines the full path name of a subdirectory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> .	
	-d device	Specify the <i>device</i> on which a <i>pkginst</i> is stored. It can be a directory path- name or the identifiers for tape, floppy disk or removable disk (for example, / var/tmp , / dev/diskette , and / dev/dsk/c1d0s0). The special token spool may be used to represent the default installation spool directory (/ var/spool/pkg).	
	- f filename	Read <i>filename</i> for parameter values.	
	pkginst	Defines a specific package instance for which parameter values should be displayed.	
	param	Defines a specific parameter whose value should be displayed.	
ERRORS	If parameter information is not available for the indicated package, the command exits with a non-zero status.		
SEE ALSO	pkgtrans(1), pl	kgmk(1), pkgparam(1), pkgproto(1)	
NOTES	extracted. This	is allows you to specify the file from which parameter values should be is file should be in the same format as a pkginfo file. As an example, such a reated during package development and used while testing software dur-	

NAME	pkgproto – generate prototype file entries for input to pkgmk command		
SYNOPSIS	pkgproto [- i] [- c <i>class</i>] [<i>path1</i>]		
	pkgproto [-i] [-c class] [path1=path2]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	pkgproto scans the indicated paths and generates prototype file entries that may be used as input to the pkgmk command.		
OPTIONS	 -i Ignores symbolic links and records the paths as ftype=f (a file) versus ftype=s(symbolic link) 		
	-c <i>class</i> Maps the class of all paths to <i>class</i> .		
	<i>path1</i> Pathname where objects are located.		
	<i>=path2</i> Pathname which should be substituted on output for <i>path1</i> .		
	If no paths are specified on the command line, standard input is assumed to be a list of paths. If the pathname listed on the command line is a directory, the contents of the directory is searched. However, if input is read from stdin , a directory specified as a pathname will not be searched.		
EXAMPLES	The following two examples show uses of pkgproto and a partial listing of the output produced		
	The following two examples show uses of pkgproto and a partial listing of the output produced. Example 1: example% pkgproto /bin=bin /usr/bin=usrbin /etc=etc f none bin/sed=/bin/sed 0775 bin bin f none bin/sed=/bin/sed 0775 bin bin f none bin/sh=/bin/sort 0755 bin daemon f none bin/sort=/bin/sort 0755 bin bin f none usrbin/sdb=/usr/bin/sdb 0775 bin bin f none usrbin/sdb=/usr/bin/shl 4755 bin bin d none etc/master.d 0755 root daemon f none etc/master.d/kernel=/etc/master.d/kernel 0644 root daemon f none etc/cr=/etc/rc 0744 root daemon Example 2: example% find / -type d -print pkgproto d none / 755 root root d none /usr 755 root root d none /usr/bin 775 bin bin d none /usr/bin 775 bin bin d none /usr/bin 775 bin bin d none /tmp 777 root root		

NOTES

SEE ALSO pkgmk(1), pkgparam(1), pkgtrans(1)

By default, **pkgproto** creates symbolic link entries for any symbolic link encountered (ftype=s). When you use the –**i** option, **pkgproto** creates a file entry for symbolic links (ftype=f). The **prototype** file would have to be edited to assign such file types as "v" (volatile), "e" (editable), or "x" (exclusive directory). **pkgproto** detects linked files. If multiple files are linked together, the first path encountered is considered the source of the link.

By default, **pkgproto** prints prototype entries on the standard output. However, the output should be saved in a file (named **Prototype** or **prototype**, for convenience) to be used as input to the **pkgmk** command.

NAME	pkgtrans	– translate package format
SYNOPSIS	pkgtrans	[-inos] device1 device2 [pkginst1 [pkginst2]]
AVAILABILITY	SUNWcs	u
DESCRIPTION	pkgtrans translates an installable package from one format to another. It translates:	
	а	file system format to a datastream
	а	datastream to a file system format
	C	one file system format to another file system format
OPTIONS	The optic	ons and arguments for this command are:
	- i	Copy only the pkginfo and pkgmap files.
	-n	Create a new instance of the package on the destination device if any instance of this package already exists, up to the number specified by
	-0	Overwrite the same instance on the destination device; package instance will be overwritten if it already exists.
	- s	Indicates that the package should be written to <i>device2</i> as a datastream rather than as a file system. The default behavior is to write a file system format on devices that support both formats.
	device1	Indicates the source device. The package or packages on this device will be translated and placed on <i>device2</i> .
	device2	Indicates the destination device. Translated packages will be placed on this device.
	pkginst	Specifies which package instance or instances on <i>device1</i> should be translated. The token all may be used to indicate all packages. <i>pkginst.</i> * can be used to indicate all instances of a package. If no packages are defined, a prompt shows all packages on the device and asks which to translate.
EXAMPLES	ES The following example translates all packages on the floppy drive / dev/diskette a places the translations on / tmp .	
	e	xample% pkgtrans /dev/diskette /tmp all
	The next example translates packages pkg1 and pkg2 on / tmp and places their transla- tions (that is, a datastream) on the 9track1 output device.	
	example% pkgtrans /tmp 9track1 pkg1 pkg2	
	The next example translates pkg1 and pkg2 on / tmp and places them on the diskette in a datastream format.	
	e	xample% pkgtrans –s /tmp /dev/diskette pkg1 pkg2

- **ENVIRONMENT** The **MAXINST** variable is set in the pkginfo file and declares the maximum number of package instances.
 - SEE ALSO pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), installf(1M), pkgadd(1M), pkgask(1M), pkgrm(1M), removef(1M)

Application Packaging Developers Guide

NOTES Device specifications can be either the special node name (for example, /dev/diskette) or a device alias (for example, diskette1). The device spool indicates the default spool directory. Source and destination devices cannot be the same.

By default, **pkgtrans** will not translate any instance of a package if any instance of that package already exists on the destination device. Using the -n option creates a new instance if an instance of this package already exists. Using the -o option overwrites an instance of this package if it already exists. Neither of these options are useful if the destination device is a datastream.

postdaisy (1)	User Commands Sur			
NAME	postdaisy	postdaisy – PostScript translator for Diablo 630 daisy-wheel files		
SYNOPSIS	[- p	$ [-\mathbf{c} num] [-\mathbf{f} num] [-\mathbf{h} num] [-\mathbf{m} num] [-\mathbf{n} num] [-\mathbf{o} list] mode] [-\mathbf{r} num] [-\mathbf{s} num] [-\mathbf{v} num] [-\mathbf{x} num] [-\mathbf{y} num] [file] $		
	/usr/lib/lj	p/postscript/postdaisy		
DESCRIPTION	results on	laisy filter translates Diablo 630 daisy-wheel <i>files</i> into PostScript and writes the the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the input is read.		
OPTIONS	–c num	Print <i>num</i> copies of each page. By default only one copy is printed.		
	-f name	Print <i>files</i> using font <i>name</i> . Any PostScript font can be used, although the best results will be obtained only with constant-width fonts. The default font is Courier.		
	– h num	Set the initial horizontal motion index to <i>num</i> . Determines the character advance and the default point size, unless the $-s$ option is used. The default is 12 .		
	- m num	Magnify each logical page by the factor <i>num</i> . Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0 .		
	–n num	Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1 .		
	–o list	Print pages whose numbers are given in the comma-separated <i>list</i> . The list contains single numbers N and ranges $N1 - N2$. A missing $N1$ means the lowest numbered page, a missing $N2$ means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4 , then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4 , when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.		
	- p mode	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.		
	- r num	Selects carriage return and line feed behavior. If <i>num</i> is 1, a line feed generates a carriage return. If <i>num</i> is 2, a carriage return generates a line feed. Setting <i>num</i> to 3 enables both modes.		
	− s num	Use point size <i>num</i> instead of the default value set by the initial horizontal motion index.		
	–v num	Set the initial vertical motion index to <i>num</i> . The default is 8 .		
	−x num	Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive <i>num</i> moves		
1-792		modified 15 Mar 1994		

	everything right. The default offset is 0.25 inches.			
	-y <i>num</i> Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves text up the page. The default offset is - 0.25 inches.

postdmd(1)	User Commands			
NAME	postdmd	postdmd – PostScript translator for DMD bitmap files		
SYNOPSIS		[-b num] [-c num] [-f] [-m num] [-n num] [-o list] [-p mode] num] [-y num] [file]		
	/usr/lib/lj	o/postscript/postdmd		
DESCRIPTION	postdmd translates DMD bitmap <i>files</i> , as produced by <i>dmdps</i> , or <i>files</i> written in the Ninth Edition bitfile (9.5) format into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is read.			
OPTIONS	- b num	- b <i>num</i> Pack the bitmap in the output file using <i>num</i> byte patterns. A value of 0 turns off all packing of the output file. By default, <i>num</i> is 6 .		
	–c num	Print num copies of each page. By default only one copy is printed	•	
	- f	Flip the sense of the bits in <i>files</i> before printing the bitmaps.		
	 m num Magnify each logical page by the factor num. Pages are scaled uniformly about the origin, which by default is located at the center of each page. The default magnification is 1.0. n num Print num logical pages on each piece of paper, where num can be any possinteger. By default num is set to 1. o list Print pages whose numbers are given in the comma-separated list. The list contains single numbers N and ranges N1 – N2. A missing N1 means the lowest numbered page, a missing N2 means the highest. The page range is expression of logical pages rather than physical sheets of paper. For examif you are printing two logical pages to a sheet, and you specified a range then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet then only page 3 and page 4 layouts would print, and they would appear on physical sheet of paper. 			
			any positive	
			ans the range is an or example, range of 4 , s. If you o a sheet;	
	- p mode	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the first charactis significant. The default <i>mode</i> is portrait.	ter of <i>mode</i>	
	−x num	Translate the origin <i>num</i> inches along the positive x axis. The defaurate system has the origin fixed at the center of the page, with positight and positive y up the page. Positive <i>num</i> moves everything r default offset is 0 inches.	tive x to the	
	−y num	Translate the origin <i>num</i> inches along the positive y axis. Positive a everything up the page. The default offset is 0 .	num moves	
	Only one bitmap is printed on each logical page, and each of the input <i>files</i> must contain complete descriptions of at least one bitmap. Decreasing the pattern size using the –b option may help throughput on printers with fast processors (such as PS-810s), while increasing the pattern size will often be the right move on older models (such as PS-800s)		g the – b , while

NAME	postio – serial interface for PostScript printers			
SYNOPSIS	postio − l line [− D] [− i] [− q] [− t] [− S] [− b speed] [− B num] [− L file] [− P string] [− R num] [file]			
	/usr/lib/lp	/usr/lib/lp/postscript/postio		
DESCRIPTION	postio sen dard inpu	nds <i>files</i> to the PostScript printer attached to <i>line.</i> If no <i>files</i> are specified the stan- t is sent.		
OPTIONS	The first g	roup of options should be sufficient for most applications:		
	–D	Enable debug mode. Guarantees that everything read on <i>line</i> will be added to the log file (standard error by default).		
	- q	Prevents status queries while <i>files</i> are being sent to the printer. When status queries are disabled a dummy message is appended to the log file before each block is transmitted.		
	-b speed	Transmit data over <i>line</i> at baud rate <i>speed</i> . Recognized baud rates are 1200, 2400, 4800, 9600, and 19200. The default <i>speed</i> is 9600 baud.		
	– B num	Set the internal buffer size for reading and writing <i>files</i> to <i>num</i> bytes. By default <i>num</i> is 2048 bytes.		
	–l line	Connect to the printer attached to <i>line</i> . In most cases there is no default and postio must be able to read and write <i>line</i> . If the <i>line</i> does not begin with a / it may be treated as a Datakit destination.		
	–L file	Data received on <i>line</i> gets put in <i>file</i> . The default log <i>file</i> is standard error. Printer or status messages that don't show a change in state are not normally written to <i>file</i> but can be forced out using the $-\mathbf{D}$ option.		
	–P string	Send <i>string</i> to the printer before any of the input files. The default <i>string</i> is simple PostScript code that disables timeouts.		
	$-\mathbf{R}$ num	Run <i>postio</i> as a single process if <i>num</i> is 1 or as separate read and write processes if <i>num</i> is 2. By default postio runs as a single process.		
	The next two <i>options</i> are provided for users who expect to run postio on their own. Nei- ther is suitable for use in spooler interface programs:			
	- i	Run the program in interactive mode. Any <i>files</i> are sent first and followed by the standard input. Forces separate read and write processes and overrides many other options. To exit interactive mode use your interrupt or quit character. To get a friendly interactive connection with the printer type executive on a line by itself.		
	-t	Data received on <i>line</i> and not recognized as printer or status information is written to the standard output. Forces separate read and write processes. Convenient if you have a PostScript program that will be returning useful data to the host.		

	The last option is not generally recommended and should only be used if all else fails to provide a reliable connection:
	-S Slow the transmission of data to the printer. Severely limits throughput, runs as a single process, disables the – q option, limits the internal buffer size to 1024 bytes, can use an excessive amount of CPU time, and does nothing in interactive mode.
	The best performance will usually be obtained by using a large internal buffer (the $-B$ option) and by running the program as separate read and write processes (the $-R 2$ option). Inability to fork the additional process causes postio to continue as a single read/write process. When one process is used, only data sent to the printer is flow controlled.
	The <i>options</i> are not all mutually exclusive. The $-i$ option always wins, selecting its own settings for whatever is needed to run interactive mode, independent of anything else found on the command line. Interactive mode runs as separate read and write processes and few of the other <i>options</i> accomplish anything in the presence of the $-i$ option. The $-t$ option needs a reliable two way connection to the printer and therefore tries to force separate read and write processes. The $-S$ option relies on the status query mechanism, so $-\mathbf{q}$ is disabled and the program runs as a single process.
	In most cases postio starts by making a connection to <i>line</i> and then attempts to force the printer into the IDLE state by sending an appropriate sequence of ^T (status query), ^C (interrupt), and ^D (end of job) characters. When the printer goes IDLE, <i>files</i> are transmitted along with an occasional ^T (unless the -q option was used). After all the <i>files</i> are sent the program waits until it's reasonably sure the job is complete. Printer generated error messages received at any time except while establishing the initial connection (or when running interactive mode) cause postio to exit with a non-zero status. In addition to being added to the log file, printer error messages are also echoed to standard error.
EXAMPLES	Run as a single process at 9600 baud and send <i>file1</i> and <i>file2</i> to the printer attached to /dev/tty01:
	example% postio –l /dev/tty01 file1 file2
	Same as above except two processes are used, the internal buffer is set to 4096 bytes, and data returned by the printer gets put in file <i>log</i> :
	example% postio –R 2 –B 4096 –l/dev/tty01 –L log file1 file2
	Establish an interactive connection with the printer at Datakit destination <i>my/printer</i> .
	example% postio –i –l <i>my/printer</i>
	Send file program to the printer connected to / dev/tty22 , recover any data in file results, and put log messages in file <i>log</i> :
	example% postio -t -l /dev/tty22 -L log program >results

1-797

SEE ALSO	<pre>download(1), dpost(1), postdaisy(1), postdmd(1), postmd(1), postprint(1), postreverse(1), posttek(1)</pre>
DIAGNOSTICS	An exit status of 0 is returned if the files ran successfully. System errors (such as an inability to open the line) set the low order bit in the exit status, while PostScript errors set bit 1. An exit status of 2 usually means the printer detected a PostScript error in the input <i>files</i> .
NOTES	The input <i>files</i> are handled as a single PostScript job. Sending several different jobs, each with their own internal end of job mark (^D) is not guaranteed to work properly. postio may quit before all the jobs have completed and could be restarted before the last one finishes.
	All the capabilities described above may not be available on every machine or even across the different versions of the UNIX system that are currently supported by the pro- gram.
	There may be no default <i>line</i> , so using the $-\mathbf{l}$ option is strongly recommended. If omitted, postio may attempt to connect to the printer using the standard output. If Datakit is involved, the $-\mathbf{b}$ option may be ineffective and attempts by postio to impose flow control over data in both directions may not work. The $-\mathbf{q}$ option can help if the printer is connected to RADIAN. The $-\mathbf{S}$ option is not generally recommended and should be used only if all other attempts to establish a reliable connection fail.

SunOS 5.5	User Commands		postmd(1)	
NAME	postmd –	postmd – matrix display program for PostScript printers		
SYNOPSIS	[-0	-b num] [-c num] [-d dimen] [-g list] [-i list] [-m num] [list] [-p mode] [-w window] [-x num] [-y num] [file]	- n num]	
	-	/postscript/postmd		
DESCRIPTION	a PostScri applicatio order, wh	The postnd filter reads a series of floating point numbers from <i>files</i> , translates them into a PostScript gray scale image, and writes the results on the standard output. In a typical application the numbers might be the elements of a large matrix, written in row major order, while the printed image could help locate patterns in the matrix. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is read.		
OPTIONS	- b num	Pack the bitmap in the output file using <i>num</i> byte patterns. A off all packing of the output file. By default, <i>num</i> is 6 .	A value of 0 turns	
	−c num	Print num copies of each page. By default, only one copy is	printed.	
	− d dimen	Sets the default matrix dimensions for all input <i>files</i> to <i>dimen</i> can be given as rows or rows x columns. If <i>columns</i> is omittee rows. By default, postmd assumes each matrix is square and of rows and columns to the square root of the number of ele input file.	d it will be set to d sets the number	
	−g list	<i>list</i> is a comma or space separated string of integers, each lyi 255 inclusive, that assigns PostScript gray scales to the region selected by the –i option. 255 corresponds to white, and 0, to postmd filter assigns a default gray scale that omits white (the gets darker as the regions move from left to right along the regions).	ns of the real line o black. The hat is, 255) and	
	−i list	<i>list</i> is a comma, space or slash(/) separated string of <i>N</i> floati that partition the real line into $2N+1$ regions. The <i>list</i> must b ing numerical order. The partitions are used to map floating read from the input <i>files</i> into gray scale integers that are eithe automatically by postmd or arbitrarily selected using the – g default interval <i>list</i> is – 1,0,1 , which partions the real line into	e given in increas- g point numbers er assigned option. The	
	- m num	Magnify each logical page by the factor <i>num</i> . Pages are scale about the origin which, by default, is located at the center of default magnification is 1.0 .		
	– n num	Print <i>num</i> logical pages on each piece of paper, where <i>num</i> c integer. By default, <i>num</i> is set to 1 .	an be any positive	
	−o list	Print pages whose numbers are given in the comma separate contains single numbers N and ranges $N1 - N2$. A missing N lowest numbered page, a missing $N2$ means the highest. The expression of logical pages rather than physical sheets of pag- if you are printing two logical pages to a sheet, and you spec- then two sheets of paper would print, containing four page N	V1 means the e page range is an per. For example, cified a range of 4 ,	

1-799

specified a page range of 3-4 , when requesting two logical pages to a sheet;
then only page 3 and page 4 layouts would print, and they would appear on
one physical sheet of paper.

- -**p** *mode* Print *files* in either portrait or landscape *mode*. Only the first character of *mode* is significant. The default *mode* is portrait.
- –**w** window

Window is a comma or space separated list of four positive integers that select the upper left and lower right corners of a submatrix from each of the input *files*. Row and column indices start at 1 in the upper left corner and the numbers in the input *files* are assumed to be written in row major order. By default, the entire matrix is displayed.

- -**x** *num* Translate the origin *num* inches along the positive x axis. The default coordinate system has the origin fixed at the center of the page, with positive x to the right and positive y up the page. Positive *num* moves everything right. The default offset is **0** inches.
- -y *num* Translate the origin *num* inches along the positive y axis. Positive *num* moves everything up the page. The default offset is **0**.

Only one matrix is displayed on each logical page, and each of the input *files* must contain complete descriptions of exactly one matrix. Matrix elements are floating point numbers arranged in row major order in each input file. White space, including newlines, is not used to determine matrix dimensions. By default, **postmd** assumes each matrix is square and sets the number of rows and columns to the square root of the number of elements in the input file. Supplying default dimensions on the command line with the $-\mathbf{d}$ option overrides this default behavior, and in that case the dimensions apply to all input *files*.

An optional header can be supplied with each input file and is used to set the matrix dimensions, the partition of the real line, the gray scale map, and a window into the matrix. The header consists of keyword/value pairs, each on a separate line. It begins on the first line of each input file and ends with the first unrecognized string, which should be the first matrix element. Values set in the header take precedence, but apply only to the current input file. Recognized header keywords are **dimension**, **interval**, **grayscale**, and **window**. The syntax of the value string that follows each keyword parallels what is accepted by the -d, -i, -g, and -w options.

EXAMPLES For example, suppose file initially contains the 1000 numbers in a 20x50 matrix. Then you can produce exactly the same output by completing three steps. First, issue the following command line:

example% postmd -d20x50 -i"-100 100" -g0,128,254,128,0 file

Second, prepend the following header to file:

dimension 20x50 interval -100.0 .100e+3 grayscale 0 128 254 128 0

Third, issue the following command line:

example% postmd file

The interval list partitions the real line into five regions and the gray scale list maps numbers less than -100 or greater than 100 into 0 (that is, black), numbers equal to -100 or 100 into 128 (that is, 50 percent black), and numbers between -100 and 100 into 254 (that is, almost white).

FILES /usr/lib/lp/postscript/forms.ps /usr/lib/lp/postscript/ps.requests

SEE ALSO dpost(1), postdaisy(1), postdmd(1), postio(1), postprint(1), postreverse(1), posttek(1)

DIAGNOSTICS An exit status of **0** is returned if *files* were successfully processed.

NOTES The largest matrix that can be adequately displayed is a function of the interval and gray scale lists, the printer resolution, and the paper size. A 600x600 matrix is an optimistic upper bound for a two element interval list (that is, five regions) using 8.5x11 inch paper on a 300 dpi printer.

Using white (that is, 255) in a gray scale list is not recommended and won't show up in the legend and bar graph that **postmd** displays below each image.

post	print	(1))

NAME	postprint – PostScript translator for text files			
SYNOPSIS	<pre>postprint [-c num] [-f name] [-l num] [-m num] [-n num] [-o list] [-p mode] [-r num] [-s num] [-t num] [-x num] [-y num] [file] /usr/lib/lp/postscript/postprint</pre>			
DESCRIPTION	The postprint filter translates text <i>files</i> into PostScript and writes the results on the stan- dard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is read.			
OPTIONS	–c num	Print <i>num</i> copies of each page. By default, only one copy is printed.		
	− f name	Print <i>files</i> using font <i>name</i> . Any PostScript font can be used, although the best results will be obtained only with constant width fonts. The default font is Courier.		
	–l num	Set the length of a page to <i>num</i> lines. By default, <i>num</i> is 66 . Setting <i>num</i> to 0 is allowed, and will cause <i>postprint</i> to guess a value, based on the point size that's being used.		
	– m num	Magnify each logical page by the factor <i>num</i> . Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0 .		
	– n num	Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1 .		
	−o list	Print pages whose numbers are given in the comma-separated <i>list</i> . The <i>list</i> contains single numbers N and ranges $N1 - N2$. A missing $N1$ means the lowest numbered page, a missing $N2$ means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4 , then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4 , when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.		
	- p mode	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.		
	–r num	Selects carriage return behavior. Carriage returns are ignored if <i>num</i> is 0 , cause a return to column 1 if <i>num</i> is 1 , and generate a newline if <i>num</i> is 2 . The default <i>num</i> is 0 .		
	−s num	Print <i>files</i> using point size <i>num</i> . When printing in landscape mode <i>num</i> is scaled by a factor that depends on the imaging area of the device. The default size for portrait mode is 10 . Note that increasing point size increases virtual image size, so you either need to load larger paper, or use the -10 option to scale the number of lines per page.		

	-t num	Assume tabs are set every <i>num</i> columns, starting with the first column. By
		default, tabs are set every 8 columns.
	−x num	Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive <i>num</i> moves everything to the right. The default offset is 0.25 inches.
	− y num	Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves text up the page. The default offset is -0.25 inches.
	wheneve changed	gical page is started after 66 lines have been printed on the current page, or r an ASCII form feed character is read. The number of lines per page can be using the -1 option. Unprintable ASCII characters are ignored, and lines that are are silently truncated by the printer.
EXAMPLES	To print <i>f</i>	file1 and file2 in landscape mode, issue the following command:
	e	xample% postprint –pland file1 file2
		three logical pages on each physical page in portrait mode:
	-	xample% postprint –n3 file

NAME	postreverse – reverse the page order in a PostScript file
SYNOPSIS	postreverse [– o <i>list</i>] [– r] [<i>file</i>]
	/usr/lib/lp/postscript/postreverse
DESCRIPTION	The postreverse filter reverses the page order in files that conform to Adobe's Version 1.0 or Version 2.0 file structuring conventions, and writes the results on the standard output. Only one input <i>file</i> is allowed and if no <i>file</i> is specified, the standard input is read.
	The postreverse filter can handle a limited class of files that violate page independence, provided all global definitions are bracketed by %% BeginGlobal and %% EndGlobal comments. In addition, files that mark the end of each page with %% EndPage: label ordinal comments will also reverse properly, provided the prologue and trailer sections can be located. If postreverse fails to find an %% EndProlog or %% EndSetup comment, the entire <i>file</i> is copied, unmodified, to the standard output.
	Because global definitions are extracted from individual pages and put in the prologue, the output file can be minimally conforming, even if the input <i>file</i> was not.
OPTIONS	 -o <i>list</i> Select pages whose numbers are given in the comma-separated <i>list</i>. The <i>list</i> contains single numbers <i>N</i> and ranges <i>N1 – N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3-4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper. -r Do not reverse the pages in <i>file</i>.
EXAMPLES	To select pages 1 to 100 from <i>file</i> and reverse the pages: example% postreverse –o1–100 <i>file</i>
	To print four logical pages on each physical page and reverse all the pages:
	example% postprint –n4 <i>file</i> postreverse
	To produce a minimally conforming file from output generated by dpost without revers- ing the pages:
	example% dpost <i>file</i> postreverse –r
SEE ALSO	<pre>download(1), dpost(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), posttek(1)</pre>
DIAGNOSTICS	An exit status of 0 is returned if <i>file</i> was successfully processed.

1-806

NOTES No attempt has been made to deal with redefinitions of global variables or procedures. If standard input is used, the input *file* will be read three times before being reversed.

posttek(1)	User Commands		SunOS 5.5		
NAME	posttek – PostScript translator for Tektronix 4014 files				
SYNOPSIS		-c num][-f name][-m num][-n num][-o list][-p mo num][-y num][file]	ode] [–w num]		
	/usr/lib/lp	/usr/lib/lp/postscript/posttek			
DESCRIPTION	results on	The posttek filter translates Tektronix 4014 graphics <i>files</i> into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i> , the standard input is read.			
OPTIONS	–c num	Print <i>num</i> copies of each page. By default, only one copy	y is printed.		
	-f name	Print text using font <i>name</i> . Any PostScript font can be us results will be obtained only with constant width fonts. Courier.			
	– m num	Magnify each logical page by the factor <i>num</i> . Pages are about the origin which, by default, is located at the center default magnification is 1.0 .			
	– n num	Print <i>num</i> logical pages on each piece of paper, where <i>nu</i> integer. By default, <i>num</i> is set to 1 .	um can be any positive		
	−o list	Print pages whose numbers are given in the comma-sep contains single numbers N and ranges $N1 - N2$. A missi lowest numbered page, a missing $N2$ means the highest. expression of logical pages rather than physical sheets or if you are printing two logical pages to a sheet, and you then two sheets of paper would print, containing four pase specified a page range of 3-4 , when requesting two logic then <i>only</i> page 3 and page 4 layouts would print, and the one physical sheet of paper.	ing <i>N1</i> means the . The page range is an f paper. For example, specified a range of 4 , age layouts. If you cal pages to a sheet;		
	- p mode	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the f is significant. The default <i>mode</i> is landscape.	ìrst character of <i>mode</i>		
	-w num	Set the line width used for graphics to <i>num</i> points, wher mately $1/72$ of an inch. By default, <i>num</i> is set to 0 points be one pixel wide.			
	−x num	Translate the origin <i>num</i> inches along the positive x axis nate system has the origin fixed at the center of the page right and positive y up the page. Positive <i>num</i> moves ex default offset is 0.0 inches.	, with positive x to the		
	−y num	Translate the origin <i>num</i> inches along the positive y axis everything up the page. The default offset is 0.0 .	. Positive <i>num</i> moves		

FILES	/usr/lib/lp/postscript/forms.ps /usr/lib/lp/postscript/ps.requests
SEE ALSO	<pre>download(1), dpost(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), postreverse(1)</pre>
DIAGNOSTICS	An exit status of 0 is returned if <i>files</i> were successfully processed.
NOTES	The default line width is too small for write-white print engines, such as the one used by the PS-2400.

NAME	pr – print files		
SYNOPSIS	/usr/bin/pr [+pa [-i [char]] [-fp] [file . /usr/xpg4/bin/pr [-h header]	ge] [–column] [– adFmrt] [–e [char][gap]] [–h header] gap]] [–l lines] [–n [char][width]] [–o offset] [–s [char]] [–w width]] [+page] [–column –c column] [– adFmrt] [–e [char][gap]] [–i [char][gap]] [–l lines] [–n [char][width]] [–o offset] [–s [char]] [–fp] [file]	
AVAILABILITY /usr/bin/pr	SUNWcsu		
/usr/xpg4/bin/pr	SUNWxcu4		
DESCRIPTION		printing and pagination filter. If multiple input files are specified, each d, and written to standard output. By default, the input is separated into ch with:	
	• a 5-line hea file	der that includes the page number, date, time and the path name of the	
	a 5-line trailer consisting of blank lines		
	If standard output is associated with a terminal, diagnostic messages will be deferred until the pr utility has completed processing.		
	of equal width; i	ecifying multi-column output are specified, output text columns will be nput lines that do not fit into a text column will be truncated. By default, separated with at least one blank character.	
OPTIONS	5 The following options are supported. In the following option descriptions, <i>colu offset</i> , <i>page</i> , and <i>width</i> are positive decimal integers; <i>gap</i> is a non-negative decimal Some of the option-arguments are optional, and some of the option-arguments specified as separate arguments from the preceding option letter. In particular, option does not allow the option letter to be separated from its argument, and the -e , -i , and -n require that both arguments, if present, not be separated from the letter.		
	The following op	tions are supported by both / usr/bin/pr and / usr/xpg4/bin/pr :	
	+page	Begin output at page number <i>page</i> of the formatted input.	
	–column	Produce multi-column output that is arranged in <i>column</i> columns (default is 1) and is written down each column in the order in which the text is received from the input file. This option should not be used with $-\mathbf{m}$. The $-\mathbf{e}$ and $-\mathbf{i}$ options will be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column will never exceed the length of the page (see the $-\mathbf{l}$ option). When used with $-\mathbf{t}$, use the minimum number of lines to write the output.	

-a	Modify the effect of the <i>-column</i> option so that the columns are filled across the page in a round-robin order (for example, when <i>column</i> is 2, the first input line heads column 1, the second heads column 2, the third is the second line in column 1, and so forth).
-d	Produce output that is double-spaced; append an extra NEWLINE char- acter following every NEWLINE character found in the input.
— e [char][gap]	Expand each input TAB character to the next greater column position specified by the formula $n * gap + 1$, where n is an integer >0. If gap is 0 or is omitted, it defaults to 8. All TAB characters in the input will be expanded into the appropriate number of SPACE characters. If any non-digit character, <i>char</i> , is specified, it will be used as the input tab character.
-f	Use a FORMFEED character for new pages, instead of the default behavior that uses a sequence of NEWLINE characters. Pause before beginning the first page if the standard output is associated with a ter- minal.
– h header	Use the string <i>header</i> to replace the contents of the <i>file</i> operand in the page header.
–l lines	Override the 66-line default and reset the page length to <i>lines</i> . If <i>lines</i> is not greater than the sum of both the header and trailer depths (in lines), pr will suppress both the header and trailer, as if the –t option were in effect.
- m	Merge files. Standard output will be formatted so pr writes one line from each file specified by <i>file</i> , side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementa- tions support merging of at least nine <i>files</i> .
- n [char][width]	Provide <i>width</i> -digit line numbering (default for <i>width</i> is 5). The number will occupy the first <i>width</i> column positions of each text column of default output or each line of – m output. If <i>char</i> (any non-digit character) is given, it will be appended to the line number to separate it from whatever follows (default for <i>char</i> is a TAB character).
–o offset	Each line of output will be preceded by offset <space>s. If the <math>-0</math> option is not specified, the default offset is <math>0</math>. The space taken will be in addition to the output line width (see $-\mathbf{w}$ option below).</space>
- p	Pause before beginning each page if the standard output is directed to a terminal (pr will write an ALERT character to standard error and wait for a carriage-return character to be read on / dev/tty).
- r	Write no diagnostic reports on failure to open files.
- s [char]	Separate text columns by the single character <i>char</i> instead of by the appropriate number of SPACE characters (default for <i>char</i> is the TAB character).
t	Write neither the five-line identifying header nor the five-line trailer

1-811

prex(1)	User Commands	SunOS 5.5
NAME	prex – probe external control	
SYNOPSIS	prex [-o trace_file_name] [-l libraries] [-s kbytes_size] cmd [cmd-args] prex [-o trace_file_name] [-l libraries] [-s kbytes_size] -p pid prex -k [-s kbytes_size]	
AVAILABILITY	SUNWtnfc	
DESCRIPTION	prex is the application used for external control of probes. It is able to find all in a target executable and it provides an interface for the user to manipulate the allows a probe to be turned on for tracing, debugging, or both. Tracing genera- trace file that can be converted to ASCII by tnfdump (1) and used for performan- analysis. Debugging generates a line to standard error whenever the probe is b time.	nem. prex ates a TNF nce hit at run
	prex does not work on static executables—it only works on dynamic executables	les.
Invoking prex	 There are three ways to invoke prex: 1). Use prex to start the target application <i>cmd</i>. In this case, the targe tion need not be built with a dependency on libtnfprobe (see TNF_PROBE(3X)), because prex will LD_PRELOAD (see ld(1)) th with libtnfprobe. prex uses the environment variable PATH to f get application. 2). Attach prex to a running application. In this case, the running ta cation should have libtnfprobe already linked in (could have be ally LD_PRELOAD'ed in by the user). 3). Use prex with the -k option, which puts prex into kernel mode used to control probes in the Solaris kernel. In kernel mode, add commands are defined, and some commands valid in other mode invalid. See Kernel Mode below. 	ne target find the tar- arget appli- en manu- : prex is litional
Control File Format and Command Language	 In a future release of prex, the command language will be moved to a syntax the ported by an existing scripting language like ksh(1). In the mean time, this is used. Commands should be in ASCII. Each command is terminated with the NEWLINE character. A command can be continued onto the next line by ending the previous line backslash ('\') character. Tokens in a command have to be separated by whitespace (one or more space). The "#" character implies that the rest of the line is a comment. 	uncommit-

SunOS 5.5	User Commands prex(1)		prex(1)
Control File Search	There are two different methods of communicating with prex :		
Path	 by specifications in a control file. During start-up, prex searches for a file named .prexrc in the directories specified below. prex does not stop at the first one it finds—this way a user can override any defaults that are set up. The search order is: \$HOME/ 		
	• by typing commands at	the prex prompt.	
	The command language for both methods is the same and is specified in USAGE . The commands that return output will not make sense in a control file—the output will go to the standard output.		
	When using prex on a target process, the target will be in one of two states—run stopped. This can be detected by the presence or absence of the prex > prompt. prompt is absent, it means that the target process is running. Typing CTRL-C wil target process and return the user to the prompt. There is no guarantee that CTR return to a prex prompt immediately. For example, if the target process is stopp job control stop (SIGSTOP), then CTRL-C in prex will wait until the target has be ued (SIGCONT). See Signals to Target Program below for more information on and the target process.		f the stop the C will d on a n contin-
OPTIONS	The following options are s	upported:	
	- k	kernel mode : prex is used to control probes in the So kernel. In kernel mode, additional commands are de and some commands valid in other modes are invali Kernel Mode below.	efined,
	-1 libraries	The <i>libraries</i> mentioned are linked in to the target apprusing LD_PRELOAD (see ld(1)). This option cannot be when attaching to a running process. The argument option should be a space separated string enclosed in quotes. Each token in the string is a library name. It f the LD_PRELOAD rules on how libraries should be spand where they will be found.	be used to the – l n double follows
	-o trace_file_name	File to be used for the trace output. <i>trace_file_name</i> is assumed to be relative to the current working director prex (i.e., the directory that the user was in when pre started).	ory of
		If prex attaches to a process that is already tracing, the <i>trace_file_name</i> (if provided) will not be used. If no <i>trace_file_name</i> is specified, the default is / \$TMPDIR /tt < <i>pid></i> where < <i>pid></i> is the process id of the target program TMPDIR is not set, / tmp is used.	race-

	-s kbytes_size	size of the trac usage, and 38 4 can be though	e of the output trace file in Kbytes. The defa e <i>kbytes_size</i> is 4096 or 4 Mbytes for normal or 384 kbytes in kernel mode. The trace fil t of as a least recently used circular buffer. as been filled, newer events will overwrite t	e
USAGE Grammar	-	ified by a list of space separ <i>ite>=<value></value></i>	rated selectors. Selectors are of the form:	
	(see TNF_PRO keys=.	BE (3X)). The " <i><attribute>=</attribute></i> "	is optional. If it is not specified, it defaults	to
	The <attribute></attribute>	or <value> (generically calle</value>	ed spec) can be any of the following:	
	IDENT	any sequence of letters, di IDENT implies an exact m	gits, _ , \setminus , ., % not beginning with a digit. atch.	
	QUOTED_STR		erved words (any commands in the comma a implies an exact match and has to be enclo	
	REGEXP		on pattern match. REGEXP has to be enclose e included in a REGEXP by escaping it with	
	The following g	grammar explains the synta	х.	
	selector_list ::=	:	/* empty */	
		<selector_list> <sel< td=""><td></td><td></td></sel<></selector_list>		
	selector ::=		/* whitespace around '=' opt */	
	spec ::=	<spec> IDENT QUOTED_STR REGEXP</spec>		
	The terminals in	n the above grammar are:		
	IDENT =	[a-zA-Z_\.%]{[a-zA	-Z0-9_\.%]}+	
	QUOTED_STR REGEXP =		/* any string in single quotes */ /* regexp's have to be in / / */	
		the remaining grammar tha uage (defined in next subse	t is needed to understand the syntax of the ction):	
	filename ::= spec_list ::=	QUOTED_STR /* empty */	/* QUOTED_STR defined above */	
	fcn_handle ::= set_name ::=	<spec_list> <spec> &IDENT \$IDENT</spec></spec_list>	/* <spec> defined above */ /* IDENT defined above */ /* IDENT defined above */</spec>	

Command Language	1. Set Creation and Set Listing create \$ <set_name> <selector_list></selector_list></set_name>		
	list sets	# list the defined sets	
		ine a set which contains probes that match the a is pre-defined as $/.*/$ — it matches all the probes.	
	2. Function Listing list fcns	<pre># list the available <fcn_handle></fcn_handle></pre>	
		fferent functions that can be connected to probe points. bug function called &debug is available.	
	3. Commands to Connect and connect & <fcn_handl connect &<fcn_handl< th=""><th>e> \$<set_name></set_name></th></fcn_handl<></fcn_handl 	e> \$ <set_name></set_name>	
	The connect command is used to connect probe functions (which must be prefixed by &) to probes. The probes are specified either as a single set (with a '\$'), or by explicitly listing the probe selectors in the command. The probe function has to be one that is listed by the list fcns command. This command does not enable the probes.		
	4. Disconnects All Connected Probe Functions clear \$ <set_name> clear <selector_list></selector_list></set_name>		
	The clear command is used to disconnect all connected probe functions from the specified probes.		
	5. Commands to Toggle the T trace \$ <set_name> trace <selector_list> untrace \$<set_name> untrace <selector_list< th=""><th></th></selector_list<></set_name></selector_list></set_name>		
	The trace and untrace commands are used to toggle the tracing action of a probe point (that is, whether a probe will emit a trace record or not if it is hit). This command does not enable the probes specified. Probes have tracing on by default. The most efficient way to turn off tracing is by using the disable com- mand. untrace is useful if you want debug output but no tracing—if so, set the state of the probe to enabled, untraced, and the debug function connected.		
	6. Commands to Enable and I enable \$ <set_name> enable <selector_list> disable \$<set_name> disable <selector_list list history</selector_list </set_name></selector_list></set_name>	> # lists probe control command history	
	form the action that th	e commands are used to control whether the probes per- ey have been setup for. To trace a probe, it has to be both sing the trace command). Probes are disabled by default.	

1-817

prex(1)	User Commands		SunOS 5.5
	list history command is used to list the probe control commands issued: connect , clear , trace , untrace , enable , and disable . These are the commands that are exe- cuted whenever a new shared object is brought in to the target program by dlopen (3X). See the subsection, dlopen'ed Libraries , below for more informa- tion.		
	7. Commands to List Probes or List Valu list <spec_list> probes \$<set_nar list <spec_list> probes <selector_ list values <spec_list></spec_list></selector_ </spec_list></set_nar </spec_list>		est.c
	The first two commands list the selected attributes and values of the specified probes. They can be used to check the state of a probe. The third command lists the various values associated with the selected attributes.		
	8. Help Command help		
	The help command lists all the co	mmands available.	
	9. Source a File source <filename></filename>		
	The source command can be used be nested (that is, a file can source	to source a file of prex commands. another file).	source can
	10. Process Control		
	continue quit kill	<pre># resumes the target process # quit prex, kill target</pre>	
	quit Kin quit resume	# quit prex, kin target # quit prex, continue target	
	quit suspend quit	# quit prex, leave target susp # quit prex (continue or kill t	
		target process if prex attached to it. m, quit will kill the target process.	. Instead, if
dlopen'ed Libraries	Probes in shared objects that are brought in by dlopen (3X) are automatically set up according to the command history of prex . When a shared object is removed by a dlclose (3X), prex again needs to refresh its understanding of the probes in the target program. This implies that there is more work to do for dlopen (3X) and dlclose (3X) —so they will take slightly longer. If a user is not interested in this feature and doesn't want to interfere with dlopen (3X) and dlclose (3X), detach prex from the target to inhibit this feature.		
Signals to Target Program	prex does not interfere with signals that are delivered directly to the target program. However, prex receives all terminal generated signals (for example, CTRL-C (SIGINT), CTRL-Z (SIGSTOP), etc.) and does not forward them to the target program. To signal the target program, use the kill (1) command from a shell.		

SunOS 5.5	User Commands pre	
Interactions with Other Applications	Process managing applications like dbx , truss (1), and prex can not operate on the same target program simultaneously. prex will not be able to attach to a target which is being controlled by another application. A user can trace and debug a program serially by the following method: first attach prex to target (or start target through prex), set up the probes using the command language, and then type quit suspend . The user can then attach dbx to the suspended process and debug it. A user can also suspend the target by sending it a SIGSTOP signal, and then by typing quit resume to prex — in this case, the user should also send a SIGCONT signal after invoking dbx on the stopped process (else dbx will be hung).	
Failure of Event Writing Operations	There are a few failure points that are possible when writing out events to a trace example, system call failures. These failures result in a failure code being set in the process. The target process continues normally (but no trace records are written) ever a user types CTRL-C to prex to get to a prex prompt, prex will check the fail in the target and inform the user if there was a tracing failure.	he target). When-
Target Executing a Fork or exec	If the target program does a fork (2), Any probes that the child encounters will be to the same trace file. Events are annotated with a process id, so it will be possible determine which process a particular event came from. In multi-threaded progra there is a race condition with a thread doing a fork while the other threads are st ning. For the trace file not to get corrupted, the user should either use fork1 (2), of sure that all other threads are quiescent when doing a fork (2),	le to ams, till run-
	If the target program itself (not any children it may fork (2)) does an exec (2), pre detaches from the target and exits. The user can reconnect prex with prex – p <i>pid</i>	
Kernel Mode	Invoking prex with the -k flag causes prex to run in kernel mode . In kernel mode controls probes in the Solaris kernel. See tnf_probes (4) for a list of available pro Solaris kernel. A few prex commands are unavailable in kernel mode; other com are valid in kernel mode only.	bes in the
	The –l , –o , and –p command line options are not valid in kernel mode (that is, th not be combined with the –k flag).	ney may
	The rest of this section describes the differences in the prex command language running prex in kernel mode.	when
	1. Prex will not stop the kernel	
	When prex attaches to a running user program, it stops the user program ously, it cannot do this when attaching to the kernel. Instead, prex prov "tracing master switch": no probes will have any effect unless the tracin switch is on. This allows the user to iteratively select probes to enable, the enable them all at once by turning on the master switch.	ides a ng master
	The command ktrace [on off]	
	is used to inspect and set the value of the master switch. Without an arg prex reports the current state of the master switch.	şument,

Since **prex** will not stop or kill the kernel, the **quit resume**

and

quit kill

commands are not valid in kernel mode.

2. No functions may be attached to probes in the kernel

In particular, the debug function is unavailable in kernel mode. Unless a probe is both enabled and traced, the probe has no effect. Thus, the only semantically meaningful values are to have the probe both enabled and traced, or neither enabled nor traced.

3. Trace output is written to an in-core buffer

In kernel mode, a trace output file is not generated directly, in order to allow probes to be placed in time-critical code. Instead, trace output is written to an in-core buffer, and copied out by a separate program, **tnfxtract**(1).

The in-core buffer is not automatically created. The following **prex** command controls buffer allocation and deallocation:

buffer [alloc [size] | dealloc]

Without an argument, the **buffer** command reports the size of the currently allocated buffer, if any. With an argument of **alloc** [*size*], **prex** allocates a buffer of the given size. *size* is in bytes, with an optional suffix of 'k' or 'm' specifying a multiplier of **1024** or **1048576**, respectively. If no *size* is specified, the *size* specified on the command line with the –**s** option is used as a default. If the –**s** command line option was not used, the "default default" is 384 kilobytes.

With an argument of **dealloc**, **prex** deallocates the trace buffer in the kernel.

prex will reject attempts to turn the tracing master switch on when no buffer is allocated, and to deallocate the buffer when the tracing master switch is on. **prex** will refuse to allocate a buffer when one is already allocated; use **buffer dealloc** first.

prex will not allocate a buffer larger than one-half of a machine's physical memory.

4. Prex supports per-process probe enabling in the kernel

In kernel mode, it is possible to select a set of processes for which probes are enabled. No trace output will be written when other processes traverse these probe points. This is called "process filter mode." By default, process filter mode is off, and all processes cause the generation of trace records when they hit an enabled probe.

Some kernel events (such as interrupts) cannot be associated with a particular user process. By convention, these events are considered to be generated by process id 0.

prex provides commands to turn process filter mode on and off; to get the current status of the process filter mode switch; to add and delete processes (by

	process id) from the process filter set; and to list the current process filter set.			
	The process filter set is maintained even when process filter mode is off, but has no effect unless process filter mode is on.			
	When a process in the process filter set exits, its process id is automatically deleted from the process filter set. prex will report this the next time the user issues a command to prex .			
	The command:			
	pfilter [on off add <pidlist> delete <pidlist>]</pidlist></pidlist>			
	With no arguments, pfil	controls the process filter switch, and process filter set membership. With no arguments, pfilter prints the current process filter set and the state of the process filter mode switch.		
	on or off set the state of the process filter mode switch. add <i><pidlist></pidlist></i>			
		delete processes from the process filter set. > is a comma-separated list of one or more ids.		
EXAMPLES	Example command language:			
	# at start up, all probes are cleared by default # set creation and set listing			
	create \$foo name='foo'	# match only on name attr being foo		
	create \$special /thr/=locks name=vm	# matches probes having either		
		<pre># attribute (reg-exp) /thr/=locks</pre>		
	1	# or attribute name=vm		
	list sets	# list the defined sets		
	list fcns	# list the defined probe fcns		
	# Commands to trace and connect probe functions			
	trace foobar='on'	# exact match on foobar attribute		
	trace \$all	# trace all probes		
	connect &debug \$special	# connect debug to the probes in "special" set		
	connect &debug /resource/ name=allocate	# connect debug to probes that have		
		# attribute keys=/resource or		
		# attribute name=allocate		
	# Commands to enable and disable probes	i		
	enable Sall	# enable all the probes		
	enable /vm/ name=allocate destroy	# enable the specified probes		
	disable \$special	# disable "special" probes		
	disable /resource/ name='malloc'	# disable the specified probes

NAME	print – shell built-in function to output characters to the screen or window		
SYNOPSIS ksh	print [–Rnprsu [<i>n</i>]] [<i>arg</i>]		
DESCRIPTION ksh	The shell output mechanism. With no flags or with flag – or – –, the arguments are printed on standard output as described by $echo(1)$. The exit status is 0, unless the output file is not open for writing.		
	-n	suppresses new-line from being added to the output.	
	- R		
	- r	(raw mode) ignore the escape conventions of echo . The $-\mathbf{R}$ option will print all subsequent arguments and options other than $-\mathbf{n}$.	
	- p	causes the arguments to be written onto the pipe of the process spawned with & instead of standard output.	
	— S	causes the arguments to be written onto the history file instead of standard output.	
	- u [<i>n</i>]	flag can be used to specify a one digit file descriptor unit number <i>n</i> on which the output will be placed. The default is 1.	
SEE ALSO	echo (1), k	csh (1)	

modified 15 Apr 1994

printenv(1B)	SunOS/BSD Compatibility Package Commands SunOS 5.5
NAME SYNOPSIS	printenv – display environment variables currently set / usr/ucb/printenv [<i>variable</i>]
AVAILABILITY	SUNWscpu
DESCRIPTION	printenv prints out the values of the variables in the environment. If a <i>variable</i> is specified, only its value is printed.
SEE ALSO	csh (1), echo (1), sh (1), stty (1), tset (1B), environ (5)
DIAGNOSTICS	If a <i>variable</i> is specified and it is not defined in the environment, printenv returns an exit status of 1 .

NAME	printf – write fo	ormatted output	
SYNOPSIS	printf format [argument]		
AVAILABILITY	SUNWloc		
DESCRIPTION	-	mand writes formatted operands to the standard output. The <i>argument</i> ormatted under control of the <i>format</i> operand.	
OPERANDS	The following operands are supported:		
	format	A string describing the format to use to write the remaining operands. The <i>format</i> operand is used as the <i>format</i> string described on the for - mats (5) manual page, with the following exceptions:	
		• A SPACE character in the format string, in any context other than a flag of a conversion specification, is treated as an ordinary character that is copied to the output.	
		• A \vartriangle character in the format string is treated as a \vartriangle character, not as a SPACE character.	
		• In addition to the escape sequences described on the formats (5) manual page (\ \ a , \ b , \ f , \ n , \ r , \ t , \ v), \ <i>ddd</i> , where <i>ddd</i> is a one-, two- or three-digit octal number, is written as a byte with the numeric value specified by the octal number.	
		• The program does not precede or follow output from the d or u conversion specifications with blank characters not specified by the <i>format</i> operand.	
		• The program does not precede output from the o conversion specification with zeros not specified by the <i>format</i> operand.	
		• An additional conversion character, b , is supported as follows. The argument is taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences are supported:	
		 the escape sequences listed on the formats(5) manual page (\ \a, \b, \f, \n, \r, \t, \v), which are converted to the characters they represent 	
		 \0ddd, where ddd is a zero-, one-, two- or three-digit octal number that is converted to a byte with the numeric value specified by the octal number 	
		 \c, which is written and causes printf to ignore any remaining characters in the string operand containing it, any remaining string operands and any additional characters in the <i>format</i> operand. 	
		The interpretation of a backslash followed by any other sequence of characters is unspecified.	

modified 28 Mar 1995

1-825

		Bytes from the converted string are written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it is taken to be infinite, so all bytes up to the end of the converted string are written. For each specification that con- sumes an argument, the next argument operand is evaluated and con- verted to the appropriate type for the conversion as specified below. The <i>format</i> operand is reused as often as necessary to satisfy the argu- ment operands. Any extra c or s conversion specifications are evaluated as if a null string argument were supplied; other extra conversion specifications are evaluated as if a zero argument were supplied. If the <i>format</i> operand contains no conversion specifications and <i>argument</i> operands are present, the results are unspecified. If a character sequence in the <i>format</i> operand begins with a % character, but does not form a valid conversion specification, the behavior is unspecified.
	argument	The strings to be written to standard output, under the control of <i>format</i> . The <i>argument</i> operands are treated as strings if the corresponding conversion character is b , c or s ; otherwise, it is evaluated as a C con- stant, as described by the ISO C standard, with the following extensions:
		 A leading plus or minus sign is allowed.
		• If the leading character is a single- or double-quote, the value is the numeric value in the underlying codeset of the character following the single- or double-quote.
		If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message is written to standard error and the utility does not exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.
USAGE	special provision specification or Applications sh	rintf utility, like the printf(3S) function on which it is based, makes no n for dealing with multi-byte characters when using the %c conversion when a precision is specified in a %b or %s conversion specification. ould be extremely cautious using either of these features when there are acters in the character set.
	Field widths and	d precisions cannot be specified as *.
		y with previous versions of SunOS 5. <i>x</i> , the \$ format specifier is supported aining <i>only</i> % s specifiers.
	as a portable wa by the echo utili	ion specification is not part of the ISO C standard; it has been added here by to process backslash escapes expanded in string operands as provided ity. See also the USAGE section of the echo (1) manual page for ways to eplacement for all of the traditional versions of the echo utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the **printf** utility reports an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion are to be reported as errors.

It is not considered an error if an argument operand is not completely used for a c or s conversion or if a string operand's first or second character is used to get the numeric value of a character.

EXAMPLES

To alert the user and then print and read a series of prompts: printf "\aPlease fill in the following: \nName: "

```
read name
printf "Phone number: "
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single tab character. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
printf "%2d right\t%2d wrong\t(%s%%)\n" \
$right $wrong $percent
```

done < database_file

The command:

printf "%5d%4d\n" 1 21 321 4321 54321

produces:

```
1 21
3214321
54321 0
```

Note that the *format* operand is used three times to print all of the given strings and that a **0** was supplied by **printf** to satisfy the last %**4d** conversion specification.

The **printf** utility tells the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when %**d** is specified as the *format* operand:

Argument	Standard Output	Diagnostic Output
5a	5	printf: 5a not completely converted
99999999999	2147483647	printf: 9999999999: Results too large
-99999999999	-2147483648	printf: -99999999999: Results too large
ABC	0	printf: ABC expected numeric value

Note that the value shown on standard output is what would be expected as the return value from the function **strtol**(3C). A similar correspondence exists between %**u** and **strtoul**(3C), and %**e**, %**f** and %**g** and **strtod**(3C).

In a locale using the ISO/IEC 646:1991 standard as the underlying codeset, the command:

printf "%d\n" 3 +3 -3 \'3 \"+3 "'-3"

	produces:		
	 3 Numeric value of constant 3 3 Numeric value of constant 3 3 Numeric value of constant 3 -3 Numeric value of constant -3 51 Numeric value of the character '3' in the ISO/IEC 646:1991 standard codeset 43 Numeric value of the character '+' in the ISO/IEC 646:1991 standard codeset 45 Numeric value of the character '-' in the SO/IEC 646:1991 standard codeset Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the wchar_t representation of the character. 		
	If an argument operand cannot be completely converted into an internal value appropri- ate to the corresponding conversion specification, a diagnostic message is written to stan- dard error and the utility does exit with a zero exit status, but continues processing any remaining operands and writes the value accumulated at the time the error was detected to standard output.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of printf : LC_COLLATE , LC_CTYPE , LC_MESSAGES , LC_TIME , TZ , and NLSPATH .		
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
SEE ALSO	awk(1), bc(1), echo(1), strtod(3C), strtol(3C), strtoul(3C), printf(3S), environ(5), for- mats(5)		

riocntl – display or set scheduling parameters of specified process(es)		
priocntl –l priocntl –d [–i idtype] [idlist] priocntl –s [–c class] [class-specific options] [–i idtype] [idlist] priocntl –e [–c class] [class-specific options] command [argument(s)]		
UNWcsu		
he priocntl command displays or sets scheduling parameters of the specified rocess(es). It can also be used to display the current configuration information for the ystem's process scheduler or execute a command with specified scheduling parameters.		
rocesses fall into distinct classes with a separate scheduling policy applied to each class. The process classes currently supported are the real-time class, time-sharing class, and the interactive class. The characteristics of these classes and the class-specific options ney accept are described below in the USAGE section under the headings Real-Time Class , Time-Sharing Class , and Inter-Active Class . With appropriate permissions, the riocntl command can change the class and other scheduling parameters associated with running process.		
n the default configuration, a runnable real-time process runs before any other process. herefore, inappropriate use of real-time processes can have a dramatic negative impact n system performance.		
E an <i>idlist</i> is present it must appear last on the command line and the elements of the list must be separated by white space. If no <i>idlist</i> is present an <i>idtype</i> argument of pid , ppid , gid , sid , class , uid , or gid specifies the process ID, parent process ID, process group ID, ession ID, class, user ID, or group ID, respectively, of the priocntl command itself.		
he command		
priocntl –d [–i idtype] [idlist]		
isplays the class and class-specific scheduling parameters of the process(es) specified by <i>ltype</i> and <i>idlist</i> .		
he command		
priocntl – s [– c class] [class-specific options] [– i idtype] [idlist]		
ets the class and class-specific parameters of the specified processes to the values given n the command line. The $-c$ class option specifies the class to be set. (The valid class rguments are RT for real-time TS for time-sharing or IA for inter-active.)		
he class-specific parameters to be set are specified by the class-specific options as xplained under the appropriate heading below. If the $-c$ class option is omitted, <i>idtype</i> nd <i>idlist</i> must specify a set of processes which are all in the same class, otherwise an rror results. If no class-specific options are specified the process's class-specific parameters are set to the default values for the class specified by $-c$ class (or to the default parameter values for the process's current class if the $-c$ class option is also omitted).		

	tive user II effective u of the user enforced f	o change the scheduling parameters of a process using priocntl the real or effec- D (respectively, groupID) of the user invoking priocntl must match the real or user ID (respectively, groupID) of the receiving process or the effective user ID r must be super-user. These are the minimum permission requirements for all classes. An individual class may impose additional permissions require- en setting processes to that class or when setting class-specific scheduling 's.
	in an impl the target	<i>pe</i> and <i>idlist</i> specify a set of processes, priocntl acts on the processes in the set ementation-specific order. If priocntl encounters an error for one or more of processes, it may or may not continue through the set of processes, depending ure of the error.
	through th user has a	r is related to permissions, priocntl prints an error message and then continue he process set, resetting the parameters for all target processes for which the ppropriate permissions. If priocntl encounters an error other than permissions, t continue through the process set but prints an error message and exits ely.
	tain specia the class o included i For examp with a UID	sys scheduling class exists for the purpose of scheduling the execution of cer- al system processes (such as the swapper process). It is not possible to change f any process to sys . In addition, any processes in the sys class that are in the set of processes specified by <i>idtype</i> and <i>idlist</i> are disregarded by priocntl . ble, if <i>idtype</i> were uid , an <i>idlist</i> consisting of a zero would specify all processes to o 0 , except processes in the sys class and (if changing the parameters using ion) the init process.
	change the and <i>idlist</i> i configured choice. (C	rocess (process ID 1) is a special case. In order for the priocntl command to e class or other scheduling parameters of the init process, <i>idtype</i> must be pid must be consist of only a 1. The init process may be assigned to any class d on the system, but the time-sharing class is almost always the appropriate other choices may be highly undesirable; see the <i>System Administration Guide</i> , for more information.)
		iocntl –e [–c class] [class-specific options] command [argument]
	executes the comma	the specified command with the class and scheduling parameters specified on and line (<i>arguments</i> are the arguments to the command). If the $-c$ class option is the command is run in the user's current class.
OPTIONS	- l	Display a list of the classes currently configured in the system along with class-specific information about each class. The format of the class-specific information displayed is described under USAGE .
	-d	Display the scheduling parameters associated with a set of processes.
	- S	Set the scheduling parameters associated with a set of processes.
	- e	Execute a specified command with the class and scheduling parameters asso- ciated with a set of processes.

−i idtype	This option together with the <i>idlist</i> arguments (if any), specify one or more processes to which the priocntl command is to apply. The interpretation of <i>idlist</i> depends on the value of <i>idtype</i> . The valid <i>idtype</i> arguments and corresponding interpretations of <i>idlist</i> are as follows:		
	- i pid <i>idlist</i> is a list of process IDs. The priocntl command applies to the specified processes.		
	–i ppid	<i>idlist</i> is a list of parent process IDs. The priocntl command applies to all processes whose parent process ID is in the list.	
	−i pgid	<i>idlist</i> is a list of process group IDs. The priocntl command applies to all processes in the specified process groups.	
	–i sid	<i>idlist</i> is a list of session IDs. The priocntl command applies to all processes in the specified sessions.	
	-i class <i>idlist</i> consists of a single class name (RT for real-time or TS fo time-sharing or IA for inter-active). The priocntl command applies to all processes in the specified class.		
	-i uid <i>idlist</i> is a list of user IDs. The priocntl command applies to all processes with an effective user ID equal to an ID from the list.		
	- i gid <i>idlist</i> is a list of group IDs. The priocntl command applies to al processes with an effective group ID equal to an ID from the list		
	–i all	The priocntl command applies to all existing processes. No <i>idlist</i> should be specified (if one is it is ignored). The permission restrictions described below still apply.	
		<i>type</i> option is omitted when using the $-\mathbf{d}$ or $-\mathbf{s}$ options the default id is assumed.	
−c class	Specifies the <i>class</i> to be set. (The valid <i>class</i> arguments are RT for real-time or TS for time-sharing or IA for inter-active.) If the specified class is not already configured, it will automatically be configured.		
The valid class-specific options for setting real-time parameters are:			
– p rtpri	<i>tpri</i> Set the real-time priority of the specified process(es) to <i>rtpri</i> .		
- t tqntm [-	m [-r res] Set the time quantum of the specified process(es) to tqntm. You may option- ally specify a resolution as explained below.		
The valid class-specific options for setting time-sharing parameters are:			
– m tsupril			
		er priority limit of the specified process(es) to <i>tsuprilim</i> .	
– p tsupri		er priority of the specified process(es) to <i>tsupri</i> .	
The valid class-specific options for setting inter-active parameters are:			
–m <i>iamode</i> Mark the specified process(es) as currently interactive, or not.			

1-831

USAGE Real-Time Class

The real-time class provides a fixed priority preemptive scheduling policy for those processes requiring fast and deterministic response and absolute user/application control of scheduling priorities. If the real-time class is configured in the system it should have exclusive control of the highest range of scheduling priorities on the system. This ensures that a runnable real-time process is given CPU service before any process belonging to any other class.

The real-time class has a range of real-time priority (*rtpri*) values that may be assigned to processes within the class. Real-time priorities range from 0 to x, where the value of x is configurable and can be displayed for a specific installation that has already configured a real-time scheduler, by using the command

priocntl –l

The real-time scheduling policy is a fixed priority policy. The scheduling priority of a real-time process never changes except as the result of an explicit request by the user/application to change the *rtpri* value of the process.

For processes in the real-time class, the *rtpri* value is, for all practical purposes, equivalent to the scheduling priority of the process. The *rtpri* value completely determines the scheduling priority of a real-time process relative to other processes within its class. Numerically higher *rtpri* values represent higher priorities. Since the real-time class controls the highest range of scheduling priorities in the system it is guaranteed that the runnable real-time process with the highest *rtpri* value is always selected to run before any other process in the system.

In addition to providing control over priority, **priocntl** provides for control over the length of the time quantum allotted to processes in the real-time class. The time quantum value specifies the maximum amount of time a process may run assuming that it does not complete or enter a resource or event wait state (**sleep**). Note that if another process becomes runnable at a higher priority, the currently running process may be preempted before receiving its full time quantum.

The command

priocntl -d [-i idtype] [idlist]

displays the real-time priority and time quantum (in millisecond resolution) for each real-time process in the set specified by *idtype* and *idlist*.

Any combination of the $-\mathbf{p}$ and $-\mathbf{t}$ options may be used with **priocntl** $-\mathbf{s}$ or **priocntl** $-\mathbf{e}$ for the real-time class. If an option is omitted and the process is currently real-time, the associated parameter is unaffected. If an option is omitted when changing the class of a process to real-time from some other class, the associated parameter is set to a default value. The default value for *rtpri* is **0** and the default for time quantum is dependent on the value of *rtpri* and on the system configuration; see **rt_dptbl**(4).

	When using the –t <i>tqntm</i> option you may optionally specify a resolution using the –r <i>res</i> option. (If no resolution is specified, millisecond resolution is assumed.) If <i>res</i> is specified it must be a positive integer between 1 and 1,000,000,000 inclusive and the resolution used is the reciprocal of <i>res</i> in seconds. For example, specifying –t 10 –r 100 would set the resolution to hundredths of a second and the resulting time quantum length would be 10/100 seconds (one tenth of a second). Although very fine (nanosecond) resolution may be specified, the time quantum length is rounded up by the system to the next integral multiple of the system clock's resolution. Requests for time quantums of zero or quantums greater than the (typically very large) implementation-specific maximum quantum result in an error.
	In order to change the class of a process to real-time (from any other class) the user invoking priocntl must have super-user privilege. In order to change the <i>rtpri</i> value or time quantum of a real-time process the user invoking priocntl must either be super-user, or must currently be in the real-time class (shell running as a real-time process) with a real or effective user ID matching the real or effective user ID of the target process.
	The real-time priority and time quantum are inherited across the fork (2) and exec (2) system calls.
Time-Sharing Class	The time-sharing scheduling policy provides for a fair and effective allocation of the CPU resource among processes with varying CPU consumption characteristics. The objectives of the time-sharing policy are to provide good response time to interactive processes and good throughput to CPU-bound jobs while providing a degree of user/application control over scheduling.
	The time-sharing class has a range of time-sharing user priority (<i>tsupri</i>) values that may be assigned to processes within the class. User priorities range from $-x$ to $+x$, where the value of x is configurable. The range for a specific installation can be displayed by using the command
	priocntl –l
	The purpose of the user priority is to provide some degree of user/application control over the scheduling of processes in the time-sharing class. Raising or lowering the <i>tsupri</i> value of a process in the time-sharing class raises or lowers the scheduling priority of the process. It is not guaranteed, however, that a time-sharing process with a higher <i>tsupri</i> value will run before one with a lower <i>tsupri</i> value. This is because the <i>tsupri</i> value is just one factor used to determine the scheduling priority of a time-sharing process. The system may dynamically adjust the internal scheduling priority of a time-sharing process based on other factors such as recent CPU usage.
	In addition to the system-wide limits on user priority (displayed with priocntl – l), there is a per process user priority limit (<i>tsuprilim</i>), which specifies the maximum <i>tsupri</i> value that may be set for a given process.
	The command
	priocntl –d [–i idtype] [idlist]

priocntl(1)	User Commands	SunOS 5.5
	displays the user priority and user priority limit for each time-shar specified by <i>idtype</i> and <i>idlist</i> .	ing process in the set
	Any time-sharing process may lower its own <i>tsuprilim</i> (or that of an the same user ID). Only a time-sharing process with super-user prite <i>tsuprilim</i> . When changing the class of a process to time-sharing from super-user privilege is required in order to set the initial <i>tsuprilim</i> to zero.	ivilege may raise a m some other class,
	Any time-sharing process may set its own <i>tsupri</i> (or that of another user ID) to any value less than or equal to the process's <i>tsuprilim</i> . DIAGNOSTICS	priocntl prints the following error messages:
	Process(es) not found None of the specified processes exists.
	Specified processes from different classes The -s option is being used to set parameters, the -c <i>class</i> option is not present, and processes from more than one class are specified.
	Invalid option or argument An unrecognized or invalid option or option argument is used.

NAME	proc, pflags, pcred, pmap, pldd, psig, pstack, pfiles, pwdx, pstop, prun, pwait, ptree, ptime – proc tools			
SYNOPSIS	/usr/proc/bin/pflags pid			
	/usr/proc/bin/pcred	1 <i>pid</i>		
	/usr/proc/bin/pmaj	-		
	/usr/proc/bin/pldd	pid		
	/usr/proc/bin/psig	pid		
	/usr/proc/bin/pstack pid			
	/usr/proc/bin/pfiles	s pid		
	/usr/proc/bin/pwdx pid			
	/usr/proc/bin/pstop	- o pid		
	/usr/proc/bin/prun	/usr/proc/bin/prun pid		
	/usr/proc/bin/pwait [–v] <i>pid</i>			
	/usr/proc/bin/ptime command [arg]			
AVAILABILITY	SUNWesu			
DESCRIPTION	The proc tools are utilities which exercise features of / proc (see proc (4)). Most of them take a list of process-ids (<i>pid</i>); those that do also accept / proc / <i>nnn</i> as a process-id, so the shell expansion / proc /* can be used to specify all processes in the system.			
	pflags	print the / proc tracing flags, the pending and held signals, and other / proc status information for each lwp in each process.		
	pcred	print the credentials (effective, real and saved UID's and GID's) of each process.		
	pmap	print the address space map of each process.		
	pldd	list the dynamic libraries linked into each process, including shared objects explicitly attached using dlopen (3X). (See also ldd (1).)		
	psig	list the signal actions of each process (See signal (5).)		
	pstack	print a hex+symbolic stack trace for each lwp in each process.		
	pfiles	report fstat (2) and fcntl (2) information for all open files in each process.		
	pwdx	print the current working directory of each process.		
	pstop	stop each process (PR_REQUESTED stop).		
	prun	set each process running (inverse of pstop).		
	pwait	wait for all of the specified processes to terminate.		
36		modified 9 Nov 1994		

	ptree	print the process trees containing the specified <i>pid</i> 's or <i>users</i> , with child processes indented from their respective parent processes. An argument of all digits is taken to be a process-id, otherwise it is assumed to be a user login name. Default is all processes.
	ptime	time a <i>command</i> , such as the time (1) command, but using micro- state accounting for reproducible precision.
OPTIONS	The following option	s are supported:
	- v	(pwait only) verbose; report each termination to standard output.
EXIT STATUS	The following exit va	lues are returned:
	0 success	
		nas occurred.
FILES	/proc/*	process files
	/usr/proc/lib/*	proc tools supporting files
SEE ALSO	ldd(1), ps(1), pwd(1) nal(5)	, time(1), truss(1), wait(1), fcntl(2), fstat(2), dlopen(3X), proc(4), sig-

modified 9 Nov 1994

NAME	prof – display profile data				
SYNOPSIS	prof [-a c n t] [-o x] [-g l] [-C] [-h] [-m mdata] [-s] [-V prog] [-z]				
DESCRIPTION	The prof command interprets a profile file produced by the monitor function. The symbol table in the object file <i>prog</i> (a.out by default) is read and correlated with a profile file (mon.out by default). For each external text symbol the percentage of time spent executing between the address of that symbol and the address of the next is printed, together with the number of times that function was called and the average number of milliseconds per call.				
OPTIONS	The mutually exclusive options $-a$, $-c$, $-n$, and $-t$ determine the type of sorting of the output lines:				
	-a Sort by increasing symbol address.				
	-c Sort by decreasing number of calls.				
	-n Sort lexically by symbol name.				
	-t Sort by decreasing percentage of total time (default).				
	The mutually exclusive options $-\mathbf{o}$ and $-\mathbf{x}$ specify the printing of the address of each symbol monitored:				
	-o Print each symbol address (in octal) along with the symbol name.				
	- x Print each symbol address (in hexadecimal) along with the symbol name.				
	The mutually exclusive options –g and –l control the type of symbols to be reported. The –l option must be used with care; it applies the time spent in a static function to the preceding (in memory) global function, instead of giving the static function a separate entry in the report. If all static functions are properly located (see example below), this feature can be very useful. If not, the resulting report may be misleading.				
	Assume that A and B are global functions and only A calls static function S . If S is located immediately after A in the source code (that is, if S is properly located), then, with the –l option, the amount of time spent in A can easily be determined, including the time spent in S . If, however, both A and B call S , then, if the –l option is used, the report will be misleading; the time spent during B 's call to S will be attributed to A , making it appear as if more time had been spent in A than really had. In this case, function S cannot be properly located.				
	-g Include static (non-global) functions.				
	-I Do not include static (non-global) functions (default).				
	The following options may be used in any combination:				
	-C Demangle C++ symbol names before printing them out.				
	 -h Suppress the heading normally printed on the report. This is useful if the report is to be processed further. 				
20	modified 26 bil 1002				

modified 26 Jul 1993

	– m mdata		
	Use file <i>mdata</i> instead of mon.out as the input profile file.		
	 -s Print a summary of several of the monitoring parameters and statistics on the standard error output. 		
	-V Print prof version information on the standard error output.		
	 -z Include all symbols in the profile range, even if associated with zero number of calls and zero time. 		
	A program creates a profile file if it has been link edited with the $-\mathbf{p}$ option of $\mathbf{cc}(1B)$. This option to the $\mathbf{cc}(1B)$ command arranges for calls to monitor at the beginning and end of execution. It is the call to monitor at the end of execution that causes the system to write a profile file. The number of calls to a function is tallied if the $-\mathbf{p}$ option was used when the file containing the function was compiled.		
	A single function may be split into subfunctions for profiling by means of the MARK macro (see prof (5)).		
ENVIRONMENT	PROFDIR The name of the file created by a profiled program is controlled by the environment variable PROFDIR . If PROFDIR is not set, mon.out is produced in the directory current when the program terminates. If PROFDIR =string, string/pid.progname is produced, where progname consists of argv[0] with any path prefix removed, and pid is the process ID of the program. If PROFDIR is set, but null, no profiling output is produced.		
FILES	mon.outdefault profile filea.outdefault namelist (object) file		
SEE ALSO	cc(1B), exit(2), profil(2), malloc(3C), malloc(3X), monitor(3C), prof(5)		
	The lprof section in <i>Programming Utilities Guide</i>		
NOTES	The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.		
	Only programs that call exit or return from main are guaranteed to produce a profile file, unless a final call to monitor is explicitly coded.		
	The times for static functions are attributed to the preceding external text symbol if the $-g$ option is not used. However, the call counts for the preceding function are still correct; that is, the static function call counts are not added to the call counts of the external function.		
	If more than one of the options $-t$, $-c$, $-a$, and $-n$ is specified, the last option specified is used and the user is warned.

1-839

Profiling may be used with dynamically linked executables, but care must be applied. Currently, shared objects cannot be profiled with **prof**. Thus, when a profiled, dynamically linked program is executed, only the "main" portion of the image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with **prof**. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the /**usr/lib/libp** directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some **libc** routine, say, **malloc()**. Suppose **malloc()** is called only from routine **B** and **B** consumes only 1 unit of time. Suppose further that routine **A** consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, **prof** will conclude that most of the time is being spent in **A** and almost no time is being spent in **B**. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine **B** and not routine **A**. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

modified 26 Jul 1993

NAME	ps – report process status			
SYNOPSIS	ps [-aAcdefjl] [-g grplist] [-n namelist] [[-o format]] [-p proclist] [-s sidlist] [-t term] [-u uidlist] [-U uidlist] [-G gidlist]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The ps command prints information about active processes. Without options, ps prints information about processes associated with the controlling terminal. The output contains only the process ID, terminal identifier, cumulative execution time, and the command name. Otherwise, the information that is displayed is controlled by the options. Some options accept lists as arguments. Items in a list can be either separated by commas			
	or else enclosed <i>grplist</i> must be i	l in quotes and separated by commas or spaces. Values for <i>proclist</i> and numeric.		
OPTIONS	The following c	options are supported:		
	-a	Print information about a ll processes most frequently requested: all those except process group leaders and processes not associated with a terminal.		
	$-\mathbf{A}$	Write information for all processes.		
	-с	Print information in a format that reflects scheduler properties as described in priocntl (1). The $-c$ option affects the output of the $-f$ and $-l$ options, as described below.		
	$-\mathbf{d}$	Print information about all processes except session leaders.		
	- e	Print information about every process now running.		
	-f	Generate a full listing. (See below for significance of columns in a full listing.)		
	− g grplist	List only process data whose group leader's ID number(s) appears in <i>grplist</i> . (A group leader is a process whose process ID number is identical to its process group ID number.)		
	–G gidlist	Write information for processes whose real group ID numbers are given in <i>grouplist</i> . The <i>grouplist</i> must be a single argument in the form of a blank- or comma-separated list.		
	-j	Print session ID and process group ID.		
	- l	Generate a long listing. (See below.)		
	– n namelist	Specify the name of an alternative system <i>namelist</i> file in place of the default. This option is accepted for compatibility, but is ignored.		
	−o format	Write information according to the format specification given in <i>format</i> . This is fully described in DISPLAY FORMATS . Multiple – o options can be specified; the format specification will be interpreted as the space-character-separated concatenation of all the <i>format</i> option-		

1-841

		argu	iments.			
	– p proclist	List	only process data whose process ID numbers are given in <i>proclist</i> .			
	– s sidlist	List	information on all session leaders whose IDs appear in <i>sidlist</i> .			
	-t term		only process data associated with <i>term</i> . Terminal identifiers are cified as a device file name, and an identifier. For example, term/a , ts/0 .			
	− u uidlist	give	only process data whose effective user ID number or login name is en in <i>uidlist</i> . In the listing, the numerical user ID will be printed ess you give the $-\mathbf{f}$ option, which prints the login name.			
	–U uidlist	nam	te information for processes whose real user ID numbers or login nes are given in <i>userlist</i> . The <i>userlist</i> must be a single argument in the n of a blank- or comma-separated list.			
	any are sp	ecified, the	of $-\mathbf{o}$ format, all of the options shown are used to select processes. If ne default list will be ignored and ps will select the processes inclusive OR of all the selection-criteria options.			
DISPLAY FORMATS						
	The column headings and the meaning of the columns in a ps listing are given below; the letters f and l indicate the option (f ull or long, respectively) that causes the corresponding heading to appear; all means that the heading always appears. Note: These two options determine only what information is provided for a process; they do not determine which processes will be listed.					
	F	 Flags (hexadecimal and additive) associated with the process. These flags are available for historical purposes; no meaning should be currently ascribed to them. 				
	S	(l)	The state of the process:			
			 O Process is running on a processor. S Sleeping: process is waiting for an event to complete. R Runnable: process is on run queue. Z Zombie state: process terminated and parent not waiting. T Process is stopped, either by a job control signal or because it is being traced. 			
	UID	(f,l)	The effective user ID number of the process (the login name is printed under the $-f$ option).			
	PID	(all)	The process ID of the process (this datum is necessary in order to kill a process).			
	PPID	(f,l)	The process ID of the parent process.			
	С	(f,l)	Processor utilization for scheduling (obsolete). Not printed when the $-c$ option is used.			

	CLS	(f,l)	Scheduling class. Printed only when the $-c$ option is used.
	PRI	(l)	The priority of the process. Without the $-c$ option, higher numbers mean lower priority. With the $-c$ option, higher numbers mean higher priority.
	NI	(1)	Nice value, used in priority computation. Not printed when the $-c$ option is used. Only processes in the certain scheduling classes have a nice value.
	ADDR	(l)	The memory address of the process.
	SZ	(l)	The size (in pages) of the swappable process's image in main memory.
	WCHAN	(l)	The address of an event for which the process is sleeping (if blank, the process is running).
	STIME	(f)	The starting time of the process, given in hours, minutes, and seconds. (A process begun more than twenty-four hours before the ps inquiry is executed is given in months and days.)
	TTY	(all)	The controlling terminal for the process (the message, ?, is printed when there is no controlling terminal).
	TIME	(all)	The cumulative execution time for the process.
	CMD	(all)	The command name (the full command name and its arguments, up to a limit of 80 characters, are printed under the $-f$ option).
	The follov	ving two ac	lditional columns are printed when the $-\mathbf{j}$ option is specified:
	PGID		The process ID of the process group leader.
	SID		The process ID of the session leader.
		that has ex < defunct >	tited and has a parent, but has not yet been waited for by the parent, .
format	The – o op	tion allows	the output format to be specified under user control.
	comma-se ridden by acters in t in the ord output. T header tey field widt	eparated. E appending he argumer er specified he field wid kt (default o h will be at	ion must be a list of names presented as a single argument, blank- or fach variable has a default header. The default header can be over- g an equals sign and the new text of the header. The rest of the char- nt will be used as the header text. The fields specified will be written I on the command line, and should be arranged in columns in the dths will be selected by the system to be at least as wide as the or overridden value). If the header text is null, such as $-\mathbf{o}$ user=, the least as wide as the default header text. If all header text fields are vill be written.
	The follow	ving names	are recognised in the POSIX locale:
	user		ective user ID of the process. This will be the textual user ID, if it can ined and the field width permits, or a decimal representation other-

-0

ruser	The real user ID of the process. This will be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.		
group	The effective group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.		
rgroup	The real group ID of the process. This will be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.		
pid	The decimal value of the process ID.		
ppid	The decimal value of the parent process ID.		
pgid	The decimal value of the process group ID.		
рсри	The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of "recently" in this con- text is unspecified. The CPU time available is determined in an unspecified manner.		
VSZ	The size of the process in (virtual) memory in kilobytes as a decimal integer.		
nice	The decimal value of the system scheduling priority of the process. See nice (1).		
etime	In the POSIX locale, the elapsed time since the process was started, in the form: [[dd-]hh:]mm:ss		
	where		
	ddwill represent the number of days,hhthe number of hours,mmthe number of minutes, andssthe number of seconds. Theddfield will be a decimal integer.		
	The <i>hh</i> , <i>mm</i> and <i>ss</i> fields will be two-digit decimal integers padded on the left with zeros.		
time	In the POSIX locale, the cumulative CPU time of the process in the form: [dd-]hh:mm:ss		
	<i>The dd</i> , <i>hh</i> , <i>mm</i> , and <i>ss</i> fields will be as described in the etime specifier.		
tty	The name of the controlling terminal of the process (if any) in the same format used by the $who(1)$ command.		
comm	The name of the command being executed (argv[0] value) as a string.		
args	The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-dependent whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the		

	command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of ps . The Solaris implementation limits the string to 80 characters; the string is the version of the argument list as it was passed to the command when it started.	
The followin	ng names are recognized in the Solaris implementation:	
f	Flags (hexadecimal and additive) associated with the process.	
S	The state of the process.	
С	Processor utilization for scheduling (obsolete).	
uid	The effective user ID number of the process as a decimal integer.	
ruid	The real user ID number of the process as a decimal integer.	
gid	The effective group ID number of the process as a decimal integer.	
rgid	The real group ID number of the process as a decimal integer.	
sid	The process ID of the session leader.	
class	The scheduling class of the process.	
pri	The priority of the process. Higher numbers mean higher priority.	
opri	The obsolete priority of the process. Lower numbers mean higher priority.	
addr	The memory address of the process.	
OSZ	The size (in pages) of the swappable process's image in main memory.	
wchan	The address of an event for which the process is sleeping (if –, the process is running).	
stime	The starting time or date of the process, printed with no blanks.	
rss	The resident set size of the process, in kilobytes as a decimal integer.	
pmem	The ratio of the process's resident set size to the physical memory on the machine, expressed as a percentage.	
fname	The first 16 characters of the base name of the process's executable file.	
Only comm and args are allowed to contain blank characters; all others, including the Solaris implementation variables, are not.		
The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.		

	For	nat Specifier	Default Header	Format Specifier	Default Header

/tmp/ps_data internal data structure

- **SEE ALSO** kill(1), nice(1), priocntl(1), who(1), getty(1M), proc(4), ttysrch(4), environ(5)
 - **NOTES** Things can change while **ps** is running; the snap-shot it gives is true only for a splitsecond, and it may not be accurate by the time you see it. Some data printed for defunct processes is irrelevant.

If no options to select processes are specified, **ps** will report all processes associated with the controlling terminal. If there is no controlling terminal, there will be no report.

ps –**ef** or **ps** –**o** stime may not report the actual start of a tty login session, but rather an earlier time, when a getty was last respawned on the tty line.

NAME	ps – display the status of current processes				
SYNOPSIS	/usr/ucb/ps [–acglnrSuUvwx] [–t term] [num]				
AVAILABILITY	SUNWscpu				
DESCRIPTION	The ps command displays information about processes. Normally, only those processes that are running with your effective user ID and are attached to a controlling terminal (see termio (7I)) are shown. Additional categories of processes can be added to the display using various options. In particular, the $-\mathbf{a}$ option allows you to include processes that are not owned by you (that do not have your user ID), and the $-\mathbf{x}$ option allows you to include processes without control terminals. When you specify both $-\mathbf{a}$ and $-\mathbf{x}$, you get processes owned by anyone, with or without a control terminal. The $-\mathbf{r}$ option restricts the list of processes printed to running and runnable processes.				
	TT ; the cpu time used by the process so far, including both user and system time, under TIME ; the state of the process, under S; and finally, an indication of the COMMAND that is muching				
	is running. The state is given by a single letter from the following:				
	 O Process is running on a processor. S Sleeping. Process is waiting for an event to complete. R Runnable. Process is on run queue. I Idle. Process is being created. Z Zombie state. Process terminated and parent not waiting. T Traced. Process stopped by a signal because parent is tracing it. X SXBRK state. Process is waiting for more primary memory. 				
OPTIONS	The following options must all be combined to form the first argument:				
	-a Include information about processes owned by others.				
	 -c Display the command name, as stored internally in the system for purposes of accounting, rather than the command arguments, which are kept in the process' address space. This is more reliable, if less informative, since the process is free to destroy the latter information. 				
	 -g Display all processes. Without this option, ps only prints interesting processes. Processes are deemed to be uninteresting if they are process group leaders. This normally eliminates top-level command interpreters and processes waiting for users to login on free terminals. 				
	-l Display a long listing, with fields F , PPID , CP , PRI , NI , SZ , RSS and WCHAN as described below.				
	-n Produce numerical output for some fields. In a user listing, the USER field is replaced by a UID field.				
	 –r Restrict output to running and runnable processes. 				

modified 26 Sep 1992

	- S	Display accumulated CPU time used by this process and all of its reaped chil-					
		dren.					
	- u	Display user-oriented output. This includes fields USER , SZ , RSS and START as described below.					
	$-\mathbf{U}$	Update a private database where ps keeps system information.					
	$-\mathbf{v}$	Display a version of the output containing virtual memory. This includes fields SIZE and RSS , described below.					
	-w	Use a wide output format (132 columns rather than 80); if repeated, that is, $-ww$, use arbitrarily wide output. This information is used to decide how much of long commands to print.					
	- x	Include processes with no controlling terminal.					
	−t term	-t term List only process data associated with the terminal, term. Terminal identifiers may be specified in one of two forms: the device's file name (for example, tty04 or term/14) or, if the device's file name starts with tty, just the digit identifier (for example, 04).					
	num	 A process number may be given, in which case the output is restricted to that process. This option must be supplied last. 					
DISPLAY	Fields that are not common to all output formats:						
FORMATS	USER	Name of the owner of the process.					
	NI	Process scheduling increment (see getpriority(3C) and nice(3B)).					
	SIZE						
	SZ	The combined size of the data and stack segments (in kilobyte units)					
	RSS	Real memory (resident set) size of the process (in kilobyte units).					
	UID	Numerical user-ID of process owner.					
	PPID	Numerical ID of parent of process.					
	СР	Short-term CPU utilization factor (used in scheduling).					
	PRI	The priority of the process (higher numbers mean lower priority).					
	START	The starting time of the process, given in hours, minutes, and seconds. A process begun more than 24 hours before the ps inquiry is executed is given in months and days.					
	WCHAI	N The address of an event for which the process is sleeping, or in SXBRK state (if blank, the process is running).					
	F	 Flags (hexadecimal and additive) associated with the process: 00 Process has terminated. Process table now available. 01 A system process, always in primary memory. 02 Parent is tracing process. 04 Tracing parent's signal has stopped process. Parent is waiting, see ptrace(2). 08 Process is currently in primary memory. 					

modified 26 Sep 1992

1B-849

10 Process currently in primary memory, locked until an event is completed.

A process that has exited and has a parent, but has not yet been waited for by the parent is marked < **defunct** >; otherwise, **ps** tries to determine the command name and arguments given when the process was created by examining the user block.

SEE ALSO kill(1), whodo(1M), lseek(2), getpriority(3C), nice(3B)

NOTES Things can change while **ps** is running; the picture it gives is only a close approximation to the current state. Some data printed for defunct processes is irrelevant.

If no *term* or *num* is specified, **ps** checks the standard input, the standard output, and the standard error in that order, looking for the controlling terminal and will attempt to report on processes associated with the controlling terminal. In this situation, if the standard input, the standard output, and the standard error are all redirected, **ps** will not find a controlling terminal, so there will be no report.

On a heavily loaded system, **ps** may report an **lseek**(2) error and exit. **ps** may seek to an invalid user area address, having obtained the address of process' user area, **ps** may not be able to seek to that address before the process exits and the address becomes invalid.

modified 26 Sep 1992

NAME	pvs – display the internal version information of dynamic objects					
SYNOPSIS	pvs [- dnorsv] [- N name] filename					
AVAILABILITY	SUNWtoo	SUNWtoo				
DESCRIPTION	pvs displays any internal version information contained within an ELF file. Commonly these files are dynamic executables and shared objects, and possibly relocatable objects. This version information can fall into one of two categories:					
		 version definitions version dependencies 				
	definition i may be ass	Version <i>definitions</i> describe the interfaces made available by an ELF file. Each version definition is associated to a set of global symbols provided by the file. Version definitions may be assigned to a file during its creation by the link-editor using the – M option and the associated <i>mapfile</i> directives (see the <i>Linker and Libraries Guide</i> for more details).				
	Version <i>dependencies</i> describe the binding requirements of dynamic objects on the version definitions of any shared object dependencies. When a dynamic object is built with a shared object, the link-editor records information within the dynamic object indicating that the shared object is a dependency. This dependency must be satisfied at runtime. If the shared object also contains version <i>definitions</i> , then those version definitions that satisfy the global symbol requirements of the dynamic object will also be recorded in the dynamic object being created. At process initialization, the runtime linker will use any version <i>dependencies</i> as a means of validating the interface requirements of the dynamic objects used to construct the process.					
OPTIONS	$-\mathbf{d}$	Print version definition information.				
		Normalize version definition information. By default, all version definitions within the object are displayed. However, version definitions may inherit other version definitions, and under normalization only the head of each inheritance list is displayed.				
		Create one-line version definition output. By default, file, version definitions, and any symbol output is indented to ease human inspection. This option preseeds each output line with the file and version definition name and may be more useful for analysis with automated tools.				
	-r	Print version dependency (requirements) information.				
		Print the symbols associated with each version definition. Any data symbols are accompanied with the size, in bytes, of the data item.				
		Verbose output. Indicates any weak version definitions, and any version definition inheritance. When used with the $-N$ and $-d$ options, the inheritance of the base version definition is also shown. When used with the $-s$ option, the version symbol definition is also shown.				

modified 16 Nov 1994

pvs(1)	User Commands	SunOS 5.5		
	 -N <i>name</i> Print only the information for the given version definition <i>name</i> and an inherited version definitions (when used with the -d option), or for the dependency file <i>name</i> (when used with the -r option). If neither the -b, or -r options are specified, both will be enabled. 			
EXAMPLES	IPLES The following example displays the version definitions of libelf.so.1 :			
	example% pvs -d /usr/lib/libelf.so.1 libelf.so.1; SUNW.1.1			
	A normalized, one-liner display, suitable for creating a <i>mapfile</i> versican be created using the $-\mathbf{n}$ and $-\mathbf{o}$ options:	ion control directive		
	example% pvs -don /usr/lib/libelf.so.1 /usr/lib/libelf.so.1 - SUNW.1.1;			
	The following example displays the version requirements of ldd , and	nd pvs :		
	example% pvs -r /usr/bin/ldd /usr/bin/pvs /usr/bin/ldd: libelf.so.1 (SUNW.1.1); libc.so.1 (SUNW.1.1); /usr/bin/pvs: libelf.so.1 (SUNW.1.1); libc.so.1 (SUNW.1.1);			
EXIT CODES	If the requested version information is not found a non-zero value a zero value is returned. Version information is determined not for option is specified and no version definitions are found; the $-\mathbf{r}$ optiversion requirements are found; neither the $-\mathbf{d}$ or $-\mathbf{r}$ option is specified definitions or version requirements are found.	und when; the – d on is specified and no

NAME	pwd – return working directory name		
SYNOPSIS	/usr/bin/pwd		
AVAILABILITY	SUNWcsu		
DESCRIPTION	pwd writes an absolute path name of the current working directory to standard output. Both the Bourne shell, sh (1), and the Korn shell, ksh (1), also have a built-in pwd command.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of pwd : LC_MESSAGES and NLSPATH .		
EXIT STATUS	 The following exit values are returned: 0 Successful completion. >0 An error occurred. If an error is detected, output will not be written to standard output, a diagnostic message will be written to standard error, and the exit status will not be 0. 		
SEE ALSO	cd(1), ksh(1), sh(1), shell_builtins(1), environ(5)		
DIAGNOSTICS	" Cannot open . ." and " Read error in . ." indicate possible file system trouble and should be referred to a UNIX system administrator.		
NOTES	If you move the current directory or one above it, pwd may not give the correct response. Use the cd (1) command with a full path name to correct this situation.		

NAME	ranlib – convert archives to random libraries
SYNOPSIS	/usr/ccs/bin/ranlib archive
AVAILABILITY	SUNWbtool
DESCRIPTION	ranlib was used in SunOS 4. <i>x</i> to add a table of contents to archive libraries, which converted each archive to a form that could be linked more rapidly. This is no longer needed as the ar (1) command automatically provides all the functionality ranlib used to provide. This script is provided as a convenience for software developers who need to maintain Makefiles that are portable across a variety of operating systems.
EXIT STATUS	ranlib has exit status 0.
SEE ALSO	ar (1), ar (4)

modified 13 Apr 1995

NAME	rcp – remote file copy			
SYNOPSIS	rcp [-p] filename1 filename2 rcp [-pr] filenamedirectory			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The rcp command copies files between machines. Each <i>filename</i> or <i>directory</i> argument is either a remote file name of the form:			
	hostname:path			
	or a local file name (containing no : characters, or a / before any : characters).			
	If a <i>filename</i> is not a full path name, it is interpreted relative to your home directory on <i>hostname</i> . A <i>path</i> on a remote host may be quoted (using \backslash , ", or ') so that the metach acters are interpreted remotely.			
	rcp does not prompt for passwords; your current local user name must exist on <i>hostnar</i> and allow remote command execution by rsh (1).			
	rcp handles third party copies, where neither source nor target files are on the current machine. Hostnames may also take the form			
	username@hostname:filename			
	to use <i>username</i> rather than your current local user name as the user name on the remote host. rcp also supports Internet domain addressing of the remote host, so that:			
	username@host.domain:filename			
	specifies the username to be used, the hostname, and the domain in which that host resides. Filenames that are not full path names will be interpreted relative to the home directory of the user named <i>username</i> , on the remote host.			
OPTIONS	- p Attempt to give each copy the same modification times, access times, modes, and ACLs if applicable as the original file. Note that the command may fail if ACLs are copied to a file system that doesn't support ACLs.			
	 -r Copy each subtree rooted at <i>filename</i>; in this case the destination must be a directory. 			
FILES	\$HOME/.profile			
SEE ALSO	cpio(1), ftp(1), setfacl(1), rlogin(1), rsh(1), tar(1), hosts.equiv(4)			
NOTES	rcp is meant to copy between different hosts; attempting to rcp a file onto itself, as with: rcp tmp/file myhost:/tmp/file			
	results in a severely corrupted file.			

rcp may not correctly fail when the target of a copy is a file instead of a directory.

rcp can become confused by output generated by commands in a **\$HOME/.profile** on the remote host.

rcp requires that the source host have permission to execute commands on the remote host when doing third-party copies.

rcp does not properly handle symbolic links. Use **tar** (see **tar**(1)) or **cpio** (see **cpio**(1)) piped to **rsh** to obtain remote copies of directories containing symbolic links or named pipes.

If you forget to quote metacharacters intended for the remote host you get an incomprehensible error message.

User Commands

NAME	rdist – remote file distribution program		
SYNOPSIS	$ rdist [-b][-D][-h][-i][-n][-q][-R][-v][-w][-y] \\ [-d macro = value][-f distfile][-m host] \dots [package \dots] $		
	$ \begin{array}{c} rdist \left[-b \right] \left[-D \right] \left[-h \right] \left[-i \right] \left[-n \right] \left[-q \right] \left[-R \right] \left[-v \right] \left[-w \right] \left[-y \right] \\ -c \ pathname \ \dots \ \left[\ login@ \ \right] \ hostname \left[: destpath \right] \end{array} $		
AVAILABILITY	SUNWcsu		
DESCRIPTION	rdist maintains copies of files on multiple hosts. It preserves the owner, group, mode, and modification time of the master copies, and can update programs that are executing. Normally, a copy on a remote host is updated if its size or modification time differs from the original on the local host. rdist reads the indicated <i>distfile</i> for instructions on updating files and/or directories. If <i>distfile</i> is '-', the standard input is used. If no -f option is present, rdist first looks in its working directory for distfile , and then for Distfile , for instructions.		
	rdist updates each <i>package</i> specified on the command line; if none are given, all packages are updated according to their entries in the <i>distfile</i> .		
	In order to be able to use rdist across machines, each host machine must have a / etc/host.equiv file, or the user must have an entry in the .rhosts file in the home directory. See hosts.equiv (4) for more information.		
OPTIONS	-b	Binary comparison. Perform a binary comparison and update files if they differ, rather than merely comparing dates and sizes.	
	- D	Enable debugging.	
	-h	Follow symbolic links. Copy the file that the link points to rather than the link itself.	
	-i	Ignore unresolved links. rdist will normally try to maintain the link structure of files being transferred and warn the user if all the links cannot be found.	
	-n	Print the commands without executing them. This option is useful for debugging a distfile.	
	- q	Quiet mode. Do not display the files being updated on the standard output.	
	- R	Remove extraneous files. If a directory is being updated, remove files on the remote host that do not correspond to those in the master (local) directory. This is useful for maintaining truly identical copies of direc- tories.	
	- v	Verify that the files are up to date on all the hosts. Any files that are out of date are displayed, but no files are updated, nor is any mail sent.	
	-w	Whole mode. The whole file name is appended to the destination direc- tory name. Normally, only the last component of a name is used when	

modified 24 Jan 1995

1-857

		renaming files. This preserves the directory structure of the files being copied, instead of flattening the directory structure. For instance, renaming a list of files such as dir1/dir2 to dir3 would create files dir3/dir1 and dir3/dir2 instead of dir3 and dir3 . When the –w option is used with a filename that begins with ~, everything except the home directory is appended to the destination name.	
	- y	Younger mode. Do not update remote copies that are younger than the master copy, but issue a warning message instead.	
	-d macro=value	Define <i>macro</i> to have <i>value</i> . This option is used to define or override macro definitions in the distfile. <i>value</i> can be the empty string, one name, or a list of names surrounded by parentheses and separated by white space.	
	–c pathname	[<i>login</i> @] <i>hostname</i> [: <i>destpath</i>] Update each <i>pathname</i> on the named host. (Relative filenames are taken as relative to your home directory.) If the ' <i>login</i> @' prefix is given, the update is performed with the user ID of <i>login</i> . If the ' <i>:destpath</i> ' is given, the remote file is installed as that pathname.	
	-f distfile	Use the description file <i>distfile</i> . A '-' as the <i>distfile</i> argument denotes the standard input.	
	– m host	Limit which machines are to be updated. Multiple $-\mathbf{m}$ arguments can be given to limit updates to a subset of the hosts listed in the distfile.	
USAGE White Space Characters	across input line	and SPACE characters are all treated as white space; a mapping continues es until the start of the next mapping: either a single <i>filename</i> followed by a ing parenthesis of a filename list.	
Comments	Comments begin with # and end with a NEWLINE.		
Macros	rdist has a limited macro facility. Macros must be defined outside of the packages. Macros are only expanded in filename or hostname lists, and in the argument lists of certain primitives. Macros cannot be used to stand for primitives or their options, or the ' \rightarrow ' or '::' symbols.		
	A macro definition is a line of the form:		
	macro = value A macro reference is a string of the form:		
	\${macro	-	
	although (as wi one character.	th make (1S)) the braces can be omitted if the macro name consists of just	

modified 24 Jan 1995

Metacharacters	The shell meta-characters: [,], {, }, * and ? are recognized and expanded (on the local host only) just as they are with csh (1). Metacharacters can be escaped by prepending a backslash.
	The ~ character is also expanded in the same way as with csh , however, it is expanded separately on the local and destination hosts.
Filenames	File names that do not begin with '/' or '~' are taken to be relative to user's home direc- tory on each destination host; they are <i>not</i> relative to the current working directory. Mul- tiple file names must be enclosed within parentheses.
Primitives	The following primitives can be used to specify actions rdist is to take when updating remote copies of each file.
	install [-b] [-h] [-i] [-R] [-v] [-w] [-y] [newname] Copy out-of-date files and directories (recursively). If no install primitive appears in the package entry, or if no newname option is given, the name of the local file is given to the remote host's copy. If absent from the remote host, parent directories in a filename's path are created. To help prevent disasters, a non-empty directory on a target host is not replaced with a regular file or a sym- bolic link by rdist. However, when using the -R option, a non-empty directory is removed if the corresponding filename is completely absent on the master host.
	The options for install have the same semantics as their command line counter- parts, but are limited in scope to a particular map. The login name used on the destination host is the same as the local host unless the destination name is of the format <i>login@host</i> . In that case, the update is performed under the username <i>login</i> .
	notify address
	Send mail to the indicated TCP/IP <i>address</i> of the form:
	user@host
	that lists the files updated and any errors that may have occurred. If an address does not contain a '@host' suffix, rdist uses the name of the destination host to complete the address.
	except <i>filename</i> Omit from updates the files named as arguments.
	<pre>except_pat pattern Omit from updates the filenames that match each regular-expression pattern (see ed(1) for more information on regular expressions). Note that '\' and '\$' charac- ters must be escaped in the distfile. Shell variables can also be used within a pat- tern, however shell filename expansion is not supported.</pre>
	special [filename] "command-line" Specify a Bourne shell, sh(1) command line to execute on the remote host after each named file is updated. If no filename argument is present, the command-line is performed for every updated file, with the shell variable FILE set to the file's

modified 24 Jan 1995

rdist(1)		User Commands	SunOS 5.5	
	name on the local host. The quotation marks allow <i>command-line</i> to span input lines in the distfile; multiple shell commands must be separated by semicolons (;).			
	The default working directory for the shell executing each <i>command-line</i> is the user's home directory on the remote host.			
EXAMPLES	PLES The following sample distfile instructs rdist to maintain identical copies of a salibrary, a shared-library initialized data file, several include files, and a direct hosts named hermes and magus . On magus , commands are executed as superdist notifies merlin@druid whenever it discovers that a local file has changed a timestamp file.			
	HOSTS = (hermes root@magus)			
	FILES = (/usr/local/lib/libcant.so.1.1 /usrlocal/lib/libcant.sa.1.1 /usr/local/include/{*.h} /usr/local/bin)			
	$(\${\rm FILES}) \to (\${\rm HOSTS})$			
	install –R ;			
	\${FILES} :: /usr/local/lib/timestamp notify merlin@druid ;			
FILES	~/.rhosts /etc/host.equiv /tmp/rdist*	user's trusted hosts and users system trusted hosts and user temporary file for update lists	rs	
SEE ALSO	csh(1), ed(1), make(1S), sh(1), stat(2), hosts.equiv(4)			
DIAGNOSTICS	A complaint about mismatch of rdist version numbers may really stem from some prob- lem with starting your shell, for example, you are in too many groups.			
WARNINGS	The super-user does not have its accustomed access privileges on NFS mounted file sys- tems. Using rdist to copy to such a file system may fail, or the copies may be owned by user "nobody".			
BUGS	BUGS Source files must reside or be mounted on the local host.			
	There is no easy way to have a special command executed only once after all files in a directory have been updated.			
	Variable expansion only works for name lists; there should be a general macro			
	rdist aborts on files that have a negative modification time (before Jan 1, 1970).			
	There should be a "force" option to allow replacement of non-empty directories by regular files or symlinks. A means of updating file modes and owners of otherwise identical files is also needed.			

modified 24 Jan 1995

NAME	read – read a line from standard input			
SYNOPSIS	/usr/bin/read [-r] var			
sh	read name			
csh	<pre>set variable = \$<</pre>			
ksh	read [- prsu [<i>n</i>]] [<i>name</i> ? <i>prompt</i>] [<i>name</i>]			
DESCRIPTION /usr/bin/read	The read utility will read a single line from standard input.			
	By default, unless the –r option is specified, backslash (\) acts as an escape character. If standard input is a terminal device and the invoking shell is interactive, read will prompt for a continuation line when:			
	• The shell reads an input line ending with a backslash, unless the -r option is specified.			
	• A here-document is not terminated after a newline character is entered.			
	 The line will be split into fields as in the shell; the first field will be assigned to the first variable <i>var</i>, the second field to the second variable <i>var</i>, and so forth. If there are fewer <i>var</i> operands specified than there are fields, the leftover fields and their intervening separators will be assigned to the last <i>var</i>. If there are fewer fields than <i>vars</i>, the remain ing <i>vars</i> will be set to empty strings. The setting of variables specified by the <i>var</i> operands will affect the current shell execution environment. If it is called in a subshell or separate utility execution environment, such as one of the following: 			
	(read foo) nohup read findexec read ∖; it will not affect the shell variables in the caller's environment. The standard input must be a text file.			
sh	One line is read from the standard input and, using the internal field separator, IFS (normally space or tab), to delimit word boundaries, the first word is assigned to the first <i>name</i> , the second word to the second <i>name</i> , etc., with leftover words assigned to the last <i>name</i> . Lines can be continued using \newline . Characters other than newline can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to <i>names</i> , and no interpretation is done on the character that follows the backslash. The return code is 0 , unless an EOF is encountered.			
csh	The notation set <i>variable</i> = \$< loads one line of standard input as the value for <i>variable</i> . (See csh (1)).			

modified 28 Mar 1995

1-861

ksh	The shell input mechanism. One line is read and is broken up into fields using the char- acters in IFS as separators. The escape character, (\), is used to remove any special mean- ing for the next character and for line continuation. In raw mode, $-\mathbf{r}$, the \ character is not treated specially. The first field is assigned to the first <i>name</i> , the second field to the second <i>name</i> , etc., with leftover fields assigned to the last <i>name</i> . The $-\mathbf{p}$ option causes the input line to be taken from the input pipe of a process spawned by the shell using &. If the $-\mathbf{s}$ flag is present, the input will be saved as a command in the history file. The flag $-\mathbf{u}$ can be used to specify a one digit file descriptor unit <i>n</i> to read from. The file descrip- tor can be opened with the exec special command. The default value of <i>n</i> is 0 . If <i>name</i> is omitted then REPLY is used as the default <i>name</i> . The exit status is 0 unless the input file is not open for reading or an end-of-file is encountered. An end-of-file with the $-\mathbf{p}$ option causes cleanup for this process so that another can be spawned. If the first argument con- tains a ?, the remainder of this word is used as a <i>prompt</i> on standard error when the shell is interactive. The exit status is 0 unless an end-of-file is encountered.			
OPTIONS	The following option is supported:			
	 -r Do not treat a backslash character in any special way. Consider each backslash to be part of the input line. 			
OPERANDS	The following operand is supported:			
	<i>var</i> The name of an existing or non-existing shell variable.			
EXAMPLES	The following example for / usr/bin/read prints a file with the first field of each line moved to the end of the line. while read -r xx yy do printf "%s %s\n" "\$yy" "\$xx" done < input_file			
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of read : LC_CTYPE , LC_MESSAGES , and NLSPATH .			
	IFS Determine the internal field separators used to delimit fields.			
	PS2 Provide the prompt string that an interactive shell will write to standard error when a line ending with a backslash is read and the –r option was not specified, or if a here-document is not terminated after a newline character is entered.			
EXIT STATUS	The following exit values are returned:0Successful completion.>0End-of-file was detected or an error occurred.			
SEE ALSO	csh (1), ksh (1), line (1), set (1), sh (1), environ (5)			

modified 28 Mar 1995

NAME	readfile, longline – reads file, gets longest line			
SYNOPSIS	readfile filename			
	longline [filename]			
DESCRIPTION	The readfile function reads <i>filename</i> and copies it to <i>stdout</i> . No translation of NEWLINE is done. It keeps track of the longest line it reads and if there is a subsequent call to long-line , the length of that line, including the NEWLINE character, is returned.			
	The longline function returns the length, including the NEWLINE character, of the longest line in <i>filename</i> . If <i>filename</i> is not specified, it uses the file named in the last call to readfile .			
EXAMPLES	Here is a typical use of readfile and longline in a text frame definition file:			
	text="`readfile myfile`" columns=`longline`			
SEE ALSO	cat (1)			
DIAGNOSTICS	If <i>filename</i> does not exist, readfile will return FALSE (that is, the expression will have an error return).			
	longline returns 0 if a readfile has not previously been issued.			
NOTES	More than one descriptor can call readfile in the same frame definition file. In text frames, if one of those calls is made from the text descriptor, then a subsequent use of longline will always get the longest line of the file read by the readfile associated with the text descriptor, even if it was not the most recent use of readfile .			

NAME	readonly – shell built-in function to protect the value of the given variable from reassign- ment				
SYNOPSIS sh	readonly [name]				
ksh	†† readonly [name[=value]]				
DESCRIPTION sh	The given <i>names</i> are marked <i>readonly</i> and the values of the these <i>names</i> may not be changed by subsequent assignment. If no arguments are given, a list of all <i>readonly</i> names is printed.				
ksh	The given <i>name</i> s are marked readonly and these names cannot be changed by subseque assignment.				
	On this man page, ksh (1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:				
	1. Variable assignment lists preceding the command remain in effect when the command completes.				
	2. I/O redirections are processed after variable assignments.				
	3. Errors cause a script that contains them to abort.				
	4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	refer – expand and insert references from a bibliographic database		
SYNOPSIS	refer [- ben] [- a <i>r</i>] [- c <i>string</i>] [- k <i>x</i>] [- l <i>m</i> , <i>n</i>] [- p <i>filename</i>] [- s <i>keys</i>] <i>filename</i>		
AVAILABILITY	SUNWdoc		
DESCRIPTION	refer is a preprocessor for nroff (1), or troff (1), that finds and formats references. The input files (standard input by default) are copied to the standard output, except for lines between '. [' and '.]' command lines, Such lines are assumed to contain keywords as for lookbib (1), and are replaced by information from a bibliographic data base. The user can avoid the search, override fields from it, or add new fields. The reference data, from whatever source, is assigned to a set of troff strings. Macro packages such as ms (5) print the finished reference text from these strings. A flag is placed in the text at the point of reference. By default, the references are indicated by numbers. When refer is used with eqn (1), neqn , or tbl (1), refer should be used first in the sequence, to minimize the volume of data passed through pipes.		
OPTIONS	- b Bare mode — do not put any flags in text (neither numbers or labels).		
of nons	 -e Accumulate references instead of leaving the references where encountered, until a sequence of the form: 		
	.[\$LIST\$.]		
	is encountered, and then write out all references collected so far. Collapse references to the same source.		
	- n Do not search the default file.		
	- a <i>r</i> Reverse the first <i>r</i> author names (Jones, J. A. instead of J. A. Jones). If <i>r</i> is omitted, all author names are reversed.		
	<i>–cstring</i> Capitalize (with SMALL CAPS) the fields whose key-letters are in <i>string</i> .		
	-kx Instead of numbering references, use labels as specified in a reference data line beginning with the characters %x; By default, x is L.		
	-lm,n Instead of numbering references, use labels from the senior author's last name and the year of publication. Only the first <i>m</i> letters of the last name and the last <i>n</i> digits of the date are used. If either of <i>m</i> or <i>n</i> is omitted, the entire name or date, respectively, is used.		
	- p filename		
	Take the next argument as a file of references to be searched. The default file is searched last.		

	-s <i>keys</i> Sort references by fields whose key-letters are in the <i>keys</i> string, and permute reference numbers in the text accordingly. Using this option implies the -e option. The key-letters in <i>keys</i> may be followed by a number indicating how many such fields are used, with a + sign taken as a very large number. The default is AD , which sorts on the senior author and date. To sort on all authors and then the date, for instance, use the options ' -sA+T '.
FILES	/usr/lib/referdirectory of programs/usr/lib/refer/papersdirectory of default publication lists and indexes

NAME	regcmp – regular expression compile			
SYNOPSIS	regcmp [–] filename			
DESCRIPTION	The regcmp command performs a function similar to regcmp and, in most cases, pre- cludes the need for calling regcmp from C programs. Bypassing regcmp saves on both execution time and program size. The command regcmp compiles the regular expres- sions in <i>filename</i> and places the output in <i>filename</i> .i.			
OPTIONS	If the – option is used, the output is placed in <i>filename.c.</i> The format of entries in <i>filename</i> is a name (C variable) followed by one or more blanks followed by one or more regular expressions enclosed in double quotes. The output of regcmp is C source code. Compiled regular expressions are represented as extern char vectors. <i>filename.i</i> files may thus be #include d in C programs, or <i>filename.c</i> files may be compiled and later loaded. In the C program that uses the regcmp output, regex(abc,line) applies the regular expression named abc to line . Diagnostics are self-explanatory.			
EXAMPLES	name "([A–Za–z][A–Za–z0–9]*)\$0"			
	telno "\({0,1}([2–9][01][1–9])\$0\){0,1} *" "([2–9][0–9]{2})\$1[–]{0,1}" "([0–9]{4})\$2"			
	The three arguments to telno shown above must all be entered on one line.			
	In the C program that uses the regcmp output,			
	regex(telno, line, area, exch, rest)			
	applies the regular expression named telno to line .			
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of regcmp for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how regcmp behaves. LC_CTYPE Determines how regcmp handles characters. When LC_CTYPE is set to a valid value, regcmp can display and handle text and filenames containing valid charac- ters for that locale. regcmp can display and handle Extended Unix Code (EUC)			
	characters where any individual character can be 1, 2, or 3 bytes wide. regcmp can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.			

LC MESSAGES	LC	MESSAGES	
-------------	----	----------	--

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

NAME	regex – match patterns against a string			
SYNOPSIS	regex [– e] [– v "string"] [pattern template] pattern [template]			
DESCRIPTION	The regex command takes a string from <i>the standard input</i> , and a list of <i>pattern / template</i> pairs, and runs regex() to compare the string against each <i>pattern</i> until there is a match. When a match occurs, regex writes the corresponding <i>template</i> to <i>the standard output</i> and returns TRUE . The last (or only) <i>pattern</i> does not need a template. If that is the pattern that matches the string, the function simply returns TRUE . If no match is found, regex returns FALSE .			
	The argument <i>pattern</i> is a regular expression of the form described in regex (). In most cases <i>pattern</i> should be enclosed in single quotes to turn off special meanings of characters. Note that only the final <i>pattern</i> in the list may lack a <i>template</i> .			
	The argument <i>template</i> may contain the strings \$m0 through \$m9 , which will be expanded to the part of <i>pattern</i> enclosed in () \$0 through () \$9 constructs (see examples below). Note that if you use this feature, you must be sure to enclose <i>template</i> in single quotes so that FMLI does not expand \$m0 through \$m9 at parse time. This feature gives regex much of the power of cut (1), paste (1), and grep (1), and some of the capabilities of sed (1). If there is no <i>template</i> , the default is \$m0\$m1\$m2\$m3\$m4\$m5\$m6\$m7\$m8\$m9 .			
OPTIONS	-e Evaluate the corresponding template and write the result to <i>the standard output.</i>			
	$-\mathbf{v}$ "string" Use string instead of the standard input to match against patterns.			
EXAMPLES	To cut the 4th through 8th letters out of a string (this example will output strin and return TRUE):			
	`regex –v "my string is nice" '^.{3}(.{5})\$0' '\$m0'`			
	In a form, to validate input to field 5 as an integer:			
	valid=`regex -v "\$F5" '^[0-9]+\$'`			
	In a form, to translate an environment variable which contains one of the numbers 1, 2, 3, 4, 5 to the letters a, b, c, d, e:			
	value=`regex –v "\$VAR1" 1 a 2 b 3 c 4 d 5 e '.*' 'Error'`			
	Note the use of the pattern '.*' to mean "anything else".			
	In the example below, all three lines constitute a single backquoted expression. This expression, by itself, could be put in a menu definition file. Since backquoted expressions are expanded as they are parsed, and output from a backquoted expression (the cat command, in this example) becomes part of the definition file being parsed, this expression would read / etc/passwd and make a dynamic menu of all the login ids on the system.			
	`cat /etc/passwd regex '^([^:]*)\$0.*\$' ' name=\$m0			
	action=`message "\$m0 is a user"```			

1F-869

DIAGNOSTICS	If none of the patterns match, regex returns FALSE , otherwise TRUE .			
NOTES	Patterns and templates must often be enclosed in single quotes to turn off the special meanings of characters. Especially if you use the \$m0 through \$m9 variables in the template, since FMLI will expand the variables (usually to "") before regex even sees them.			
	Single characters in character classes (inside []) must be listed before character ranges, otherwise they will not be recognized. For example, [a-zA-Z_/] will not find underscores (_) or slashes (/), but [_/a-zA-Z] will.			
	The regular expressions accepted by regcmp differ slightly from other utilities (that i sed , grep , awk , ed , etc.).			
	regex with the –e option forces subsequent commands to be ignored. In other words if a backquoted statement appears as follows:			
	`regex -e; command1; command2`			
	<i>command1</i> and <i>command2</i> would never be executed. However, dividing the expression into two:			
	`regex -e``command1; command2`			
	would yield the desired result.			
SEE ALSO	D awk(1), cut(1), grep(1), paste(1), sed(1), regcmp(3G)			

NAME	reinit – runs an initialization file			
SYNOPSIS	reinit filename			
DESCRIPTION	The reinit command is used to change the values of descriptors defined in the initializa- tion file that was named when fmli was invoked and/or define additional descriptors. FMLI will parse and evaluate the descriptors in <i>filename</i> , and then continue running the current application. The argument <i>filename</i> must be the name of a valid FMLI initializa- tion file. The reinit command does not re-display the introductory frame or change the layout of screen labels for function keys.			

1F-871

NAME	renice – alter priority of running processes			
SYNOPSIS	renice $[-n increment] [-g -p -u] ID$ renice priority $[-p] pid [-g gid] [-p pid] [-u user]$ renice priority $-g gid [-g gid] [-p pid] [-u user]$ renice priority $-u user [-g gid] [-p pid] [-u user]$			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The renice command alters the scheduling priority of one or more running processes default, the processes to be affected are specified by their process IDs.			
	priority (as in al	The first operand is a number within the valid range of priorities, renice will treat it as a <i>riority</i> (as in all but the first synopsis form); otherwise, renice will treat it as an <i>ID</i> (as in the first synopsis form).		
Altering Process Priority	Users other than the privileged user may only alter the priority of processes they own, and can only monotonically increase their "nice value" within the range 0 to 19 . This prevents overriding administrative fiats. The privileged user may alter the priority of any process and set the priority to any value in the range – 20 to 19 . Useful priorities are: 19 (the affected processes will run only when nothing else in the system wants to), 0 (the "base" scheduling priority) and any negative value (to make things go very fast).			
OPTIONS	•	 s the following option features: The first operand, <i>priority</i>, must precede the options and can have the appearance of a multi-digit option. The -g, -p and -u options can each take multiple option-arguments. The <i>pid</i> option-argument can be used without its -p option. 		
	The following options are supported:			
	-g	Interpret all operands or just the <i>gid</i> arguments as unsigned decimal integer process group IDs.		
	-n increment	Specify how the system scheduling priority of the specified process or processes is to be adjusted. The <i>increment</i> option-argument is a positive or negative decimal integer that will be used to modify the system scheduling priority of the specified process or processes.		
		Positive <i>increment</i> values cause a lower system scheduling priority. Negative <i>increment</i> values may require appropriate privileges and will cause a higher system scheduling priority.		
	- p	Interpret all operands or just the <i>pid</i> arguments as unsigned decimal integer process IDs. The $-\mathbf{p}$ option is the default if no options are specified.		
	–u	Interpret all operands or just the <i>user</i> argument as users. If a user exists with a user name equal to the operand, then the user ID of that user will be used in further processing. Otherwise, if the operand represents an		

modified 28 Mar 1995

		unsigned decimal integer, it will be used as the numeric user ID of the user.	
OPERANDS	The following operands are supported:		
		A process ID, process group ID or user name/user ID, depending on the option selected.	
	I	The value specified is taken as the actual system scheduling priority, rather than as an increment to the existing system scheduling priority. Specifying a scheduling priority higher than that of the existing process may require appropriate privileges.	
EXAMPLES	Adjust the system scheduling priorit	n scheduling priority so that process IDs 987 and 32 would have a lower ty:	
	example%	% renice -n 5 -p 987 32	
		n scheduling priority so that group IDs 324 and 76 would have a higher ty, if the user has the appropriate privileges to do so:	
	example%	% renice -n -4 -g 324 76	
	Adjust the system a lower schedulin	a scheduling priority so that numeric user ID 8 and user sas would have g priority:	
	example%	% renice -n 4 -u 8 sas	
ENVIRONMENT		r descriptions of the following environment variables that affect the exe- LC_CTYPE, LC_MESSAGES, and NLSPATH.	
EXIT STATUS	The following exi	t values are returned:	
	0 Succes	ssful completion.	
	> 0 An err	or occurred.	
FILES	/etc/passwd	map user names to user ID's	
SEE ALSO	nice(1), priocntl(1	l), environ(5)	
NOTES	If you make the p	riority very negative, then the process cannot be interrupted.	
		you must make the priority greater than 0 .	
	Users other than t	the privileged user cannot increase scheduling priorities of their own they were the ones that decreased the priorities in the first place.	
	The priocntl com	mand subsumes the function of renice .	

modified 28 Mar 1995

NAME	reset – reset the current form field to its default values
SYNOPSIS	reset
DESCRIPTION	The reset function changes the entry in a field of a form to its default value; that is, the value displayed when the form was opened.
	I

NAME	rlogin – remote	login	
SYNOPSIS	rlogin [–L] [–8] [–ec] [–l username] hostname		
AVAILABILITY	SUNWcsu		
DESCRIPTION	 rlogin establishes a remote login session from your terminal to the remote machine named <i>hostname</i>. Hostnames are listed in the <i>hosts</i> database, which may be contained in the /etc/hosts file, the Network Information Service (NIS) hosts map, the Internet domain name server, or a combination of these. Each host has one official name (the first name in the database entry), and optionally one or more nicknames. Either official hostnames or nicknames may be specified in <i>hostname</i>. Each remote machine may have a file named /etc/hosts.equiv containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may rlogin from the machines listed in the remote machine's /etc/hosts.equiv file without supplying a password. Individual users may set up a similar private equivalence list with the file .rhosts in their home directories. Each line in this file contains two names: a <i>hostname</i> and a <i>username</i> separated by a space. An entry in a remote user's .rhosts file permits the user named <i>username</i> who is logged into <i>hostname</i> to log in to the remote machine as the remote user without supplying a password. If the name of the local host is not found in the /etc/hosts.equiv file on the remote machine, and the local username and hostname are not found in the remote user's .rhosts file, then the remote machine will prompt for a password. Hostnames listed in /etc/hosts.equiv and .rhosts files must be the official hostnames listed in the hosts database; nicknames may not be used in either of these files. 		
	For security reasons, the .rhosts file must be owned by either the remote user or by root. The remote terminal type is the same as your local terminal type (as given in your environment TERM variable). The terminal or window size is also copied to the remote system if the server supports the option, and changes in size are reflected as well. All echoing takes place at the remote site, so that (except for delays) the remote login is tran- sparent. Flow control using CTRL-S and CTRL-Q and flushing of input and output on interrupts are handled properly.		
OPTIONS	–L	Allow the rlogin session to be run in "litout" mode.	
	-8	Pass eight-bit data across the net instead of seven-bit data.	
	- e <i>c</i>	Specify a different escape character, c , for the line used to disconnect from the remote host.	
	-l username	Specify a different <i>username</i> for the remote login. If you do not use this option, the remote username used is the same as your local username.	

Escape Sequences	Lines that you type which start with the tilde character are "escape sequences" (the escape character can be changed using the $-e$ options):			
	 Disconnect from the remote host — this is not the same as a logout, because the local host breaks the connection with no warning to the remote end. 			
	*susp Suspend the login session (only if you are using a shell with Job Control). susp is your "suspend" character, usually CTRL-Z; see tty (1).			
	`dsusp Suspend the input half of the login, but output will still be seen (only if you are using a shell with Job Control). dsusp is your "deferred suspend" character, usually CTRL-Y; see tty (1).			
FILES	/etc/passwd			
	/usr/hosts/* for <i>hostname</i> version of the command			
	/etc/hosts.equivlist of trusted hostnames with shared usernames\$HOME/.rhostsprivate list of trusted hostname/username combinations			
SEE ALSO	<pre>rsh(1), stty(1), tty(1), in.named(1M), hosts(4), hosts.equiv(4)</pre>			
NOTES	When a system is listed in hosts.equiv , its security must be as good as local security. One insecure system listed in hosts.equiv can compromise the security of the entire system.			
	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed.			
	This implementation can only use the TCP network service.			

NAME	rm, rmdir – remove directory entries
SYNOPSIS	/usr/bin/rm [-f] [-i] file /usr/bin/rm -rR [-f] [-i] dirname [file] /usr/xpg4/bin/rm [-fiRr] file /usr/bin/rmdir [-ps] dirname
AVAILABILITY /usr/bin/rm /usr/bin/rmdir /usr/xpg4/bin/rm	SUNWcsu SUNWxcu4
DESCRIPTION rm	The rm command removes the directory entry specified by each <i>file</i> argument. If a <i>file</i> has no write permission and the standard input is a terminal, the full set of permissions (in octal) for the file are printed followed by a question mark. This is a prompt for confirmation. If the answer begins with y (for yes), the file is deleted, otherwise the file remains. If <i>file</i> is a symbolic link, the link will be removed, but the file or directory to which it refers will not be deleted. Users do not need write permission to remove a symbolic link, provided they have write permissions in the directory. If multiple <i>files</i> are specified and removal of a <i>file</i> fails for any reason, rm will write a diagnostic message to standard error, do nothing more to the current <i>file</i> , and go on to any remaining <i>files</i> . If the standard input is not a terminal, the command will operate as if the -f option is in effect.
rmdir	The rmdir command will remove the directory entry specified by each <i>dirname</i> operand, which must refer to an empty directory. Directories will be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of rmdir , the subdirectory must be specified before the parent directory so that the parent directory will be empty when rmdir tries to remove it.
OPTIONS	The following options apply to rm :
/usr/bin/rm	-f Remove all files (whether write-protected or not) in a directory without prompt- ing the user. In a write-protected directory, however, files are never removed (whatever their permissions are), but no messages are displayed. If the removal of a write-protected directory is attempted, this option will not suppress an error message.

modified 28 Feb 1995

1-877

n(1)		User Commands	SunOS 5.5
/usr/xpg4/bin/rm		Do not prompt for confirmation. Do not write diagnostic messages or exit status in the case of non-existent operands. Any previous occurer –i option will be ignored.	v
/usr/xpg4/bin/rm		Interactive. With this option, rm prompts for confirmation before ren files. It overrides the $-\mathbf{f}$ option and remains in effect even if the stand not a terminal.	
/usr/xpg4/bin/rm	- i	Prompt for confirmation. Any occurences of the $-\mathbf{f}$ option will be ign	ored.
10	- r	Recursively remove directories and subdirectories in the argument list directory will be emptied of files and removed. The user is normally for removal of any write-protected files which the directory contains. protected files are removed without prompting, however, if the $-\mathbf{f}$ op or if the standard input is not a terminal and the $-\mathbf{i}$ option is not used.	t. The prompted The write- tion is used,
		Symbolic links that are encountered with this option will not be trave	rsed.
		If the removal of a non-empty, write-protected directory is attempted mand will always fail (even if the –f option is used), resulting in an er sage.	
	- R	Same as – r option.	
	The follo	owing options apply to rmdir :	
		Allow users to remove the directory <i>dirname</i> and its parent directories become empty. A message is printed on the standard error about wh whole path is removed or part of the path remains for some reason.	
	-s	Suppress the message printed on the standard error when $-{f p}$ is in effe	ect.
OPERANDS	The follo	owing operand is supported:	
	file	A path name of a directory entry to be removed.	
	dirname	A path name of an empty directory to be removed.	
EXAMPLES rm		owing command: example% rm a.out core	
		the directory entries: a.out and core . owing command:	
		example% rm -rf junk	
		the directory junk and all its contents, without prompting.	
rmdir	empty e	ctory a in the current directory is empty except it contains a directory ccept it contains a directory c , example% rmdir -p a/b/c	b and a/b is
		example % fmuir -p a/b/c

NAME	roffbib – format and print a bibliographic database		
SYNOPSIS	roffbib $[-e] [-h] [-m filename] [-np] [-olist] [-Q] [-raN] [-sN] [-Tterm] [-V] [-x] [filename]$		
AVAILABILITY	SUNW	doc	
DESCRIPTION		prints out all records in a bibliographic database, in bibliography format rather footnotes or endnotes. Generally it is used in conjunction with sortbib (1):	
		example% sortbib database roffbib	
OPTIONS	roffbib	accepts all options understood by nroff (1) except –i and –q .	
	- e	Produce equally-spaced words in adjusted lines using full terminal resolution.	
	-h	Use output tabs during horizontal spacing to speed output and reduce output character count. TAB settings are assumed to be every 8 nominal character widths.	
	– m filen	name Prepend the macro file / usr/share/lib/tmac/tmac.name to the input files. There should be a space between the – m and the macro filename. This set of macros will replace the ones defined in / usr/share/lib/tmac/tmac.bib .	
	$-\mathbf{n}p$	Number first generated page <i>p</i> .	
	-olist	Print only page numbers that appear in the comma-separated <i>list</i> of numbers and ranges. A range $N-M$ means pages N through M ; an initial $-N$ means from the beginning to page N ; a final N - means from page N to end.	
	$-\mathbf{Q}$	Queue output for the phototypesetter. Page offset is set to 1 inch.	
	-raN	Set register <i>a</i> (one-character) to <i>N</i> . The command-line argument $-\mathbf{rN1}$ will number the references starting at 1.	
		Four command-line registers control formatting style of the bibliography, much like the number registers of $ms(5)$. The flag $-rV2$ will double space the bibliography, while $-rV1$ will double space references but single space annotation paragraphs. The line length can be changed from the default 6.5 inches to 6 inches with the $-rL6i$ argument, and the page offset can be set from the default of 0 to one inch by specifying $-rO1i$ (capital O, not zero).	
	-sN	Halt prior to every N pages for paper loading or changing (default $N=1$). To resume, enter NEWLINE or RETURN.	
	- T term	Specify <i>term</i> as the terminal type.	
	$-\mathbf{V}$	Send output to the Versatec. Page offset is set to 1 inch.	
	- x	If abstracts or comments are entered following the % X field key, roffbib will for- mat them into paragraphs for an annotated bibliography. Several % X fields may be given if several annotation paragraphs are desired.	

FILES	/usr/share/lib/tmac/tmac.bib	file of macros used by nroff/troff
SEE ALSO	<pre>addbib(1), indxbib(1), lookbib(1)</pre>	1), nroff(1) refer(1), sortbib(1), troff(1)
BUGS	Users have to rewrite macros to create customized formats.	

NAME	rpcgen – an RPC protocol compiler
SYNOPSIS	rpcgen infile
	rpcgen [- a] [- A] [- b] [- C] [- D name [= value]] [- i size] [- I [- K seconds]] [- L] [- M] [- N] [- T] [- Y pathname] infile
	rpcgen [-c -h -l -m -t -Sc -Ss -Sm] [-o outfile] [infile]
	rpcgen [– s nettype] [– o outfile] [infile]
	rpcgen [–n <i>netid</i>] [–o <i>outfile</i>] [<i>infile</i>]
AVAILABILITY	SUNWcsu
DESCRIPTION	rpcgen is a tool that generates C code to implement an RPC protocol. The input to rpcgen is a language similar to C known as RPC Language (Remote Procedure Call Language).
	rpcgen is normally used as in the first synopsis where it takes an input file and generates three output files. If the <i>infile</i> is named proto.x , then rpcgen generates a header in proto.h , XDR routines in proto_xdr.c , server-side stubs in proto_svc.c , and client-side stubs in proto_clnt.c . With the -T option, it also generates the RPC dispatch table in proto_tbl.i .
	rpcgen can also generate sample client and server files that can be customized to suit a particular application. The -Sc , -Ss and -Sm options generate sample client, server and makefile, respectively. The -a option generates all files, including sample files. If the infile is proto.x , then the client side sample file is written to proto_client.c , the server side sample file to proto_server.c and the sample makefile to makefile.proto .
	The server created can be started both by the port monitors (for example, inetd or listen) or by itself. When it is started by a port monitor, it creates servers only for the transport for which the file descriptor 0 was passed. The name of the transport must be specified by setting up the environment variable PM_TRANSPORT . When the server generated by rpcgen is executed, it creates server handles for all the transports specified in NETPATH environment variable, or if it is unset, it creates server handles for all the visible transports from /etc/netconfig file. Note: the transports are chosen at run time and not at compile time. When the server is self-started, it backgrounds itself by default. A special define symbol RPC_SVC_FG can be used to run the server process in foreground.
	 The second synopsis provides special features which allow for the creation of more sophisticated RPC servers. These features include support for user provided #defines and RPC dispatch tables. The entries in the RPC dispatch table contain: pointers to the service routine corresponding to that procedure, a pointer to the input and output arguments the size of these routines

modified 15 Feb 1994

A server can use the dispatch table to check authorization and then to execute the service routine; a client library may use it to deal with the details of storage management and XDR data conversion.

The other three synopses shown above are used when one does not want to generate all the output files, but only a particular one. See the **EXAMPLES** section below for examples of **rpcgen** usage. When **rpcgen** is executed with the –**s** option, it creates servers for that particular class of transports. When executed with the –**n** option, it creates a server for the transport specified by *netid*. If *infile* is not specified, **rpcgen** accepts the standard input.

The C preprocessor, cc - E is run on the input file before it is actually interpreted by **rpcgen**. For each type of output file, **rpcgen** defines a special preprocessor symbol for use by the **rpcgen** programmer:

RPC_HDR	defined when compiling into headers
RPC_XDR	defined when compiling into XDR routines
RPC_SVC	defined when compiling into server-side stubs
RPC_CLNT	defined when compiling into client-side stubs
RPC_TBL	defined when compiling into RPC dispatch tables

Any line beginning with "%" is passed directly into the output file, uninterpreted by **rpcgen**. To specify the path name of the C preprocessor use $-\mathbf{Y}$ flag.

For every data type referred to in *infile*, **rpcgen** assumes that there exists a routine with the string **xdr**_ prepended to the name of the data type. If this routine does not exist in the RPC/XDR library, it must be provided. Providing an undefined data type allows customization of XDR routines.

OPTIONS	- a	Generate all files, including sample files.
	-A	Enable the Automatic MT mode in the server main program. In this mode, the RPC library automatically creates threads to service client requests. This option generates multithread-safe stubs by implicitly turning on the -M option. Server multithreading modes and parameters can be set using the rpc_control () call. rpcgen generated code does not change the default values for the Automatic MT mode.
	- b	Backward compatibility mode. Generate transport specific RPC code for older versions of the operating system.
	- c	Compile into XDR routines.
	- C	Generate header and stub files which can be used with ANSI C com- pilers. Headers generated with this flag can also be used with C++ pro- grams.
	-Dname[=value]	Define a symbol <i>name</i> . Equivalent to the #define directive in the source. If no <i>value</i> is given, <i>value</i> is defined as 1 . This option may be specified more than once.
	-h	Compile into C data-definitions (a header). $-T$ option can be used in conjunction to produce a header which supports RPC dispatch tables.

modified 15 Feb 1994

1-883

Size at which to start generating inline code. This option is useful for optimization. The default size is 5.
Compile support for inetd (1M) in the server side stubs. Such servers can be self-started or can be started by inetd . When the server is self-started, it backgrounds itself by default. A special define symbol RPC_SVC_FG can be used to run the server process in foreground, or the user may simply compile without the –I option.
If there are no pending client requests, the inetd servers exit after 120 seconds (default). The default can be changed with the –K option. All of the error messages for inetd servers are always logged with syslog (3).
Note: This option is supported for backward compatibility only. It should always be used in conjunction with the –b option which generates backward compatibility code. By default (i.e., when –b is not specified), rpcgen generates servers that can be invoked through portmonitors.
By default, services created using rpcgen and invoked through port monitors wait 120 seconds after servicing a request before exiting. That interval can be changed using the $-\mathbf{K}$ flag. To create a server that exits immediately upon servicing a request, use $-\mathbf{K}$ 0. To create a server that never exits, the appropriate argument is $-\mathbf{K}$ –1.
When monitoring for a server, some portmonitors, like listen (1M), <i>always</i> spawn a new process in response to a service request. If it is known that a server will be used with such a monitor, the server should exit immediately on completion. For such servers, rpcgen should be used with –K 0 .
Compile into client-side stubs.
When the servers are started in foreground, use syslog (3) to log the server errors instead of printing them on the standard error.
Compile into server-side stubs, but do not generate a "main" routine. This option is useful for doing callback-routines and for users who need to write their own "main" routine to do initialization.
Generate multithread-safe stubs for passing arguments and results between rpcgen generated code and user written code. This option is useful for users who want to use threads in their code.
This option allows procedures to have multiple arguments. It also uses the style of parameter passing that closely resembles C. So, when pass- ing an argument to a remote procedure, you do not have to pass a pointer to the argument, but can pass the argument itself. This behavior is different from the old style of rpcgen generated code. To maintain backward compatibility, this option is not the default.

modified 15 Feb 1994

	-n netid	Compile into server-side stubs for the transport specified by <i>netid</i> . There should be an entry for <i>netid</i> in the netconfig database. This option may be specified more than once, so as to compile a server that serves multiple transports.
	–o outfile	Specify the name of the output file. If none is specified, standard output is used (-c, -h, -l, -m, -n, -s, -Sc, -Sm, -Ss, and -t modes only).
	−s nettype	Compile into server-side stubs for all the transports belonging to the class <i>nettype</i> . The supported classes are netpath , visible , circuit_n , circuit_v , datagram_n , datagram_v , tcp , and udp (see rpc (3N) for the meanings associated with these classes). This option may be specified more than once. Note: the transports are chosen at run time and not at compile time.
	-Sc	Generate sample client code that uses remote procedure calls.
	–Sm	Generate a sample Makefile which can be used for compiling the appli- cation.
	-Ss	Generate sample server code that uses remote procedure calls.
	t	Compile into RPC dispatch table.
	$-\mathbf{T}$	Generate the code to support RPC dispatch tables.
		The options – c , – h , – l , – m , – s , – Sc , – Sm , – Ss , and – t are used exclusively to generate a particular type of file, while the options – D and – T are global and can be used with the other options.
	-Y pathname	Give the name of the directory where rpcgen will start looking for the C-preprocessor.
EXAMPLES	The following e	example:
	0	le% rpcgen –T prot.x
		e five files: prot.h, prot_clnt.c, prot_svc.c, prot_xdr.c and prot_tbl.i.
	The following e	example sends the C data-definitions (header) to the standard output.
	examp	le% rpcgen –h prot.x
		t version of the - DTEST , server side stubs for all the transport belonging agram_n to standard output, use:
	examp	le% rpcgen –s datagram_n –DTEST prot.x
	To create the se	rver side stubs for the transport indicated by <i>netid</i> tcp, use:
	examp	le% rpcgen –n tcp –o prot_svc.c

NAME	rsh, remsh, remote_shell – remote shell
IOPSIS	rsh [–n] [–l username] hostname command

IS rsh [-n] [-l username] hostname command rsh hostname [-n] [-l username] command remsh [-n] [-l username] hostname command remsh hostname [-n] [-l username] command hostname [-n] [-l username] command

AVAILABILITY SUNWcsu

DESCRIPTION

SYN

rsh connects to the specified *hostname* and executes the specified *command*. **rsh** copies its standard input to the remote command, the standard output of the remote command to its standard output, and the standard error of the remote command to its standard error. Interrupt, quit and terminate signals are propagated to the remote command; **rsh** normally terminates when the remote command does.

If you omit *command*, instead of executing a single command, **rsh** logs you in on the remote host using **rlogin**(1). Shell metacharacters which are not quoted are interpreted on the local machine, while quoted metacharacters are interpreted on the remote machine. See **EXAMPLES**.

Hostnames are given in the *hosts* database, which may be contained in the /etc/hosts file, the Internet domain name database, or both. Each host has one official name (the first name in the database entry) and optionally one or more nicknames. Official hostnames or nicknames may be given as *hostname*.

If the name of the file from which **rsh** is executed is anything other than **rsh**, **rsh** takes this name as its *hostname* argument. This allows you to create a symbolic link to **rsh** in the name of a host which, when executed, will invoke a remote shell on that host. By creating a directory and populating it with symbolic links in the names of commonly used hosts, then including the directory in your shell's search path, you can run **rsh** by typing *hostname* to your shell.

If **rsh** is invoked with the basename **remsh**, **rsh** will check for the existence of the file /**usr/bin/remsh**. If this file exists, **rsh** will behave as if **remsh** is an alias for **rsh**. If /**usr/bin/remsh** does not exist, **rsh** will behave as if **remsh** is a host name.

Each remote machine may have a file named /etc/hosts.equiv containing a list of trusted hostnames with which it shares usernames. Users with the same username on both the local and remote machine may rsh from the machines listed in the remote machine's /etc/hosts file. Individual users may set up a similar private equivalence list with the file .rhosts in their home directories. Each line in this file contains two names: a *hostname* and a *username* separated by a space. The entry permits the user named *username* who is logged into *hostname* to use rsh to access the remote machine as the remote user. If the name of the local host is not found in the /etc/hosts.equiv file on the remote machine, and the local username and hostname are not found in the remote user's .rhosts file, then the access is denied. The hostnames listed in the /etc/hosts.equiv and .rhosts files must be the official hostnames listed in the hosts database; nicknames may not be used in either of

modified 14 Jul 1994

	these files.	
	rsh will not pror <i>command</i> argume	npt for a password if access is denied on the remote machine unless the ent is omitted.
OPTIONS	–l username	Use <i>username</i> as the remote username instead of your local username. In the absence of this option, the remote username is the same as your local username.
	-n	Redirect the input of rsh to / dev/null . You sometimes need this option to avoid unfortunate interactions between rsh and the shell which invokes it. For example, if you are running rsh and invoke a rsh in the background without redirecting its input away from the terminal, it will block even if no reads are posted by the remote command. The – n option will prevent this.
		ote shell (sh , rsh , or other) is determined by the user's entry in the file he remote system.
EXIT CODES	Returns 0 upon s	successful completion, 1 otherwise.
EXAMPLES	The following command:	
	example	% rsh lizard cat lizard.file >> example.file
		note file lizard.file from the machine called "lizard" to the file called the machine called "example," while the command:
	example	% rsh lizard cat lizard.file ">>" lizard.file2
		lizard.file on the machine called "lizard" to the file another.lizard.file es on the machine called "lizard."
FILES	/etc/hosts /etc/hosts.equiv /etc/passwd	Internet host table trusted remote hosts and users system password file
SEE ALSO	on(1), rlogin(1),	telnet(1), vi(1), in.named(1M), hosts(4), hosts.equiv(4)
NOTES	insecure system You cannot run a Stop signals stop fix for reasons to	s listed in hosts.equiv , its security must be as good as local security. One listed in hosts.equiv can compromise the security of the entire system. an interactive command (such as vi (1)); use rlogin if you wish to do so. the local rsh process only; this is arguably wrong, but currently hard to be complicated to explain here.
		l environment is not passed to the remote shell.
	sometimes the – the command:	n option is needed for reasons that are less than obvious. For example,

modified 14 Jul 1994

example% rsh somehost dd if=/dev/nrmt0 bs=20b | tar xvpBf -

will put your shell into a strange state. Evidently, what happens is that the **tar** terminates before the **rsh**. The **rsh** then tries to write into the "broken pipe" and, instead of terminating neatly, proceeds to compete with your shell for its standard input. Invoking **rsh** with the $-\mathbf{n}$ option avoids such incidents.

This bug occurs only when **rsh** is at the beginning of a pipeline and is not reading standard input. Do not use the -n if **rsh** actually needs to read standard input. For example,

example% tar cf - . | rsh sundial dd of=/dev/rmt0 obs=20b

does not produce the bug. If you were to use the -n in a case like this, **rsh** would incorrectly read from /**dev**/**null** instead of from the pipe.

modified 14 Jul 1994

NAME	run – run an executable		
SYNOPSIS	run [g–s] [–e] [–n] [–t string] program		
DESCRIPTION	The grun function runs <i>program</i> , using the PATH variable to find it. By default, when <i>pro-gram</i> has completed, the user is prompted (Press ENTER to continue:), before being returned to FMLI. The argument <i>program</i> is a system executable followed by its options (if any).		
OPTIONS	g–e	If g-e is specified the user will be prompted before returning to FMLI only if there is an error condition	
	g–n	If g-n is specified the user will never be prompted before returning to FMLI (useful for programs like gvi , in which the user must do some specific action to exit in the first place).	
	g–s	The g - s option means "silent", implying that the screen will not have to be repainted when <i>program</i> has completed. Note that the g - s option should only be used when <i>program</i> does not write to the terminal. In addition, when g - s is used, <i>program</i> cannot be interrupted, even if it recognizes interrupts.	
	g–t string	If g – t is specified, <i>string</i> is the name this process will have in the pop-up menu generated by the gfrm-list command. This feature requires the executable gfacesuspend , (See face (1)), to suspend the process and return to the FMLI application.	
EXAMPLE	Here is a n	nenu that uses grun :	
	•	nenu="Edit special System files"	
	name="Password file" action=`run –e vi /etc/passwd`		
	name="Group file"		
	action=`run –e vi /etc/group`		
		me="My .profile" tion=`run –n vi \$HOME/.profile`

NAME	rup – show host status of remote machines (RPC version)		
SYNOPSIS	rup [-hlt] rup [host]		
AVAILABILITY	SUNWesu		
DESCRIPTION	rup gives a status similar to uptime for remote machines. It broadcasts on the local net work, and displays the responses it receives.		
	Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.		
	When <i>host</i> arguments are given, rather than broadcasting rup will only query the list of specified hosts.		
	A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd (1M).		
OPTIONS	-h Sort the display alphabetically by host name.		
	-l Sort the display by load average.		
	-t Sort the display by up time.		
FILES	/etc/servers		
SEE ALSO	ruptime(1), inetd(1M)		
	SPARC: Installing Solaris Software		
	x86: Installing Solaris Software		
BUGS	Broadcasting does not work through gateways.		

NAME	rup – show host status of remote machines (RPC version)
SYNOPSIS	rup [-hlt] rup [host]
DESCRIPTION	rup gives a status similar to uptime for remote machines. It broadcasts on the local network, and displays the responses it receives.
	Normally, the listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.
	When <i>host</i> arguments are given, rather than broadcasting rup only queries the list of specified hosts.
	A remote host will only respond if it is running the rstatd daemon, which is normally started up from inetd (1M).

modified 13 Feb 1991

1C-891

NAME	ruptime – show host status of local machines		
SYNOPSIS	ruptime [–alrtu]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	ruptime gives a status line like uptime for each machine on the local network; these are formed from packets broadcast by each host on the network once a minute.		
	Machines for which no status report has been received for 5 minutes are shown as being down.		
	Normally, the listing is sorted by host name, but this order can be changed by specifying one of the options listed below.		
OPTIONS	-a Count even those users who have been idle for an hour or more.		
	-l Sort the display by load average.		
	-r Reverse the sorting order.		
	-t Sort the display by up time.		
	-u Sort the display by number of users.		
FILES	/var/spool/rwho/whod.* data files		
SEE ALSO	rwho(1), in.rwhod(1M)		

NAME	rusage – print resource usage for a command		
SYNOPSIS	/usr/ucb/rusage command		
AVAILABILITY	SUNWscpu		
DESCRIPTION	The rusage command is similar to time (1). It runs the given <i>command</i> , which must be specified; that is, <i>command</i> is not optional as it is in the C shell's timing facility. When the command is complete, rusage displays the real (wall clock), the system CPU, and the user CPU times which elapsed during execution of the command, plus other fields in the rusage structure, all on one long line. Times are reported in seconds and hundredths of a second.		
EXAMPLES	The example below shows the format of rusage output.		
	 example% rusage wc /usr/share/man/man1/csh (1) 3045 13423 78071 /usr/share/man/man1/csh (1) 2.26 real 0.80 user 0.36 sys 11 pf 38 pr 0 sw 11 rb 0 wb 16 vcx 37 icx 24 mx 0 ix 1230 id 9 is example% Each of the fields identified corresponds to an element of the rusage structure, as described in getrusage(3C), as follows: 		
	real elapsed real time		
	realetapsed real timeuserru_utimeuser time usedsysru_stimesystem time usedpfru_majfltpage faults requiring physical I/Oprru_minfltpage faults not requiring physical I/Oswru_nswapswapsrbru_inblockblock input operationswbru_oublockblock output operationsvcxru_nvcswvoluntary context switchesicxru_nivcswinvoluntary context switchesixru_ixrssmaximum resident set sizeixru_ixrsscurrently 0idru_idrssintegral resident set sizeisru_isrsscurrently 0		
SEE ALSO	csh(1), time(1), getrusage(3C)		
BUGS	When the command being timed is interrupted, the timing values displayed may be inac- curate.		

1B-893

NAME	rusers – who's logged in on remote machines		
SYNOPSIS	rusers [–ahilu] host		
AVAILABILITY	SUNWesu		
DESCRIPTION	The rusers command produces output similar to who (1), but for remote machines. The listing is in the order that responses are received, but this order can be changed by specifying one of the options listed below.		
	The default is to print out the names of the users logged in. When the –1 flag is given, additional information is printed for each user:		
	userid hostname:terminal login date login time idle time login host		
	If <i>hostname</i> and <i>login host</i> are the same value, the <i>login host</i> field is not displayed. Likewise, if <i>hostname</i> is not idle, the <i>idle time</i> is not displayed.		
	A remote host will only respond if it is running the rusersd daemon, which may be started up from inetd (1M) or listen (1M).		
OPTIONS	-a Give a report for a machine even if no users are logged on.		
	-h Sort alphabetically by host name.		
	-i Sort by idle time.		
	-I Give a longer listing in the style of who (1).		
	- u Sort by number of users.		
SEE ALSO	who(1), inetd(1M), listen(1M), pmadm(1M), sacadm(1M)		

rwho [–a]		
SUNWcsu		
The rwho command produces output similar to who (1), but for all machines on your net- work. If no report has been received from a machine for 5 minutes, rwho assumes the machine is down, and does not report users last known to be logged into that machine.		
If a user has not typed to the system for a minute or more, rwho reports this idle time. If a user has not typed to the system for an hour or more, the user is omitted from the output of rwho unless the $-a$ flag is given.		
-a Report all users whether or not they have typed to the system in the past hour.		
/var/spool/rwho/whod.* information about other machines		
<pre>finger(1), ruptime(1), who(1), in.rwhod(1M)</pre>		
rwho does not work through gateways. The directory /var/spool/rwho must exist on the host from which rwho is run. This service takes up progressively more network bandwith as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive. The rwho service daemon, in.rwhod(1M), must be enabled for this command to return useful results.		

NAME	sag – system activity graph		
SYNOPSIS	sag [-e time] [-f file] [-i sec] [-s time] [-T term] [-x spec] [-y spec]		
DESCRIPTION	sag graphically displays the system activity data stored in a binary data file by a previous sar (1) run. Any of the sar data items may be plotted singly, or in combination; as cross plots, or versus time. Simple arithmetic combinations of data may be specified. sag invokes sar and finds the desired data by string-matching the data column header (run sar to see what is available).		
OPTIONS	These <i>options</i> are passed through to sar :		
	–e time	Select data up to <i>time</i> . Default is 18:00.	
	-f file	Use <i>file</i> as the data source for sar . Default is the current daily data file / usr/adm/sa/sa <i>d</i> .	
	–i sec	Select data at intervals as close as possible to <i>sec</i> seconds.	
	–s time	Select data later than <i>time</i> in the form <i>hh</i> [: <i>mm</i>]. Default is 08:00.	
	Other op	tions:	
	-T term	Produce output suitable for terminal <i>term</i> . Default for <i>term</i> is STERM .	
	-x spec	x axis specification with <i>spec</i> in the form: <i>name</i> [op name][lo hi]	
		<i>name</i> is either a string that will match a column header in the sar report, with an optional device name in square brackets, for example, r + w / s [dsk - 1], or an integer value. <i>op</i> is $+-*$ or / surrounded by blank spaces. Up to five names may be specified. Parentheses are not recognized. Contrary to custom, $+$ and $-$ have precedence over $*$ and /. Evaluation is left to right. Thus, A / A + B * 100 is evaluated as (A/(A+B))*100, and A + B / C + D is (A+B)/(C+D). <i>lo</i> and <i>hi</i> are optional numeric scale limits. If unspecified, they are deduced from the data.	
		Enclose <i>spec</i> in double-quotes (" ") if it includes white space.	
		A single <i>spec</i> is permitted for the x axis. If unspecified, <i>time</i> is used.	
	-y spec	y axis specification with <i>spec</i> in the same form as for -x . Up to 5 <i>spec</i> 's separated by a semi-colon (;) may be given for -y . The -y default is: -y "% usr 0 100 ; % usr + %sys 0 100 ; % usr + %sys + %wio 0 100 "

modified 20 Jul 1994

NAME	sar – system activity reporter
SYNOPSIS	sar [–aAbcdgkmpqruvwy] [–o filename] t [n]
	sar [-aAbcdgkmpqruvwy] [-e time] [-f filename] [-i sec] [-s time]
DESCRIPTION	In the first instance sar samples cumulative activity counters in the operating system at <i>n</i> intervals of <i>t</i> seconds, where <i>t</i> should be 5 or greater. If <i>t</i> is specified with more than one option, all headers are printed together and the output may be difficult to read. (If the sampling interval is less than 5, the activity of sar itself may effect the sample.) If the -0 option is specified, it saves the samples in <i>filename</i> in binary format. The default value of <i>n</i> is 1.
	In the second instance no sampling interval is specified. sar extracts data from a previously recorded <i>filename</i> , either the one specified by the –f option or, by default, the standard system activity daily data file / var/adm/sa/sa <i>dd</i> for the current day <i>dd</i> . The starting and ending times of the report can be bounded using the – e and – s arguments with <i>time</i> specified in the form <i>hh</i> [: <i>mm</i> [: <i>ss</i>]]. The – i option selects records at <i>sec</i> second intervals. Otherwise, all intervals found in the data file are reported.
OPTIONS	The following options modify the subsets of information reported by sar .
	 -a Report use of file access system routines: iget/s, namei/s, dirblk/s.
	-A Report all data. Equivalent to -abcdgkmpqruvwy.
	 -b Report buffer activity: bread/s, bwrit/s – transfers per second of data between system buffers and disk or other block devices; lread/s, lwrit/s – accesses of system buffers; %rcache, %wcache – cache hit ratios, that is, (1–bread/lread) as a percentage; pread/s, pwrit/s – transfers using raw (physical) device mechanism.
	 -c Report system calls: scall/s – system calls of all types; sread/s, swrit/s, fork/s, exec/s – specific system calls; rchar/s, wchar/s – characters transferred by read and write system calls. No incoming or outgoing exec(2) and fork(2) calls are reported.
	 -d Report activity for each block device (for example, disk or tape drive) with the exception of XDC disks and tape drives. When data is displayed, the device specification <i>dsk</i>- is generally used to represent a disk drive. The device specification used to represent a tape drive is machine dependent. The activity data reported is: %busy, avque – portion of time device was busy servicing a transfer request, average number of requests outstanding during that time; read/s, write/s, blks/s – number of read/write transfers from or to device, number of bytes transferred in 512-byte units; avseek – number of milliseconds per average seek.

modified 27 May 1993

	For more general system statistics, use iostat (1M), sar (1M), or vmstat (1M). See <i>System Administration Guide, Volume I</i> for naming conventions for disks.
-g	Report paging activities: pgout/s – page-out requests per second; ppgout/s – pages paged-out per second; pgfree/s – pages per second placed on the free list by the page stealing dae- mon;
	pgscan/s – pages per second scanned by the page stealing daemon. %ufs_ipf – the percentage of UFS inodes taken off the freelist by iget which had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus this is the percentage of igets with page flushes.
-k	Report kernel memory allocation (KMA) activities: sml_mem, alloc, fail – information about the memory pool reserving and allo- cating space for small requests: the amount of memory in bytes KMA has for the small pool, the number of bytes allocated to satisfy requests for small amounts of memory, and the number of requests for small amounts of memory that were not satisfied (failed); lg_mem, alloc, fail – information for the large memory pool (analogous to the information for the small memory pool); ovsz_alloc, fail – the amount of memory allocated for oversize requests and the number of oversize requests which could not be satisfied (because over- sized memory is allocated dynamically, there is not a pool).
-m	Report message and semaphore activities: msg/s, sema/s – primitives per second.
-p	Report paging activities: atch/s – page faults per second that are satisfied by reclaiming a page currently in memory (attaches per second); pgin/s – page-in requests per second; ppgin/s – pages paged-in per second; pflt/s – page faults from protection errors per second (illegal access to page) or "copy-on-writes"; vflt/s – address translation page faults per second (valid page not in memory); slock/s – faults per second caused by software lock requests requiring physi- cal I/O.
- q	Report average queue length while occupied, and % of time occupied: runq-sz, %runocc – run queue of processes in memory and runnable; swpq-sz, %swpocc – these are no longer reported by sar.
- r	Report unused memory pages and disk blocks: freemem – average pages available to user processes; freeswap – disk blocks available for page swapping.

modified 27 May 1993

	- u	%usr, %sys, %w	ization (the default): rio, %idle – portion of time running in user mode, running in lle with some process waiting for block I/O, and otherwise
	$-\mathbf{v}$	proc-sz, inod-sz sampling point;	process, i-node, file tables: , file-sz, lock-sz – entries/size for each table, evaluated once at that occur between sampling points for each table.
	-w	swpin/s, swpot	
	- y	cessed by canon	ice activity: /s, outch/s – input character rate, input character rate pro- a, output character rate; s, mdmin/s – receive, transmit and modem interrupt rates.
	–e time	Select data up to	o time. Default is 18:00.
	-f filename	Use <i>filename</i> as t / usr/adm/sa/sa d	he data source for sar . Default is the current daily data file d.
	–i sec	Select data at int	tervals as close as possible to <i>sec</i> seconds.
	– o filename		
		-	file, <i>filename</i> , in binary format.
	–s time	Select data later	than <i>time</i> in the form <i>hh</i> [: <i>mm</i>]. Default is 08:00.
EXAMPLES	To see tod	ay's CPU activity	so far:
		ample% sar	
		-	ve for 10 minutes and save data:
		ample% sar –o t	
	To later re	view disk and taj	pe activity from that period:
	ex	ample% sar –d -	–f temp
FILES	/var/adm/s	sa/sadd	daily data file, where <i>dd</i> are digits representing the day of the month

modified 27 May 1993

NAME	sccs-admin, admin – create and administer SCCS history files		
SYNOPSIS	[–e username g	-bhnz] [–a username groupid] [–d flag] groupid] [–f flag [value]] [–i [filename]] grelease] [–t [description-file]] [–y[comment]] s.filename	
AVAILABILITY	SUNWsprot		
DESCRIPTION		ifies the flags and other parameters of SCCS history files. Filenames egin with the ' s .' prefix, and are referred to as s .files, or ''history''	
	modified according to	eated if it does not exist already. Its parameters are initialized or the options you specify. Parameters not specified are given he file is initialized, otherwise they remain unchanged.	
	applies to all s.files in	used in place of the <i>s.filename</i> argument, the admin command that directory. Unreadable s. files produce an error. The use of '–' nent indicates that the names of files are to be read from the stan- per line.	
OPTIONS	-b	Force encoding of binary data. Files that contain ASCII NUL or other control characters, or that do not end with a NEWLINE, are recognized as binary data files. The contents of such files are stored in the history file in encoded form. See uuencode (1C) for details about the encoding. This option is normally used in con- junction with – i to force admin to encode initial versions not recognized as containing binary data.	
	-h	Check the structure of an existing s .file (see sccsfile (4)), and compare a newly computed check-sum with one stored in the first line of that file. – h inhibits writing on the file; and so nullifies the effect of any other options.	
	- n	Create a new SCCS history file.	
	- Z	Recompute the file check-sum and store it in the first line of the s .file. Caution: it is important to verify the contents of the history file (see sccs-val (1), and the print subcommand in sccs (1)), since using – z on a truly corrupted file may prevent detection of the error.	
	– a username groupid	Add a user name, or a numerical group ID, to the list of users who may check deltas in or out. If the list is empty, any user is allowed to do so.	
	−d flag	Delete the indicated <i>flag</i> from the SCCS file. The $-\mathbf{d}$ option may be specified only for existing s.files. See $-\mathbf{f}$ for the list of recognized flags.	

modified 1 Feb 1995

1-901

-e username groupid	Erase a user nam make deltas.	ne or group ID from the list of users allowed to
-f flag [value]	Set the indicated ing flags are reco	<i>flag</i> to the (optional) <i>value</i> specified. The follow- ognized:
	b	Enable branch deltas. When b is set, branches can be created using the -b option of the SCCS get command (see sccs-get (1)).
	cceil	Set a ceiling on the releases that can be checked out. <i>ceil</i> is a number less than or equal to 9999. If c is not set, the ceiling is 9999.
	ffloor	Set a floor on the releases that can be checked out. The floor is a number greater than 0 but less than 9999. If f is not set, the floor is 1.
	dsid	The default delta number, or SID, to be used by an SCCS get command.
	i	Treat the ' No id keywords (ge6) ' message issued by an SCCS get or delta command as an error rather than a warning.
	j	Allow concurrent updates.
	la	
	lrelease[,release	.]
		Lock the indicated list of releases against deltas. If a is used, lock out deltas to all releases. An SCCS ' get – e ' command fails when applied against a locked release.
	n	Create empty releases when releases are skipped. These null (empty) deltas serve as anchor points for branch deltas.
	qvalue	Supply a <i>value</i> to which the % Q % keyword is to expand when a read-only version is retrieved with the SCCS get command.
	m module	Supply a value for the module name to which the % M % keyword is to expand. If the m flag is not specified, the value assigned is the name of the SCCS file with the leading s . removed.
	ttype	Supply a value for the module type to which the %Y% keyword is to expand.
	v [program]	Specify a validation <i>program</i> for the MR numbers associated with a new delta. The optional <i>pro- gram</i> specifies the name of an MR number validity checking <i>program</i> . If this flag is set when creating

modified 1 Feb 1995

		an SCCS file, the $-\mathbf{m}$ option must also be used, in which case the list of MRs may be empty.
	−i [filename]	Initialize the history file with text from the indicated file. This text constitutes the initial delta, or set of checked-in changes. If <i>filename</i> is omitted, the initial text is obtained from the standard input. Omitting the $-i$ option altogether creates an empty s .file. You can only initialize one s .file with text using $-i$. This option implies the $-n$ option.
	- m [mr-list]	Insert the indicated Modification Request (MR) numbers into the commentary for the initial version. When specifying more than one MR number on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. A warning results if the v flag is not set or the MR validation fails.
	-rrelease	Specify the release for the initial delta. $-\mathbf{r}$ may be used only in conjunction with $-\mathbf{i}$. The initial delta is inserted into release 1 if this option is omitted. The level of the initial delta is always 1; initial deltas are named 1.1 by default.
	-t [description-file]	Insert descriptive text from the file <i>description-file</i> . When -t is used in conjunction with -n , or -i to initialize a new s.file, the <i>description-file</i> must be supplied. When modifying the description for an existing file: a -t option without a <i>description-file</i> removes the descriptive text, if any; a -t option with a <i>description-file</i> replaces the existing text.
	-y [comment]	Insert the indicated <i>comment</i> in the "Comments:" field for the initial delta. Valid only in conjunction with $-\mathbf{i}$ or $-\mathbf{n}$. If $-\mathbf{y}$ option is omitted, a default comment line is inserted that notes the date and time the history file was created.
EXIT STATUS	The following exit va	aluas ara raturnad:
EATI STATUS		il completion.
		occurred.
FILES	S. *	history file
	SCCS/s.*	history file in SCCS subdirectory
	Z. *	temporary lock file

modified 1 Feb 1995

1-903

WARNINGSThe last component of all SCCS filenames must have the 's.' prefix. New SCCS files are
given mode 444 (see chmod(1)). All writing done by admin is to a temporary file with an
x. prefix, created with mode 444 for a new SCCS file, or with the same mode as an existing
SCCS file. After successful execution of admin, the existing s. file is removed and
replaced with the x.file. This ensures that changes are made to the SCCS file only when no
errors have occurred.

It is recommended that directories containing SCCS files have permission mode 755, and that the **s**.files themselves have mode 444. The mode for directories allows only the owner to modify the SCCS files contained in the directories, while the mode of the **s**.files prevents all modifications except those performed using SCCS commands.

If it should be necessary to patch an SCCS file for any reason, the mode may be changed to 644 by the owner to allow use of a text editor. However, extreme care must be taken when doing this. The edited file should *always* be processed by an '**admin** –**h**' to check for corruption, followed by an '**admin** –**z**' to generate a proper check-sum. Another '**admin** –**h**' is recommended to ensure that the resulting **s**.file is valid.

admin also uses a temporary lock **s**.file, starting with the '**z**.' prefix, to prevent simultaneous updates to the **s**.file. See **sccs-get**(1) for further information about the '**z**.file'.

modified 1 Feb 1995

NAME	sccs-cdc, cdc –	change the delta commentary of an SCCS delta
SYNOPSIS	/usr/ccs/bin/cd	c – r sid [– m mr-list] [– y [comment]] s.filename
DESCRIPTION	cdc annotates th in each named a	he delta commentary for the SCCS delta ID (SID) specified by the $-\mathbf{r}$ option s .file.
	If the v flag is so (MR) list.	et in the s. file, you can also use cdc to update the Modification Request
		in the delta, or, if you own the file and directory and have write permisse cdc to annotate the commentary.
	Rather than rep followed by a li	placing the existing commentary, cdc inserts the new comment you supply, ine of the form:
	*** CH	ANGED *** yy/mm/dd hh/mm/ss username
	above the existi	ing commentary.
	in that directory file (if any). If	named as the <i>s.filename</i> argument, the cdc command applies to all s .files y. Unreadable s .files produce an error; processing continues with the next –' is given as the <i>s.filename</i> argument, each line of the standard input is me of an SCCS history file to be processed, and the – m and – y options
OPTIONS	–rsid	Specify the SID of the delta to change.
	- m mr-list	Specify one or more MR numbers to add or delete. When specifying more than one MR on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. To delete an MR number, precede it with a ! character (an empty MR list has no effect). A list of deleted MRs is placed in the comment section of the delta commentary. If –m is not used and the standard input is a terminal, cdc prompts with MRs? for the list (before issuing the comments? prompt). –m is only useful when the v flag is set in the s .file. If that flag has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, cdc terminates and the delta commentary remains unchanged.
	-y[comment]	
		Use <i>comment</i> as the annotation in the delta commentary. The previous comments are retained; the <i>comment</i> is added along with a notation that the commentary was changed. A null <i>comment</i> leaves the commentary unaffected. If $-y$ is not specified and the standard input is a terminal, cdc prompts with comments? for the text of the notation to be added. An unescaped NEWLINE character terminates the annotation text.

EXAMPLES	The following command: example% cdc –r1.6 –y"corrected commentary" s.program.c
	produces the following annotated commentary for delta 1.6 in s.program.c :
	D 1.6 88/07/05 23:21:07 username 9 0 00001/00000/00000 MRs: COMMENTS: corrected commentary *** CHANGED *** 88/07/07 14:09:41 username performance enhancements in main()
FILES	z.file temporary lock file

	Programming Utilities Guide
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).

NAME	sccs-comb, comb – combine SCCS deltas
SYNOPSIS	/usr/ccs/bin/comb [-os] [-csid-list] [-psid] s.filename
DESCRIPTION	comb generates a shell script (see sh (1)) that you can use to reconstruct the indicated s. files. This script is written to the standard output.
	If a directory name is used in place of the <i>s.filename</i> argument, the comb command applies to all s .files in that directory. Unreadable s .files produce an error; processing continues with the next file (if any). The use of '–' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one s .file per line.
	If no options are specified, comb preserves only the most recent (leaf) delta in a branch, and the minimal number of ancestors needed to preserve the history.
OPTIONS	 For each 'get –e' generated, access the reconstructed file at the release of the delta to be created. Otherwise, the reconstructed file is accessed at the most recent ancestor. The use of –o may decrease the size of the reconstructed s.file. It may also alter the shape of the delta tree of the original file.
	 -s Generate scripts to gather statistics, rather than combining deltas. When run, the shell scripts report: the file name, size (in blocks) after combining, original size (also in blocks), and the percentage size change, computed by the formula: 100 * (original – combined) / original
	This option can be used to calculate the space that will be saved, before actually doing the combining.
	–csid-list
	Include the indicated list of deltas. All other deltas are omitted. <i>sid-list</i> is a comma-separated list of SCCS delta IDs (SIDs). To specify a range of deltas, use a '–' separator instead of a comma, between two SIDs in the list.
	- p <i>SID</i> The SID of the oldest delta to be preserved.
FILES	s. COMBreconstructed SCCS filecomb????temporary file
SEE ALSO	<pre>sccs(1), sccs-admin(1), sccs-cdc(1), sccs-delta(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs-rmdel(1), sccs-sccsdiff(1), what(1), sccsfile(4)</pre>
	Programming Utilities Guide
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).
BUGS	comb may rearrange the shape of the tree of deltas. It may not save any space; in fact, it is possible for the reconstructed file to actually be larger than the original.

1-907

NAME	sccs-d	elta, delta – make a delta to an SCCS file	
SYNOPSIS	/usr/co	cs/bin/delta [–nps] [–gsid-list] [–mmr-list] [–rsid] [–y[comment]] s.filename	
DESCRIPTION	file un was re	checks in a record of the line-by-line differences made to a checked-out version of a ider SCCS control. These changes are taken from the writable working copy that etrieved using the SCCS get command (see sccs-get (1)). This working copy does not he ' s .' prefix, and is also referred to as a g -file.	
	applie tinues the na	rectory name is used in place of the <i>s.filename</i> , argument, the delta command is to all s .files in that directory. Unreadable s .files produce an error; processing con- with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that mes of files are to be read from the standard input, one s.file per line (requires - y , a some cases, - m).	
	and th	may issue prompts on the standard output depending upon the options specified as flags that are set in the s .file (see sccs-admin (1), and the $-\mathbf{m}$ and $-\mathbf{y}$ options , for details).	
OPTIONS	-n	Retain the edited g -file, which is normally removed at the completion of process- ing.	
	- p	Display line-by-line differences (in diff (1) format) on the standard output.	
	-S	Silent. Do not display warning or confirmation messages. Do not suppress error messages (which are written to standard error).	
	-gsid-	list	
	Specify a list of deltas to omit when the file is accessed at the SCCS version ID (SID) created by this delta. <i>sid-list</i> is a comma-separated list of SIDs. To specify a range of deltas, use a '–' separator instead of a comma, between two SIDs in the list.		
	- m [<i>n</i>	nr-list]	
		If the SCCS file has the v flag set (see sccs-admin(1)), you must supply one or more Modification Request (MR) numbers for the new delta. When specifying more than one MR number on the command line, <i>mr-list</i> takes the form of a quoted, space-separated list. If – m is not used and the standard input is a termi- nal, delta prompts with MRs ? for the list (before issuing the comments ? prompt). If the v flag in the s.file has a value, it is taken to be the name of a program to validate the MR numbers. If that validation program returns a non-zero exit status, delta terminates without checking in the changes.	
	-rsid	When two or more versions are checked out, specify the version to check in. This SID value can be either the SID specified on the get command line, or the SID of the new version to be checked in as reported by get . A diagnostic results if the specified SID is ambiguous, or if one is required but not supplied.	

	-y[comment] Supply a comment for the delta table (version log). A null comment is accepted, and produces an empty commentary in the log. If -y is not specified and the standard input is a terminal, delta prompts with 'comments?'. An unescaped NEWLINE terminates the comment.
FILES	d.filetemporary file of differencesp.filelock file for a checked-out versionq.filetemporary files.fileSCCS history filex.filetemporary copy of the s.filez.filetemporary file
SEE ALSO	<pre>sccs(1), sccs-admin(1), sccs-cdc(1), sccs-get(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs- rmdel(1), sccs-sccsdiff(1), sccs-unget(1), what(1), sccsfile(4) Programming Utilities Guide</pre>
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).
WARNINGS	Lines beginning with an ASCII SOH character (binary 001) cannot be placed in the SCCS file unless the SOH is escaped. This character has special meaning to SCCS (see sccsfile(4)) and produces an error.

NAME	sccs-g	et, get – retrieve a version of an SCCS file
SYNOPSIS		ss/bin/get [–begkmnpst] [–l [p]] [–asequence] [–cdate-time] [–Gg-file] l-list] [–rsid] [–xsid-list] s.filename
DESCRIPTION	get ret option	rieves a working copy from the SCCS history file, according to the specified s.
	For ea retriev	ch <i>s.filename</i> argument, get displays the SCCS delta ID (SID) and number of lines red.
	to all s with tl	rectory name is used in place of the <i>s.filename</i> argument, the get command applies .files in that directory. Unreadable s .files produce an error; processing continues ne next file (if any). The use of '–' as the <i>s.filename</i> argument indicates that the of files are to be read from the standard input, one s .file per line.
		trieved file normally has the same filename base as the s .file, less the prefix, and is ed to as the g -file.
		ch file processed, get responds (on the standard output) with the SID being ed, and with the number of lines retrieved from the s .file.
OPTIONS	-b	Create a new branch. Used with the –e option to indicate that the new delta should have an SID in a new branch. Instead of incrementing the level for version to be checked in, get indicates in the p .file that the delta to be checked in should either initialize a new branch and sequence (if there is no existing branch at the current level), or increment the branch component of the SID. If the b flag is not set in the s .file, this option is ignored.
	- e	Retrieve a version for editing. With this option, get places a lock on the s .file, so that no one else can check in changes to the version you have checked out. If the j flag is set in the s .file, the lock is advisory: get issues a warning message. Concurrent use of ' get – e ' for different SIDs is allowed, however, get will not check out a version of the file if a writable version is present in the directory. All SCCS file protections stored in the s .file, including the release ceiling, floor, and authorized user list, are honored by ' get – e '.
	–g	Get the SCCS version ID, without retrieving the version itself. Used to verify the existence of a particular SID.
	$-\mathbf{k}$	Suppress expansion of ID keywords. $-\mathbf{k}$ is implied by the $-\mathbf{e}$.
	- m	Precede each retrieved line with the SID of the delta in which it was added to the file. The SID is separated from the line with a TAB.
	-n	Precede each line with the MM ID keyword and a TAB. When both the $-m$ and $-n$ options are used, the ID keyword precedes the SID, and the line of text.
	- p	Write the text of the retrieved version to the standard output. All messages that normally go to the standard output are written to the standard error instead.
	1	

- -s Suppress all output normally written on the standard output. However, fatal error messages (which always go to the standard error) remain unaffected.
- Retrieve the most recently created (top) delta in a given release (for example: -r1).
- -l[p] Retrieve a summary of the delta table (version log) and write it to a listing file, with the 'l.' prefix (called 'l.file'). When -lp is used, write the summary onto the standard output.
- -a sequence

Retrieve the version corresponding to the indicated delta sequence number. This option is used primarily by the SCCS **comb** command (see **sccs-comb**(1)); for users, $-\mathbf{r}$ is an easier way to specify a version. $-\mathbf{a}$ supersedes $-\mathbf{r}$ when both are used.

-cdate-time

Retrieve the latest version checked in prior to the date and time indicated by the *date-time* argument. *date-time* takes the form: yy[mm[dd[hh[mm[ss]]]]]. Units omitted from the indicated date and time default to their maximum possible values; that is -c7502 is equivalent to -c750228235959. Any number of non-numeric characters may separate the various 2 digit components. If white-space characters occur, the *date-time* specification must be quoted.

-Gnewname

Use *newname* as the name of the retrieved version.

-isid-list

Specify a list of deltas to include in the retrieved version. The included deltas are noted in the standard output message. *sid-list* is a comma-separated list of SIDs. To specify a range of deltas, use a '-' separator instead of a comma, between two SIDs in the list.

-rsid Retrieve the version corresponding to the indicated SID (delta).

The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the *release* and *level* fields, and for branch deltas, the *branch* and *sequence* fields. For instance, if **1.2** is the SID, **1** is the release, and **2** is the level number. If **1.2.3.4** is the SID, **3** is the branch and **4** is the sequence number.

You need not specify the entire SID to retrieve a version with **get**. When you omit –**r** altogether, or when you omit both release and level, **get** normally retrieves the highest release and level. If the **d** flag is set to an SID in the **s**.file and you omit the SID, **get** retrieves the default version indicated by that flag.

When you specify a release but omit the level, **get** retrieves the highest level in that release. If that release does not exist, **get** retrieves highest level from the next-highest existing release.

Similarly with branches, if you specify a release, level and branch, **get** retrieves the highest sequence in that branch.

	no To	clude the indicated deltas from the retrieved version. The excluded deltas are ted in the standard output message. <i>sid-list</i> is a comma-separated list of SIDs. specify a range of deltas, use a '-' separator instead of a comma, between two Ds in the list.
USAGE ID Keywords		nce of -e or -k, get expands the following ID keywords by replacing them dicated values in the text of the retrieved source. <i>Value</i> Shorthand notation for an ID line with data for what(1): %Z%%Y% %M% %I%%Z% SID branch component Current line number. Intended for identifying messages output by the pro- gram such as '' <i>this shouldn't have happened</i> '' type errors. It is <i>not</i> intended to be used on every line to provide sequence numbers. Current date: <i>yy/mm/dd</i> Date newest applied delta was created: <i>yy/mm/dd</i> SCCS s.file name Date newest applied delta was created: <i>mm/dd/yy</i> Current date: <i>mm/dd/yy</i> SID of the retrieved version: %R%.%L%.%B%.%S% SID level component Module name: either the value of the m flag in the s.file (see sccs-admin(1)), or the name of the s.file less the prefix Fully qualified s.file name Value of the q flag in the s.file SID Release component SID Sequence component Current time: <i>hh:mm:ss</i> Time the newest applied delta was created: <i>hh:mm:ss</i> Shorthand notation for an ID line with data for what: %Z%%M% %I% Module type: value of the t flag in the s.file 4-character string; '@(#)', recognized by what.
ID String	The table b and creatin	below explains how the SCCS identification string is determined for retrieving ang deltas.

Determination of SCCS Identification String				
SID*	- b Option	Other	SID	SID of Delta
Specified	Used†	Conditions	Retrieved	to be Created
none‡	no	R defaults to mR	mR.mL	mR.(mL+1)
none‡	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1***
R	no	$\mathbf{R} = \mathbf{mR}$	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	$\mathbf{R} = \mathbf{mR}$	mR.mL	mR.mL.(mB+1).1
R	_	R < mR and R does <i>not</i> exist	hR.mL**	hR.mL.(mB+1).1
R	_	Trunk succ.# in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk succ.	R.L	R.(L+1)
R.L	yes	No trunk succ.	R.L	R.L.(mB+1).1
R.L	_	Trunk succ. in release ≥ R	R.L	R.L.(mB+1).1
R.L.B	no	No branch succ.	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch succ.	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch succ.	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch succ.	R.L.B.S	R.L.(mB+1).1
R.L.B.S	_	Branch succ.	R.L.B.S	R.L.(mB+1).1

* 'R', 'L', 'B', and 'S' are the 'release', 'level', 'branch', and 'sequence' components of the SID, respectively; 'm' means 'maximum'. Thus, for example, 'R.mL' means 'the maximum level number within release R'; 'R.L.(mB+1).1' means 'the first sequence number on the *new* branch (that is, maximum branch number plus one) of level L within release R'. Note: if the SID specified is of the form 'R.L', 'R.L.B', or 'R.L.B.S', each of the specified components *must* exist.

** 'hR' is the highest *existing* release that is lower than the specified, *nonexistent*, release R.

*** Forces creation of the *first* delta in a *new* release.

Successor.

[†] The –**b** option is effective only if the **b** flag is present in the file. An entry of '–' means 'irrelevant'.

[‡] This case applies if the **d** (default SID) flag is *not* present in the file. If the **d** flag *is* present in the file, the SID obtained from the **d** flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

DIAGNOSTICS	Use the SCCS help co	mmand for explanations (see sccs-help (1)).
BUGS	If the effective user h	as write permission (either explicitly or implicitly) in the directory iles, but the real user does not, only one file may be named when

NAME	sccs-help, help – ask for help regarding SCCS error or warning messages		
SYNOPSIS	/usr/ccs/bin/help [argument]		
DESCRIPTION	help retrieves information to further explain errors messages and warnings from SCCS commands. It also provides some information about SCCS command usage. If no arguments are given, help prompts for one.		
	An <i>argument</i> may be a message number (which normally appears in parentheses follow- ing each SCCS error or warning message), or an SCCS command name. help responds with an explanation of the message or a usage line for the command.		
	When all else fails, try '/usr/ccs/bin/help stuck'.		
FILES	/usr/ccs/lib/help directory containing files of message text

modified 17 May 1994

NAME	sccs-prs, prs – display selected portions of an SCCS history		
SYNOPSIS	/usr/ccs/bin/prs [–ael] [–cdate-time] [–ddataspec] [–rsid] s.filename		
DESCRIPTION	prs displays part or all of the SCCS file (see sccsfile (4)) in a user supplied format.		
	If a directory name is used in place of the <i>s.filename</i> argument, the prs command applies to all s .files in that directory. Unreadable s .files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one s .file per line.		
OPTIONS	In the absence of options, prs displays the delta table (version log). In the absence of –d , or –l , prs displays the entry for each delta indicated by the other options.		
	-a Include all deltas, including those marked as removed (see sccs-rmdel (1)).		
	 Request information for all deltas created <i>earlier</i> than, and including, the delta indicated with -r or -c. 		
	-l Request information for all deltas created <i>later</i> than, and including, the delta indicated with - r or - c .		
	-cdate-time		
	Display information on the latest delta checked in prior to the date and time indi- cated by the <i>date-time</i> argument. <i>date-time</i> takes the form:		
	<i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]].		
	Units omitted from the indicated date and time default to their maximum possible values; that is $-c7502$ is equivalent to $-c750228235959$. Any number of non- numeric characters may separate the various 2 digit components. If white-space characters occur, the <i>date-time</i> specification must be quoted.		
	-ddataspec		
	Produce a report according to the indicated data specification. <i>dataspec</i> consists of a (quoted) text string that includes embedded data keywords of the form: ': <i>key</i> :' (see <i>Data Keywords</i> , below). prs expands these keywords in the output it produces. To specify a TAB character in the output, use \t ; to specify a NEWLINE in the output, use \n .		
	- r <i>sid</i> Specify the SCCS delta ID (SID) of the delta for which information is desired. If no SID is specified, the most recently created delta is used.		

USAGE Data Keywords

Data keywords specify which parts of an SCCS file are to be retrieved. All parts of an SCCS file (see **sccsfile**(4)) have an associated data keyword. A data keyword may appear any number of times in a data specification argument to -d. These data keywords are listed in the table below:

Keyword	Data Item	File Section [*]	Value	Format ^{**}
:A:	a format for the what string :	N/A	:Z::Y: :M: :I::Z:	S
:B:	branch number	D	nnnn	S
:BD:	body	В	text	Μ
:BF:	branch flag	F	yes or no	S
:СВ:	ceiling boundary	F	:R:	S

NAME	sccs-pi	rt, prt – display delta table information from an SCCS file
SYNOPSIS	/usr/cc	s/bin/prt [–abdefistu] [–cdate-time] [–rdate-time] [–ysid] s.filename
DESCRIPTION	prt pri log).	nts selected portions of an SCCS file. By default, it prints the delta table (version
	to all s with tł	rectory name is used in place of the <i>s.filename</i> argument, the prt command applies s.files in that directory. Unreadable s .files produce an error; processing continues ne next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the of files are to be read from the standard input, one s .file per line.
OPTIONS		option other than – y , – c , or – r is supplied, the name of each file being processed ded by one NEWLINE and followed by two NEWLINE characters) appears above its its.
		e of the $-\mathbf{u}$, $-\mathbf{f}$, $-\mathbf{t}$, or $-\mathbf{b}$ options are used, $-\mathbf{d}$ is assumed. $-\mathbf{s}$, $-\mathbf{i}$ are mutually ive, as are $-\mathbf{c}$ and $-\mathbf{r}$.
	-a	Display log entries for all deltas, including those marked as removed.
	$-\mathbf{b}$	Print the body of the s. file.
	-d	Print delta table entries. This is the default.
	- e	Everything. This option implies $-\mathbf{d}$, $-\mathbf{i}$, $-\mathbf{u}$, $-\mathbf{f}$, and $-\mathbf{t}$.
	-f	Print the flags of each named s. file.
	—i	Print the serial numbers of included, excluded, and ignored deltas.
	-S	Print only the first line of the delta table entries; that is, only up to the statistics.
	-t	Print the descriptive text contained in the s .file.
	-u	Print the user-names and/or numerical group IDs of users allowed to make del- tas.
	-cdate-	time
		Exclude delta table entries that are specified cutoff date and time. Each entry is printed as a single line, preceded by the name of the SCCS file. This format (also produced by $-\mathbf{r}$, and $-\mathbf{y}$) makes it easy to sort multiple delta tables in chronological order. When both $-\mathbf{y}$ and $-\mathbf{c}$, or $-\mathbf{y}$ and $-\mathbf{r}$ are supplied, prt stops printing when the first of the two conditions is met.
	-rdate-	
		Exclude delta table entries that are newer than the specified cutoff date and time.
	–ysid	Exclude delta table entries made prior to the SID specified. If no delta in the table has the specified SID, the entire table is printed. If no SID is specified, the most recent delta is printed.

modified 5 Oct 1990

USAGE Output Format	 The following format is used to print those portions of the s.file that are specified by the various options. NEWLINE Type of delta (D or R) SPACE SCCS delta ID (SID) TAB Date and time of creation in the form: <i>yy/mm/dd hh/mm/ss</i> SPACE Username the delta's creator TAB Serial number of the delta SPACE Predecessor delta's serial number TAB Line-by-line change statistics in the form: <i>inserted/deleted/unchanged</i> NEWLINE List of included deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of excluded deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of ignored deltas, followed by a NEWLINE (only if there were any such deltas and the -i options was used) List of modification requests (MR s), followed by a NEWLINE (only if any MR numbers were supplied). Lines of the delta commentary (if any), followed by a NEWLINE.
EXAMPLES	The following command:
	example% /usr/ccs/bin/prt –y program.c
	produces a one-line display of the delta table entry for the most recent version:
	s.program.c: D 1.6 88/07/06 21:39:39 username 5 4 00159/00080/00636

DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).

modified 5 Oct 1990

NAME	sccs-rmdel, rmdel – remove a delta from an SCCS file			
SYNOPSIS	/usr/ccs/bin/rmdel –rsid s.filename			
DESCRIPTION	rmdel removes the delta specified by the SCCS delta ID (SID) supplied with – r . The delta to be removed must be the most recent (leaf) delta in its branch. In addition, the SID must <i>not</i> be that of a version checked out for editing: it must not appear in any entry of the version lock file (p .file).			
	If you created the delta, or, if you own the file and directory and have write permission, you can remove it with rmdel .			
	If a directory name is used in place of the <i>s.filename</i> argument, the rmdel command applies to all s .files in that directory. Unreadable s .files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one s .file per line.			
OPTIONS	<i>–rsid</i> Remove the version corresponding to the indicated SID (delta).			
FILES	p.filepermissions files.filehistory filez.filetemporary copy of the s.file

DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).			

NAME	sccs-sact, sact – show editing activity status of an SCCS file
SYNOPSIS	/usr/ccs/bin/sact s.filename
DESCRIPTION	 sact informs the user of any SCCS files that are checked out for editing. The output for each named file consists of five fields separated by SPACE characters. SID of a delta that currently exists in the SCCS file, to which changes will be made to make the new delta SID for the new delta to be created Username of the person who has the file checked out for editing. Date that the version was checked out. Time that the version was checked out. If a directory name is used in place of the <i>s.filename</i> argument, the sact command applies to all <i>s</i>.files in that directory. Unreadable <i>s</i>.files produce an error; processing continues
	with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one s. file per line.
SEE ALSO	sccs(1), sccs-delta(1), sccs-get(1), sccs-help(1), sccs-prs(1), sccs-prt(1), what(1), sccsfile(4) Programming Utilities Guide
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).
BUGS	sact is not recognized as a subcommand of sccs (1).

NAME	sccs-sccsdiff, sccsdiff – compare two versions of an SCCS file			
SYNOPSIS	/usr/ccs/bin/sccsdiff [–p] –rsid –rsid [diff-options] s.filename			
DESCRIPTION	sccsdiff compares two versions of an SCCS file and displays the differences between the two versions. Any number of SCCS files may be specified; the options specified apply to all named s .files.			
OPTIONS	- p Pipe output for each file through pr (1).			
	-r sid Specify a version corresponding to the indicated SCCS delta ID (SID) for comparison. Versions are passed to diff (1) in the order given.			
	diff-options Pass options to diff (1), including: -c , -e , -f , -h , -b and -D .			
FILES	/tmp/get????? temporary files			
SEE ALSO	diff(1), sccs(1), sccs-delta(1), sccs-get(1), sccs-help(1), sccs-prs(1), sccs-prt(1), what(1), sccsfile(4)			
	Programming Utilities Guide			
DIAGNOSTICS	<i>filename</i> : No differences If the two versions are the same. Use the SCCS help command for explanations of other messages (see sccs-help (1)).			

NAME	sccs-unget, unget – undo a previous get of an SCCS file		
SYNOPSIS	/usr/ccs/bin/unget [–ns] [–rsid] s.filename		
DESCRIPTION	unget undoes the effect of a ' get $-e$ ' done prior to the creation of the pending delta.		
	If a directory name is used in place of the <i>s.filename</i> argument, the unget command applies to all s .files in that directory. Unreadable s .files produce an error; processing continues with the next file (if any). The use of '-' as the <i>s.filename</i> argument indicates that the names of files are to be read from the standard input, one s .file per line.		
OPTIONS	-n Retain the retrieved version, which is otherwise removed.		
	-s Suppress display of the SCCS delta ID (SID).		
	- r <i>sid</i> When multiple versions are checked out, specify which pending delta to abort. A diagnostic results if the specified SID is ambiguous, or if it is necessary but omitted from the command line.		
SEE ALSO	<pre>sccs(1), sccs-delta(1), sccs-get(1), sccs-help(1), sccs-prs(1), sccs-prt(1), sccs-rmdel(1), sccs-sact(1), sccs-sccsdiff(1), what(1), sccsfile(4)</pre>		
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).		

modified 11 Oct 1990

NAME	sccs-val, val – validate an SCCS file			
SYNOPSIS	/usr/ccs/bin/val –			
	/usr/ccs/bin/val [-s] [-m name] [-rsid] [-y type] s.filename			
DESCRIPTION	val determines if the specified s .files files meet the characteristics specified by the indi- cated arguments. val can process up to 50 files on a single command line.			
	val has a special argument, '–', which reads the standard input until the end-of-file condi- tion is detected. Each line read is independently processed as if it were a command line argument list.			
	val generates diagnostic messages on the standard output for each command line and file processed and also returns a single 8–bit code upon exit as described below.			
	The 8-bit code returned by val is a disjunction of the possible errors, that is, it can be interpreted as a bit string where (moving from left to right) the bits set are interpreted as follows:			
	bit 0 = missing file argument bit 1 = unknown or duplicate option bit 2 = corrupted s .file			
	bit 3 = can not open file or file not in s .file format bit 4 = the SCCS delta ID (SID) is invalid or ambiguous			
	bit 5 = the SID does not exist			
	bit 6 = mismatch between % Y % and –y argument bit 7 = mismatch between % M % – m argument			
	val can process two or more files on a given command line, and in turn can process mul- tiple command lines (when reading the standard input). In these cases, an aggregate code is returned which is the logical OR of the codes generated for each command line and file processed.			
OPTIONS	-s Silent. Suppress the normal error or warning messages.			
	- m <i>name</i> Compare <i>name</i> with the % M % ID keyword in the s .file.			
	 -rsid Check to see if the indicated SID is ambiguous, invalid, or absent from the s.file. 			
	-y <i>type</i> Compare <i>type</i> with the %Y% ID keyword.			
SEE ALSO	<pre>sccs(1), sccs-admin(1), sccs-delta(1), sccs-get(1), sccs-help(1), what(1), sccsfile(4)</pre>			
	Programming Utilities Guide			
DIAGNOSTICS	Use the SCCS help command for explanations (see sccs-help (1)).			

NAME	sccs – front end for the Source Code Control System (SCCS)		
SYNOPSIS	/usr/ccs/bin/sccs[-r][-d rootprefix][-p subdir] subcommand[option][file]		
AVAILABILITY	SUNWsprot		
DESCRIPTION	The sccs command is a comprehensive, straightforward front end to the various utili programs of the Source Code Control System (SCCS).		
	sccs applies the indicated <i>subcommand</i> to the history file associated with each of the indicated files.		
	The name of an SCCS history file is derived by prepending the 's.' prefix to the filename of a working copy. The sccs command normally expects these 's.files' to reside in an SCCS subdirectory. Thus, when you supply sccs with a <i>file</i> argument, it normally applies the subcommand to a file named s. <i>file</i> in the SCCS subdirectory. If <i>file</i> is a path name, sccs looks for the history file in the SCCS subdirectory of that file's parent directory. If <i>file</i> is a directory, however, sccs applies the subcommand to every s.file file it contains. Thus, the command:		
	example% sccs get program.c		
	would apply the get subcommand to a history file named:		
	SCCS/s.program.c		
	while the command:		
	example% sccs get SCCS		
	would apply it to every s .file in the SCCS subdirectory.		
	Options for the sccs command itself must appear before the <i>subcommand</i> argument. Options for a given subcommand must appear after the <i>subcommand</i> argument. These options are specific to each subcommand, and are described along with the subcom- mands themselves (see Subcommands , below).		
Running Setuid	The sccs command also includes the capability to run "setuid" to provide additional pro- tection. However this does not apply to subcommands such as sccs-admin (1), since this would allow anyone to change the authorizations of the history file. Commands that would do so always run as the real user.		
OPTIONS	The following options are supported:		
	-d <i>rootprefix</i> Define the root portion of the path name for SCCS history files. The default root portion is the current directory. Note: <i>rootprefix</i> is prepended to the entire <i>file</i> argument, even if <i>file</i> is an absolute path named overrides any directory specified by the PROJECTDIR environment variable (see ENVIRONMENT , below).		
	-p <i>subdir</i> Define the (sub)directory within which a history file is expected to reside. SCCS is the default. (See EXAMPLES , below).		

	-r	Run sccs with th	ne real user ID, rather than set to the effective user ID.	
OPERANDS	The following o	perands are supp	ported:	
	subcommand		name or the name of one of the pseudo-utilities listed in	
	options	An option or op	tion-argument to be passed to <i>subcommand</i> .	
	operands		be passed to <i>subcommand</i> .	
USAGE Subcommands	Many of the foll Many of these s	owing sccs subco ubcommands acc	ommands invoke programs that reside in / usr/ccs/bin . ept additional arguments that are documented in the gram the subcommand invokes.	
	admin	Modify the flags or checksum of an SCCS history file. Refer to sccs - admin (1) for more information about the admin utility. While admin can be used to initialize a history file, you may find that the create sub- command is simpler to use for this purpose.		
	cdc - r sid [-y]			
	cdc – r <i>sid</i> [– y [<i>c</i> d	<pre>comment] Annotate (change) the delta commentary. Refer to sccs-cdc(1). Note: The fix subcommand can be used to replace the delta, rather than merely annotating the existing commentary.</pre>		
		−r sid −rsid	Specify the SCCS delta ID (SID) to which the change notation is to be added. The SID for a given delta is a number, in Dewey decimal format, composed of two or four fields: the <i>release</i> and <i>level</i> fields, and for branch deltas, the <i>branch</i> and <i>sequence</i> fields. For instance, the SID for the initial delta is normally 1.1 .	
		-y [comment]	Specify the comment with which to annotate the delta commentary. If $-y$ is omitted, sccs prompts for a comment. A null <i>comment</i> results in an empty annotation.	
	check [–b] [–u [u [<i>username</i>] −U] Check for files currently being edited. Like info and tell , but returns an exit code, rather than producing a listing of files. check returns a non-zero exit status if anything is being edited.		
		- b	Ignore branches.	
		–u [username]	- U Only check files being edited by you. When <i>username</i> is specified, only check files being edited by that user.	
	clean [–b]	•	ning in the current directory that can be retrieved from Does not remove files that are being edited.	
		-b	Do not check branches to see if they are being edited.	

1-927

		' clean $-\mathbf{b}$ ' is dangerous when branch versions are kept in the same directory.		
comb	Generate scripts to combine deltas. Refer to sccs-comb (1).			
create	Create (initializ	Create (initialize) history files. create performs the following steps:		
	• Renames the original source file to , program.c in the current direc-			
		istory file called s.program.c in the SCCS subdirectory. a ' sccs get ' on program.c to retrieve a read-only copy of ersion.		
deledit [-s] [-y				
	Equivalent to an ' sccs delta ' and then an ' sccs edit '. deledit checks in a delta, and checks the file back out again, but leaves the current working copy of the file intact.			
	— s	Silent. Do not report delta numbers or statistics.		
	-y [comment]	Supply a comment for the delta commentary. If –y is omitted, delta prompts for a comment. A NULL <i>comment</i> results in an empty comment field for the delta.		
delget [-s] [-y	[comment]]			
8 ,	Perform an 'sccs delta' and then an 'sccs get' to check in a delta and retrieve read-only copies of the resulting new version. See the deledit subcommand for a description of –s and –y. sccs performs a delta on all the files specified in the argument list, and then a get on all the files. If an error occurs during the delta, the get is not performed.			
delta [–s] [–y [a	comment]]			
Check in pending changes. Records the line-by-line changes introduced while the file was checked out. The effective user ID must be the same as the ID of the person who has the file checked out. Refer to sccs - delta (1). See the deledit subcommand for a description of – s and – y . diffs [– C] [– c <i>date-time</i>] [– r <i>sid</i>] <i>diff-options</i>				
diffs [-C] [-cdate-time] [-rsid] diff-options				
	Compare (in diff (1) format) the working copy of a file that is checked out for editing, with a version from the SCCS history. Use the most recent checked-in version by default. The diffs subcommand accepts the same options as diff , with the exception that the $-c$ option to diff must be specified as $-C$.			
	- C	Pass the $-\mathbf{c}$ option to diff .		
	−c date-time −	-cdate-time Use the most recent version checked in before the indi- cated date and time for comparison. <i>date-time</i> takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]]. Omitted units default to their maximum possible values; that is –c7502 is equivalent to –c750228235959.		

	− r sid − r sid	Use the version corresponding to the indicated delta for comparison.	
edit	Retrieve a version of the file for editing. 'sccs edit' extracts a version of the file that is writable by you, and creates a p .file in the SCCS subdirectory as lock on the history, so that no one else can check that version in or out. ID keywords are retrieved in unexpanded form. edit accepts the same options as get, below.		
enter	Similar to create , but omits the final ' sccs get '. This may be used if an ' sccs edit ' is to be performed immediately after the history file is initial- ized.		
fix –r sid			
fix –rsid	Revise a (leaf) delta. Remove the indicated delta from the SCCS history, but leave a working copy of the current version in the directory. This is useful for incorporating trivial updates for which no audit record is needed, or for revising the delta commentary. fix must be followed by a – r option, to specify the SID of the delta to remove. The indicated delta must be the most recent (leaf) delta in its branch. Use fix with caution since it does not leave an audit trail of differences (although the previ- ous commentary is retained within the history file).		
get [–ekmps] [-	-c date-time] [–r s	id]	
get [–ekmps] [-	-cdate-time] [–rsic		
	Retrieve a version from the SCCS history. By default, this is a read-only working copy of the most recent version; ID keywords are in expanded form. Refer to sccs-get (1).		
	- e	Retrieve a version for editing. Same as sccs edit.	
	- k	Retrieve a writable copy but do not check out the file. ID keywords are unexpanded.	
	-m	Precede each line with the SID of the delta in which it was added.	
	- p	Produce the retrieved version on the standard output. Reports that would normally go to the standard output (delta ID's and statistics) are directed to the standard error.	
	- s	Silent. Do not report version numbers or statistics.	
	– c date-time –	-cdate-time	
	·	Retrieve the latest version checked in prior to the date and time indicated by the <i>date-time</i> argument. <i>date-time</i> takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]]].	
	$-\mathbf{r} sid \mid -\mathbf{r} sid$	Retrieve the version corresponding to the indicated SID.	
	de sccs-command		
help stuck	Supply more in	formation about SCCS diagnostics. help displays a brief	

1-929

explanation of the error when you supply the code displayed by an SCCS diagnostic message. If you supply the name of an SCCS command, it prints a usage line. help also recognizes the keyword stuck . Refer to sccs-help (1). info [- b] [- u [<i>username</i>] - U]			
		f files being edited including the version number checked	
	Display a list of files being edited, including the version number checked out, the version to be checked in, the name of the user who holds the lock, and the date and time the file was checked out.		
	- b	Ignore branches.	
	–u [username]	-U	
		List only files checked out by you. When <i>username</i> is specified, only list files checked out by that user.	
print	Print the entire history of each named file. Equivalent to an 'sccs prs $-e$ ' followed by an 'sccs get $-p - m$ '.		
prs [–el] [–c da	te-time] [– r sid]		
prs [–el] [–cdat			
	Peruse (display sccs-prs(1).) the delta table, or other portion of an s .file. Refer to	
	- e	Display delta table information for all deltas earlier than the one specified with –r (or all deltas if none is specified).	
	- l	Display information for all deltas later than, and including, that specified by $-c$ or $-r$.	
	-c date-time -cdate-time		
		Specify the latest delta checked in before the indicated date and time. The <i>date-time</i> argument takes the form: <i>yy</i> [<i>mm</i> [<i>dd</i> [<i>hh</i> [<i>mm</i> [<i>ss</i>]]]].	
	–r sid –rsid	Specify a given delta by SID.	
prt [–y]			
	Display the delta table, but omit the MR field (see sccsfile (4) for more information on this field). Refer to sccs-prt (1).		
	- y	Display the most recent delta table entry. The format is a single output line for each file argument, which is convenient for use in a pipeline with $awk(1)$ or $sed(1)$.	
rmdel –r sid rmdel –rsid	Remove the indicated delta from the history file. That delta must be the most recent (leaf) delta in its branch. Refer to sccs-rmdel (1).		
sccsdiff –rold-sid –rnew-sid diff-options			
	Compare two versions corresponding to the indicated SIDs (deltas) using diff . Refer to sccs-sccsdiff (1).		

	tell [-b] [-u [<i>username</i>] -U] Display the list of files that are currently checked out, one file per line		
		Ignore branches.	
		-u [username] -U	
		Only list files checked out to you. When <i>username</i> is specified, only list files check out to that user.	
	unedit	"Undo" the last edit or 'get $-e$ ', and return the working copy to its pre- vious condition. unedit backs out all pending changes made since the file was checked out.	
	unget	Same as unedit . Refer to sccs-unget (1).	
	val	Validate the history file. Refer to sccs-val (1).	
	what	Display any expanded ID keyword strings contained in a binary (object) or text file. Refer to what (1) for more information.	
EXAMPLES	sccs converts t	he command:	
	examp	le% sccs –d/usr/src/include get stdio.h	
	to:		
	/usr/cc	s/bin/get /usr/src/include/SCCS/s.stdio.h	
	The command:		
	example% sccs -pprivate get include/stdio.h becomes: /usr/ccs/bin/get include/private/s.stdio.h To initialize the history file for a source file named program.c: make the SCCS subdirectory, and then use 'sccs create': example% mkdir SCCS example% sccs create program.c program.c: 1.1 14		
	After verifying the working copy, you can remove the backup file that starts with a comma:		
		le% diff program.c ,program.c le% rm ,program.c	
	To check out a	copy of program.c for editing, edit it, and then check it back in:	
	examp 1.1	le% sccs edit program.c	
		elta 1.2	
	14		
		le% vi program.c liting session	

1-931

	example% sccs delget program.c		
	comments? clarified cryptic diagnostic 1.2		
	3 inserted		
	2 deleted		
	12 unchanged		
	1.2		
	15		
	To retrieve a file from another directory into the current directory:		
	example	% sccs get /usr/src/sccs/cc.c	
	or:		
	example	% sccs –p/usr/src/sccs/ get cc.c	
	To check out all f	iles under SCCS in the current directory:	
	example	% sccs edit SCCS	
	To check in all file	es currently checked out to you:	
	example% sccs delta `sccs tell –u`		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of sccs : LC_CTYPE, LC_MESSAGES, and NLSPATH.		
		If contains an absolute path name (beginning with a slash), sccs searches for SCCS history files in the directory given by that variable.	
]	If PROJECTDIR does not begin with a slash, it is taken as the name of a user, and sccs searches the src or source subdirectory of that user's home directory for history files. If such a directory is found, it is used. Otherwise, the value is used as a relative path name.	
EXIT STATUS	The following exit values are returned:		
LAII SIMICS	The following exit values are returned: 0 Successful completion.		
		An error occurred.	
FILES	SCCS	SCCS subdirectory	
TILLO	SCCS/d.file	temporary file of differences	
	SCCS/p.file	lock (permissions) file for checked-out versions	
	SCCS/q.file	temporary file	
	SCCS/s.file	SCCS history file	
	SCCS/x.file	temporary copy of the s.file	
	SCCS/z.file	temporary lock file	
	/usr/ccs/bin/*	SCCS utility programs

Programming Utilities Guide

BUGS There is no sact subcommand to invoke /usr/ccs/bin/sact (see sccs-sact(1)). However, the info subcommand performs an equivalent function.

modified 18 Jul 1995

NAME	script – make record of a terminal session			
SYNOPSIS	script [-a] [filename]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	script makes a record of everything printed on your screen. The record is written to <i>filename</i> . If no file name is given, the record is saved in the file typescript .			
	The script command forks and creates a sub-shell, according to the value of \$SHELL , and records the text from this session. The script ends when the forked shell exits or when CTRL-D is typed.			
OPTIONS	- a Append the session record to <i>filename</i> , rather than overwrite it.			
NOTES	script places everything that appears on the screen in <i>filename</i> , including prompts.			

modified 8 Feb 1994

sdiff – print differences between two files side-by-side				
sdiff [–l] [–s] [–o output] [–w n] filename1 filename2				
SUNWesu				
sdiff uses the output of the diff command to produce a side-by-side listing of two files indicating lines that are different. Lines of the two files are printed with a blank gutter between them if the lines are identical, $a < in$ the gutter if the line appears only in <i>filename1</i> , $a > in$ the gutter if the line appears only in <i>filename2</i> , and $a \mid for$ lines that are different. (See the EXAMPLES section below.)				
-l Print only the left side of any lines that are identical.				
-s Do not print identical lines.				
 -o output Use the argument output as the name of a third file that is created as a user-controlled merge of filename1 and filename2. Identical lines of filename1 and filename2 are copied to output. Sets of differences, as produced by diff, are printed; where a set of differences share a common gutter character. After printing each set of differences, sdiff prompts the user with a % and waits for one of the following user-typed commands: 				
 Append the left column to the output file. r Append the right column to the output file. s Turn on silent mode; do not print identical lines. v Turn off silent mode. e l Call the editor with the left column. e r Call the editor with the right column. e b Call the editor with the concatenation of left and right. e Call the editor with a zero length file. q Exit from the program. 				
On exit from the editor, the resulting file is concatenated to the end of the <i>output</i> file.				
$-\mathbf{w} \ n$ Use the argument <i>n</i> as the width of the output line. The default line length is 130 characters.				
A sample output of sdiff follows. x y a a b < c < d d > c				

modified 14 Sep 1992

	1	
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of sdiff for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to over- ride both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how sdiff behaves. LC_CTYPE	
	Determines how sdiff handles characters. When LC_CTYPE is set to a valid value, sdiff can display and handle text and filenames containing valid characters for that locale. sdiff can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. sdiff can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.	
SEE ALSO	diff(1), ed(1), environ(5)	
SEE ALSO	sdiff can display and handle text and filenames containing valid characters for that locale. sdiff can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. sdiff can also handl EUC characters of 1, 2, or more column widths. User Commands

NAME	sed – stream editor				
SYNOPSIS	<pre>/usr/bin/sed [-n] script [file] /usr/bin/sed [-n] [-e script] [-f script_file] [file] /usr/xpg4/bin/sed [-n] script [file] /usr/xpg4/bin/sed [-n] [-e script] [-f script_file] [file]</pre>				
AVAILABILITY /usr/bin/sed	SUNWcsu				
/usr/xpg4/bin/sed	SUNWxcu4				
DESCRIPTION	The sed command is a stream editor that reads one or more text files, makes editing changes according to a script of editing commands, and writes the results to standard output. The script is obtained from either the <i>script</i> operand string, or a combination of the option-arguments from the $-e$ <i>script</i> and $-f$ <i>script_file</i> options.				
OPTIONS	The following o	ptions are supported;			
	–e script	<i>script</i> is an edit command for sed . See USAGE below for more information on the format of <i>script</i> . If there is just one $-\mathbf{e}$ option and no $-\mathbf{f}$ options, the flag $-\mathbf{e}$ may be omitted.			
	-f script_file	Take the script from <i>script_file</i> . <i>script_file</i> consists of editing commands, one per line.			
	-n	Suppress the default output.			
	Multiple $-\mathbf{e}$ and $-\mathbf{f}$ options may be specified. All commands are added to the script in the order specified, regardless of their origin.				
OPERANDS	The following operands are supported:				
	file	A path name of a file whose contents will be read and edited. If multiple <i>file</i> operands are specified, the named files will be read in the order specified and the concatenation will be edited. If no <i>file</i> operands are specified, the standard input will be used.			
	script	A string to be used as the script of editing commands. The application must not present a <i>script</i> that violates the restrictions of a text file except that the final character need not be a NEWLINE character.			
USAGE	A script consists of editing commands, one per line, of the following form:				
	[address [, address]] function [arguments]				
		ank characters are accepted before the first address and before <i>command</i> . semicolons are accepted before the first address.			

sed(1)	User Commands	SunOS 5.5		
	In normal operation, sed cyclically copies a line of input character) into a <i>pattern space</i> (unless there is something l in sequence all commands whose <i>addresses</i> select that par ing pattern space to the standard output (except under – Whenever the pattern space is written to standard output immediately follow it with a NEWLINE character.	left after a D command), applies ttern space, and copies the result- n) and deletes the pattern space.		
	Some of the commands use a <i>hold space</i> to save all or par quent retrieval. The <i>pattern</i> and <i>hold spaces</i> will each be a			
sed Addresses	An <i>address</i> is either empty, a decimal number that counts files, a \$ that addresses the last line of input, or a context <i>ular expression</i> / as described on the regexp (5) manual page	address, which consists of a /reg-		
	A command line with no addresses selects every pattern	space.		
	A command line with one address selects each pattern s	pace that matches the address.		
	A command line with two addresses selects the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second address. Thereafter the process is repeated, looking again for the first address. (If the second address is a number less than or equal to the line number selected by the first address, only the line corresponding to the first address is selected.)			
	Typically, address are separated from each other by a co separated by a semicolon (;).	mma (,). They may also be		
sed Regular Expressions	sed supports the basic regular expressions described on the regexp (5) manual page, with the following additions:			
	\cREc In a context address, the construction \ other than a backslash or NEWLINE cha the character designated by c appears for considered to be that literal character, w For example, in the context address \xa for itself, so that the regular expression	racter, is identical to $/RE/$. If ollowing a backslash, then it is which does not terminate the RE. bb \ xdefx , the second x stands		
	`n The escape sequence `n matches a NEW pattern space. A literal NEWLINE chara ular expression of a context address or	acter must not be used in the reg-		
	Editing commands can be applied only to non-selected p tion command ! (described below).	pattern spaces by use of the nega-		
sed Editing Commands	In the following list of functions the maximum number of function is indicated.	of permissible addresses for each		
	The r and w commands take an optional <i>rfile</i> (or <i>wfile</i>) pa command letter by one or more blank characters; implen separation as an extension.			

Multiple commands can be specified by separating them with a semicolon (;) on the same command line.

The *text* argument consists of one or more lines, all but the last of which end with $\$ to hide the NEWLINE. Each embedded NEWLINE character in the text must be preceded by a backslash. Other backslashes in text are removed and the following character is treated literally. Backslashes in text are treated like backslashes in the replacement string of an **s** command, and may be used to protect initial blanks and tabs against the stripping that is done on every script line. The *rfile* or *wfile* argument must terminate the command line and must be preceded by exactly one blank. The use of the *wfile* parameter causes that file to be initially created, if it does not exist, or will replace the contents of an existing file. There can be at most 10 distinct *wfile* arguments.

Regular expressions match entire strings, not just individual lines, but a NEWLINE character is matched by n in a sed RE; a NEWLINE character is not allowed in an RE. Also note that n cannot be used to match a NEWLINE character at the end of an input line; NEWLINE characters appear in the pattern space as a result of the N editing command.

Two of the commands take a *command-list*, which is a list of **sed** commands separated by NEWLINE characters, as follows:

{ command command }

The { can be preceded with blank characters and can be followed with white space. The *commands* can be preceded by white space. The terminating } must be preceded by a NEWLINE character and can be preceeded or followed by <blank>s. The braces may be preceeded or followed by <blank>s. The command may be preceeded by
blank>s, but may not be followed by <blank>s.

The following table lists the functions.

Maximum Number of Addresses	Com- mand	Description	
2	{command-list }	Execute <i>command-list</i> only when the pattern space is selected.	
1	a∖ text	Append by executing N command or beginning a new cycle. Place <i>text</i> on the output before reading the next input line.	
2	b label	Branch to the : command bearing the <i>label</i> . If <i>label</i> is empty, branch to the end of the script. Labels are recognized unique up to eight characters.	
2	c∖ text	Change. Delete the pattern space. Place <i>text</i> on the output. Start the next cycle.	
2	d	Delete the pattern space. Start the next cycle.	
2	D	Delete the initial segment of the pattern space through the first new-line. Start the next cycle. (See the N command below.)	
2	g	Replace the contents of the pattern space by the contents of the hold space.	
2	G	Append the contents of the hold space to the pattern space.	
2	h	Replace the contents of the hold space by the contents of the pattern space.	
2	Н	Append the contents of the pattern space to the hold space.	
1	i∖ text	Insert. Place <i>text</i> on the standard output.	
2	1	List the pattern space on the standard output in an unambiguous form. Non-printable characters are displayed in octal notation and long lines are folded. The characters $(\backslash\backslash, \backslash a, \backslash b, \backslash f, \backslash r, \backslash t, and \backslash v)$ are written as the corresponding escape sequences. Non-printable characters not in that table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first). If the size of a byte on the system is greater than nine bits, the format used for non-printable characters is implementation-dependent.	
		Long lines will be folded, with the point of folding indicated by writing a backslash followed by a newline character; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line will be marked with a \$.	

Maximum Number of Addresses	Com- mand	Description		
2	n	Copy the pattern space to the standard output if default output is not supressed. Replace the pattern space with the next line of input.		
2	N	Append the next line of input to the pattern space with an embedded new-line. (The current line number changes.) If no next line of input is available, the N command verb shall branch to the end of the script and quit without starting a new cycle and without writing the pattern space.		
2	р	Print. Copy the pattern space to the standard output.		
2	Р	Copy the initial segment of the pattern space through the first new-line to the standard output.		
1	q	Quit. Branch to the end of the script. Do not start a new cycle.		
2	r rfile	Read the contents of <i>rfile</i> . Place them on the output before reading the next input line. If <i>rfile</i> does not exist or cannot be read, it is treated as if it were an empty file, causing no error condition.		
2	t label	Test. Branch to the : command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t . If <i>label</i> is empty, branch to the end of the script.		
2	w wfile	Write. Append the pattern space to <i>wfile</i> . The first occurrence of w will cause <i>wfile</i> to be cleared. Subsequent invocations of w will append. Each time the sed command is used, <i>wfile</i> is overwritten.		
2	x	Exchange the contents of the pattern and hold spaces.		
2	! command	Don't. Apply the <i>command</i> (or group, if <i>command</i> is {) only to lines <i>not</i> selected by the address(es).		
0	: label	This command does nothing; it bears a <i>label</i> for b and t commands to branch to.		
1	=	Place the current line number on the standard output as a line.		
2	{	Execute the following commands through a matching } only when the pattern space is selected.		
0		An empty command is ignored.		
0	#	If a # appears as the first character on a line of a script file, then that entire line is treated as a comment, with one exception: if a # appears on the first line and the character after the # is an n , then the default output will be suppressed. The rest of the line after # n is also ignored. A script file must contain at least one non-comment line.		

Maximum Number of Addresses	Command (Using <i>strings</i>) and Description
2	s /regular expression/replacement/flags Substitute the <i>replacement</i> string for instances of the <i>regular expression</i> in the pattern space. Any character other than backslash or newline can be used instead of a slash to delimit the RE and the replacement. Within the RE and the replacement, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.
	An ampersand (&) appearing in the <i>replacement</i> will be replaced by the string matching the RE. The special meaning of & in this context can be suppressed by preceding it by backslash. The characters \n , where <i>n</i> is a digit, will be replaced by the text matched by the corresponding backreference expression. For each backslash (\) encountered in scanning <i>replacement</i> from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &, \ or digits.
	A line can be split by substituting a newline character into it. The application must escape the newline character in the <i>replacement</i> by preceding it by backslash. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.
	<i>flags</i> is zero or more of:
	<i>n n</i> = 1 - 512. Substitute for just the <i>n</i> th occurrence of the <i>regular expression</i> .
	g Global. Substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one. If both <i>g</i> and <i>n</i> are specified, the results are unspecified.
	p Print the pattern space if a replacement was made.
	P Copy the initial segment of the pattern space through the first new-line to the standard output.
	\mathbf{w} <i>wfile</i> Write. Append the pattern space to <i>wfile</i> if a replacement was made. The first occurrence of \mathbf{w} will cause <i>wfile</i> to be cleared. Subsequent invocations of \mathbf{w} will append. Each time the sed command is used, <i>wfile</i> is overwritten.
2	y/ string1 / string2 / Transform. Replace all occurrences of characters in string1 with the corresponding characters in string2. string1 and string2 must have the same number of characters, or if any of the characters in string1 appear more than once, the results are undefined. Any character other than backslash or newline can be used instead of slash to delimit the strings. Within string1 and string2, the delimiter itself can be used as a literal character if it is preceded by a backslash. For example, y/abc/ABC/ replaces a with A, b with B, and c with C.

EXAMPLES	standard input. sed -n ' # Write non-empty lines. /./ { P			
	d } # Write a single empty line, then look for more empty lines. /^\$/ p			
	/^\$/ p # Get next line, discard the held <newline> (empty line),</newline>			
	# and look for more empty lines.			
	:Empty /^\$/ {			
	Ν			
	s/.// b Empty			
	}			
	# Write the non-empty line before going back to search # for the first in a set of empty lines.			
	p			
	,			
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of sed : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .			
EXIT STATUS	The following exit values are returned:			
	0 Successful completion.			
	>0 An error occurred.

sed(1B)	SunOS/BSD Compatibility Package CommandsSunOS 5.5					
	l					
NAME	sed – stream edit	or				
SYNOPSIS	sed [–n] [–e scr	ipt][-f sfilename][filename]				
DESCRIPTION	sed copies the <i>file</i> to a script of com	enames (standard input default) to the standard outpo mands.	ut, edited according			
OPTIONS	-n	Suppress the default output.				
	-	script is an edit command for sed. If there is just one options, the $-e$ flag may be omitted.	–e option and no –f			
	- f sfilename	Take the script from <i>sfilename</i> .				
USAGE sed Scripts	-	st of editing commands, one per line, of the followin	g form:			
	_	[, address]] function [arguments]				
	In normal operation sed cyclically copies a line of input into a <i>pattern space</i> (unless there is something left after a D command), sequentially applies all commands with <i>addresses</i> matching that pattern space until reaching the end of the script, copies the pattern space to the standard output (except under $-n$), and finally, deletes the pattern space.					
	Some commands use a <i>hold space</i> to save all or part of the pattern space for subsequent retrieval.					
	An <i>address</i> is either:					
	a decimal number linecount, which is cumulative across input files;					
	a \$, which addresses the last input line;					
	or a context address, which is a <i>/regular expression/</i> as described on the regexp (manual page, with the following exceptions:					
	\?RE?	In a context address, the construction \ ?regular ex any character, is identical to /regular expression/. N address \ xabc \ xdefx , the second x stands for itsel expression is abcxdef .	lote: in the context			
	\n	Matches a NEWLINE embedded in the pattern space	ce.			
		Matches any character except the NEWLINE ending	g the pattern space.			
	null	A command line with no address selects every part	ttern space.			
	addres	s Selects each pattern space that matches.				
	addres	is1, address2 Selects the inclusive range from the first pattern sp address1 to the first pattern space matching address line if address1 is greater than or equal to address2.				

Comments	If the first nonwhite character in a line is a '#' (pound sign), sed treats that line as a comment, and ignores it. If, however, the first such line is of the form:			
	# n sed runs as	if the -n flag were specified.		
Functions				
	∖ to hide th string of an	nt denoted <i>text</i> consists of one or more lines, all but the last of which end with e NEWLINE. Backslashes in text are treated like backslashes in the replacement s command, and may be used to protect initial SPACE and TAB characters stripping that is done on every script line.		
	be preceded	nt denoted <i>rfilename</i> or <i>wfilename</i> must terminate the command line and must d by exactly one SPACE. Each <i>wfilename</i> is created before processing begins. e at most 10 distinct <i>wfilename</i> arguments.		
	(1) a \ text	Append: place <i>text</i> on the output before reading the next input line.		
	(2) b label	Branch to the ':' command bearing the <i>label</i> . Branch to the end of the script if <i>label</i> is empty.		
	(2) c\ text	Change: delete the pattern space. With 0 or 1 address or at the end of a 2 address range, place <i>text</i> on the output. Start the next cycle.		
	(2) d	Delete the pattern space. Start the next cycle.		
	(2) D	Delete the initial segment of the pattern space through the first NEWLINE. Start the next cycle.		
	(2) g	Replace the contents of the pattern space by the contents of the hold space.		
	(2) G	Append the contents of the hold space to the pattern space.		
	(2) h	Replace the contents of the hold space by the contents of the pattern space.		
	(2) H	Append the contents of the pattern space to the hold space.		
	(1) i \			
	text	Insert: place <i>text</i> on the standard output.		
	(2) 1	List the pattern space on the standard output in an unambiguous form. Non-printing characters are spelled in two digit ASCII and long lines are folded.		
	(2) n	Copy the pattern space to the standard output. Replace the pattern space with the next line of input.		
	(2) N Append the next line of input to the pattern space with an embedd line. (The current line number changes.)			
	(2) p	Print: copy the pattern space to the standard output.		
	(2) P	Copy the initial segment of the pattern space through the first NEWLINE to		

1B-945

		the standard output.Quit: branch to the end of the script. Do not start a new cycle. <i>ilename</i> Read the contents of <i>rfilename</i> . Place them on the output before reading the next input line. <i>rgular expression/replacement/flags</i> Substitute the <i>replacement string</i> for instances of the <i>regular expression</i> in the pattern space. Any character may be used instead of '/'. For a fuller description see regexp (5). <i>flags</i> is zero or more of: n $n = 1 - 512$. Substitute for just the <i>n</i> th occurrence of the <i>regular</i> expression.		
	(1) q			
	(1) q (2) r rfilenam			
	(2) s/regular e			
		g	Global: substitute for all nonoverlapping instances of the <i>regular expression</i> rather than just the first one.	
		р	Print the pattern space if a replacement was made.	
		w wfilename	Write: append the pattern space to <i>wfilename</i> if a replacement was made.	
	(2) t label	Test: branch to the ':' command bearing the <i>label</i> if any substitutions have been made since the most recent reading of an input line or execution of a t . If <i>label</i> is empty, branch to the end of the script.		
	(2) w wfilenai	ne		
		 Write: append the pattern space to <i>wfilename</i>. Exchange the contents of the pattern and hold spaces. g1/string2/ Transform: replace all occurrences of characters in <i>string1</i> with the corresponding character in <i>string2</i>. The lengths of <i>string1</i> and <i>string2</i> must be equal. 		
	(2) x			
	(2) y/string1/.			
	(2)! function			
	(0) : <i>label</i>	This command does nothing; it bears a <i>label</i> for b and t commands to branch to. Note: the maximum length of <i>label</i> is seven characters.		
	(1) =	Place the cur	rent line number on the standard output as a line.	
	(2) {	Execute the following commands through a matching '}' only when the pattern space is selected. Commands are separated by ';'.		
	(0)	An empty co	ommand is ignored.	
DIAGNOSTICS		any commands The command list contained more than 200 commands.		
	Too much command text The command list was too big for sed to handle. Text in the a , c , and i com- mands, text read in by r commands, addresses, regular expressions and			

1B-946

replacement strings in **s** commands, and translation tables in **y** commands all require **sed** to store data internally.

Command line too long

A command line was longer than 4000 characters.

Too many line numbers

More than 256 decimal number linecounts were specified as addresses in the command list.

Too many files in w commands

More than 10 different files were specified in ${\bf w}$ commands or ${\bf w}$ options for ${\bf s}$ commands in the command list.

Too many labels

More than 50 labels were specified in the command list.

Unrecognized command

A command was not one of the ones recognized by sed.

Extra text at end of command

A command had extra text after the end.

Illegal line number

An address was neither a decimal number linecount, a \$, nor a context address.

Space missing before filename

There was no space between a \mathbf{r} or \mathbf{w} command, or the \mathbf{w} option for a \mathbf{s} command, and the filename specified for that command.

Too many {'s

There were more { than } in the list of commands to be executed.

Too many }'s

There were more } than { in the list of commands to be executed.

No addresses allowed

A command that takes no addresses had an address specified.

Only one address allowed

A command that takes one address had two addresses specified.

"\digit" out of range

The number in a n item in a regular expression or a replacement string in a **s** command was greater than 9.

Bad number

One of the endpoints in a range item in a regular expression (that is, an item of the form $\{n\}$ or $\{n,m\}$) was not a number.

Range endpoint too large

One of the endpoints in a range item in a regular expression was greater than 255.

More than 2 numbers given in $\{ \}$

More than two endpoints were given in a range expression.

	} expected after \ A \ appe	eared in a range expression and was not followed by a } .
	First number exc	endpoint in a range expression was greater than the second.
	Illegal or missin The delin	g delimiter niter at the end of a regular expression was absent.
	∖(∖) imbalance There we	ere more $(than), or more) than (, in a regular expression.$
	[] imbalance There we	ere more [than], or more] than [, in a regular expression.
	First RE may not The first	t be null regular expression in an address or in a s command was null (empty).
		r missing on substitution ng delimiter in a s command was absent.
		r missing on string ng delimiter in a y command was absent.
		gs not the same size strings in a y command were not the same size.
		512 max x in a s command, specifying which occurrence of the regular expression e replaced, was greater than 512.
	Label too long A label ir	n a command was longer than 8 characters.
	Duplicate labels The same	e label was specified by more than one : command.
	File name too lor The filena was long	ng ame specified in a r or w command, or in the w option for a s command, ger than 1024 characters.
	Output line too l An outpu	long. ut line was longer than 4000 characters long.
		nds or reads after line <i>n</i> In 20 a or r commands were to be executed for line <i>n</i> .
	Hold space over More tha	flowed. In 4000 characters were to be stored in the <i>hold space</i> .

SEE

BUGS There is a combined limit of 200 –e and –f arguments. In addition, there are various internal size limits which, in rare cases, may overflow. To overcome these limitations, either combine or break out scripts, or use a pipeline of **sed** commands.

NAME	set, unset, setenv, unsetenv, export – shell built-in functions to determine the characteris- tics for environmental variables of the current shell and its descendents	
SYNOPSIS sh	<pre>set [—aefhkntuvx [argument]] unset [name] export [name]</pre>	
csh	<pre>set [var [= value]] set var[n] = word unset pattern setenv [VAR [word]] unsetenv variable</pre>	
ksh	<pre>set [±aefhkmnopstuvx] [±o option] [±A name] [arg] unset [-f] name †† export [name[=value]]</pre>	
DESCRIPTION sh	 The set built-in command has the following options: -a Mark variables which are modified or created for export. -e Exit immediately if a command exits with a non-zero exit status. -f Disable file name generation. -h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed). -k All keyword arguments are placed in the environment for a command, not just those that precede the command name. -n Read commands but do not execute them. -t Exit after reading and executing one command. -u Treat unset variables as an error when substituting. -v Print shell input lines as they are read. -x Print commands and their arguments as they are executed. -Do not change any of the flags; useful in setting \$1 to Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$ The remaining arguments are positional parameters and are assigned, in order, to \$1, \$2, If no arguments are given the values of all names are printed. 	

For each *name*, **unset** removes the corresponding variable or function value. The variables **PATH**, **PS1**, **PS2**, **MAILCHECK**, and **IFS** cannot be unset.

With the **export** built-in, the given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

csh With no arguments, **set** displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, **set** assigns an empty (null) value to the variable *var*. With arguments of the form *var* = *value* **set** assigns *value* to *var*, where *value* is one of:

word A single word (or quoted string).

(wordlist) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form **set** *var*[*n*] = *word* replaces the *n*'th word in a multiword value with *word*.

unset removes variables whose names match (filename substitution) *pattern*. All variables are removed by '**unset** *'; this has noticeably distasteful side effects.

With no arguments, **setenv** displays all environment variables. With the *VAR* argument, **setenv** sets the environment variable *VAR* to have an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both *VAR* and *word* arguments, **setenv** sets the environment variable **NAME** to the value *word*, which must be either a single word or a quoted string. The most commonly used environment variables, USER, TERM, and PATH, are automatically imported to and exported from the **csh** variables **user**, **term**, and **path**; there is no need to use **setenv** for these. In addition, the shell sets the **PWD** environment variable from the **csh** variable **cwd** whenever the latter changes.

The environment variables LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY take immediate effect when changed within the C shell.

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of csh for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how csh behaves.

LC_CTYPE

Determines how **csh** handles characters. When **LC_CTYPE** is set to a valid value, **csh** can display and handle text and filenames containing valid characters for that locale. **csh** can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. **csh** can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S./English).

LC_NUMERIC

Determines the value of the radix character (decimal point (".") in the "C" locale) and thousand separator (empty string ("") in the "C" locale).

unsetenv removes *variable* from the environment. As with **unset**, pattern matching is not performed.

ksh The flags for the set built-in have meaning as follows:

- -A Array assignment. Unset the variable *name* and assign values sequentially from the list *arg*. If +A is used, the variable *name* is not unset first.
- -a All subsequent variables that are defined are automatically exported.
- -e If a command has a non-zero exit status, execute the ERR trap, if set, and exit. This mode is disabled while reading profiles.
- -f Disables file name generation.
- -h Each command becomes a tracked alias when first encountered.
- -k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- -m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- –n Read commands and check them for syntax errors, but do not execute them.
 Ignored for interactive shells.
- **-o** The following argument can be one of the following option names:

allexport

Same as –**a**.

- errexit Same as –e.
- **bgnice** All background jobs are run at a lower priority. This is the default mode. **emacs** Puts you in an **emacs** style in-line editor for command entry.
- **gmacs** Puts you in a **gmacs** style in-line editor for command entry.

ignoreeof

The shell will not exit on end-of-file. The command **exit** must be used. **keyword**

Same as -k.

markdirs

All directory names resulting from file name generation have a trailing / appended. monitor Same as -m. noclobber Prevents redirection > from truncating existing files. Require > to truncate a file when turned on. **noexec** Same as –**n**. noglob Same as -f. nolog Do not save function definitions in history file. nounset Same as -u. privileged Same as -p. verbose Same as -v. trackall Same as -h. Puts you in insert mode of a **vi** style in-line editor until you hit escape vi character 033. This puts you in control mode. A return sends the line. Each character is processed as it is typed in vi mode. viraw xtrace Same as -x. If no option name is supplied then the current option settings are printed. Disables processing of the \$HOME/.profile file and uses the file /etc/suid_profile instead of the ENV file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid. Sort the positional parameters lexicographically. Exit after reading and executing one command. Treat unset parameters as an error when substituting. Print shell input lines as they are read. Print commands and their arguments as they are executed. Turns off –x and –v flags and stops examining arguments for flags. Do not change any of the flags; useful in setting \$1 to a value beginning with -. If no arguments follow this flag then the positional parameters are unset. Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in S-. Unless -A is specified, the remaining arguments are positional parameters and are assigned, in order, to \$1 \$2 If no arguments are given then the names and values of all variables are printed on the standard output.

The variables given by the list of names are unassigned, i.e., their values and attributes are erased. readonly variables cannot be unset. If the -f, flag is set, then the names refer to function names. Unsetting ERRNO, LINENO, MAILCHECK, OPTARG, OPTIND, RANDOM,

-p

-s

-t -u

-**v**

-**X**

_ _

_

SECONDS, **TMOUT**, and _ removes their special meaning even if they are subsequently assigned.

When using **unset**, the variables given by the list of *names* are unassigned, i.e., their values and attributes are erased. **readonly** variables cannot be unset. If the –f, flag is set, then the names refer to *function* names. Unsetting **ERRNO**, **LINENO**, **MAILCHECK**, **OPTARG**, **OPTIND**, **RANDOM**, **SECONDS**, **TMOUT**, and _ removes their special meaning even if they are subsequently assigned.

With the **export** built-in, the given *names* are marked for automatic export to the **environment** of subsequently-executed commands.

On this man page, **ksh**(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

- 1. Variable assignment lists preceding the command remain in effect when the command completes.
- 2. I/O redirections are processed after variable assignments.
- 3. Errors cause a script that contains them to abort.
- 4. Words, following a command preceded by *††* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	set, unset – set and unset local or global environment variables		
SYNOPSIS	set [-l variable[=value]] set [-e variable[=value]] set [-ffile variable[=value]]		
	unset –l variable unset –ffile variable		
DESCRIPTION	The set command sets <i>variable</i> in the environment, or adds <i>variable=value</i> to <i>file</i> . If <i>variable</i> is not equated it to a value, set expects the value to be on <i>stdin</i> . The unset command removes <i>variable</i> . Note that the FMLI predefined, read-only variables (such as ARG1), may not be set or unset.		
	Note that at least one of the above options must be used for each variable being set or unset. If you set a variable with the <i>-ffilename</i> option, you must thereafter include <i>filename</i> in references to that variable. For example, <i>\${(file)VARIABLE}</i> .		
	FMLI inherits the UNIX environment when invoked.		
OPTIONS	 -I Sets or unsets the specified variable in the local environment. Variables set with -I will not be inherited by processes invoked from FMLI. 		
	 -e Sets the specified variable in the UNIX environment. Variables set with -e will be inherited by any processes started from FMLI. Note that these variables cannot be unset. 		
	-ffile Sets or unsets the specified variable in the global environment. The argument file is the name, or pathname, of a file containing lines of the form <i>variable=value</i> . file will be created if it does not already exist. Note that no space intervenes between -f and file.		
EXAMPLE	Storing a selection made in a menu:		
	name=Selection 2 action=`set -l SELECTION=2`close		
NOTES	Variables set to be available to the UNIX environment (those set using the $-e$ option) can only be set for the current fmli process and the processes it calls.		
	When using the $-\mathbf{f}$ option, unless <i>file</i> is unique to the process, other users of FMLI on the same machine will be able to expand these variables, depending on the read/write permissions on <i>file</i> .		
	A variable set in one frame may be referenced or unset in any other frame. This includes local variables.

NAME SYNOPSIS	setcolor – redefine or create a color setcolor color red_level green_level blue_level
DESCRIPTION	The setcolor command takes four arguments: <i>color</i> , which must be a string naming the color; and the arguments <i>red_level</i> , <i>green_level</i> , and <i>blue_level</i> , which must be integer values defining, respectively, the intensity of the red, green, and blue components of <i>color</i> . Intensities must be in the range of 0 to 1000. If you are redefining an existing color, you must use its current name (default color names are: black , blue , green , cyan , red , magenta , yellow , and white). setcolor returns the color's name string.
EXAMPLES	The following is an example of the arguments that setcolor takes: ` setcolor blue 100 24 300 `

modified 5 Jul 1990

NAME	setfacl – modify the Access Control List (ACL) for a file or files	
SYNOPSIS	setfacl [-r] -s acl_entries file	
	setfacl [-r] -md acl_entries file	
	setfacl [-r] -f acl_file file	
AVAILABILITY	SUNWcsu	
DESCRIPTION	For each file specified, setfacl will either replace its entire ACL, including the default ACL on a directory, or it will add, modify, or delete one or more ACL entries, including default entries on directories.	
	The $-s$ option will set the ACL to the entries specified on the command line. The $-f$ option will set the ACL the entries contained within the file <i>acl_file</i> . The $-d$ option will delete one or more specified entries from the file's ACL. The $-m$ option will add or modify one or more specified ACL entries. The $-r$ option will cause the permissions specified in the mask entry to be ignored and replaced by the maximum permissions needed for the file group class.	
	One of the options $-s$, $-m$, $-d$, or $-f$ must be specified. If $-s$ or $-f$ are specified, other options are invalid. The $-m$ and $-d$ options may be combined.	
	When the setfacl command is used, it may result in changes to the file permission bits. When the user ACL entry for the file owner is changed, the file owner class permission bits will be modified. When the group ACL entry for the file group class is changed, the file group class permission bits will be modified. When the other ACL entry is changed, the file other class permission bits will be modified.	
	A directory may contain default ACL entries. If a file is created in a directory, which con- tains default ACL entries, the newly created file will an ACL initialized to the default ACL entries.	
acl_entries Syntax	For the -m and -s options, <i>acl_entries</i> are one or more comma separated ACL entries selected from the following list. For the -f option, <i>acl_file</i> must contain ACL entries, one to a line, selected from the following list. Default entries may only be specified for directories. Bold face indicates that characters must be typed as specified, brackets denote optional characters, and italicized characters are to be specified by the user.	
	u[ser]::operm perm u[ser]:uid:operm perm g[roup]::operm perm g[roup]:gid:operm perm m[ask]:operm perm o[ther]:operm perm d[efault]:u[ser]::operm perm d[efault]:u[ser]:uid:operm perm d[efault]:g[roup]::operm perm d[efault]:g[roup]::operm perm	

	d[efault]:m[ask]:operm perm d[efault]:o[ther]:operm perm			
	For the – missions group, fi g	<pre>he -d option, acl_entries are one or more comma separated ACL entries without per- ons, selected from the following list. Note that the entries for file owner, owning p, file group class, and others may not be deleted. u[ser]:uid g[roup]:gid d[fault]:u[ser]:uid d[fault]:g[roup]:gid d[fault]:m[ask]:</pre>		
		d[fault]:o[ther]:		
	where: <i>perm</i>	is a permissions string composed of the character \mathbf{r} (read), \mathbf{w} (write), and \mathbf{x} (execute), each of which may appear at most one time. The character – may be specified as a place holder.		
	operm	is the octal representation of the above permissions, with 7 representing all permissions, or rwx , and 0 representing no permissions, or		
	uid	is a login name or user ID.		
	gid	is a group name or group ID.		
OPTIONS	The optic	ons have the following meaning:		
	-s acl_en			
		with the newly specified ACL.		
		Required entries: • Exactly one user entry specified for the owner of the file • Exactly one group entry for the owning group of the file • Exactly one other entry specified.		
		 If there are additional user and group entries: Exactly one mask entry specified for the file group class of the file Must not be duplicate user entries with the same uid Must not be duplicate group entries with the same gid. 		
		 If <i>file</i> is a directory: Default ACL entries may be specified. Exactly one default user entry for the owner of the file Exactly one default group entry for for the owning group of the file Exactly one default mask entry for the file group class of the file Exactly one default other entry. 		
		There may be additional default user entries and additional default group entries specified, but there may not be duplicate		

		additional default user entries with the same <i>uid</i> , or duplicate default group entries with the same <i>gid</i> . The entries need not be in any specific order. They will be sorted by the command before being applied to the file.	
	-m acl_entries	Add one or more new ACL entries to the file, and/or modify one or more existing ACL entries on the file. If an entry already exists for a specified <i>uid</i> or <i>gid</i> , the specified permissions will replace the current permissions. If an entry does not exist for the specified <i>uid</i> or <i>gid</i> , an entry will be created.	
	- d acl_entries	Delete one or more entries from the file. The entries for the file owner, the owning group, and others may not be deleted from the ACL. Note that delete an entry does not necessarily have the same effect as removing all permissions from the entry.	
	-f acl_file	Set a file's ACL with the ACL entries contained in the file named acl_file . The same constraints on specified entries hold as with the $-s$ option. The entries are not required to be in any specific order in the file.	
		The character "#" in <i>acl_file</i> may be used to indicate a comment. All characters, starting with the "#", until the end of the line, will be ignored. Note that if the <i>acl_file</i> has been created as the output of the getfacl (1) command, any effective permissions, which will follow a "#", will be ignored.	
	- r	Recalculate the permissions for the file group class entry, i.e. the mask entry. The permissions specified in the file group class entry are ignored and replaced by the maximum permissions necessary to grant the access in any additional user, owning group, and additional group entries in the ACL. The permissions in the additional user, owning group, and additional group entries are left unchanged.	
EXAMPLES	1) To add one ACL entry to file "foo", giving user "shea" read permission only, type:		
	setfacl -m user:shea:r foo		
	read/write access, ar group allowing read	re ACL for the file "foo", adding an entry for user "shea", allowing a entry for the file owner allowing all access, an entry for the file access only, an entry for file group class allowing read/write, and sallowing all access, type:	
	setfacl -s use	er:shea:rw -,user::rwx,group::r,mask:rw -,other: foo	
	Even though the file available to all additi	his command, the file permission bits will be set to rwxrw owning group has only read permission, the maximum permissions onal user ACL entries, and all group ACL entries, are read and e the mask entry specifies these permissions.	

		on file "foo" as the file "bar", type: setfacl -f - foo	
FILES	/etc/passwd /etc/group	password file group file	
SEE ALSO	getfacl(1), aclcheck(3	3), aclsort(3), group(4), passwd(4)	
	I		

NAME	sh, jsh – shell: the standard shell, and job control shell command interpreters	
SYNOPSIS	/usr/bin/sh [–acefhiknprstuvx] [argument] /usr/xpg4/bin/sh [±abCefhikmnoprstuvx] [±o option] [–c string] [arg]	
	/usr/bin/jsh [–acefhiknprstuvx] [argument]	
AVAILABILITY /usr/bin/sh /usr/bin/jsh	SUNWcsu	
/usr/xpg4/bin/sh	SUNWxcu4	
DESCRIPTION	/usr/xpg4/bin/sh is identical to /usr/bin/ksh. See ksh(1).	
	/ usr/bin/sh is a command programming language that executes commands read from a terminal or a file. The command jsh is an interface to the shell which provides all of the functionality of sh and enables Job Control (see "Job Control," below). See "Invocation," below for the meaning of arguments to the shell.	
Definitions	A <i>blank</i> is a tab or a space. A <i>name</i> is a sequence of ASCII letters, digits, or underscores, beginning with a letter or an underscore. A <i>parameter</i> is a name, a digit, or any of the characters $*$, @, #, ?, –, $$$, and !\^.	
USAGE Commands	A <i>simple-command</i> is a sequence of non-blank <i>words</i> separated by <i>blanks</i> . The first <i>word</i> specifies the name of the command to be executed. Except as specified below, the remaining <i>words</i> are passed as arguments to the invoked command. The command name is passed as argument 0 (see exec (2)). The <i>value</i> of a <i>simple-command</i> is its exit status if it terminates normally, or (octal) 200 + <i>status</i> if it terminates abnormally; see signal (5) for a list of status values. A <i>pipeline</i> is a sequence of one or more <i>commands</i> separated by . The standard output of each <i>command</i> but the last is connected by a pipe (2) to the standard input of the next <i>command</i> . Each <i>command</i> is run as a separate process; the shell waits for the last <i>command</i> to terminate. The exit status of a <i>pipeline</i> is the exit status of the last command in the <i>pipeline</i> . A <i>list</i> is a sequence of one or more <i>pipeline</i> separated by ;, & , && , or , and optionally terminated by ; or & . Of these four symbols, ; and & have equal precedence, which is lower than that of && and . The symbols && and also have equal precedence. A semicolon (;) causes sequential execution of the preceding <i>pipeline</i> (that is, the shell waits for the <i>pipeline</i> to finish before executing any commands following the semicolon); an ampersand (&) causes asynchronous execution of the preceding pipeline (that is, the shell does <i>not</i> wait for that pipeline to finish). The symbol && () causes the <i>list</i> following it to be executed only if the preceding pipeline returns a zero (non-zero) exit status. An arbitrary number of newlines may appear in a <i>list</i> , instead of semicolons, to delimit commands.	

modified 8 May 1995

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last *simple-command* executed in the command.

	manu.
	for name [in word] do list done
	Each time a for command is executed, <i>name</i> is set to the next <i>word</i> taken from the
	in word list. If in word is omitted, then the for command executes the do list
	once for each positional parameter that is set (see "Parameter Substitution,"
	below). Execution ends when there are no more words in the list.
	case word in [pattern [pattern]) list ;;] esac
	A case command executes the <i>list</i> associated with the first <i>pattern</i> that matches
	word. The form of the patterns is the same as that used for file-name generation
	(see "File Name Generation") except that a slash, a leading dot, or a dot immedi-
	ately following a slash need not be matched explicitly.
	if list; then list; [elif list; then list;] [else list;] fi
	The <i>list</i> following if is executed and, if it returns a zero exit status, the <i>list</i> follow-
	ing the first then is executed. Otherwise, the <i>list</i> following elif is executed and, if
	its value is zero, the <i>list</i> following the next then is executed. Failing that, the else
	<i>list</i> is executed. If no else <i>list</i> or then <i>list</i> is executed, then the if command
	returns a zero exit status.
	while list do list done
	A while command repeatedly executes the while <i>list</i> and, if the exit status of the
	last command in the list is zero, executes the do <i>list</i> ; otherwise the loop ter-
	minates. If no commands in the do <i>list</i> are executed, then the while command
	returns a zero exit status; until may be used in place of while to negate the loop
	termination test.
	(list)
	Execute <i>list</i> in a sub-shell.
	{ <i>list</i> ;}
	<i>list</i> is executed in the current (that is, parent) shell. The { must be followed by a
	space.
	name () { list;}
	Define a function which is referenced by <i>name</i> . The body of the function is the <i>list</i>
	of commands between { and }. The { must be followed by a space. Execution of
	functions is described below (see "Execution"). The { and } are unnecessary if the
	body of the function is a <i>command</i> as defined above, under "Commands."
	The following words are only recognized as the first word of a command and when not
	quoted:
	if then else elif fi case esac for while until do done { }
Comments Lines	A word beginning with # causes that word and all the following characters up to a new-
	line to be ignored.

modified 8 May 1995

Command Substitution	The shell reads commands from the string between two grave accents ('') and the stan- dard output from these commands may be used as all or part of a word. Trailing new- lines from the standard output are removed.
	No interpretation is done on the string before the string is read, except to remove backslashes (\setminus) used to escape other characters. Backslashes may be used to escape a grave accent (') or another backslash (\setminus) and are removed before the command string is read. Escaping grave accents allows nested command substitution. If the command substitution lies within a pair of double quotes ("'"), a backslash used to escape a double quote (\setminus ") will be removed; otherwise, it will be left intact.
	If a backslash is used to escape a newline character (\newline), both the backslash and the newline are removed (see the later section on "Quoting"). In addition, backslashes used to escape dollar signs (\\$) are removed. Since no parameter substitution is done on the command string before it is read, inserting a backslash to escape a dollar sign has no effect. Backslashes that precede characters other than \ , ', ", newline , and \$ are left intact when the command string is read.
Parameter Substitution	The character \$ is used to introduce substitutable <i>parameters</i> . There are two types of parameters, positional and keyword. If <i>parameter</i> is a digit, it is a positional parameter. Positional parameters may be assigned values by set . Keyword parameters (also known as variables) may be assigned values by writing:
	name=value [name=value]
	Pattern-matching is not performed on <i>value</i> . There cannot be a function and a variable with the same <i>name</i> .
	<pre>\${parameter} The value, if any, of the parameter is substituted. The braces are required only when parameter is followed by a letter, digit, or underscore that is not to be inter- preted as part of its name. If parameter is * or @, all the positional parameters, starting with \$1, are substituted (separated by spaces). Parameter \$0 is set from argument zero when the shell is invoked.</pre>
	\${parameter:-word}
	If <i>parameter</i> is set and is non-null, substitute its value; otherwise substitute <i>word</i> .
	<pre>\${parameter:=word} If parameter is not set or is null set it to word; the value of the parameter is substi- tuted. Positional parameters may not be assigned in this way.</pre>
	<pre>\${parameter:?word} If parameter is set and is non-null, substitute its value; otherwise, print word and exit from the shell. If word is omitted, the message "parameter null or not set" is printed.</pre>
	\${parameter:+word} If <i>parameter</i> is set and is non-null, substitute <i>word</i> ; otherwise substitute nothing.

modified 8 May 1995

In the above, *word* is not evaluated unless it is to be used as the substituted string, so that, in the following example, **pwd** is executed only if **d** is not set or is null:

echo \${d:-'pwd'}

If the colon (:) is omitted from the above expressions, the shell only checks whether *parameter* is set or not.

The following parameters are automatically set by the shell.

- # The number of positional parameters in decimal.
- Flags supplied to the shell on invocation or by the **set** command.
- ? The decimal value returned by the last synchronously executed command.
- **\$** The process number of this shell.
- ! The process number of the last background command invoked.

The following parameters are used by the shell. The parameters in this section are also referred to as environment variables.

- **HOME** The default argument (home directory) for the **cd** command, set to the user's login directory by **login**(1) from the password file (see **passwd**(4)).
- PATH The search path for commands (see "Execution," below).

CDPATH

The search path for the cd command.

MAIL If this parameter is set to the name of a mail file *and* the **MAILPATH** parameter is not set, the shell informs the user of the arrival of mail in the specified file.

MAILCHECK

This parameter specifies how often (in seconds) the shell will check for the arrival of mail in the files specified by the MAILPATH or MAIL parameters. The default value is **600** seconds (10 minutes). If set to 0, the shell will check before each prompt.

MAILPATH

A colon (:) separated list of file names. If this parameter is set, the shell informs the user of the arrival of mail in any of the specified files. Each file name can be followed by % and a message that will be printed when the modification time changes. The default message is you have mail.

- **PS1** Primary prompt string, by default ".SB \$ ".
- **PS2** Secondary prompt string, by default " > ".
- **IFS** Internal field separators, normally **space**, **tab**, and **newline** (see "Blank Interpretation").

	SHACCT	
	If this parameter is set to the name of a file writable by the user, the s will write an accounting record in the file for each shell procedure ex cuted.	
	SHELL When the shell is invoked, it scans the environment (see ENVIRON- MENT, below) for this name.	
	LC_CTYPE	
	Determines how the shell handles characters. When LC_CTYPE is set to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. The shell can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. The shell can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.	
	LC_MESSAGES	
	Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the mes- sages are presented in the default form found in the program itself (in most cases, U.S. English).	
	If LC_CTYPE and LC_MESSAGES (see environ(5)) are not set in the environment, the operational behavior of the shell for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how the shell behaves.	
	The shell gives default values to PATH , PS1 , PS2 , MAILCHECK , and IFS . HOME and MAIL are set by login (1).	
Blank Interpretation	After parameter and command substitution, the results of substitution are scanned for internal field separator characters (those found in IFS) and split into distinct arguments where such characters are found. Explicit null arguments ("" or '') are retained. Implicit null arguments (those resulting from <i>parameters</i> that have no values) are removed.	
Input/Output Redirection	A command's input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a <i>simple-command</i> or may precede or follow a <i>command</i> and are <i>not</i> passed on as arguments to the invoked command. Note: Parameter and command substitution occurs before <i>word</i> or <i>digit</i> is used.	
	<i><word< i=""> Use file <i>word</i> as standard input (file descriptor 0).</word<></i>	
	> <i>word</i> Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist, it is created; otherwise, it is truncated to zero length.	

modified 8 May 1995

>>word	Use file <i>word</i> as standard output. If the file exists, output is appended to it (by first seeking to the EOF); otherwise, the file is created.
<<[-]word	After parameter and command substitution is done on <i>word</i> , the shell input is read up to the first line that literally matches the resulting <i>word</i> , or to an EOF. If, however, – is appended to <<:
	 leading tabs are stripped from <i>word</i> before the shell input is read (but after parameter and command substitution is done on <i>word</i>),
	2) leading tabs are stripped from the shell input as it is read and before each line is compared with <i>word</i> , and
	3) shell input is read up to the first line that literally matches the result- ing <i>word</i> , or to an EOF.
	If any character of <i>word</i> is quoted (see "Quoting," later), no additional processing is done to the shell input. If no characters of <i>word</i> are quoted:
	1) parameter and command substitution occurs,
	2) (escaped) \ newline s are removed, and
	3) \land must be used to quote the characters \land , \$, and '.
	The resulting document becomes the standard input.
<&digit	Use the file associated with file descriptor <i>digit</i> as standard input. Simi- larly for the standard output using >& <i>digit</i> .
<&-	The standard input is closed. Similarly for the standard output using $>\&-$.
If any of the above is preceded by a digit, the file descriptor which will be associated with the file is that specified by the digit (instead of the default 0 or 1). For example:	
2>&1	
associates file descriptor 2 with the file currently associated with file descriptor 1.	
The order in which redirections are specified is significant. The shell evaluates redirec- tions left-to-right. For example:	
1>	xxx 2>&1
first associates file descriptor 1 with file <i>xxx</i> . It associates file descriptor 2 with the file associated with file descriptor 1 (that is, <i>xxx</i>). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and file descriptor 1 would be associated with file <i>xxx</i> .	
composed of s <i>mand</i> before it tion for the ent	ninology introduced on the first page, under "Commands," if a <i>command</i> is everal <i>simple commands</i> , redirection will be evaluated for the entire <i>com</i> - is evaluated for each <i>simple command</i> . That is, the shell evaluates redirec- tire <i>list</i> , then each <i>pipeline</i> within the <i>list</i> , then each <i>command</i> within each each <i>list</i> within each <i>command</i> .
If a command is followed by & the default standard input for the command is the empty file /dev/null. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.	
	modified 8 May 1995

File Name Generation	 Before a command is executed, each command <i>word</i> is scanned for the characters *, ?, and [. If one of these characters appears the word is regarded as a <i>pattern</i>. The word is replaced with alphabetically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. The character . at the start of a file name or immediately following a /, as well as the character / itself, must be matched explicitly. * Matches any string, including the null string. ? Matches any single character. [] Matches any one of the enclosed characters. A pair of characters separated by – matches any character lexically between the pair, inclusive. If the first character following the opening [is a !, any character not enclosed is matched. Note: All quoted characters (see below) must be matched explicitly in a filename.
Quoting	The following characters have a special meaning to the shell and cause termination of a word unless quoted:
	; & () $$ < > newline space tab
	A character may be <i>quoted</i> (that is, made to stand for itself) by preceding it with a backslash (\) or inserting it between a pair of quote marks (· · or ""). During processing, the shell may quote certain characters to prevent them from taking on a special meaning. Backslashes used to quote a single character are removed from the word before the command is executed. The pair \newline is removed from a word before command and parameter substitution.
	All characters enclosed between a pair of single quote marks (< <), except a single quote, are quoted by the shell. Backslash has no special meaning inside a pair of single quotes. A single quote may be quoted inside a pair of double quote marks (for example, " < "), but a single quote can not be quoted inside a pair of single quotes.
	Inside a pair of double quote marks (""), parameter and command substitution occurs and the shell quotes the results to avoid blank interpretation and file name generation. If \$ is within a pair of double quotes, the positional parameters are substituted and quoted, separated by quoted spaces (" $\$1 \ \$2 \$ "); however, if $\$$ [@] is within a pair of dou- ble quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (" $\$1 \ \$2 \$ "); however, if $\$$ [@] is within a pair of dou- ble quotes, the positional parameters are substituted and quoted, separated by unquoted spaces (" $\$1 \ \$2 \$). \ quotes the characters ', , and $\$$. The pair \ newline is removed before parameter and command substitution. If a backslash precedes characters other than ', , $\$$, and newline, then the backslash itself is quoted by the shell.
Prompting	When used interactively, the shell prompts with the value of PS1 before reading a command. If at any time a newline is typed and further input is needed to complete a command, the secondary prompt (that is, the value of PS2) is issued.
Environment	The <i>environment</i> (see environ (5)) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a

modified 8 May 1995

parameter for each name found, giving it the corresponding value. If the user modifies the value of any of these parameters or creates new parameters, none of these affects the environment unless the **export** command is used to bind the shell's parameter to the environment (see also **set** –**a**). A parameter may be removed from the environment with the **unset** command. The environment seen by any executed command is thus composed of any unmodified name-value pairs originally inherited by the shell, minus any pairs removed by **unset**, plus any modifications or additions, all of which must be noted in **export** commands.

The environment for any *simple-command* may be augmented by prefixing it with one or more assignments to parameters. Thus:

```
TERM=450 command
and
(export TERM; TERM=450; command)
```

are equivalent as far as the execution of *command* is concerned if *command* is not a Special Command. If *command* is a Special Command, then

TERM=450 command

will modify the TERM variable in the current shell.

If the $-\mathbf{k}$ flag is set, *all* keyword arguments are placed in the environment, even if they occur after the command name. The following example first prints $\mathbf{a}=\mathbf{b} \mathbf{c}$ and \mathbf{c} :

```
echo a=b c
a=b c
set -k
echo a=b c
c
```

SignalsThe INTERRUPT and QUIT signals for an invoked command are ignored if the command
is followed by &; otherwise signals have the values inherited by the shell from its parent,
with the exception of signal 11 (but see also the trap command below).

Execution Each time a command is executed, the command substitution, parameter substitution, blank interpretation, input/output redirection, and filename generation listed above are carried out. If the command name matches the name of a defined function, the function is executed in the shell process (note how this differs from the execution of shell script files, which require a sub-shell for invocation). If the command name does not match the name of a defined function, but matches one of the *Special Commands* listed below, it is executed in the shell process.

The positional parameters **\$1**, **\$2**, are set to the arguments of the function. If the command name matches neither a *Special Command* nor the name of a defined function, a new process is created and an attempt is made to execute the command via **exec**(2).

The shell parameter **PATH** defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is /**usr/bin**. The current directory is specified by a null path name, which can appear

modified 8 May 1995

	immediately after the equal sign, between two colon delimiters anywhere in the path list, or at the end of the path list. If the command name contains a / the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not an a.out file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. A parenthesized command is also executed in a sub-shell.
	The location in the search path where a command was found is remembered by the shell (to help avoid unnecessary <i>execs</i> later). If the command was found in a relative directory, its location must be re-determined whenever the current directory changes. The shell forgets all remembered locations whenever the PATH variable is changed or the hash – r command is executed (see below).
Special Commands	Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional <i>Special Commands</i> are added to the shell's environment (see ''Job Control'').
	: No effect; the command does nothing. A zero exit code is returned.
	<i>. filename</i> Read and execute commands from <i>filename</i> and return. The search path specified by PATH is used to find the directory containing <i>filename</i> .
	 bg [%jobid] When Job Control is enabled, the bg command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the background. If %jobid is omitted the current job is assumed. (See "Job Control" section below for more detail).
	break [<i>n</i>] Exit from the enclosing for or while loop, if any. If <i>n</i> is specified, break <i>n</i> levels.
	<pre>cd [argument] Change the current directory to argument. The shell parameter HOME is the default argument. The shell parameter CDPATH defines the search path for the directory containing argument. Alternative directory names are separated by a colon (:). The default path is <null> (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immedi- ately after the equal sign or between the colon delimiters anywhere else in the path list. If argument begins with a / the search path is not used. Otherwise, each directory in the path is searched for argument.</null></pre>
	 chdir [dir] chdir changes the shell's working directory to directory dir. If no argument is given, change to the home directory of the user. If dir is a relative pathname not found in the current directory, check for it in those directories listed in the CDPATH variable. If dir is the name of a shell variable whose value starts with a /, change to the directory named by that value.
	continue $[n]$ Resume the next iteration of the enclosing for or while loop. If <i>n</i> is specified,

1-969

resume at the *n*-th enclosing loop.

echo [arguments ...]

The words in *arguments* are written to the shell's standard output, separated by space characters. See **echo**(1) for fuller usage and description.

eval [argument ...]

The arguments are read as input to the shell and the resulting command(s) executed.

exec [argument ...]

The command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.

exit [n]

Causes the calling shell or shell script to exit with the exit status specified by *n*. If *n* is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)

export [name ...]

The given *names* are marked for automatic export to the *environment* of subsequently executed commands. If no arguments are given, variable names that have been marked for export during the current shell's execution are listed. (Variable names exported from a parent shell are listed only if they have been exported again during the current shell's execution.) Function names are *not* exported.

fg [%jobid . . .]

When Job Control is enabled, the **fg** command is added to the user's environment to manipulate jobs. Resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If *%jobid* is omitted the current job is assumed. (See **"Job Control"** section below for more detail).

getopts

Use in shell scripts to support command syntax standards (see intro(1)); it parses positional parameters and checks for legal options. See getoptcvt(1) for usage and description.

hash [-r] [name ...]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The –**r** option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

jobs [**-p** | **-l**] [%jobid ...]

Reports all jobs that are stopped or executing in the background. If *%jobid* is omitted, all jobs that are stopped or running in the background will be reported. (See **"Job Control**" section below for more detail).

- kill [–sig] %job . . .
- kill –l Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in signal(5) stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See "Job Control" section below for a description of the format of *job*. In the second form, kill –l, the signal numbers and names are listed. (See kill(1)).
- login [argument ...]

Equivalent to '**exec login** *argument*....' See **login**(1) for usage and description. **newgrp** [*argument*]

- Equivalent to **exec newgrp** *argument*. See **newgrp**(1) for usage and description.
- **pwd** Print the current working directory. See **pwd**(1) for usage and description.

read name ...

One line is read from the standard input and, using the internal field separator, **IFS** (normally space or tab), to delimit word boundaries, the first word is assigned to the first *name*, the second word to the second *name*, etc., with leftover words assigned to the last *name*. Lines can be continued using **newline**. Characters other than **newline** can be quoted by preceding them with a backslash. These backslashes are removed before words are assigned to *names*, and no interpretation is done on the character that follows the backslash. The return code is **0**, unless an EOF is encountered.

readonly [name ...]

The given *names* are marked *readonly* and the values of the these *names* may not be changed by subsequent assignment. If no arguments are given, a list of all *readonly* names is printed.

return [n]

Causes a function to exit with the return value specified by n. If n is omitted, the return status is that of the last command executed.

- set [---aefhkntuvx [argument ...]]
 - -a Mark variables which are modified or created for export.
 - -e Exit immediately if a command exits with a non-zero exit status.
 - -f Disable file name generation.
 - -h Locate and remember function commands as functions are defined (function commands are normally located when the function is executed).

-k	All keyword arguments are placed in the environment for a command,
	not just those that precede the command name.

- **-n** Read commands but do not execute them.
- -t Exit after reading and executing one command.
- -u Treat unset variables as an error when substituting.
- -v Print shell input lines as they are read.
- -**x** Print commands and their arguments as they are executed.
- -- Do not change any of the flags; useful in setting **\$1** to -.

Using + rather than – causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$–. The remaining arguments are positional parameters and are assigned, in order, to $\$1, \$2, \ldots$. If no arguments are given the values of all names are printed.

shift [n]

The positional parameters from n+1... are renamed 1.... If *n* is not given, it is assumed to be 1.

stop pid ...

Halt execution of the process number *pid*. (see **ps**(1)).

suspend

Stops the execution of the current shell (but not if it is the login shell).

test

Evaluate conditional expressions. See **test**(1) for usage and description.

times

Print the accumulated user and system times for processes run from the shell.

trap [*argument* n [n2 ...]]

The command *argument* is to be read and executed when the shell receives numeric or symbolic signal(s) (*n*). (Note: *argument* is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If *argument* is absent all trap(s) *n* are reset to their original values. If *argument* is the null string this signal is ignored by the shell and by the commands it invokes. If *n* is 0 the command *argument* is executed on exit from the shell. The **trap** command with no arguments prints a list of commands associated with each signal number.

type [name ...]

For each *name*, indicate how it would be interpreted if used as a command name.

ulimit [-[HS][a | cdfnstv]]

```
ulimit [-[HS][c | d | f | n | s | t | v]] limit
```

ulimit prints or sets hard or soft resource limits. These limits are described in

	getrlimit(2).		
	If <i>limit</i> is not present, ulimit prints the specified limits. Any number of limits may be printed at one time. The $-a$ option prints all limits.		
	If <i>limit</i> is present, ulimit sets the specified limit to <i>limit</i> . The string unlimited requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see su (1M).		
	The $-\mathbf{H}$ option specifies a hard limit. The $-\mathbf{S}$ option specifies a soft limit. If neither option is specified, ulimit will set both limits and print the soft limit.		
	The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set.		
	-c maximum core file size (in 512-byte blocks)		
	-d maximum size of data segment or heap (in kbytes)		
	–f maximum file size (in 512-byte blocks)		
	–n maximum file descriptor plus 1		
	-s maximum size of stack segment (in kbytes)		
	-t maximum CPU time (in seconds)		
	-v maximum size of virtual memory (in kbytes) (Run the sysdef (1M) command to obtain the maximum possible limits for your system. The values reported are in hexidecimal, but can be translated into decimal numbers using the bc (1) command. Also, see swap (1M).)		
	Example of ulimit: to limit the size of a core file dump to 0 Megabytes, type the following: ulimit -c 0		
	umask [nnn]		
	The user file-creation mask is set to <i>nnn</i> (see umask (1)). If <i>nnn</i> is omitted, the current value of the mask is printed.		
	<pre>unset [name] For each name, remove the corresponding variable or function value. The vari- ables PATH, PS1, PS2, MAILCHECK, and IFS cannot be unset.</pre>		
	 wait [n] Wait for your background process whose process id is n and report its termination status. If n is omitted, all your shell's currently active background processes are waited for and the return code will be zero. 		
Invocation	If the shell is invoked through exec (2) and the first character of argument zero is –, com- mands are initially read from /etc/profile and from \$HOME/.profile , if such files exist. Thereafter, commands are read as described below, which is also the case when the shell is invoked as /usr/bin/sh . The flags below are interpreted by the shell on invocation only. Note: Unless the – c or – s flag is specified, the first argument is assumed to be the name of a file containing commands, and the remaining arguments are passed as positional		

1-973

	parameters to that command file:			
	–c string	If the -c flag is present commands are read from <i>string</i> .		
	 -i If the -i flag is present or if the shell input and output are attact nal, this shell is <i>interactive</i>. In this case TERMINATE is ignored does not kill an interactive shell) and INTERRUPT is caught and that wait is interruptible). In all cases, QUIT is ignored by the s 			
		If the –p flag is present, the shell will not set the effective user and group IDs to the real user and group IDs.		
	-r	If the -r flag is present the shell is a restricted shell (see rsh (1M)).		
		If the –s flag is present or if no arguments remain, commands are read from the standard input. Any remaining arguments specify the positional parameters. Shell output (except for <i>Special Commands</i>) is written to file descriptor 2.		
	The remain	ing flags and arguments are described under the set command above.		
Job Control (jsh)	When the shell is invoked as jsh , Job Control is enabled in addition to all of the functionality described previously for sh . Typically Job Control is enabled for the intersection shell only. Non-interactive shells typically do not benefit from the added functional Job Control.			
	called a <i>job</i> stopped. T write acces and has con is a job that	With Job Control enabled every command or pipeline the user enters at the terminal is called a <i>job</i> . All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal (see stty (1)); 3) a stopped job is a job that has been placed in a suspended state, usually as a result of a SIGTSTP signal (see signal (5)).		
	Every job that the shell starts is assigned a positive integer, called a <i>job number</i> which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the <i>current</i> and <i>previous</i> jobs. The <i>current job</i> is the most recent job to be started or restarted. The <i>previous job</i> is the first non-current job.			
	The acceptable syntax for a Job Identifier is of the form:			
	%jobid			
	where, <i>jobi</i>	d may be specified in any of the following formats:		
	%	or + for the current job		
	-	for the previous job		
	?<:	<i>string></i> specify the job for which the command line uniquely contains <i>string</i> .		
	n	for job number <i>n</i> , where <i>n</i> is a job number		
	pre	f where <i>pref</i> is a unique prefix of the command name (for example, if the command ls – l name were running in the background, it could be referred to as % ls); <i>pref</i> cannot contain blanks unless it is quoted.		

	When Job Control is enabled, the following commands are added to the user's environ- ment to manipulate jobs:
	bg [% <i>jobid</i>] Resumes the execution of a stopped job in the background. If % <i>jobid</i> is omitted the current job is assumed.
	fg [%jobid] Resumes the execution of a stopped job in the foreground, also moves an execut- ing background job into the foreground. If %jobid is omitted the current job is assumed.
	jobs [-p -l] [%jobid]
	jobs –x command [arguments] Reports all jobs that are stopped or executing in the background. If %jobid is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of jobs:
	-l Report the process group ID and working directory of the jobs.
	- p Report only the process group ID of the jobs.
	- x Replace any <i>jobid</i> found in <i>command</i> or <i>arguments</i> with the corresponding process group ID, and then execute <i>command</i> passing it <i>arguments</i> .
	kill [-signal] %jobid Builtin version of kill to provide the functionality of the kill command for processes identified with a jobid.
	stop %jobid Stops the execution of a background job(s).
	<pre>suspend Stops the execution of the current shell (but not if it is the login shell). wait [%jobid]</pre>
	wait builtin accepts a job identifier. If % <i>jobid</i> is omitted wait behaves as described above under Special Commands .
EXIT CODES	Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed (see also the exit command above).
jsh Only	If the shell is invoked as jsh and an attempt is made to exit the shell while there are stopped jobs, the shell issues one warning:
	There are stopped jobs.
	This is the only message. If another exit attempt is made, and there are still stopped jobs they will be sent a SIGHUP signal from the kernel and the shell is exited.

FILES	\$HOME/.profile /dev/null /etc/profile /tmp/sh*
SEE ALSO	$bc(1), intro(1), echo(1), getoptcvt(1) \ login(1), newgrp(1), pwd(1), ps(1), shell_builtins(1), stty(1), rsh(1M), swap(1M), sysdef(1M), dup(2), exec(2), fork(2), getrlimit(2), pipe(2), ulimit(2), setlocale(3C), profile(4), passwd(4), environ(5), signal(5)$
NOTES	Words used for filenames in input/output redirection are not interpreted for filename generation (see File Name Generation , above). For example, cat file1 > a * will create a file named a *.
	Because commands in pipelines are run as separate processes, variables set in a pipeline have no effect on the parent shell.
	If you get the error message cannot fork , too many processes , try using the wait (1) com- mand to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.)
	Only the last process in a pipeline can be waited for.
	If a command is executed, and a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to exec the original command. Use the hash command to correct this situa- tion.

NAME	shell – run a command using shell		
SYNOPSIS	shell command [command]		
DESCRIPTION	The shell function concatenate its arguments, separating each by a space, and passes this string to the shell (\$SHELL if set, otherwise / usr/bin/sh).		
EXAMPLES	Since the Form and Menu Language does not directly support background processing, the shell function can be used instead.		
	`shell "build prog > /dev/null &"`		
	If you want the user to continue to be able to interact with the application while the back- ground job is running, the output of an executable run by shell in the background must be redirected: to a file if you want to save the output, or to / dev/null if you don't want to save it (or if there is no output), otherwise your application may appear to be hung until the background job finishes processing.		
	shell can also be used to execute a command that has the same name as an FMLI built-in function.		
NOTES	The arguments to shell will be concatenate using spaces, which may or may not do what is expected. The variables set in local environments will not be expanded by the shell because "local" means "local to the current process."

NAME

shell_builtins – shell command interpreter built-in functions

DESCRIPTION The shell command interpreters (**sh**(1), **csh**(1), and **ksh**(1)), have special built-in functions which are interpreted by the shell as commands. Many of these built-in commands are implemented by more than one of the shells, and some are unique to a particular shell. These are:

command	built into
alias	csh, ksh
bg	csh, ksh, sh
break	csh, ksh, sh
case	csh, ksh, sh
cd	csh, ksh, sh
chdir	csh, sh
continue	csh, ksh, sh
dirs	csh
echo	csh, ksh, sh
eval	csh, ksh, sh
exec	csh, ksh, sh
exit	csh, ksh, sh
export	ksh, sh
fc	ksh
fg	csh, ksh, sh
for	ksh, sh
foreach	csh
function	ksh
getopts	ksh, sh
glob	csh
goto	csh
hash	ksh, sh
hashstat	csh
history	csh
if	csh, ksh, sh
jobs	csh, ksh, sh
kill	csh, ksh, sh
let	ksh
limit	csh
login	csh, ksh, sh
logout	csh, ksh, sh
nice	csh
newgrp	ksh, sh
notify	csh
onintr	csh

	popd	csh	
	print	ksh	
	pushd	csh	
	pwd	ksh, sh	
	read	ksh, sh	
	readonly	ksh, sh	
	rehash	csh	
	repeat	csh	
	return	ksh, sh	
	select	ksh	
	set	csh, ksh, sh	
	setenv	csh	
	shift	csh, ksh, sh	
	source	csh	
	stop	csh, ksh, sh	
	suspend	csh, ksh, sh	
	switch	csh	
	test	ksh, sh	
	time	csh	
	times	ksh, sh	
	trap	ksh, sh	
	type	ksh, sh	
	typeset	ksh	
	ulimit	ksh, sh	
	umask	csh, ksh, sh	
	unalias	csh, ksh	
	unhash	csh	
	unlimit	csh	
	unset	csh, ksh, sh	
	unsetenv	csh	
	until	ksh, sh	
	wait	csh, ksh, sh	
	whence	ksh	
	while	csh, ksh, sh	
	White		
Bourne Shell, sh, Special Commands	Input/output redirection is now permitted for these commands. File descriptor 1 is the default output location. When Job Control is enabled, additional <i>Special Commands</i> are added to the shell's environment.		
	Additional to these built-in reserved command	words, sh also uses:	
	: No effect; the command does nothing. A zero exit code is returned.		
	. filename		
	Read and execute commands from <i>filename</i> and return. The search path specified by PATH is used to find the directory containing <i>filename</i> .		
		-	

modified 1 Feb 1995

1-979

C shell, csh	 Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell. Additional to these built-in reserved command words, csh also uses: Null command. This command is interpreted, but performs no action. 		
	. The command. This command is interpreted, but performs no action.		
Korn Shell, ksh, Special Commands	Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is zero.		
	 Commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort. 4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and 		
	file name generation are not performed.		
	Additional to these built-in reserved command words, ksh also uses:		
	† : [arg] The command only expands parameters.		
	 file [arg] Read the complete <i>file</i> then execute the commands. The commands are executed in the current shell environment. The search path specified by PATH is used to find the directory containing <i>file</i>. If any arguments <i>arg</i> are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed. the loop termination test. 		
SEE ALSO	alias(1), break(1), case(1), cd(1), chmod(1), csh(1), echo(1), exec(1), exit(1), for(1), find(1), function(1), getoptcvt(1) getopts(1), glob(1), hash(1), history(1), if(1), intro(1), jobs(1), kill(1), ksh(1), let(1), limit(1), login(1), logout(1), newgrp(1), nice(1), nohup(1), print(1), pwd(1), read(1), readonly(1), repeat(1), set(1), sh(1), shift(1), suspend(1), test(1B), time(1), times(1), trap(1), typeset(1), umask(1), wait(1), while(1), chdir(2), chmod(2), creat(2), umask(2), getopt(3C), profile(4), environ(5)		

NAME	shift – shell built-in function to traverse either a shell's argument list or a list of field- separated words		
SYNOPSIS sh	shift [n]		
csh	shift [variable]		
ksh	† shift [<i>n</i>]		
DESCRIPTION sh	The positional parameters from $n+1$ are renamed 1 If <i>n</i> is not given, it is assumed to be 1.		
csh	The components of argv , or <i>variable</i> , if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.		
ksh	The positional parameters from $n+1$ are renamed $1 \dots$, default <i>n</i> is 1. The parameter <i>n</i> can be any arithmetic expression that evaluates to a non-negative number less than or equal to 4 .		
SEE ALSO	 On this man page, ksh(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort. 4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed. csh(1), ksh(1), sh(1)

shutdown(1B)	SunOS/BSD Compatibility Package Commands	SunOS 5.5		
NAME	shutdown close down the system at a given time			
	shutdown – close down the system at a given time			
SYNOPSIS	/usr/ucb/shutdown [–fhknr] time [warning-message]			
AVAILABILITY	SUNWscpu			
DESCRIPTION	 shutdown provides an automated procedure to notify users when the system is to be shut down. <i>time</i> specifies when shutdown will bring the system down; it may be the word now (indicating an immediate shutdown), or it may specify a future time in one of two formats: +number and hour:min. The first form brings the system down in number minutes, and the second brings the system down at the time of day indicated in 24-hour notation. At intervals that get closer as the apocalypse approaches, warning messages are displayed at terminals of all logged-in users, and of users who have remote mounts on that machine. At shutdown time a message is written to the system log daemon, syslogd(1M), containing the time of shutdown, the instigator of the shutdown, and the reason. Then a terminate signal is sent to init, which brings the system down to single-user mode. 			
OPTIONS	As an alternative to the above procedure, these options can be specified:			
	- f Arrange, in the manner of fastboot (1B), that when the system is reboot systems will not be checked.	ed, the file		
	-h Execute halt(1M).			
	-k Simulate shutdown of the system. Do not actually shut down the system	m.		
	- n Prevent the normal sync (2) before stopping.			
	- r Execute reboot (1M).			
FILES	/etc/rmtab remote mounted file system table			
SEE ALSO	<pre>fastboot(1B), login(1), halt(1M), reboot(1M), syslogd(1M), sync(2), rmtab(4)</pre>			
NOTES	Only allows you to bring the system down between now and 23:59 if you use the lute time for shutdown.	ne abso-		

NAME	size – print section sizes in bytes of object files				
SYNOPSIS	size $[-f][-F][-n][-o][-V][-x] filename$				
DESCRIPTION	The size command produces segment or section size information in bytes for each loader section in ELF or COFF object files. size prints out the size of the text, data, and bss (unit itialized data) segments (or sections) and their total.				
	size processes ELF and COFF object files entered on the command line. If an archive file is input to the size command, the information for each object file in the archive is displayed.				
	When calculating segment information, the size command prints out the total file size of the non-writable segments, the total file size of the writable segments, and the total memory size of the writable segments minus the total file size of the writable segments.				
	If it cannot calculate segment information, size calculates section information. When cal- culating section information, it prints out the total size of sections that are allocatable, non-writable, and not NOBITS, the total size of the sections that are allocatable, writable, and not NOBITS, and the total size of the writable sections of type NOBITS. (NOBITS sec- tions do not actually take up space in the <i>filename</i> .)				
	If size cannot calculate either segment or section information, it prints an error message and stops processing the file.				
OPTIONS	 -f Print out the size of each allocatable section, the name of the section, and the total of the section sizes. If there is no section data, size prints out an error message and stops processing the file. 				
	 -F Print out the size of each loadable segment, the permission flags of the segment, then the total of the loadable segment sizes. If there is no segment data, size prints an error message and stops processing the file. 				
	 –n Print out non-loadable segment or non-allocatable section sizes. If segment data exists, size prints out the memory size of each loadable segment or file size of each non-loadable segment, the permission flags, and the total size of the segments. If there is no segment data, size prints out, for each allocatable and non-allocatable section, the memory size, the section name, and the total size of the sections. If there is no segment or section data, size prints an error message and stops processing. 				
	- o Print numbers in octal, not decimal.				
	-V Print the version information for the size command on the standard error output.				
	- x Print numbers in hexadecimal; not decimal.				

modified 5 Jul 1990

EXAMPLES	The examples below are typical size output. example% size <i>filename</i>
	2724 + 88 + 0 = 2812
	example% size –f filename
	26(.text) + 5(.init) + 5(.fini) = 36
	example% size –F filename
	2724(r-x) + 88(rwx) + 0(rwx) = 2812 (If statically linked)
SEE ALSO	as(1), cc(1B), ld(1), a.out(4), ar(4)
NOTES	Since the size of bss sections is not known until link-edit time, the size command will not give the true total size of pre-linked objects.

modified 5 Jul 1990

NAME	sleep – suspend execution for an interval
SYNOPSIS	sleep time
AVAILABILITY	SUNWcsu
DESCRIPTION	The sleep utility will suspend execution for at least the integral number of seconds specified by the <i>time</i> operand.
OPERANDS	The following operands are supported:
	<i>time</i> A non-negative decimal integer specifying the number of seconds for which to suspend execution.
EXAMPLES	To execute a command after a certain amount of time:
	(sleep 105; command)&
	or to execute a command every so often:
	while true
	do command
	sleep 37
	done
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of sleep : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 The execution was successfully suspended for at least <i>time</i> seconds, or a SIGALRM signal was received (see NOTES).
	>0 An error has occurred.
SEE ALSO	<pre>wait(1), alarm(2), sleep(3C), wait(3B), environ(5)</pre>
NOTES	If the sleep utility receives a SIGALRM signal, one of the following actions will be taken:
	• Terminate normally with a zero exit status.
	• Effectively ignore the signal.
	The sleep utility will take the standard action for all other signals.

NAME	soelim – resolve and eliminate .so requests from nroff or troff input
SYNOPSIS	soelim [filename]
AVAILABILITY	SUNWdoc
DESCRIPTION	soelim reads the specified files or the standard input and performs the textual inclusion implied by the nroff (1) directives of the form
	.so somefile
	when they appear at the beginning of input lines. This is useful since programs such as tbl (1) do not normally do this; it allows the placement of individual tables in separate files to be run as a part of a large document.
	An argument consisting of '-' is taken to be a file name corresponding to the standard input.
	Note: Inclusion can be suppressed by using '´' instead of '.', that is,
	´ so /usr/share/lib/tmac/tmac.s
EXAMPLES	A sample usage of soelim would be
	example% soelim exum?.n tbl nroff –ms col lpr
SEE ALSO	more(1), nroff(1), tbl(1)

User Commands

NAME	sort – sort, merge, or sequence check text files		
SYNOPSIS	/usr/bin/sort [−cmu] [−o output] [−T directory] [−y [kmem]] [−z recsz] [−dfiMnr] [−b] [−t char] [−k keydef] [+pos1 [−pos2]] [file]		
		bin/sort [-cmu] [-o output] [-T directory] [-y [kmem]] [-z recsz] iMnr] [-b] [-t char] [-k keydef] [+pos1 [-pos2]] [file]	
AVAILABILITY /usr/bin/sort	SUNWesu		
/usr/xpg4/bin/sort	SUNWxcu	4	
DESCRIPTION	The sort command sorts lines of all the named files together and writes the result on the standard output.		
	default, th	ons are based on one or more sort keys extracted from each line of input. By ere is one sort key, the entire input line. Lines are ordered according to the col- nence of the current locale.	
OPTIONS	The follow	ing options alter the default behavior:	
/usr/bin/sort	- c	Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. The exit code is set and no output is produced unless the file is out of sort.	
/usr/xpg4/bin/sort	- c	Same as /usr/bin/sort except no output is produced under any curcumstances.	
	- m	Merge only. The input files are assumed to be already sorted.	
	- u	Unique: suppress all but one in each set of lines having equal keys. If used with the $-c$ option, check that there are no lines with duplicate keys in addition to checking that the input file is sorted.	
	–o output	Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.	
	- T director		
		The <i>directory</i> argument is the name of a directory in which to place temporary files.	
	−y kmem	The amount of main memory initially used by sort . If this option is omitted, sort begins using a system default memory size, and continues to use more space as needed. If <i>kmem</i> is present, sort will start using that number of Kbytes of memory, unless the administrative minimum or maximum is exceeded, in which case the corresponding extremum will be used. Thus, -y 0 is guaranteed to start with minimum memory. -y with no <i>kmem</i> argument starts with maximum memory.	

sort(1)	User Commands Sun		SunOS 5.5
	−z recsz	(obsolete). This option was used to prevent abnormal longer than the system-dependent default buffer size Because sort automatically allocates buffers large end line, this option has no effect.	e are encountered.
appear independent of any key field specific applied globally to all sort keys. When atta the specified ordering options override all g		ing options override the default ordering rules. When ependent of any key field specifications, the requested abally to all sort keys. When attached to a specific key ed ordering options override all global ordering option t forms, if one or more of these options follows a $+pos$ y field specified by that preceding option.	d field ordering rules are (see Sort Key Options), ns for that key. In the
	-d	"Dictionary" order: only letters, digits, and blanks (s significant in comparisons.	paces and tabs) are
	-f	Fold lower-case letters into upper case.	
	-i	Ignore non-printable characters.	
	- M	Compare as months. The first three non-blank charace folded to upper case and compared. For example, in is "JAN" < "FEB" < < "DEC". Invalid fields compare option implies the – b option (see below).	English the sorting order
	-n	Restrict the sort key to an initial numeric string, cons characters, optional minus sign, and zero or more dia radix character and thousands separators (as defined which will be sorted by arithmetic value. An empty zero. Leading zeros and signs on zeros do not affect	gits with an optional l in the current locale), digit string is treated as
	-r	Reverse the sense of comparisons.	
Field Separator Options	The treatment of field separators can be altered using the following options:		
	-b	Ignore leading blank characters when determining the positions of a restricted sort key. If the $-\mathbf{b}$ option is a sort key option, it is applied to all sort key options. C can be attached independently to each $-\mathbf{k}$ field_start, $-pos2$ option-argument (see below).	specified before the first Dtherwise, the -b option
	−t char	Use <i>char</i> as the field separator character. <i>char</i> is not c field (although it can be included in a sort key). Each significant (for example, <i><char><char></char></char></i> delimits an en specified, blank characters are used as default field so non-empty sequence of blank characters that follows a field separator.	n occurrence of <i>char</i> is npty field). If –t is not eparators; each maximal
Sort Key Options	Sort keys c	an be specified using the options:	
	U	The <i>keydef</i> argument is a restricted sort key field defined the definition is: - k field_start [type] [,field_end [type]]	nition. The format of this

where:

field_start and field_end

define a key field restricted to a portion of the line.

type is a modifier from the list of characters bdfiMnr. The b modifier behaves like the -b option, but applies only to the *field_start* or *field_end* to which it is attached and characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.) The other modifiers behave like the corresponding options, but apply only to the key field to which they are attached. They have this effect if specified with *field_start*, *field_end* or both. If any modifier is attached to a *field_start* or to a *field_end*, no option applies to either.

When there are multiple key fields, later keys are compared only after all earlier keys compare equal. Except when the $-\mathbf{u}$ option is specified, lines that otherwise compare equal are ordered as if none of the options $-\mathbf{d}$, $-\mathbf{f}$, $-\mathbf{i}$, $-\mathbf{n}$ or $-\mathbf{k}$ were present (but with $-\mathbf{r}$ still in effect, if it was specified) and with all bytes in the lines significant to the comparison.

The notation:

-k field_start[type][,field_end[type]]

defines a key field that begins at *field_start* and ends at *field_end* inclusive, unless *field_start* falls beyond the end of the line or after *field_end*, in which case the key field is empty. A missing *field_end* means the last character of the line.

A field comprises a maximal sequence of non-separating characters and, in the absence of option –t, any preceding field separator.

The *field_start* portion of the *keydef* option-argument has the form:

field_number[.first_character]

Fields and characters within fields are numbered starting with 1. *field_number* and *first_character*, interpreted as positive decimal integers, specify the first character to be used as part of a sort key. If *.first_character* is omitted, it refers to the first character of the field.

The *field_end* portion of the *keydef* option-argument has the form:

field_number[.last_character]

The *field_number* is as described above for *field_start*. *last_character*, interpreted as a non-negative decimal integer, specifies the last character to be used as part of the sort key. If *last_character* evaluates to zero or *.last_character* is omitted, it refers to the last character of the field specified by *field_number*.

If the $-\mathbf{b}$ option or \mathbf{b} type modifier is in effect, characters within a field are counted from the first non-blank character in the field. (This applies separately to *first_character* and *last_character*.)

acter in the $m+1$ st field. A last position specified by $-m.n$ is interpreted to mean the n th character				
(including separators) after the last character of the <i>m</i> th field. A missing <i>.n</i> means .0, indicating the last character of the <i>m</i> th field. If the b flag is in effern is counted from the last leading blank in the $m+1$ st field; $-m.1b$ refers to the first non-blank in the $m+1$ st field.				
The fully specified <i>+pos1 –pos2</i> form with type modifiers T and U : + w.xT - y.zU				
is equivalent to:				
undefined (z==0 & U contains b & -t is present) -k w+1.x+1T,y.0U (z==0 otherwise) -k w+1.x+1T,y+1.zU (z > 0)	$-\mathbf{k} \mathbf{w}+1\cdot\mathbf{x}+1\mathbf{T},\mathbf{y}\cdot0\mathbf{U}$ (z==0 otherwise)			
Implementations support at least nine occurrences of the sort keys (the $-\mathbf{k}$ option and obsolescent + <i>pos1</i> and – <i>pos2</i>) which are significant in command line order. If no sort key is specified, a default sort key of the entire line is used.				
OPERANDS The following operand is supported:				
<i>file</i> A path name of a file to be sorted, merged or checked. If no <i>file</i> operands ar specified, or if a <i>file</i> operand is –, the standard input will be used.	е			
EXAMPLES In the following examples, non-obsolescent and obsolescent ways of specifying sort key are given as an aid to understanding the relationship between the two forms.	/S			
Either of the following commands sorts the contents of infile with the second field as the sort key:	ıe			
example% sort –k 2,2 infile example% sort +1 –2 infile				
Either of the following commands sorts, in reverse order, the contents of infile1 and infile2 , placing the output in outfile and using the second character of the second field is the sort key (assuming that the first character of the second field is the field separator):	as			
example% sort –r –o outfile –k 2.2,2.2 infile1 infile2 example% sort –r –o outfile +1.1 –1.2 infile1 infile2				
Either of the following commands sorts the contents of infile1 and infile2 using the second non-blank character of the second field as the sort key:

NAME	sortbib – sort a bibliographic database		
SYNOPSIS	sortbib [-sKEYS] database		
AVAILABILITY	SUNWdoc		
DESCRIPTION	may be separat be mixed toget which are sorte length of corre	les of records containing refer key-letters by user-specified keys. Records ted by blank lines, or by '.[' and '.]' delimiters, but the two styles may not her. This program reads through each <i>database</i> and pulls out key fields, ed separately. The sorted key fields contain the file pointer, byte offset, and sponding records. These records are delivered using disk seeks and reads, o not be used in a pipeline to read standard input.	
	The most com	non key-letters and their meanings are given below.	
	%A	Author's name	
	% B	Book containing article referenced	
	%C	City (place of publication)	
	%D	Date of publication	
	%E	Editor of book containing article referenced	
	% F	Footnote number or label (supplied by refer)	
	% G	Government order number	
	%H	Header commentary, printed before reference	
	%I	Issuer (publisher)	
	%J	Journal containing article	
	% K	Keywords to use in locating reference	
	%L	Label field used by -k option of refer	
	% M	Bell Labs Memorandum (undefined)	
	%N	Number within volume	
	% O	Other commentary, printed at end of reference	
	% P	Page number(s)	
	% Q	Corporate or Foreign Author (unreversed)	
	% R	Report, paper, or thesis (unpublished)	
	%S	Series title	
	%Т	Title of article or book	
	%V	Volume number	
	%X	Abstract — used by roffbib , not by refer	
	%Y,Z	Ignored by refer	
992		modified 14 Sep 1992	

	By default, sortbib alphabetizes by the first % A and the % D fields, which contain the senior author and date.		
	senior author and uate. sortbib sorts on the last word on the %A line, which is assumed to be the author's last name. A word in the final position, such as ' jr .' or ' ed .', will be ignored if the name beforehand ends with a comma. Authors with two-word last names or unusual con- structions can be sorted correctly by using the nroff convention '\0' in place of a blank. A %Q field is considered to be the same as %A, except sorting begins with the first, not the last, word. sortbib sorts on the last word of the %D line, usually the year. It also ignores leading articles (like 'A' or 'The') when sorting by titles in the %T or %J fields; it will ignore articles of any modern European language. If a sort-significant field is absent from a record, sortbib places that record before other records containing that field. No more than 16 databases may be sorted together at one time. Records longer than 4096 characters will be truncated.		
OPTIONS	- s <i>KEYS</i> Specify new <i>KEYS</i> . For instance, - sATD will sort by author, title, and date, while - sA + D will sort by all authors, and date. Sort keys past the fourth are not meaningful.		
SEE ALSO	<pre>addbib(1), indxbib(1), lookbib(1), refer(1), roffbib(1)</pre>		
BUGS	Records with missing author fields should probably be sorted by title.		

modified 14 Sep 1992

NAME	spell – find spelling errors		
SYNOPSIS	<pre>spell [-bivx] [+local_file] [file]</pre>		
AVAILABILITY	SUNWesu		
DESCRIPTION	The spell command collects words from the named <i>files</i> and looks them up in a spelling list. Words that neither occur among nor are derivable (by applying certain inflections, prefixes, and/or suffixes) from words in the spelling list are printed on the standard output. If no <i>files</i> are named, words are collected from the standard input. Copies of all output are accumulated in the spellhist file.		
OPTIONS	The following	g options are supported:	
	gı		ides preferring "centre," "colour," "pro- ed," and so forth, this option insists upon <i>–ise</i> in
		his option causes deroff (1) to ot present on the system, ther	ignore .so and .nx commands. If deroff (1) is a this option is ignored.
	 All words not literally in the spelling list are printed, and plausible derivations from the words in the spelling list are indicated. 		
	- x Every plausible stem is displayed, one per line, with = preceding each word.		
	w ar W or	vords, one per line. With this re correct spellings (in additic Vords found in <i>local_file</i> are re	provided file that contains a sorted list of option, the user can specify a set of words that on to spell 's own spelling list) for each job. moved from spell 's output. Use sort (1) to ag sequence. If this ordering is not followed, e ignored.
OPERANDS	The following	g operands are supported:	
		a path name of a text file to ch words are collected from the st	eck for spelling errors. If no files are named, andard input.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of spell : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	0 Si	g exit values are returned: uccessful completion. an error occurred.	
FILES	S_SPELL=/us	sr/lib/spell/hlist[ab] sr/lib/spell/hstop ar/adm/spellhist b/dict/words	hashed spelling lists, American & British hashed stop list history file master dictionary

SEE ALSO deroff(1), sort(1), environ(5)

NOTES Because copies of all output are accumulated in the **spellhist** file, **spellhist** may grow quite large and require purging.

NAME	spline – interpolate smooth curve
SYNOPSIS	spline [–aknpx]
AVAILABILITY	SUNWesu
DESCRIPTION	spline takes pairs of numbers from the standard input as abcissas and ordinates of a function. It produces a similar set, which is approximately equally spaced and includes the input set, on the standard output. The cubic spline output (R. W. Hamming, <i>Numerical Methods for Scientists and Engineers,</i> 2nd ed., 349ff) has two continuous derivatives, and sufficiently many points to look smooth when plotted, for example by graph (1).
OPTIONS	 -a Supply abscissas automatically (they are missing from the input); spacing is given by the next argument, or is assumed to be 1 if next argument is not a number. -k The constant <i>k</i> used in the boundary value computation
	 y''_0 = ky''_1, y''_n = ky''_{n-1}101 is set by the next argument. By default k = 0. -n Space output points so that approximately n intervals occur between the lower and upper x limits. (Default n = 100.) -p Make output periodic, that is, match derivatives at ends. First and last input values should normally agree. -x Next 1 (or 2) arguments are lower (and upper) x limits. Normally these limits are calculated from the data. Automatic abcissas start at lower limit (default 0).
SEE ALSO	graph (1) R. W. Hamming, <i>Numerical Methods for Scientists and Engineers</i> , 2nd ed.
DIAGNOSTICS	When data is not strictly monotonic in <i>x</i> , spline reproduces the input without interpolat- ing extra points.
BUGS	A limit of 1000 input points is enforced silently.

modified 14 Sep 1992

User Commands

NAME	split – split a file into pieces		
SYNOPSIS	split [<i>-linecount</i> <i>-l linecount</i>] [<i>-a suffixlength</i>] [<i>file</i> [<i>name</i>]] split - b <i>n</i> [k m] [-a <i>suffixlength</i>] [<i>file</i> [<i>name</i>]]		
AVAILABILITY	SUNWesu		
DESCRIPTION	The split utility reads <i>file</i> and writes it in <i>linecount</i> -line pieces into a set of output-files. The name of the first output-file is <i>name</i> with aa appended, and so on lexicographically, up to zz (a maximum of 676 files). The maximum length of <i>name</i> is 2 characters less than the maximum filename length allowed by the filesystem. See statvfs (2). If no output name is given, x is used as the default (output-files will be called xaa , xab , and so forth).		
OPTIONS	The following options are supported:		
	−linecount − l l	linecount	
		Number of lines in each piece. Defaults to 1000 lines.	
	–a suffixlength	Use <i>suffixlength</i> letters to form the suffix portion of the filenames of the split file. If $-a$ is not specified, the default suffix length is 2 . If the sum of the <i>name</i> operand and the <i>suffixlength</i> option-argument would create a filename exceeding NAME_MAX bytes, an error will result; split will exit with a diagnostic message and no files will be created.	
	- b <i>n</i>	Split a file into pieces <i>n</i> bytes in size.	
	−b <i>n</i> k	Split a file into pieces <i>n</i> * 1024 bytes in size.	
	- b <i>n</i> m	Split a file into pieces <i>n</i> * 1 048 576 bytes in size.	
OPERANDS	The following operands are supported:		
	file	The path name of the ordinary file to be split. If no input file is given or <i>file</i> is –, the standard input will be used.	
	name	The prefix to be used for each of the files resulting from the split opera- tion. If no <i>name</i> argument is given, x will be used as the prefix of the output files. The combined length of the basename of <i>prefix</i> and <i>suffixlength</i> cannot exceed NAME_MAX bytes; see OPTIONS .	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of split : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following e	xit values are returned:	
	0 Successful completion.		
	>0 An error occurred.

NAME	srchtxt – display contents of, or search for a text string in, message data bases		
SYNOPSIS	srchtxt [-s] [-l locale] [-m msgfile,] [text]		
AVAILABILITY	SUNWloc		
DESCRIPTION	The srchtxt utility is used to display all the text strings in message data bases, or to see for a text string in message data bases (see mkmsgs (1)). These data bases are files in directory / usr/lib/locale / <i>locale</i> / LC_MESSAGES (see setlocale (3C)), unless a file name given with the – m option contains a /. The directory <i>locale</i> can be viewed as the name the language in which the text strings are written. If the –l option is not specified, the files accessed will be determined by the value of the environment variable LC_MESSAGES . If LC_MESSAGES is not set, the files accessed will be determined by value of the environment variable LANG . If LANG is not set, the files accessed will be the directory / usr/lib/locale // C / LC_MESSAGES , which contains default strings.		
	If no <i>text</i> argument is present, then all the text strings in the files accessed will be displayed.		
	If the -s option is not specified, the displayed text is prefixed by message sequence numbers. The message sequence numbers are enclosed in angle brackets: < <i>msgfile:msgnum</i> >.		
	msgfile	name of the file where the displayed text occurred	
	msgnum	sequence number in <i>msgfile</i> where the displayed text occurred	
	This display is in the format used by gettxt (1) and gettxt (3C).		
OPTIONS	s	Suppress printing of the message sequence numbers of the messages being displayed.	
	-l locale	Access files in the directory / usr/lib/locale / <i>locale</i> /LC_MESSAGES. If -m <i>msgfile</i> is also supplied, <i>locale</i> is ignored for <i>msgfile</i> s containing a /.	
	– m msgfile	Access files specified by one or more <i>msgfiles</i> . If <i>msgfile</i> contains a / character, then <i>msgfile is</i> interpreted as a pathname; otherwise, it will be assumed to be in the directory determined as described above. To specify more than one <i>msgfile</i> , separate the file names using commas.	
	text	Search for the text string specified by <i>text</i> and display each one that matches. <i>text</i> can take the form of a regular expression; see regexp (5).	

modified 28 Mar 1995

EXAMPLES	The following examples show uses of srchtxt .			
	Example 1:			
	If message files have been installed in a locale named french by using mkmsgs (1), then you could display the entire set of text strings in the french locale (/ usr/lib/locale/french/LC_MESSAGES /*) by typing:			
	example% srchtxt –l french			
	Example 2:			
	If a set of error messages associated with the operating system have been installed in the file UX in the french locale (/usr/lib/locale/french/LC_MESSAGES/UX), then, using the value of the LANG environment variable to determine the locale to be searched, you could search that file in that locale for all error messages dealing with files by typing:			
	example% setenv LANG=french; export LANG example% srchtxt –m UX "[Ff]ichier"			
	If /usr/lib/locale/french/LC_MESSAGES/UX contained the following strings:			
	Erreur E/S\n			
	Liste d'arguments trop longue\n			
	Fichier inexistant\n Argument invalide\n			
	Trop de fichiers ouverts\n			
	Fichier trop long\n			
	Trop de liens\n			
	Argument hors du domaine\n			
	Identificateur supprim\n			
	Etreinte fatale\n			
	•			
	then the following strings would be displayed:			
	<ux:3>Fichier inexistant\n</ux:3>			
	<ux:5>Trop de fichiers ouverts\n</ux:5>			
	<ux:6>Fichier trop long\n</ux:6>			
	Example 3:			
	If a set of error messages associated with the operating system have been installed in the file UX and a set of error messages associated with the INGRESS data base product have been installed in the file ingress , both in the german locale, then you could search for the pattern [Dd]atei in both the files UX and ingress in the german locale by typing: example% srchtxt –l german –m UX,ingress "[Dd]atei "			

modified 28 Mar 1995

ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of srchtxt for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how srchtxt behaves. LC_CTYPE Determines how srchtxt handles characters. When LC_CTYPE is set to a valid value, srchtxt can display and handle text and filenames containing valid characters for that locale. srchtxt can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. srchtxt can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.			
FILES	/usr/lib/locale/C/LC_MESSAGES/*default files created by mkmsgs(1)/usr/lib/locale/locale/LC_MESSAGES/*message files created by mkmsgs(1)			
SEE ALSO	exstr(1), gettxt(1), mkmsgs(1), gettxt(3C), setlocale(3C), environ(5), regexp(5)			
DIAGNOSTICS	The error messages produced by srchtxt are intended to be self-explanatory. They indicate an error in the command line or errors encountered while searching for a particular locale and/or message file.

1-1001

NAME	strchg, strconf – change or query stream configuration		
SYNOPSIS	<pre>strchg -h module1[,module2] strchg -p [-a -u module] strchg -f filename strconf [-m -t module]</pre>		
AVAILABILITY	SUNWcsu		
DESCRIPTION	with the use modules off	hands are used to alter or query the configuration of the stream associated er's standard input. The strchg command pushes modules on and/or pops if the stream. The strconf command queries the configuration of the stream. per-user or owner of a STREAMS device may alter the configuration of that	
	well as the t name printe	hout any arguments, strconf prints a list of all the modules in the stream as opmost driver. The list is printed with one name per line where the first ed is the topmost module on the stream (if one exists) and the last item printed of the driver.	
OPTIONS	The followin	ng options apply to strchg and, $-h$, $-f$, and $-p$ are mutually exclusive.	
	-h module1	[, <i>module2</i>] Mnemonic for push, pushes modules onto a stream. It takes as arguments the names of one or more pushable streams modules. These modules are pushed in order; that is, <i>module1</i> is pushed first, <i>module2</i> is pushed second, etc.	
	- p	Mnemonic for po <i>p</i> , pops modules off the stream. With the – p option alone, strchg pops the topmost module from the stream.	
	– a module	Pop all the modules above the topmost driver off the stream. This option requires the $-\mathbf{p}$ option.	
	– u module	All modules above, but not including <i>module</i> are popped off the stream. This option requires the $-\mathbf{p}$ option.	
	-f filename	Specify a <i>filename</i> that contains a list of modules representing the desired configuration of the stream. Each module name must appear on a separate line where the first name represents the topmost module and the last name represents the module that should be closest to the driver. strchg will determine the current configuration of the stream and pop and push the necessary modules in order to end up with the desired configuration.	
		ng options apply to strconf and, $-\mathbf{m}$ and $-\mathbf{t}$ are mutually exclusive.	
	mes	ermine if the named <i>module</i> is present on a stream. If it is, strconf prints the sage yes and returns zero. If not, strconf prints the message no and returns a -zero value. The -t and -m options are mutually exclusive.	

modified 14 Sep 1992

	- t <i>module</i> Print only the topmost module (if one exists). The - t and - m options are mutu- ally exclusive.		
EXAMPLES	The following command pushes the module ldterm on the stream associated with the user's standard input:		
	example% strchg –h ldterm		
	The following command pops the topmost module from the stream associated with / dev/term/24 . The user must be the owner of this device or the super-user.		
	example% strchg –p < /dev/term/24		
	If the file fileconf contains the following:		
	ttcompat Idterm		
	ptem		
	then the command		
	example% strchg –f fileconf		
	will configure the user's standard input stream so that the module ptem is pushed over the driver, followed by ldterm and ttcompat closest to the stream head.		
	The strconf command with no arguments lists the modules and topmost driver on the stream; for a stream that has only the module ldterm pushed above the zs driver, it would produce the following output:		
	ldterm zs		
	The following command asks if ldterm is on the stream		
	example% strconf –m ldterm		
	and produces the following output while returning an exit status of 0: yes		
SEE ALSO	streamio(7I)		
DIAGNOSTICS	strchg returns zero on success. It prints an error message and returns non-zero status for various error conditions, including usage error, bad module name, too many modules to push, failure of an ioctl on the stream, or failure to open <i>filename</i> from the $-\mathbf{f}$ option.		
	strconf returns zero on success (for the $-\mathbf{m}$ or $-\mathbf{t}$ option, "success" means the named or topmost module is present). It returns a non-zero status if invoked with the $-\mathbf{m}$ or $-\mathbf{t}$ option and the module is not present. It prints an error message and returns non-zero status for various error conditions, including usage error or failure of an ioctl on the stream.		

modified 14 Sep 1992

1-1003

NOTES If the user is neither the owner of the stream nor the super-user, the **strchg** command will fail. If the user does not have read permissions on the stream and is not the super-user, the **strconf** command will fail.

If modules are pushed in the wrong order, one could end up with a stream that does not function as expected. For ttys, if the line discipline module is not pushed in the correct place, one could have a terminal that does not respond to any commands.

modified 14 Sep 1992

NAME	strings – find printable strings in an object or binary file		
SYNOPSIS			
51N0P515	strings $[-a -] [-t \text{ format } -o] [-n \text{ number } -number] [file]$		
AVAILABILITY	SUNWtoo		
DESCRIPTION	The strings utility looks for ASCII strings in a binary file. A string is any sequence of 4 or more printing characters ending with a newline or a null character.		
	strings is useful for identifying random object files and many other things.		
OPTIONS	The following options are supported:		
	 -a - Look everywhere in the file for strings. If this flag is omitted, strings only looks in the initialized data space of object files. 		
	 -n number -number Use a number as the minimum string length rather than the default, which is 4. 		
	-o Equivalent to -t d option.		
	-t <i>format</i> Write each string preceded by its byte offset from the start of the file. The format is dependent on the single character used as the <i>format</i> optionargument:		
	 d The offset will be written in decimal. o The offset will be written in octal. x The offset will be written in hexadecimal. 		
OPERANDS	The following operand is supported:		
	<i>file</i> A path name of a regular file to be used as input. If no <i>file</i> operand is specified, the strings utility will read from the standard input.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of strings : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred.		
SEE ALSO	od (1), environ (5)		
NOTES	The algorithm for identifying strings is extremely primitive.		
	For backwards compatibility, the options $-a$ and $-a$ re interchangeable.		

NAME	strip – strip symbol table, debugging and line number information from an object file			
SYNOPSIS	/usr/ccs/bin/strip [-blrVx] file			
AVAILABILITY	SUNWbtool			
DESCRIPTION	The strip command removes the symbol table, debugging information, and line number information from ELF object files. Once this stripping process has been done, no symbolic debugging access will be available for that file; therefore, this command is normally run only on production modules that have been debugged and tested.			
	If strip is executed on a common archive file (see ar (4)) in addition to processing the members, strip will remove the archive symbol table. The archive symbol table must be restored by executing the ar (1) command with the – s option before the archive can be linked by the ld (1) command. strip will produce appropriate warning messages when this situation arises.			
	strip is used to reduce the file storage overhead taken by the object file.			
OPTIONS	The amount of information stripped from the ELF object file can be controlled by using any of the following options:			
	-b Same effect as the default behavior. This option is obsolete and will be removed in the next release.			
	 -I Strip line number information only; do not strip the symbol table or debug- ging information. 			
	 -r Same effect as the default behavior. This option is obsolete and will be removed in the next release. 			
	-V Print, on standard error, the version number of strip .			
	 -x Do not strip the symbol table; debugging and line number information may be stripped. 			
OPERANDS	The following operand is supported:			
	file A path name referring to an executable file.			
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of strip: LC_CTYPE , LC_MESSAGES , and NLSPATH .			
EXIT STATUS	The following exit values are returned:			
	0 Successful completion.			
	>0 An error occurred.			
FILES	/tmp/strp* temporary files			

1-1006

SEE ALSO ar(1), **as**(1), **ld**(1), **tmpnam**(3S), **a.out**(4), **ar**(4), **elf**(3E), **environ**(5)

NOTES The symbol table section will not be removed if it is contained within a segment, or the file is either a relocatable or dynamic shared object.

The line number and debugging sections will not be removed if they are contained within a segment, or their associated relocation section is contained within a segment.

NAME	stty – set the options for a terminal			
SYNOPSIS	/usr/bin/stty [-a] [-g] /usr/bin/stty [modes]			
	/usr/xpg4/bin/stty [– /usr/xpg4/bin/stty [n			
AVAILABILITY /usr/bin/stty	SUNWcsu			
/usr/xpg4/bin/stty	SUNWxcu4			
DESCRIPTION	The stty command sets certain terminal I/O options for the device that is the current stan- dard input; without arguments, it reports the settings of certain options.			
	In this report, if a character is preceded by a caret (^), then the value of that option is the corresponding control character (for example, " ^h " is CTRL-H; in this case, recall that CTRL-H is the same as the "back-space" key.) The sequence " ^ " means that an option has a null value.			
	See termio (7I) for detailed information about the modes listed from Control Modes through Local Modes . For detailed information about the modes listed under Hardware Flow Control Modes and Clock Modes , below, see termiox (7I).			
	in the earlier sections	in the Combination Modes section are implemented using options . Note that many combinations of options make no sense, but no formed. Hardware flow control and clock modes options may not ardware interfaces.		
OPTIONS	The following options are supported:			
	-a Write to standard output all of the option settings for the terminal.			
	 -g Report current settings in a form that can be used as an argument to another stty command. Emits termios-type output if the underlying driver supports it; otherwise, it emits termio-type output. 			
OPERANDS	The following <i>mode</i> operands are supported:			
Control Modes	parenb (–parenb)	Enable (disable) parity generation and detection.		
	parext (–parext)	Enable (disable) extended parity generation and detection for mark and space parity.		
	parodd (-parodd)	Select odd (even) parity, or mark (space) parity if parext is enabled.		
	cs5 cs6 cs7 cs8	Select character size (see termio (7I)).		
	0	Hang up line immediately.		

modified 1 Mar 1995

1				
	110 300 600 1200 1800	2400 4800 9600 19200 38400		
		Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)		
i	ispeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400			
		Set terminal input baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the input baud rate is set to 0 , the input baud rate will be specified by the value of the output baud rate.		
	ospeed 0 110 300 600 1200 1800 2400 4800 9600 19200 38400			
		Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the output baud rate is set to 0 , the line will be hung up immediately.		
]	hupcl (–hupcl)	Hang up (do not hang up) connection on last close.		
]	hup (–hup)	Same as hupcl (-hupcl).		
	cstopb (–cstopb)	Use two (one) stop bits per character.		
	cread (-cread)	Enable (disable) the receiver.		
•	crtscts (-crtscts)	Enable output hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to Send) line is raised.		
	crtsxoff (-crtsxoff)	Enable input hardware flow control. Raise the RTS (Request to Send) modem control line to receive data. Suspends input when RTS is low.		
	clocal (–clocal)	Assume a line without (with) modem control.		
]	loblk (–loblk)	Block (do not block) output from a non-current layer.		
	defeucw	Set the widths of multibyte Extended Unix Code (EUC) characters in struct eucioc to default values for the current locale specified by LC_CTYPE; width is expressed in terms of bytes per character, and screen or display columns per character (see getwidth(3I) and ldterm(7M)).		
Input Modes	ignbrk (–ignbrk)	Ignore (do not ignore) break on input.		
1	brkint (–brkint)	Signal (do not signal) INTR on break.		
j	ignpar (–ignpar)	Ignore (do not ignore) parity errors.		
	parmrk (–parmrk)	Mark (do not mark) parity errors (see termio (7I)).		
j	inpck (–inpck)	Enable (disable) input parity checking.		
j	istrip (–istrip)	Strip (do not strip) input characters to seven bits.		
ļi				
j	inlcr (–inlcr)	Map (do not map) NL to CR on input.		
	inlcr (–inlcr) igncr (–igncr)	Map (do not map) NL to CR on input. Ignore (do not ignore) CR on input.		

stty(1)		User Commands	SunOS 5.5
	ixon (–ixon)	Enable (disable) START/STOP output control. Output is by sending STOP control character and started by sendi START control character.	
	ixany (–ixany)	Allow any character (only DC1) to restart output.	
	ixoff (-ixoff)	Request that the system send (not send) START/STOP cl when the input queue is nearly empty/full.	naracters
	imaxbel (-imaxbel)	Echo (do not echo) BEL when the input line is too long.	
Output Modes	opost (–opost)	Post-process output (do not post-process output; ignore output modes).	e all other
	olcuc (–olcuc)	Map (do not map) lower-case alphabetics to upper case	on output.
	onlcr (-onlcr)	Map (do not map) NL to CR-NL on output.	
	ocrnl (–ocrnl)	Map (do not map) CR to NL on output.	
	onocr (–onocr)	Do not (do) output CRs at column zero.	
	onlret (–onlret)	On the terminal NL performs (does not perform) the CR	e function.
	ofill (–ofill)	Use fill characters (use timing) for delays.	
	ofdel (-ofdel)	Fill characters are DELs (NULs).	
	cr0 cr1 cr2 cr3	Select style of delay for carriage returns (see termio(7I))).
	nl0 nl1	Select style of delay for line-feeds (see termio (7I)).	
	tab0 tab1 tab2 tab3	Select style of delay for horizontal tabs (see termio(7I)).	
	bs0 bs1	Select style of delay for backspaces (see termio(7I)).	
	ff0 ff1	Select style of delay for form-feeds (see termio(7I)).	
	vt0 vt1	Select style of delay for vertical tabs (see termio(7I)).	
Local Modes	isig (–isig)	Enable (disable) the checking of characters against the s trol characters INTR, QUIT, SWTCH, and SUSP.	pecial con-
	icanon (–icanon)	Enable (disable) canonical input (ERASE and KILL proce Does not set MIN or TIME .	essing).
	xcase (-xcase)	Canonical (unprocessed) upper/lower-case presentatio	n.
	echo (–echo)	Echo back (do not echo back) every character typed.	
	echoe (–echoe)	Echo (do not echo) ERASE character as a backspace-space backspace string. Note: This mode will erase the ERAS ter on many CRT terminals; however, it does not keep to column position and, as a result, it may be confusing fo characters, tabs, and backspaces.	Eed charac- rack of
	echok (–echok)	Echo (do not echo) NL after KILL character.	
	lfkc (–lfkc)	The same as echok (–echok); obsolete.	
	echonl (-echonl)	Echo (do not echo) NL.	

	noflsh (–noflsh)	Disable (enable) flush after INTR, QUIT, or SUSP.
	stwrap (–stwrap)	Disable (enable) truncation of lines longer than 79 characters on a synchronous line.
	tostop (–tostop)	Send (do not send) SIGTTOU when background processes write to the terminal.
	echoctl (-echoctl)	Echo (do not echo) control characters as <i>char</i> , delete as <i>?</i> .
	echoprt (-echoprt)	Echo (do not echo) erase character as character is "erased".
	echoke (–echoke)	BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	flusho (–flusho)	Output is (is not) being flushed.
	pendin (–pendin)	Retype (do not retype) pending input at next read or input charac- ter.
	iexten (–iexten)	Enable (disable) special control characters not currently controlled by icanon , isig , ixon , or ixoff : VEOLZ, VSWTCH, VREPRINT, VDISCARD, VDSUSP, VWERASE, and VLNEXT.
	stflush (-stflush)	Enable (disable) flush on a synchronous line after every write (2).
	stappl (-stappl)	Use application mode (use line mode) on a synchronous line.
Hardware Flow	rtsxoff (-rtsxoff)	Enable (disable) RTS hardware flow control on input.
Control Modes	ctsxon (-ctsxon)	Enable (disable) CTS hardware flow control on output.
	dtrxoff (-dtrxoff)	Enable (disable) DTR hardware flow control on input.
	cdxon (-cdxon)	Enable (disable) CD hardware flow control on output.
	isxoff (-isxoff)	Enable (disable) isochronous hardware flow control on input.
Clock Modes	xcibrg	Get transmit clock from internal baud rate generator.
	xctset	Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	xcrset	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	rcibrg	Get receive clock from internal baud rate generator.
	rctset	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	rcrset	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	tsetcoff	Transmitter signal element timing clock not provided.
	tsetcrbrg	Output receive baud rate generator on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.
	tsetctbrg	Output transmit baud rate generator on transmitter signal element
		timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24.

NAME	stty – set the options for a terminal			
SYNOPSIS	/usr/ucb/stty [–a] [-g] [-h] [modes]		
AVAILABILITY	SUNWscpu			
DESCRIPTION	stty sets certain terminal I/O options for the device that is the current standard output; without arguments, it reports the settings of certain options.			
OPTIONS	corresponding CTRL	aracter is preceded by a caret ($$), then the value of that option is the character (for example, " $$ h" is CTRL-H; in this case, recall that is the "back-space" key.) The sequence " $$ " means that an option		
	-a Report al	l of the option settings.		
	-g Report cu stty comr	rrent settings in a form that can be used as an argument to another nand.		
	– h Report al column fo	l the option settings with the control characters in an easy to read prmat.		
	Many combinations Hardware flow cont	roup are implemented using options in the previous groups. Note: of options make no sense, but no sanity checking is performed. rol and clock modes options may not be supported by all hardware ons are selected from the following:		
Special Requests	all everything speed size	Reports the same option settings as stty without arguments, but with the control characters in column format. Everything stty knows about is printed. Same as -h option. The terminal speed alone is reported on the standard output. The terminal (window) sizes are printed on the standard output, first rows and then columns. This option is only appropriate if currently running a window system. size and speed always report on the settings of / dev/tty , and always report the settings to the standard output.		
Control Modes	parenb (–parenb)	Enable (disable) parity generation and detection.		
	parext (–parext)	Enable (disable) extended parity generation and detection for mark and space parity.		
	parodd (-parodd)	Select odd (even) parity, or mark (space) parity if parext is enabled.		
	cs5 cs6 cs7 cs8	Select character size (see termio (7I)).		
	0	Hang up line immediately.		
	110 300 600 1200 180	0 2400 4800 9600 19200 exta 38400 extb		
		Set terminal baud rate to the number given, if possible. (All speeds are not supported by all hardware interfaces.)		
	ispeed 0 110 300 600	1200 1800 2400 4800 9600 19200 exta 38400 extb		
		Set terminal input baud rate to the number given, if possible. (Not		

1B-1015

	ospeed 0 110 300 600 hupcl (–hupcl) hup (–hup) cstopb (–cstopb) cread (–cread) clocal (–clocal) crtscts (-crtscts)	all hardware supports split baud rates.) If the input baud rate is set to zero, the input baud rate will be specified by the value of the output baud rate. 1200 1800 2400 4800 9600 19200 exta 38400 extb Set terminal output baud rate to the number given, if possible. (Not all hardware supports split baud rates.) If the baud rate is set to zero, the line will be hung up immediately. Hang up (do not hang up) connection on last close. Same as hupcl (- hupcl). Use two (one) stop bits per character. Enable (disable) the receiver. Assume a line without (with) modem control. Enable hardware flow control. Raise the RTS (Request to Send) modem control line. Suspends output until the CTS (Clear to
	loblk (–loblk)	Send) line is raised. Block (do not block) output from a non-current layer.
Input Modes	ignbrk (-ignbrk) ignpar (-ignpar) parmrk (-parmrk) inpck (-inpck) istrip (-istrip) inlcr (-inlcr) igncr (-igncr) icrnl (-icrnl) iuclc (-iuclc) ixon (-ixon) ixany (-ixany) decctlq (-decctlq) ixoff (-ixoff) tandem (-tandem) imaxbel (-imaxbel) iexten (-iexten)	Ignore (do not ignore) break on input. Signal (do not signal) INTR on break. Ignore (do not ignore) parity errors. Mark (do not mark) parity errors (see termio (7I)). Enable (disable) input parity checking. Strip (do not strip) input characters to seven bits. Map (do not map) NL to CR on input. Ignore (do not ignore) CR on input. Map (do not map) CR to NL on input. Map (do not map) upper-case alphabetics to lower case on input. Enable (disable) START/STOP output control. Output is stopped by sending an STOP and started by sending an START. Allow any character (only START) to restart output. Same as -ixany . Request that the system send (not send) START/STOP characters when the input queue is nearly empty/full. Same as ixoff . Echo (do not echo) BEL when the input line is too long. Enable (disable) extended (implementation-defined) functions for
Output Modes	opost (-opost) olcuc (-olcuc) onlcr (-onlcr) ocrnl (-ocrnl) onocr (-onocr) onlret (-onlret)	 input data. Post-process output (do not post-process output; ignore all other output modes). Map (do not map) lower-case alphabetics to upper case on output. Map (do not map) NL to CR-NL on output. Map (do not map) CR to NL on output. Do not (do) output CRs at column zero. On the terminal NL performs (does not perform) the CR function.

	ofill (-ofill) ofdel (-ofdel) cr0 cr1 cr2 cr3 nl0 nl1 tab0 tab1 tab2 tab3 bs0 bs1 ff0 ff1 vt0 vt1	Use fill characters (use timing) for delays. Fill characters are DELs (NULs). Select style of delay for carriage returns (see termio (7I)). Select style of delay for line-feeds (see termio (7I)). Select style of delay for horizontal tabs (see termio (7I)). Select style of delay for backspaces (see termio (7I)). Select style of delay for form-feeds (see termio (7I)). Select style of delay for vertical tabs (see termio (7I)).
Local Modes	isig (–isig)	Enable (disable) the checking of characters against the special con- trol characters INTR, QUIT, and SWTCH.
	icanon (–icanon)	Enable (disable) canonical input (ERASE and KILL processing). Does not set MIN or TIME.
	cbreak (–cbreak)	Equivalent to - icanon min 1 time 0 .
	xcase (-xcase)	Canonical (unprocessed) upper/lower-case presentation.
	echo (–echo)	Echo back (do not echo back) every character typed.
	echoe (–echoe)	Echo (do not echo) ERASE character as a backspace-space-
		backspace string. Note: This mode will erase the ERASEed charac-
		ter on many CRT terminals; however, it does <i>not</i> keep track of
		column position and, as a result, may be confusing on escaped
		characters, tabs, and backspaces.
	crterase (–crterase)	Same as echoe .
	echok (–echok)	Echo (do not echo) NL after KILL character.
	lfkc (–lfkc)	The same as echok (–echok); obsolete.
	echonl (–echonl)	Echo (do not echo) NL.
	noflsh (–noflsh)	Disable (enable) flush after INTR, QUIT, or SWTCH.
	stwrap (–stwrap)	Disable (enable) truncation of lines longer than 79 characters on a
		synchronous line. (Does not apply to the 3B2.)
	tostop (–tostop)	Send (do not send) SIGTTOU for background processes.
	echoctl (–echoctl)	Echo (do not echo) control characters as <i>`char</i> , delete as <i>`</i> ?
	ctlecho (–ctlecho)	Same as echoctl .
	echoprt (-echoprt)	Echo (do not echo) erase character as character is "erased".
	prterase (–prterase) echoke (–echoke)	Same as echoprt . BS-SP-BS erase (do not BS-SP-BS erase) entire line on line kill.
	crtkill (–crtkill)	Same as echoke .
	flusho (–flusho)	Output is (is not) being flushed.
	pendin (–pendin)	Retype (do not retype) pending input at next read or input charac-
	r (r)	ter.
	stflush (–stflush)	Enable (disable) flush on a synchronous line after every write (2).
		(Does not apply to the 3B2.)
	stappl (–stappl)	Use application mode (use line mode) on a synchronous line.
		(Does not apply to the 3B2.)

1B-1017

Hardware Flow Control Modes	rtsxoff (–rtsxoff) ctsxon (–ctsxon) dterxoff (–dterxoff) rlsdxon (–rlsdxon) isxoff (–isxoff)	Enable (disable) RTS hardware flow control on input. Enable (disable) CTS hardware flow control on output. Enable (disable) DTER hardware flow control on input. Enable (disable) RLSD hardware flow control on output. Enable (disable) isochronous hardware flow control on input.
Clock Modes	xcibrg xctset	Get transmit clock from internal baud rate generator. Get the transmit clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	xcrset	Get transmit clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	rcibrg	Get receive clock from internal baud rate generator.
	rctset	Get receive clock from transmitter signal element timing (DCE source) lead, CCITT V.24 circuit 114, EIA-232-D pin 15.
	rcrset	Get receive clock from receiver signal element timing (DCE source) lead, CCITT V.24 circuit 115, EIA-232-D pin 17.
	tsetcoff	Transmitter signal element timing clock not provided.
	tsetcrc	Output receive clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	tsetcxc	Output transmit clock on transmitter signal element timing (DTE source) lead, CCITT V.24 circuit 113, EIA-232-D pin 24, clock source.
	rsetcoff	Receiver signal element timing clock not provided.
	rsetcrc	Output receive clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
	rsetcxc	Output transmit clock on receiver signal element timing (DTE source) lead, CCITT V.24 circuit 128, no EIA-232-D pin, clock source.
Control Assignments	control-character c	Set <i>control-character</i> to <i>c</i> , where <i>control-character</i> is intr , quit , erase , kill , eof , eol , eol2 , swtch , start , stop , susp , dsusp , rprnt , flush , werase , lnext min , ctab , time , or brk) (ctab is used with – stappl ; min and time are used with – icanon ; see termio (7I)). If <i>c</i> is preceded by an (escaped from the shell) caret (^), then the value used is the corresponding CTRL character (for example, "^d" is a CTRL-d); "^?" is interpreted as DEL and "^–" is interpreted as undefined. Set line discipline to <i>i</i> (0 < <i>i</i> < 127).
Combination Modes	evenp or parity –evenp, or –parity even (–even) oddp –oddp	Enable parenb and cs7 . Disable parenb , and set cs8 . Same as evenp (–evenp). Enable parenb , cs7 , and parodd . Disable parenb and parodd , and set cs8 .

	odd (-odd)	Same as oddp (-oddp).
	spacep	Enable parenb , cs7 , and parext .
	-spacep	Disable parenb and parext , and set cs8 .
	markp	Enable parenb , cs7 , parodd , and parext .
	–markp	Disable parenb , parodd , and parext , and set cs8 .
	raw (-raw or cooked)	Enable (disable) raw input and output (no ERASE, KILL, INTR,
		QUIT, SWTCH, EOT, or output post processing).
	nl (–nl)	Unset (set) icrnl, onlcr. In addition –nl unsets inlcr, igncr, ocrnl,
		and onlret .
	lcase (-lcase)	Set (unset) xcase , iuclc , and olcuc .
	LCASE (-LCASE)	Same as lcase (-lcase).
	tabs (–tabs or tab3)	Preserve (expand to spaces) tabs when printing.
	ek	Reset ERASE and KILL characters back to normal # and @.
	sane	Resets all modes to some reasonable values.
	term	Set all modes suitable for the terminal type term, where term is one
		of tty33 , tty37 , vt05 , tn300 , ti700 , or tek .
	async	Set normal asynchronous communications where clock settings
		are xcibrg , rcibrg , tsetcoff and rsetcoff .
	litout (–litout)	Disable (enable) parenb , istrip , and opost , and set cs8 (cs7).
	pass8 (–pass8)	Disable (enable) parenb and istrip , and set cs8 (cs7).
	crt	Set options for a CRT (echoe , echoctl , and, if >= 1200 baud,
		echoke.)
	dec	Set all modes suitable for Digital Equipment Corp. operating sys-
		tems users ERASE, KILL, and INTR characters to ^? , ^U , and ^C ,
		decctlq, and crt.)
Window Size	rowsn	Set window size to <i>n rows</i> .
	columns n	Set window size to <i>n columns</i> .
	cols n	An alias for columns <i>n</i> .
	ypixels <i>n</i>	Set vertical window size to <i>n pixels</i> .
	xpixels n	Set horizontal window size to <i>n pixels</i> .
SEE ALSO	tabs(1), ioctl(2), termi	o(7I), termiox(7I)

1B-1019

NAME	sum – print checksum and block count for a file
SYNOPSIS	sum [-r] [file]
AVAILABILITY	SUNWesu
DESCRIPTION	The sum utility calculates and prints a 16-bit checksum for the named file, and also prints the number of 512-byte blocks in the file. It is typically used to look for bad spots, or to validate a file communicated over some transmission line.
OPTIONS	The following options are supported:
	- r Use an alternate (machine-dependent) algorithm in computing the checksum.
OPERANDS	The following operands are supported:
	<i>file</i> A path name of a file. If no files are named, the standard input is used.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of sum: LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned.
	0 Successful completion.
	>0 An error occurred.
SEE ALSO	cksum(1), wc(1), environ(5)
DIAGNOSTICS	"Read error" is indistinguishable from end of file on most devices; check the block count.
NOTES	Portable applications should use cksum (1).

NAME	sum – calculate a checksum for a file
SYNOPSIS	/usr/ucb/sum filename
AVAILABILITY	SUNWscpu
DESCRIPTION	sum calculates and displays a 16-bit checksum for the named file, and also displays the size of the file in kilobytes. It is typically used to look for bad spots, or to validate a file communicated over some transmission line. The checksum is calculated by an algorithm which may yield different results on machines with 16-bit ints and machines with 32-bit ints , so it cannot always be used to validate that a file has been transferred between machines with different-sized ints .
SEE ALSO	sum(1), wc(1)
DIAGNOSTICS	Read error is indistinguishable from EOF on most devices; check the block count.
NOTES	Obsolete.

modified 14 Sep 1992

1B-1021

NAME	suspend – shell built-in function to halt the current shell
SYNOPSIS sh	suspend
csh	suspend
ksh	suspend
DESCRIPTION sh	Stops the execution of the current shell (but not if it is the login shell).
csh	Stop the shell in its tracks, much as if it had been sent a stop signal with 2 . This is most often used to stop shells started by su .
ksh	Stops the execution of the current shell (but not if it is the login shell).
SEE ALSO	csh (1), ksh (1), kill (1), sh (1), su (1M)

modified 15 Apr 1994

NAME	symorder – rearrange a list of symbols
SYNOPSIS	symorder [–s] objectfile symbolfile
DESCRIPTION	<i>objectfile</i> is updated in place to put the requested symbols first in the symbol table, in the order specified. This is done by swapping the old symbols in the required spots with the new ones. If all of the order symbols are not found, an error is generated. <i>symbolfile</i> is a file containing symbols to be found in <i>objectfile</i> , one symbol per line.
OPTIONS	-s Work silently, that is, display nothing except error messages. This is useful for checking the error status.
SEE ALSO	nlist(3E)

NAME	sysV-make – maintain, update, and regenerate groups of programs				
SYNOPSIS	/usr/ccs/lib/svr4	.make [–f makefile] [–eiknpqrst] [names]			
DESCRIPTION	This is the "vanilla" System V version of make . If the environment variable USE_SVR4_MAKE is set, then the command make will invoke this version of make . (See also the ENVIRONMENT section.)				
	make allows the programmer to maintain, update, and regenerate groups of computer programs. make executes commands in <i>makefile</i> to update one or more target <i>names</i> (<i>names</i> are typically programs). If the –f option is not present, then makefile , Makefile , and the Source Code Control System (SCCS) files s.makefile , and s.Makefile are tried in order. If <i>makefile</i> is '–' the standard input is taken. More than one –f <i>makefile</i> argument pair may appear.				
	make updates a target only if its dependents are newer than the target. All prerequisite files of a target are added recursively to the list of targets. Missing files are deemed to be outdated.				
	The following list of four directives can be included in <i>makefile</i> to extend the options provided by make . They are used in <i>makefile</i> as if they were targets:				
	.DEFAULT: If a file must be made but there are no explicit commands or relevant built-in rules, the commands associated with the name .DEFAULT are used if it exists.				
	.IGNORE: Same effect as the $-\mathbf{i}$ option.				
	.PRECIOUS:	PRECIOUS: Dependents of the . PRECIOUS entry will not be removed when quit or interrupt are hit.			
	.SILENT:				
	The options for make are listed below:				
	-е	Environment variables override assignments within makefiles.			
	-f makefile	Description filename (<i>makefile</i> is assumed to be the name of a description file).			
	-i	Ignore error codes returned by invoked commands.			
	-k	Abandon work on the current entry if it fails, but continue on other branches that do not depend on that entry.			
	-n	No execute mode. Print commands, but do not execute them. Even command lines beginning with an '@' are printed.			
	- p	Print out the complete set of macro definitions and target descriptions.			
	- q	Question. make returns a zero or non-zero status code depending on whether or not the target file has been updated.			
	-r	Do not use the built-in rules.			
	-s Silent mode. Do not print command lines before executing.				

modified 18 Jul 1994

Touch the target files (causing them to be updated) rather than issue -t the usual commands. **Creating the makefile** The makefile invoked with the $-\mathbf{f}$ option is a carefully structured file of explicit instructions for updating and regenerating programs, and contains a sequence of entries that specify dependencies. The first line of an entry is a blank-separated, non-null list of targets, then a ':', then a (possibly null) list of prerequisite files or dependencies. Text following a ';' and all following lines that begin with a tab are shell commands to be executed to update the target. The first non-empty line that does not begin with a tab or '#' begins a new dependency or macro definition. Shell commands may be continued across lines with a backslash-new-line (\-NEWLINE) sequence. Everything printed by make (except the initial TAB) is passed directly to the shell as is. Thus, echo a b will produce ab exactly the same as the shell would. Number-sign (#) and NEWLINE surround comments including contained '\-NEWLINE' sequences. The following makefile says that **pgm** depends on two files **a.o** and **b.o**, and that they in turn depend on their corresponding source files (a.c and b.c) and a common file incl.h: pgm: a.o b.o cc a.o b.o -o pgm a.o: incl.h a.c cc –c a.c b.o: incl.h b.c cc –c b.c Command lines are executed one at a time, each by its own shell. The SHELL environment variable can be used to specify which shell **make** should use to execute commands. The default is /usr/bin/sh. The first one or two characters in a command can be the following: '@', '-', '@-', or '-@'. If '@' is present, printing of the command is suppressed. If '-' is present, **make** ignores an error. A line is printed when it is executed unless the -s option is present, or the entry .SILENT: is included in makefile, or unless the initial character sequence contains a @. The -n option specifies printing without execution; however, if the command line has the string **\$(MAKE)** in it, the line is always executed (see the dis-

> (touch) option updates the modified date of a file without executing any commands. Commands returning non-zero status normally terminate **make**. If the -i option is present, if the entry **.IGNORE**: is included in *makefile*, or if the initial character sequence of the command contains '-', the error is ignored. If the -k option is present, work is abandoned on the current entry, but continues on other branches that do not depend on that entry.

> cussion of the MAKEFLAGS macro in the make Environment sub-section below). The -t

modified 18 Jul 1994

sysV-make(1)	User Commands	SunOS 5.5	
	Interrupt and quit cause the target to be deleted unless the target is a depend directive .PRECIOUS .	lent of the	
make Environment	The environment is read by make . All variables are assumed to be macro definitions and are processed as such. The environment variables are processed before any makefile and after the internal rules; thus, macro assignments in a makefile override environment variables. The – e option causes the environment to override the macro assignments in a makefile. Suffixes and their associated rules in the makefile will override any identical suffixes in the built-in rules.		
	The MAKEFLAGS environment variable is processed by make as containing input option (except $-\mathbf{f}$ and $-\mathbf{p}$) defined for the command line. Further, upor make "invents" the variable if it is not in the environment, puts the current of it, and passes it on to invocations of commands. Thus, MAKEFLAGS always current input options. This feature proves very useful for "super-makes". In noted above, when the $-\mathbf{n}$ option is used, the command $\$(MAKE)$ is executed hence, one can perform a make $-\mathbf{n}$ recursively on a whole software system to would have been executed. This result is possible because the $-\mathbf{n}$ is put in M and passed to further invocations of $\$(MAKE)$. This usage is one way of debut the makefiles for a software project without actually doing anything.	n invocation, options into contains the n fact, as anyway; o see what AKEFLAGS	
Include Files	If the string include appears as the first seven letters of a line in a <i>makefile</i> , and by a blank or a tab, the rest of the line is assumed to be a filename and will be current invocation, after substituting for any macros.		
Macros	Entries of the form <i>string1</i> = <i>string2</i> are macro definitions. <i>string2</i> is defined ters up to a comment character or an unescaped NEWLINE. Subsequent app $\$(string1[:subst1=[subst2]])$ are replaced by <i>string2</i> . The parentheses are optic single-character macro name is used and there is no substitute sequence. Th : <i>subst1=subst2</i> is a substitute sequence. If it is specified, all non-overlapping of <i>subst1</i> in the named macro are replaced by <i>subst2</i> . Strings (for the purpos type of substitution) are delimited by BLANKs, TABs, NEWLINE characters, at nings of lines. An example of the use of the substitute sequence is shown in sub-section below.	earances of onal if a e optional occurrences es of this nd begin-	
Internal Macros	There are five internally maintained macros that are useful for writing rules targets. \$* The macro \$* stands for the filename part of the current dependent with	C	
	deleted. It is evaluated only for inference rules.\$@ macro stands for the full target name of the current target. It is only for explicitly named dependencies.	evaluated	

modified 18 Jul 1994

\$< The \$< macro is only evaluated for inference rules or the .DEFAULT rule. It is the module that is outdated with respect to the target (the "manufactured" dependent file name). Thus, in the .c.o rule, the \$< macro would evaluate to the .c file. An example for making optimized .o files from .c files is:</p>

```
.c.o:
cc -c -O $*.c
```

or:

.c.o:

cc -c -O \$<

- **\$?** The **\$?** macro is evaluated when explicit rules from the makefile are evaluated. It is the list of prerequisites that are outdated with respect to the target, and essentially those modules that must be rebuilt.
- \$% The \$% macro is only evaluated when the target is an archive library member of the form lib(file.o). In this case, \$@ evaluates to lib and \$% evaluates to the library member, file.o.

Four of the five macros can have alternative forms. When an upper case **D** or **F** is appended to any of the four macros, the meaning is changed to "directory part" for **D** and "file part" for **F**. Thus, **\$(@D)** refers to the directory part of the string **\$@**. If there is no directory part, ./ is generated. The only macro excluded from this alternative form is **\$?**.

SuffixesCertain names (for instance, those ending with .o) have inferable prerequisites such as .c,
.s, etc. If no update commands for such a file appear in *makefile*, and if an inferable prere-
quisite exists, that prerequisite is compiled to make the target. In this case, **make** has
inference rules that allow building files from other files by examining the suffixes and
determining an appropriate inference rule to use. The current default inference rules are:

.sh~ .c~ .f .f~ .s .s~ .sh .C .C~ .c .c.a .c.o .c~.a .c~.c .c~.o .f.a .f.o .f~.a .f~.f .f~.o .h~.h .l.c .l.o .l~.c .l~.l .l~.o .s.a .s.o .s~.a .s~.o .sh~.sh .s~.s .y.c .y.o .y~.c .y~.o .y~.y .C.a .C.o .C~.a .C~.C .C~.o .L.C .L~.C .L~.L .Y.C .Y.o .L.o .L~.o Y~ C .Y~.Y .Y~.o

The internal rules for **make** are contained in the source file **make.rules** for the **make** program. These rules can be locally modified. To print out the rules compiled into the **make** on any machine in a form suitable for recompilation, the following command is used:

make -pf - 2>/dev/null </dev/null

A tilde in the above rules refers to an SCCS file (see **sccsfile**(4)). Thus, the rule **.c**^{*}.**o** would transform an SCCS C source file into an object file (.**o**). Because the **s**. of the SCCS files is a prefix, it is incompatible with the **make** suffix point of view. Hence, the tilde is a way of changing any file reference into an SCCS file reference.

A rule with only one suffix (for example, .c:) is the definition of how to build *x* from *x*.c. In effect, the other suffix is null. This feature is useful for building targets from only one source file, for example, shell procedures and simple C programs.

modified 18 Jul 1994

Additional suffixes are given as the dependency list for **.SUFFIXES**. Order is significant: the first possible name for which both a file and a rule exist is inferred as a prerequisite. The default list is:

.SUFFIXES: .o .c .c [~].y .y [~].l .l [~].s .s [~].sh .sh [~].h .h [~].f .f [~].C .C [~].Y .Y [~].L .L [~]

Here again, the above command for printing the internal rules will display the list of suffixes implemented on the current machine. Multiple suffix lists accumulate; **.SUF-FIXES:** with no dependencies clears the list of suffixes.

Inference Rules The first example can be done more briefly.

pgm: a.o b.o cc a.o b.o –o pgm a.o b.o: incl.h

This abbreviation is possible because **make** has a set of internal rules for building files. The user may add rules to this list by simply putting them in the *makefile*.

Certain macros are used by the default inference rules to permit the inclusion of optional matter in any resulting commands. For example, CFLAGS, LFLAGS, and YFLAGS are used for compiler options to cc(1B). Again, the previous method for examining the current rules is recommended.

The inference of prerequisites can be controlled. The rule to create a file with suffix **.o** from a file with suffix **.c** is specified as an entry with **.c.o**: as the target and no dependents. Shell commands associated with the target define the rule for making a **.o** file from a **.c** file. Any target that has no slashes in it and starts with a dot is identified as a rule and not a true target.

Libraries If a target or dependency name contains parentheses, it is assumed to be an archive library, the string within parentheses referring to a member within the library. Thus, lib(file.o) and \$(LIB)(file.o) both refer to an archive library that contains file.o. (This example assumes the LIB macro has been previously defined.) The expression \$(LIB)(file1.0 file2.0) is not legal. Rules pertaining to archive libraries have the form .*XX.a* where the *XX* is the suffix from which the archive member is to be made. An unfortunate by-product of the current implementation requires the *XX* to be different from the suffix of the archive member. Thus, one cannot have lib(file.0) depend upon file.o explicitly. The most common use of the archive interface follows. Here, we assume the source files are all C type source:

lib: lib(file1.o) lib(file2.o) lib(file3.o) @echo lib is now up-to-date

.c.a:

\$(CC) -c \$(CFLAGS) \$< \$(AR) \$(ARFLAGS) \$@ \$*.0 rm -f \$*.0

modified 18 Jul 1994

NAME	tabs – set tabs on a terminal			
SYNOPSIS	[+m	tabs $[-n -file [[-code] -a -a2 -c -c2 -c3 -f -p -s -u]]$ [+m[n]] [-T type] tabs $[-T type] [+m[n]] n1[,n2,]$		
AVAILABILITY	SUNWcsu	1		
DESCRIPTION		tabs sets the tab stops on the user's terminal according to a tab specification, after clear- ing any previous settings. The user's terminal must have remotely settable hardware tabs.		
OPTIONS	The following options are supported. If a given flag occurs more than once, the last value given takes effect:			
	-T type	tabs needs to know the type of terminal in order to set tabs and margins. <i>type</i> is a name listed in term (5). If no – T flag is supplied, tabs uses the value of the environment variable TERM . If the value of TERM is NULL or TERM is not defined in the environment (see environ (5)), tabs uses ansi+tabs as the terminal type to provide a sequence that will work for many terminals.		
	+ m [<i>n</i>]	The margin argument may be used for some terminals. It causes all tabs to be moved over <i>n</i> columns by making column $n+1$ the left margin. If $+\mathbf{m}$ is given without a value of <i>n</i> , the value assumed is 10 . For a TermiNet, the first value in the tab list should be 1 , or the margin will move even further to the right. The normal (leftmost) margin on most terminals is obtained by $+\mathbf{m0}$. The margin for most terminals is reset only when the $+\mathbf{m}$ flag is given explicitly.		
Tab Specification		s of tab specification are accepted. They are described below: canned, repetitive rary $(n1,n2,)$, and file $(file)$.		
	tabs. The most colu	pecification is given, the default value is –8 , that is, UNIX system ''standard'' lowest column number is 1 . Note: For tabs , column 1 always refers to the left- mn on a terminal, even one whose column markers begin at 0, for example, the DASI 300s, and DASI 450.		
Canned –code		f the codes listed below to select a canned set of tabs. If more than one code is the last code option will be used. The legal codes and their meanings are as fol-		
	-a -a2 -c	1,10,16,36,72 Assembler, IBM S/370, first format 1,10,16,40,72 Assembler, IBM S/370, second format 1,8,12,16,20,55 COBOL, normal format		
	I			

	-c2	 1,6,10,14,49 COBOL compact format (columns 1-6 omitted). Using this code, the first typed character corresponds to card column 7, one space gets you to column 8, and a tab reaches column 12. Files using this tab setup should include a format specification as follows (see fspec(4)):
		<:t-c2 m6 s66 d:>
	- c 3	1,6,10,14,18,22,26,30,34,38,42,46,50,54,58,62,67 COBOL compact format (columns 1-6 omitted), with more tabs than $-c2$. This is the recommended format for COBOL. The appropriate format specification is (see fspec (4)):
		<:t-c3 m6 s66 d:>
	-f -p	1,7,11,15,19,23 FORTRAN 1,5,9,13,17,21,25,29,33,37,41,45,49,53,57,61
	r	PL/I
	- S	1,10,55 SNOBOL
	- u	1,12,20,44 UNIVAC 1100 Assembler
Repetitive	- <u>n</u>	A <i>repetitive</i> specification requests tabs at columns $1+n$, $1+2*n$, etc., where <i>n</i> is a single-digit decimal number. Of particular importance is the value 8 : this represents the UNIX system "standard" tab setting, and is the most likely tab setting to be found at a terminal. When -0 is used, the tab stops are cleared and no new ones are set.
Arbitrary	See OPE	RANDS.
File	file	If the name of a <i>file</i> is given, tabs reads the first line of the file, searching for a format specification (see fspec (4)). If it finds one there, it sets the tab stops according to it, otherwise it sets them as -8 . This type of specification may be used to make sure that a tabbed file is printed with correct tab settings, and would be used with the pr command:
		example% tabs — file; pr file
	Tab and	margin setting is performed via the standard output.
OPERANDS	The follo	owing operand is supported:
	n1[,n2,.] The <i>arbitrary</i> format consists of tab-stop values separated by commas or spaces. The tab-stop values must be positive decimal integers in ascending order. Up to 40 numbers are allowed. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. Thus, the formats 1,10,20,30 , and 1,10,+10,+10 are considered identical.

EXAMPLES	The command:		
	example% tabs –a		
	is an example using –code (<i>canned</i> specification) to set tabs to the settings required by the IBM assembler: columns 1, 10, 16, 36, 72.		
	The next command:		
	example% tabs –8		
	is an example of using $-n$ (<i>repetitive</i> specification), where <i>n</i> is 8 , causes tabs to be set every eighth position: $1+(1*8), 1+(2*8), \ldots$ which evaluate to columns 9, 17,		
	The command:		
	example% tabs 1,8,36		
	is an example of using <i>n1,n2,</i> (<i>arbitrary</i> specification) to set tabs at columns 1, 8, and 36.		
	The last command:		
	example% tabs ——\$HOME/fspec.list/att4425		
	is an example of using — <i>file</i> (<i>file</i> specification) to indicate that tabs should be set accord- ing to the first line of \$HOME/fspec.list/att4425 (see fspec (4)).		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tabs : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
	TERM Determine the terminal type. If this variable is unset or null, and if the –T option is not specified, terminal type ansi+tabs will be used.		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred.		
SEE ALSO	expand(1), newform(1), pr(1), stty(1), tput(1), fspec(4), terminfo(4), environ(5), term(5)		
NOTES	There is no consistency among different terminals regarding ways of clearing tabs and setting the left margin.		
	tabs clears only 20 tabs (on terminals requiring a long sequence), but is willing to set 64.		
	The <i>tabspec</i> used with the tabs command is different from the one used with the newform command. For example, tabs -8 sets every eighth position; whereas newform $-i-8$ indicates that tabs are set every eighth position.		

NAME	tail – deliver the last part of a file		
SYNOPSIS	/usr/bin/tail [± number [lbcr]] [file] /usr/bin/tail [–lbcr] [file] /usr/bin/tail [± number [lbcf]] [file] /usr/bin/tail [–lbcf] [file]		
	/usr/xpg4/bin/ta	ail [-f -r] [-c number -n number] [file] ail [± number [l b c] [f]] [file] ail [± number [l] [f r]] [file]	
AVAILABILITY /usr/bin/tail	SUNWcsu		
/usr/xpg4/bin/tail	SUNWxcu4		
DESCRIPTION	The tail command copies the named file to the standard output beginning at a desig place. If no file is named, the standard input is used.		
	Copying begins at a point in the file indicated by the $-\mathbf{c}$ number, $-\mathbf{n}$ number, or $\pm number$ options (if + <i>number</i> is specified, begins at distance number from the beginning; if <i>-number</i> is specified, from the end of the input; if <i>number</i> is NULL , the value 10 is assumed). <i>number</i> is counted in units of lines or byte according to the $-\mathbf{c}$ or $-\mathbf{n}$ options, or lines, blocks, or bytes, according to the appended option 1 , b , or c . When no units are specified, counting is by lines.		
	The r and f opti the f option wil	ions are mutually exclusive. If both are specified on the command line, l be ignored.	
OPTIONS	The following o	options are supported:	
	-b	Units of blocks.	
/usr/xpg4/bin/tail	–c number	The <i>number</i> option-argument must be a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:	
		 + Copying starts relative to the beginning of the file. - Copying starts relative to the end of the file. none Copying starts relative to the end of the file. The origin for counting is 1; that is, -c +1 represents the first byte of the file, -c -1 the last. 	
	- c	Units of bytes.	
	-f	Follow. If the input-file is not a pipe, the program will not terminate after the line of the input-file has been copied, but will enter an endless loop, wherein it sleeps for a second and then attempts to read and copy further records from the input-file. Thus it may be used to monitor the growth of a file that is being written by some other process.	
l	- l	Units of lines.	

/usr/xpg4/bin/tail	– n number	Equivalent to $-c$ <i>number</i> , except the starting location in the file is measured in lines instead of bytes. The origin for counting is 1 ; that is, $-n + 1$ represents the first line of the file, $-n - 1$ the last.		
	- r	Reverse. Copies lines from the specified starting point in the file in reverse order. The default for r is to print the entire file in reverse order.		
OPERANDS	The following operand is supported:			
	file	A path name of an input file. If no <i>file</i> operands are specified, the stan- dard input will be used.		
EXAMPLES	For example, the command:			
	example% tail –f fred			
	between the tin	ist ten lines of the file fred , followed by any lines that are appended to fred ne tail is initiated and killed. As another example, the command:		
	example% tail –15cf fred			
		ist 15 bytes of the file fred , followed by any lines that are appended to fred ne tail is initiated and killed.		
ENVIRONMENT		for descriptions of the following environment variables that affect the exe- C_CTYPE, LC_MESSAGES, and NLSPATH.		
EXIT STATUS	The following exit values are returned:			
	0	Successful completion.		
	>0	An error occurred.		
SEE ALSO	cat(1), head(1), more(1), pg(1), dd(1M), environ(5)			
NOTES	-	tive to the end of the file are stored in a buffer, and thus are limited in s kinds of anomalous behavior may happen with character special files.		

SYNOPSIS talk	- talk to another user address [terminal] Wcsu alk utility is a two-way, screen-oriented communication program.		
	Wcsu		
AVAILABILITY SUN	alk utility is a two-way, screen-oriented communication program.		
	n first invoked, talk sends a message similar to: Message from TalkDaemon@ her_machine at time talk: connection requested by your_address talk: respond with: talk your_address		
to the	e specified <i>address</i> . At this point, the recipient of the message can reply by typing:		
	talk your_address		
	communication is established, the two parties can type simultaneously, with their ut displayed in separate regions of the screen. Characters are processed as follows:		
	Typing the alert character will alert the recipient's terminal. Typing CTRL-L will cause the sender's screen regions to be refreshed. Typing the erase and kill characters will affect the sender's terminal in the manner described by the termios (3) interface. Typing the interrupt or end-of-file (EOF) characters will terminate the local talk util- ity. Once the talk session has been terminated on one side, the other side of the talk session will be notified that the talk session has been terminated and will be able to do nothing except exit. Typing characters from LC_CTYPE classifications print or space will cause those characters to be sent to the recipient's terminal. When and only when the stty iexten local mode is enabled, additional special con- trol characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable. Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a '^' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\ 003 ' is displayed as ' C ' and '\ 372 ' as ' M - z '.		
mess bility order	Permission to be a recipient of a talk message can be denied or granted by use of the mesg (1) utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. Certain commands, such as pr (1), disallow messages in order to prevent interference with their output. talk will fail when the user lacks the appropriate privileges to perform the requested action.		
simu not b	in block-mode terminals do not have all the capabilities necessary to support the ltaneous exchange of messages required for talk . When this type of exchange can- e supported on such terminals, the implementation may support an exchange with ced levels of simultaneous interaction or it may report an error describing the		

	terminal-related deficiency.		
OPERANDS	The following operands are supported:		
	<i>address</i> The recipient of the talk session. One form of <i>address</i> is the <i>username</i> , as returned by the who (1) utility. Other address formats and how they are handled are unspecified.		
	<i>terminal</i> If the recipient is logged in more than once, <i>terminal</i> can be used to indicate the appropriate terminal name. If <i>terminal</i> is not specified, the talk message will be displayed on one or more accessible terminals in use by the recipient. The format of <i>terminal</i> will be the same as that returned by who .		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of talk : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
	TERM Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified terminal type will be used.		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred or talk was invoked on a terminal incapable of supporting it		
FILES	/etc/hosts host name database /var/adm/utmp user and accounting information for talk		
SEE ALSO	mail (1), mesg (1), pr (1), stty (1), who (1), write (1), termios (3), environ (5)		
NOTES	Because the handling of non-printable, non-space characters is tied to the stty (1) description of iexten , implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.		

NAME	tar – create tape archives, and add or extract files			
SYNOPSIS	/usr/sbin/tar c [bBefFhilvwX [0-7]] [device] [block] [exclude-file] [–I include-file] file [–C directory file]			
	/usr/sbin/tar r [bBefFhilvw [0-7]] [device] [block] [–I include-file] file [–C directory file]			
	/usr/sbin/tar t [BefFhilvX [0-7]] [device] [exclude-file] [–I include-file] [file]			
	/usr/sbin/tar u [bBefFhilvw [0-7]] [device] [block] file			
	/usr/sbin/tar x [BefFhilmopvwX [0-7]] [device] [exclude-file] [file]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The tar command archives and extracts files to and from a single file called a <i>tarfile</i> . A tarfile is usually a magnetic tape, but it can be any file. tar 's actions are controlled by the <i>key</i> argument. The <i>key</i> is a string of characters containing exactly one function letter (c , r , t , u , or x) and one or more function modifiers, depending on the function letter used. Other arguments to the command are <i>files</i> (or directory names) specifying which files are to be archived or extracted. In all cases, appearance of a directory name refers to the files and (recursively) subdirectories of that directory.			
OPERANDS	The following operands are supported:			
Function Letters	The function portion of the key is specified by one of the following letters:			
	c Create. Writing begins at the beginning of the tarfile, instead of at the end. This key implies the r key.			
	r Replace. The named <i>file</i> s are written on the end of the tape. The c and u functions imply this function. See NOTES for more information.			
	tTable of Contents. The names of the specified files are listed each time they occur on the <i>tarfile</i> . If no <i>files</i> arguments are given, all the names on the <i>tarfile</i> are listed. With the v function modifier, additional information for the specified files is displayed. The listing is similar to the format produced by the ls -l command.			
	 Update. The named <i>files</i> are added to the tarfile if they are not already there, or have been modified since last written on that tarfile. This key implies the r key. See NOTES for more information. 			
	x Extract, or restore. The named <i>files</i> are extracted from the tarfile and written to the current directory. If a named file matches a directory whose contents had been written onto the tarfile, this directory is (recursively) extracted. Use the file or directory's relative path when appropriate, or tar will not find a match. The owner, modification time, and mode are restored (if possible); otherwise, to restore owner, you must be the superuser. If no <i>files</i> argument is given, the entire content of the tarfile is extracted. Note: If several files with the same name are on the tarfile, the last one overwrites all earlier ones. See NOTES for more			

	information.	
Function Modifiers	he characters below may be used in addition to the letter that selects the desire on. Use them in the order shown in the SYNOPSIS .	ed func-
	Blocking Factor. This causes tar to use the <i>block</i> argument as the block for tape records. The default is 1 , the maximum is 20 . This function sl be supplied when operating on regular archives or block special device mandatory however, when reading archives on raw magnetic tape arc f below). The block size is determined automatically when reading tap created on block special devices (key letters x and t). This determinati blocking factor may be fooled when reading from a pipe or a socket (s key letter below). The maximum blocking factor is determined only b amount of memory available to tar when it is run. Larger blocking factor in better throughput, longer blocks on nine-track tapes, and better med tion.	hould not es. It is chives (see pes on of the ee the B y the ctors result
	Block. Force tar to perform multiple reads (if necessary) so as to read enough bytes to fill a block. This option exists so that tar can work acr Ethernet, since pipes and sockets return partial blocks even when mor coming. When reading from standard input, '-', this option is automa- selected to make sure that tar can recover from short reads.	oss the e data is
	Error. If any unexpected errors occur tar will exit immediately with a exit status.	positive
	 File. This causes tar to use the <i>device</i> argument as the name of the tarfigiven, /etc/default/tar is not searched. If f is omitted, tar will use the condicated by the TAPE environment variable, if set; otherwise, it will use the fault values defined in /etc/default/tar. If the name of the tarfile is 'writes to the standard output or reads from the standard input, which appropriate. Thus, tar can be used as the head or tail of a pipeline. tar be used to move hierarchies with the command: example% cd fromdir; tar cf (cd todir; tar xfBp –) 	levice se the –', tar ever is
	With one F argument, tar will exclude all directories named SCCS and the tarfile. With two arguments, FF , tar will exclude all directories namand RCS, all files with .o as their suffix, and all files named errs , core , a	ned SCCS
	Follow symbolic links as if they were normal files or directories. Norm does not follow symbolic links.	nally, tar
	Ignore. With this option tar will ignore directory checksum errors.	
	Link. This tells tar to complain if it cannot resolve all of the links to th being archived. If l is not specified, no error messages are printed.	e files
	Modify. This tells tar to not extract the modification times from the tar modification time of the file will be the time of extraction. This option valid with the x key.	
	Ownership. This causes extracted files to take on the user and group i	dentifier

- **p** Restore the named files to their original modes, and ACLs if applicable, ignoring the present **umask**(2). SETUID and sticky information are also extracted if your are the super-user. When this option is used with the **c** key letter, ACLs are created in the tarfile along with other information. Note that errors will occur when a tarfile with ACLs is extracted by previous versions of **tar**.
- Verbose. Normally, tar does its work silently. This option causes tar to type the name of each file it treats, preceded by the function letter. With the t function, v gives more information about the tape entries than just the name.
- W What. This option causes tar to print the action to be taken, followed by the name of the file, and then wait for the user's confirmation. If a word beginning with y is given, the action is performed. Any other input means no. This is not valid with the t key.
- Exclude. Use the *exclude-file* argument as a file containing a list of named files (or directories) to be excluded from the tarfile when using the key letters c, x, or
 t. Multiple X arguments may be used, with one *exclude-file* per argument. See NOTES for more information.
- **[0-7]** Select an alternative drive on which the tape is mounted. The default entries are specified in /etc/default/tar.
- *file* A path name of a regular file or directory to be archived (when the **c**, **r** or **u** function letters are used), extracted (**x**) or listed (**t**). When *file* is the path name of a directory, the action applies to all of the files and (recursively) subdirectories of that directory. When either or both of the **b** or **f** letters are used in the *key* operand, the initial *file* operands are interpreted as a blocking factor or archive name, as described previously.

If a file name is preceded by -I then the file is opened. A list files, one per line, is treated as if each appeared separately on the command line. Be careful of trailing white space in both include and exclude file lists.

In the case where excluded files (see **X** option) also exist, excluded files take precedence over all included files. So, if a file is specified in both the include and exclude files (or on the command line), it will be excluded.

If a file name is preceded by -C in a c (create) or r (replace) operation, tar will perform a chdir (see csh(1)) to that file name. This allows multiple directories not related by a close common parent to be archived using short relative path names.

Note: the $-\mathbf{C}$ option only applies to *one* following directory name and *one* following file name.

If no digit or 'f' is given, the entry in /etc/default/tar with digit "0" will be the default.

EXAMPLES To archive files from /**usr/include** and from /**etc**, onto default tape drive **0** one might use:

example% tar c –C /usr include –C /etc .

If you get a table of contents from the resulting *tarfile*, you might see something like:

include/ include/a.out.h and all the other files in /usr/include ... /chown and all the other files in /etc To extract all files under include:

> example% tar xv include x include/, 0 bytes, 0 tape blocks and all files under include...

Here is a simple example using **tar** to create an archive of your home directory on a tape mounted on drive /**dev/rmt/0**:

example% cd example% tar cvf /dev/rmt/0. messages from tar

The **c** option means create the archive; the **v** option makes **tar** tell you what it is doing as it works; the **f** option means that you are specifically naming the file onto which the archive should be placed (/**dev/rmt/0** in this example).

Now you can read the table of contents from the archive like this:

example% tar tvf /dev/rmt/0 rw-r--r- 1677/40 2123 Nov 7 18:15 1985 ./test.c ... example%

The columns have the following meanings:

- column 1 is the access permissions to ./test.c
- column 2 is the *user-id/group-id* of ./**test.c**
- column 3 is the size of ./test.c in bytes
- column 4 is the modification date of ./test.c
- column 5 is the name of ./test.c

You can extract files from the archive like this:

example% tar xvf /dev/rmt/0 messages from tar example%

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. To have **tar** read the first and second archives from a tape with multiple archives on it, the *non-rewinding* version of the tape device name must be used with the **f** option, as follows:

example% tar xvfp /dev/rmt/0n read first archive from tape

modified 1 Feb 1995

	messages from tar example% tar xvfp /dev/rmt/0n read second archive from tape messages from tar example%				
	(Note that in some earlier releases, the above scenario did not work correctly, and intervention with mt(1) between tar invocations was necessary.)				
	Finally, here is an example using tar to transfer files across the Ethernet. First, here is how to archive files from the local machine (example) to a tape on a remote system (host):				
	example% tar cvfb – 20 files rsh host dd of=/dev/rmt/0 obs=20b messages from tar example%				
	In the example above, we are <i>creating</i> a <i>tarfile</i> with the c key letter, asking for <i>verbose</i> output from tar with the v option, specifying the name of the output <i>tarfile</i> using the f option (the standard output is where the <i>tarfile</i> appears, as indicated by the '-' sign), and specifying the blocksize (20) with the b option. If you want to change the blocksize, you must change the blocksize arguments both on the tar command <i>and</i> on the dd command.				
	Now, here is how to use tar to get files from a tape on the remote system back to the local system: example% rsh –n host dd if=/dev/rmt/0 bs=20b tar xvBfb – 20 <i>files</i> <i>messages from</i> tar example%				
	In the example above, we are <i>extracting</i> from the <i>tarfile</i> with the x key letter, asking for <i>verbose output from</i> tar with the v option, telling tar it is reading from a pipe with the B option, specifying the name of the input <i>tarfile</i> using the f option (the standard input is where the <i>tarfile</i> appears, as indicated by the '-' sign), and specifying the blocksize (20) with the b option.				
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tar : LC_COLLATE , LC_CTYPE , LC_MESSAGES , LC_TIME , TZ , and NLSPATH .				
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.				
FILES	/dev/rmt/[0-7][b][n] /dev/rmt/[0-7]n[b][n] /dev/rmt/[0-7]m[b][n] /dev/rmt/[0-7]u[b][n] /dev/rmt/[0-7]c[b][n] /dev/rmt/[0-7]c[b][n] /det/default/tar Settings may look like this: archive0=/dev/rmt/0 archive1=/dev/rmt/0n				

modified 1 Feb 1995

	archive2=/dev/rmt/1 archive3=/dev/rmt/1n archive4=/dev/rmt/0 archive5=/dev/rmt/0n archive6=/dev/rmt/1 archive7=/dev/rmt/1n
	/tmp/tar*
SEE ALSO	ar (1), chown (1), cpio (1), csh (1), ls (1), mt (1), setfacl (1), umask (2), environ (5)
DIAGNOSTICS	Complaints about bad key characters and tape read/write errors. Complaints if enough memory is not available to hold the link tables.
NOTES	There is no way to ask for the <i>n</i> -th occurrence of a file.
	Tape errors are handled ungracefully.
	The u option can be slow.
	The b option should not be used with archives that are going to be updated. The current magnetic tape driver cannot backspace raw magnetic tape. If the archive is on a disk file, the b option should not be used at all, because updating an archive stored on disk can destroy it.
	The r option and the u option cannot be used with many tape drives due to limitations in the drive such as the absence of backspace or append capability.
	When extracting tapes created with the ${f r}$ or ${f u}$ option, directory modification times may not be set correctly.
	When using r , u , x , or X , the named files must match exactly to the corresponding files in the <i>tarfile</i> . For example, to extract <i>./file</i> , you must specify <i>./file</i> , and not <i>file</i> . The t option displays how each file was archived.
	The full path name length cannot exceed 255 characters.
	The file name (or leaf) length cannot exceed 100 characters.
	The prefix of the path name cannot exceed 155 characters.
	tar does not copy empty directories or special files such as devices.
	Filename substitution wildcards do not work for extracting files from the archive. To get around this, use a command of the form: tar xvf /dev/rmt/0 'tar tf /dev/rmt/0 grep 'pattern''
	When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (eg, /dev/rdiskette) may not succeed. See vold (1M) for further details.

NAME	tbl – format tables for nroff or troff			
SYNOPSIS	tbl [–me] [–mm] [–ms] [filename]			
AVAILABILITY	SUNWdoc			
DESCRIPTION	 tbl is a preprocessor for formatting tables for nroff(1) or troff(1). The input <i>filenames</i> are copied to the standard output, except that lines between .TS and .TE command lines are assumed to describe tables and are reformatted. If no arguments are given, tbl reads the standard input, so tbl may be used as a filter. When tbl is used with eqn(1) or neqn, the tbl command should be first, to minimize the volume of data passed through pipes. 			
OPTIONS	- me Copy the - me macro package to the from	of the output file.		
	-mm Copy the -mm macro package to the from	t of the output file.		
	-ms Copy the -ms macro package to the from	of the output file.		
EXAMPLES	As an example, letting '@' (at-sign) represent a TAB, which should be typed as an actual TAB character in the input file

NAME	tcopy – copy a magnetic tape		
SYNOPSIS	tcopy source [destination]		
AVAILABILITY	SUNWesu		
DESCRIPTION	tcopy copies the magnetic tape mounted on the tape drive specified by the <i>source</i> argument. The only assumption made about the contents of a tape is that there are two tape marks at the end.		
	When only a source drive is specified, tcopy scans the tape, and displays information about the sizes of records and tape files. If a destination is specified, tcopy makes a copies the source tape onto the <i>destination</i> tape, with blocking preserved. As it copies, tcopy produces the same output as it does when only scanning a tape.		
SEE ALSO	mt(1), ioctl(2)		
NOTES	tcopy will only run on systems supporting an associated set of ioctl (2) requests.		

modified 14 Sep 1992

NAME	tee – replicate the standard output		
SYNOPSIS	tee [-ai] [file]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The tee utility will copy standard input to standard output, making a copy in zero or more files. tee will not buffer its output. The options determine if the specified files are overwritten or appended to.		
OPTIONS	 The following options are supported. -a Append the output to the files rather than overwriting them. -i Ignore interrupts. 		
OPERANDS	The following operands are supported:fileA path name of an output file. Processing of at least 13 file operands will be supported.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tee : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	 The following exit values are returned: 0 The standard input was successfully copied to all output files. >0 The number of files that could not be opened or whose status could not be obtained. 		
SEE ALSO	cat(1), environ(5)		

modified 1 Feb 1995

NAME	telnet – user interface to a remote system using the TELNET protocol			
SYNOPSIS	telnet [-8ELcdr] [-e escape_char] [-l user] [-n file] [host [port]]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	telnet communicates with another host using the TELNET protocol. If telnet is invoked without arguments, it enters command mode, indicated by its prompt telnet >. In this mode, it accepts and executes its associated commands. (See "TELNET Commands" below.) If it is invoked with arguments, it performs an open command with those arguments.			
	Once a connection has been opened, telnet enters input mode. In this mode, text typed is sent to the remote host. The input mode entered will be either "line mode," "character at a time," or "old line by line," depending on what the remote system supports.			
	In line mode, character processing is done on the local system, under the control of the remote system. When input editing or character echoing is to be disabled, the remote system will relay that information. The remote system will also relay changes to any special characters that happen on the remote system, so that they can take effect on the local system.			
	In character at a time mode, most text typed is immediately sent to the remote host for processing.			
	In old line by line mode, all text is echoed locally, and (normally) only completed lines are sent to the remote host. The "local echo character" (initially `E) may be used to turn off and on the local echo. (Use this mostly to enter passwords without the password being echoed.).			
	If the "line mode" option is enabled, or if the <i>localchars</i> toggle is TRUE (the default in "old line by line" mode), the user's quit , intr , and flush characters are trapped locally, and sent as TELNET protocol sequences to the remote side. If "line mode" has ever been enabled, then the user's susp and eof are also sent as TELNET protocol sequences. quit is then sent as a TELNET ABORT instead of BREAK. The options toggle autoflush , and toggle autosynch cause this action to flush subsequent output to the terminal (until the remote host acknowledges the TELNET sequence) and flush previous terminal input, in the case of quit and intr .			
	While connected to a remote host, the user can enter telnet command mode by typing the telnet escape character (initially ^]). When in command mode, the normal terminal editing conventions are available.			
OPTIONS	 -8 Specifies an 8-bit data path. Negotiating the TELNET BINARY option is attempted for both input and output. 			
	-E Stops any character from being recognized as an escape character.			
	-L Specifies an 8-bit data path on output. This causes the BINARY option to be negotiated on output.			

modified 27 Feb 1995

	-с	Disables the reading of the user's telnetrc file. (See the toggle skiprc command on this man page.)			
	$-\mathbf{d}$	Sets the initial value of the debug toggle to true.			
	<pre>pe_char Sets the initial escape character to escape_char. Escape_char may also be a two character sequence consisting of '^' followed by one character. If the second char- acter is '?', the DEL character is selected. Otherwise the second character is con- verted to a control character and used as the escape character. If the escape char- acter is the null string, (i.ee ''), it is disabled.</pre>				
	–l user	<i>er</i> When connecting to a remote system that understands the ENVIRON option, then user will be sent to the remote system as the value for the variable USER.			
	–n trac				
		Opens tracefile for recording trace information. See the set tracefile command below.			
	-r	Specifies a user interface similar to rlogin . In this mode, the escape character is set to the tilde (~) character, unless modified by the -e option. The rlogin escape character is only recognized when it is preceded by a carriage return. In this mode, the telnet escape character, normally '^]', must still precede a telnet command. The rlogin escape character can also be followed by '.\r' or ' ^ Z', and, like rlogin (1), closes or suspends the connection, respectively. This option is an uncommitted interface and may change in the future.			
USAGE telnet Commands					
	open [-l user] host [port]				
	• -	Open a connection to the named host. If no port number is specified, telnet will attempt to contact a TELNET server at the default port. The host specification may be either a host name (see hosts (4)) or an Internet address specified in the "dot notation" (see inet (7P)). The -l option passes the <i>user</i> as the value of the ENVIRON variable USER to the remote system.			
	close	Close any open TELNET session and exit telnet . An EOF (in command mode) will also close a session and exit.			
	quit	Same as close , above.			
	z	Suspend telnet . This command only works when the user is using a shell that supports job control, such as $sh(1)$.			
	mode				
		The remote host is asked for permission to go into the requested mode. If the remote host is capable of entering that mode, the requested mode will be entered. <i>Type</i> is one of:			
		character			

		Disable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then enter "character at a time" mode.		
	line	Enable the TELNET LINEMODE option, or, if the remote side does not understand the LINEMODE option, then attempt to enter "old-line-by- line" mode.		
	isig (-is	ig)		
	O \	Attempt to enable (disable) the TRAPSIG mode of the LINEMODE option This requires that the LINEMODE option be enabled.		
	edit (-e	lit)		
		Attempt to enable (disable) the EDIT mode of the LINEMODE option. This requires that the LINEMODE option be enabled.		
	softtab	s (-softtabs)		
		Attempt to enable (disable) the SOFT_TAB mode of the LINEMODE option. This requires that the LINEMODE option be enabled.		
	litecho	(-litecho)		
		Attempt to enable (disable) the LIT_ECHO mode of the LINEMODE option. This requires that the LINEMODE option be enabled.		
	?	Prints out help information for the mode command.		
status		he current status of telnet . This includes the peer one is connected to, as the current mode.		
display	[argume	ent]		
1 5	Display all, or some, of the set and toggle values (see toggle , <i>arguments</i>).			
? [comm	nand]			
L	Get hel	p. With no arguments, telnet prints a help summary. If a command is d, telnet will print the help information for just that command.		
sendarg	guments			
	Send or are the	ne or more special character sequences to the remote host. The following arguments that can be specified: (More than one argument may be d at a time.)		
	escape	Send the current telnet escape character (initially ^]).		
	-	Send the TELNET SYNCH sequence. This sequence discards all previ-		
	synch	ously typed, but not yet read, input on the remote system. This sequence is sent as TCP urgent data and may not work if the remote system is a 4.2 BSD system. If it does not work, a lower case 'r' may be echoed on the terminal.		
	brk	Send the TELNET BRK (Break) sequence, which may have significance to the remote system.		
	ір	Send the TELNET IP (Interrupt Process) sequence, which aborts the currently running process on the remote system.		
	abort	Send the TELNET ABORT (abort process) sequence.		
	ao	Send the TELNET AO (Abort Output) sequence, which flushes all output		

modified 27 Feb 1995

from the remote system to the user's terminal.

- **ayt** Send the TELNET AYT (Are You There) sequence, to which the remote system may or may not respond.
- **ec** Send the TELNET EC (Erase Character) sequence, which erases the last character entered.
- **el** Send the TELNET EL (Erase Line) sequence, which should cause the remote system to erase the line currently being entered.
- **eof** Send the TELNET EOF (end of file) sequence.
- **eor** Send the TELNET EOR (end of record) sequence.
- **ga** Send the TELNET GA (Go Ahead) sequence, which probably has no significance for the remote system.

getstatus

If the remote side supports the TELNET STATUS command, **getstatus** will send the subnegotiation to request that the server send its current option status.

nop Send the TELNET NOP (No Operation) sequence.

susp Send the TELNET SUSP (suspend process) sequence.

do option

dont option

will option

wont option

Send the TELNET protocol option negotiation indicated. Option may be the text name of the protocol option, or the number corresponding to the option. The command will be silently ignored if the option negotiation indicated is not valid in the current state. If the *option* is given as 'help' or '?', the list of option names known is listed. This command is mostly useful for unusual debugging situations.

Print out help information for the **send** command.

set argument [value]

?

unset argument

Set any one of a number of **telnet** variables to a specific value. The special value "off" turns off the function associated with the variable. The values of variables may be interrogated with the **display** command. If *value* is omitted, the value is taken to be true, or "on." If the **unset** form is used, the value is taken to be false, or "off." The variables that may be specified are:

- **echo** This is the value (initially **`E**) that, when in "line by line" mode, toggles between local echoing of entered characters for normal processing, and suppressing echoing of entered characters, for example, entering a password.
- **escape** This is the **telnet** escape character (initially ^]), which enters **telnet**

command mode when connected to a remote system.

interrupt

If **telnet** is in **localchars** mode (see **toggle localchars**) and the **interrupt** character is typed, a TELNET IP sequence (see **send** and **ip**) is sent to the remote host. The initial value for the interrupt character is taken to be the terminal's **intr** character.

quit If **telnet** is in **localchars** mode and the **quit** character is typed, a TELNET BRK sequence (see **send**, **brk**) is sent to the remote host. The initial value for the quit character is taken to be the terminal's **quit** character.

flushoutput

If **telnet** is in **localchars** mode and the **flushoutput** character is typed, a TELNET AO sequence (see **send**, **ao**) is sent to the remote host. The initial value for the flush character is taken to be the terminal's **flush** character.

- erase If telnet is in localchars mode *and* operating in "character at a time" mode, then when the erase character is typed, a TELNET EC sequence (see send, ec) is sent to the remote system. The initial value for the erase character is taken to be the terminal's erase character.
- **kill** If **telnet** is in **localchars** mode *and* operating in "character at a time" mode, then when the **kill** character is typed, a TELNET EL sequence (see **send**, **el**) is sent to the remote system. The initial value for the **kill** character is taken to be the terminal's **kill** character.
- eof If telnet is operating in "line by line" mode, entering the eof character as the first character on a line sends this character to the remote system. The initial value of eof is taken to be the terminal's eof character.
- ayt If telnet is in localchars mode, or LINEMODE is enabled, and the status character is typed, a TELNET AYT ("Are You There") sequence is sent to the remote host. (See send ayt above.) The initial value for ayt is the terminal's status character.

forw1

- **forw2** If **telnet** is operating in LINEMODE, and the **forw1** or **forw2** characters are typed, this causes the forwarding of partial lines to the remote system. The initial values for the forwarding characters comes from the terminal's **eol** and **eol2** characters.
- **Inext** If **telnet** is operating in LINEMODE or "old line by line" mode, then the **lnext** character is assumed to be the terminal's **lnext** character. The initial value for the **lnext** character is taken to be the terminal's **lnext** character.
- **reprint** If **telnet** is operating in LINEMODE or "old line by line" mode, then the **reprint** character is assumed to be the terminal's **reprint** character. The initial value for **reprint** is taken to be the terminal's **reprint** character.
- **rlogin** This is the **rlogin** escape character. If set, the normal **telnet** escape character is ignored, unless it is preceded by this character at the beginning of

a line. The **rlogin** character, at the beginning of a line followed by a '.' closes the connection. When followed by a **'Z**, the **rlogin** command suspends the **telnet** command. The initial state is to disable the **rlogin** escape character.

- **start** If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the **start** character is taken to be the terminal's **start** character. The initial value for the **kill** character is taken to be the terminal's **start** character.
- **stop** If the TELNET TOGGLE-FLOW-CONTROL option has been enabled, then the **stop** character is taken to be the terminal's **stop** character. The initial value for the **kill** character is taken to be the terminal's **stop** character.
- susp If telnet is in localchars mode, or LINEMODE is enabled, and the suspend character is typed, a TELNET SUSP sequence (see send susp above) is sent to the remote host. The initial value for the suspend character is taken to be the terminal's suspend character.

tracefile

This is the file to which the output, caused by the **netdata** or the **debug** option being TRUE, will be written. If it is set to '-', then tracing information will be written to standard output (the default).

worderase

If **telnet** is operating in LINEMODE or "old line by line" mode, then this character is taken to be the terminal's **worderase** character. The initial value for the **worderase** character is taken to be the terminal's **worderase** character.

- ? Displays the legal **set** and **unset** commands.
- slc state The slc (Set Local Characters) command is used to set or change the state of special characters when the TELNET LINEMODE option has been enabled. Special characters are characters that get mapped to TELNET commands sequences (like ip or quit) or line editing characters (like erase and kill). By default, the local special characters are exported.
 - **check** Verifies the settings for the current special characters. The remote side is requested to send all the current special character settings. If there are any discrepancies with the local side, the local settings will switch to the remote values.
 - **export** Switches to the local defaults for the special characters. The local default characters are those of the local terminal at the time when **telnet** was started.
 - **import** Switches to the remote defaults for the special characters. The remote default characters are those of the remote system at the time when the TELNET connection was established.
 - ? Prints out help information for the **slc** command.

toggle arguments...

Toggle between TRUE and FALSE the various flags that control how **telnet** responds to events. More than one argument may be specified. The state of these flags may be interrogated with the **display** command. Valid arguments are:

autoflush

If **autoflush** and **localchars** are both TRUE, then when the **ao**, **intr**, or **quit** characters are recognized (and transformed into TELNET sequences; see **set** for details), **telnet** refuses to display any data on the user's terminal until the remote system acknowledges (using a TELNET Timing Mark option) that it has processed those TELNET sequences. The initial value for this toggle is TRUE if the terminal user has not done an "stty noflsh." Otherwise, the value is FALSE (see **stty**(1)).

autosynch

If **autosynch** and **localchars** are both TRUE, then when either the **interrupt** or **quit** characters are typed (see **set** for descriptions of **interrupt** and **quit**), the resulting TELNET sequence sent is followed by the TELNET SYNCH sequence. This procedure *should* cause the remote system to begin throwing away all previously typed input until both of the TELNET sequences have been read and acted upon. The initial value of this toggle is FALSE.

binary Enable or disable the TELNET BINARY option on both input and output.

inbinary

Enable or disable the TELNET BINARY option on input.

outbinary

Enable or disable the TELNET BINARY option on output.

- **crlf** Determines how carriage returns are sent. If the value is TRUE, then carriage returns will be sent as <CR><LF>. If this is FALSE, then carriage returns will be send as <CR><NUL>. The initial value for this toggle is FALSE.
- **crmod** Toggle RETURN mode. When this mode is enabled, most RETURN characters received from the remote host will be mapped into a RETURN followed by a line feed. This mode does not affect those characters typed by the user, only those received from the remote host. This mode is useful only for remote hosts that send RETURN, but never send LINEFEED. The initial value for this toggle is FALSE.
- **debug** Toggle socket level debugging (only available to the superuser). The initial value for this toggle is FALSE.

localchars

If this toggle is TRUE, then the **flush**, **interrupt**, **quit**, **erase**, and **kill** characters (see **set**) are recognized locally, and transformed into appropriate TELNET control sequences, respectively **ao**, **ip**, **brk**, **ec**, and **el** (see **send**). The initial value for this toggle is TRUE in "line by line" mode, and FALSE

in "character at a time" mode. When the LINEMODE option is enabled, the value of **localchars** is ignored, and assumed to always be TRUE. If LINEMODE has ever been enabled, then **quit** is sent as **abort**, and **eof** and **suspend** are sent as **eof** and **susp** (see **send** above).

netdata

Toggle the display of all network data (in hexadecimal format). The initial value for this toggle is FALSE.

options

Toggle the display of some internal TELNET protocol processing (having to do with **telnet** options). The initial value for this toggle is FALSE.

prettydump

When the **netdata** toggle is enabled, if **prettydump** is enabled, the output from the **netdata** command will be formatted in a more user readable format. Spaces are put between each character in the output. The beginning of any TELNET escape sequence is preceded by an asterisk (*) to aid in locating them.

skiprc When the **skiprc** toggle is TRUE, TELNET skips the reading of the **.tel**-**netrc** file in the user's home directory when connections are opened. The initial value for this toggle is FALSE.

termdata

Toggles the display of all terminal data (in hexadecimal format). The initial value for this toggle is FALSE.

? Display the legal **toggle** commands.

environ arguments...

The **environ** command is used to manipulate variables that may be sent through the TELNET ENVIRON option. The initial set of variables is taken from the users environment. Only the **DISPLAY** and **PRINTER** variables are exported by default.

Valid arguments for the **environ** command are:

define variable value

Define *variable* to have a value of *value*. Any variables defined by this command are automatically exported. The *value* may be enclosed in single or double quotes, so that tabs and spaces may be included.

undefine variable

Remove variable from the list of environment variables. export variable

export *variable* Mark the *variable* to be exported to the remote side.

unexport variable

Mark the *variable* to not be exported unless explicitly requested by the remote side.

list List the current set of environment variables. Those marked with an asterisk (*) will be sent automatically. Other variables will be sent only if explicitly requested.

? Prints out help information for the **environ** command.

logout Sends the **telnet logout** option to the remote side. This command is similar to a **close** command. However, if the remote side does not support the **logout** option, nothing happens. If, however, the remote side does support the **logout** option, this command should cause the remote side to close the TELNET connection. If the remote side also supports the concept of suspending a user's session for later reattachment, the **logout** argument indicates that the remote side should terminate the session immediately.

FILES \$HOME/.telnetrc

- **SEE ALSO rlogin**(1), **sh**(1), **stty**(1), **hosts**(4), **inet**(7P)
 - **NOTES** On some remote systems, echo has to be turned off manually when in "line by line" mode.

In "old line by line" mode, or LINEMODE the terminal's EOF character is only recognized (and sent to the remote system) when it is the first character on a line.

NAME	test – condition evaluation command			
SYNOPSIS	/usr/ucb/test e	xpression		
	[expression]			
AVAILABILITY	SUNWscpu			
	Soliwschu			
DESCRIPTION	test evaluates the expression <i>expression</i> and, if its value is true, sets a zero (true) exit status; otherwise, a non-zero (false) exit status is set; test also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.			
		All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to the test command; normally these items are separated by spaces.		
USAGE				
Primitives		primitives are used to construct <i>expression</i> :		
	- r filename	True if <i>filename</i> exists and is readable.		
	-w filename	True if <i>filename</i> exists and is writable.		
	-x filename	True if <i>filename</i> exists and is executable.		
	−f filename	True if <i>filename</i> exists and is a regular file. Alternatively, if /usr/bin/sh users specify /usr/ucb before /usr/bin in their PATH environment variable, then test will return true if <i>filename</i> exists and is (not–a–directory). This is also the default for /usr/bin/csh users.		
	-d filename	True if <i>filename</i> exists and is a directory.		
	–c filename	True if <i>filename</i> exists and is a character special file.		
	- b filename	True if <i>filename</i> exists and is a block special file.		
	- p filename	True if <i>filename</i> exists and is a named pipe (fifo).		
	- u filename	True if <i>filename</i> exists and its set-user-ID bit is set.		
	− g filename	True if <i>filename</i> exists and its set-group-ID bit is set.		
	-k filename	True if <i>filename</i> exists and its sticky bit is set.		
	–s filename	True if <i>filename</i> exists and has a size greater than zero.		
	-t [fildes]	True if the open file whose file descriptor number is <i>fildes</i> (1 by default) is associated with a terminal device.		
	- z s1	True if the length of string <i>s1</i> is zero.		
	- n <i>s1</i>	True if the length of the string <i>s1</i> is non-zero.		
	s1 = s2	True if strings <i>s1</i> and <i>s2</i> are identical.		
	s1 != s2	True if strings <i>s1</i> and <i>s2</i> are <i>not</i> identical.		
	s1	True if <i>s1</i> is <i>not</i> the null string.		

modified 26 Sep 1992

	n1 – eq n2	True if the integers $n1$ and $n2$ are algebraically equal. Any of the comparisons $-ne$, $-gt$, $-ge$, $-lt$, and $-le$ may be used in place of $-eq$.		
	–L filename	True if <i>filename</i> exists and is a symbolic link. With all other primitives, the symbolic links are followed by default.		
Operators	These primarie	s may be combined with the following operators:		
	!	Unary negation operator.		
	- a	Binary <i>and</i> operator.		
	-0	Binary <i>or</i> operator (– a has higher precedence than – o).		
	(expression)	Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.		
SEE ALSO	find (1), sh (1)			
NOTES	The not–a–directory alternative to the –f option is a transition aid for BSD applications and may not be supported in future releases.			
	The –L option is a migration aid for users of other shells which have similar options and may not be supported in future releases.			
	If you test a file you own (the -r , -w , or -x tests), but the permission tested does not have the <i>owner</i> bit set, a non-zero (false) exit status will be returned even though the file may have the <i>group</i> or <i>other</i> bit set for that permission. The correct exit status will be set if you are super-user.			
	The = and != operators have a higher precedence than the $-\mathbf{r}$ through $-\mathbf{n}$ operators, and = and != always expect arguments; therefore, = and != cannot be used with the $-\mathbf{r}$ through $-\mathbf{n}$ operators.			
		he argument follows the $-\mathbf{r}$ through $-\mathbf{n}$ operators, only the first argument is others are ignored, unless a $-\mathbf{a}$ or a $-\mathbf{o}$ is the second argument.

NAME	tftp – trivial file transfer program				
SYNOPSIS	tftp [host]				
AVAILABILITY	SUNWcsu				
DESCRIPTION	tftp is the user interface to the Internet TFTP (Trivial File Transfer Protocol), which allows users to transfer files to and from a remote machine. The remote <i>host</i> may be specified on the command line, in which case tftp uses <i>host</i> as the default host for future transfers (see the connect command below).				
USAGE	Once tftp is running, it issues the prompt tftp > and recognizes the following commands:				
Commands	connect <i>host-name</i> [<i>port</i>] Set the <i>host</i> (and optionally <i>port</i>) for transfers. The TFTP protocol, unlike the FTP protocol, does not maintain connections between transfers; thus, the connect command does not actually create a connection, but merely remembers what host is to be used for transfers. You do not have to use the connect command; the remote host can be specified as part of the get or put commands.				
	mode <i>transfer-mode</i> Set the mode for transfers; <i>transfer-mode</i> may be one of ascii or binary . The default is ascii .				
	put filename put localfile remotefile put filename1 filename2 filenameN remote-directory Transfer a file, or a set of files, to the specified remote file or directory. The destination can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form: host:filename				
	 to specify both a host and filename at the same time. If the latter form is used, the specified host becomes the default for future transfers. If the remote-directory form is used, the remote host is assumed to be running the UNIX system. Files may be written only if they already exist and are publicly writable (see in.tftpd(1M)). get filename get remotename localname 				
	<pre>get filename1 filename2 filename3 filenameN Get a file or set of files (three or more) from the specified remote sources. source can be in one of two forms: a filename on the remote host if the host has already been specified, or a string of the form: host:filename</pre>				
	to specify both a host and filename at the same time. If the latter form is used, the last host specified becomes the default for future transfers.

modified 19 May 1994

NAME	time – time a simple command			
SYNOPSIS	time [-p] utility [argument]			
AVAILABILITY	SUNWcsu			
DESCRIPTION	The time utility invokes <i>utility</i> operand with <i>argument</i> , and writes a message to standard error that lists timing statistics for <i>utility</i> . The message includes the following information:			
	• The elapsed (real) time between invocation of <i>utility</i> and its termination.			
	• The User CPU time, equivalent to the sum of the <i>tms_utime</i> and <i>tms_cutime</i> fields returned by the times (2) function for the process in which <i>utility</i> is executed.			
	• The System CPU time, equivalent to the sum of the <i>tms_stime</i> and <i>tms_cstime</i> fields returned by the times() function for the process in which <i>utility</i> is executed.			
	When time is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities a and c , respectively.			
	time a b c { time a } b c a b time c a b (time c)			
OPTIONS	The following option is supported:			
	-p Write the timing output to standard error in the following format: real %f\nuser %f\nsys %f\n <real seconds="">, <user seconds="">, <system seconds=""></system></user></real>			
OPERANDS	The following operands are supported:			
	<i>utility</i> The name of the utility that is to be invoked.			
	<i>argument</i> Any string to be supplied as an argument when invoking <i>utility</i> .			
USAGE	The time utility returns exit status 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication." The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked.			
EXAMPLES	It is frequently desirable to apply time to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the time applies to everything in the file.			
	Alternatively, the following command can be used to apply time to a complex command: time sh -c 'complex-command-line'			

modified 1 Feb 1995

	The following two examples show the differences between the csh version of time and the version in / usr/bin/time . These examples assume that csh is the shell in use. example% time find / -name csh.1 -print / usr/share/man/man1/csh.1 95.0u 692.0s 1:17:52 16% 0+0k 0+0io 0pf+0w See csh (1) for an explanation of the format of time output.		
	example% /usr/bin/time find / -name csh.1 -print /usr/share/man/man1/csh.1 real 1:23:31.5 user 1:33.2 sys 11:28.2		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of time : LC_CTYPE , LC_MESSAGES , LC_NUMERIC , NLSPATH , and PATH .		
EXIT STATUS	If utility is invoked, the exit status of time will be the exit status of utility; otherwise, thetime utility will exit with one of the following values:1–125An error occurred in the time utility.126utility was found but could not be invoked.127utility could not be found.		
SEE ALSO	csh(1), shell_builtins(1), timex(1), times(2), environ(5)		
NOTES	When the time command is run on a multiprocessor machine, the total of the values printed for user and sys can exceed real . This is because on a multiprocessor machine it is possible to divide the task between the various processors. When the command being timed is interrupted, the timing values displayed may not always be accurate.		
BUGS	Elapsed time is accurate to the second, while the CPU times are measured to the 100th second. Thus the sum of the CPU times can be up to a second larger than the elapsed time.		

modified 1 Feb 1995

NAME	times – shell built-in function to report time usages of the current shell
SYNOPSIS sh	times
ksh	† times
DESCRIPTION sh	Print the accumulated user and system times for processes run from the shell.
ksh	Print the accumulated user and system times for the shell and for processes run from the shell.
	On this man page, ksh (1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:
	1. Variable assignment lists preceding the command remain in effect when the command completes.
	2. I/O redirections are processed after variable assignments.
	3. Errors cause a script that contains them to abort.
	4. Words, following a command preceded by †† that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
SEE ALSO	ksh (1), sh (1), time (1)

modified 15 Apr 1994

NAME	timex – time a command; report process data and system activity			
SYNOPSIS	timex [–o]	[– p	[- fhkmrt]] [- s] command	
AVAILABILITY	SUNWaccu			
DESCRIPTION	The given <i>command</i> is executed; the elapsed time, user time and system time spent in execution are reported in seconds. Optionally, process accounting data for the <i>command</i> and all its children can be listed or summarized, and total system activity during the execution interval can be reported. The output of timex is written on standard error.			
OPTIONS	t	transf	rt the total number of blocks read or written and total characters Ferred by <i>command</i> and all its children. This option works only if the pro- ccounting software is installed.	
	- 1	works	rocess accounting records for <i>command</i> and all its children. This option s only if the process accounting software is installed. Suboptions f , h , k , and t modify the data items reported. The options are as follows:	
	-	-f	Print the fork (2) / exec (2) flag and system exit status columns in the output.	
	-	-h	Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This "hog factor" is computed as (total CPU time)/(elapsed time).	
	-	-k	Instead of memory size, show total kcore-minutes.	
	-	-m	Show mean core size (the default).	
	-	-r	Show CPU factor (user time/(system-time + user-time).	
	-	-t	Show separate system and user CPU times. The number of blocks read or written and the number of characters transferred are always reported.	
	i		rt total system activity (not just that due to <i>command</i>) that occurred dur- ne execution interval of <i>command</i> . All the data items listed in sar (1) are ted.	
EXAMPLES	A simple ex	ampl	e:	
		-	% timex –ops sleep 60	
		-	on of arbitrary complexity can be measured by timing a sub-shell:	
	example% timex –opskmt sh session commands			
	EOT			

modified 14 Sep 1992

SEE ALSO sar(1), **time**(1), **times**(2)

NOTES Process records associated with *command* are selected from the accounting file /**var/adm/pacct** by inference, since process genealogy is not available. Background processes having the same user ID, terminal ID, and execution time window will be spuriously included.

modified 14 Sep 1992

NAME	tip – connect to remote system				
SYNOPSIS	tip [-v] [-speed-entry] hostname phone-number				
AVAILABILITY	SUNWcsu				
DESCRIPTION	tip establishes a full-duplex terminal connection to a remote host. Once the connection is established, a remote session using tip behaves like an interactive session on a local terminal.				
	The <i>remote</i> file contains entries describing remote systems and line speeds used by tip .				
	Each host has a default baud rate for the connection, or you can specify a speed with the <i>–speed-entry</i> command line argument.				
	When <i>phone-number</i> is specified, tip looks for an entry in the <i>remote</i> file of the form:				
	tip -speed-entry				
	When it finds such an entry, it sets the connection speed accordingly. If it finds no such entry, tip interprets <i>–speed-entry</i> as if it were a system name, resulting in an error message.				
	If you omit <i>-speed-entry</i> , tip uses the tip0 entry to set a speed for the connection.				
	When establishing the connection tip sends a connection message to the remote system. The default value for this message can be found in the <i>remote</i> file.				
	When tip attempts to connect to a remote system, it opens the associated device with an exclusive-open ioctl (2) call. Thus only one user at a time may access a device. This is to prevent multiple processes from sampling the terminal line. In addition, tip honors the locking protocol used by uucp (1C).				
	When tip starts up it reads commands from the file .tiprc in your home directory.				
OPTIONS	-v Display commands from the .tiprc file as they are executed.				
USAGE	Typed characters are normally transmitted directly to the remote machine (which does the echoing as well).				
	At any time that tip prompts for an argument (for example, during setup of a file transfer) the line typed may be edited with the standard erase and kill characters. A null line in response to a prompt, or an interrupt, aborts the dialogue and returns you to the remote machine.				
Commands	A tilde (~) appearing as the first character of a line is an escape signal which directs tip to perform some special action. tip recognizes the following escape sequences: ~ D				
	 Drop the connection and exit (you may still be logged in on the remote machine). c [name] Change directory to name (no argument implies change to your home directory). 				

modified 13 Mar 1994

- ". Escape to an interactive shell on the local machine (exiting the shell returns you to **tip**).
- ~> Copy file from local to remote.
- ~ Copy file from remote to local.
- **~p** from [to]

Send a file to a remote host running the UNIX system. When you use the put command, the remote system runs the command string

cat > to

while **tip** sends it the *from* file. If the *to* file is not specified, the *from* file name is used. This command is actually a UNIX-system-specific version of the ">" command.

"t from [to]

Take a file from a remote host running the UNIX system. As in the put command the *to* file defaults to the *from* file name if it is not specified. The remote host executes the command string

cat from; echo ^A

to send the file to **tip**.

- Pipe the output from a remote command to a local process. The command string sent to the local system is processed by the shell.
- **~C** Connect a program to the remote machine. The command string sent to the program is processed by the shell. The program inherits file descriptors 0 as remote line input, 1 as remote line output, and 2 as tty standard error.
- ***** Pipe the output from a local process to the remote host. The command string sent to the local system is processed by the shell.
- *"#* Send a BREAK to the remote system.
- **s** Set a variable (see the discussion below).
- **~Z** Stop **tip** (only available when run under a shell that supports job control, such as the C shell).
- **~Y** Stop only the "local side" of **tip** (only available when run under a shell that supports job control, such as the C shell); the "remote side" of **tip**, the side that displays output from the remote host, is left running.
- **?** Get a summary of the tilde escapes.

Copying files requires some cooperation on the part of the remote host. When a ~> or ~< escape is used to send a file, **tip** prompts for a file name (to be transmitted or received) and a command to be sent to the remote system, in case the file is being transferred from the remote system. While **tip** is transferring a file the number of lines transferred will be continuously displayed on the screen. A file transfer may be aborted with an interrupt.

Auto-call Units	tip may be used to dial up remote systems using a number of auto-call unit's (ACU's). When the remote system description contains the du capability, tip uses the call-unit (d ACU type (at), and phone numbers (pn) supplied. Normally tip displays verbose messages as it dials.		
	Depending on the type of auto-dialer being used to establish a connection the remote host may have garbage characters sent to it upon connection. The user should never assume that the first characters typed to the foreign host are the first ones presented to it. The recommended practice is to immediately type a kill character upon establishing a connection (most UNIX systems either support @ or CTRL-U as the initial kill character).		
	tip currently supports the Ventel MD-212+ modem and DC Hayes-compatible modems.		
	When tip initializes a Hayes-compatible modem for dialing, it sets up the modem to auto-answer. Normally, after the conversation is complete, tip drops DTR, which causes the modem to "hang up."		
	Most modems can be configured such that when DTR drops, they re-initialize themselves to a preprogrammed state. This can be used to reset the modem and disable auto-answer, if desired.		
	Additionally, it is possible to start the phone number with a Hayes S command so that you can configure the modem before dialing. For example, to disable auto-answer, set up all the phone numbers in /etc/remote using something like pn=S0=0DT5551212 . The S0=0 disables auto-answer.		
Remote Host Description	Descriptions of remote hosts are normally located in the system-wide file /etc/remote. However, a user may maintain personal description files (and phone numbers) by defining and exporting the REMOTE shell variable. The <i>remote</i> file must be readable by tip , but a secondary file describing phone numbers may be maintained readable only by the user. This secondary phone number file is /etc/phones, unless the shell variable PHONES is defined and exported. The phone number file contains lines of the form:		
	system-name phone-number		
	Each phone number found for a system is tried until either a connection is established, or an end of file is reached. Phone numbers are constructed from ' 0123456789 –=*', where the '=' and '*' are used to indicate a second dial tone should be waited for (ACU dependent).		
tip Internal Variables	tip maintains a set of variables which are used in normal operation. Some of these variables are read-only to normal users (root is allowed to change anything of interest). Variables may be displayed and set through the s escape. The syntax for variables is patterned after vi (1) and mail (1). Supplying all as an argument to the s escape displays all variables that the user can read. Alternatively, the user may request display of a particular variable by attaching a ? to the end. For example "s escape?" displays the current escape character.		
	Variables are numeric (num), string (str), character (char), or Boolean (bool) values. Boolean variables are set merely by specifying their name. They may be reset by prepending a ! to the name. Other variable types are set by appending an = and the		

value. The entire assignment must not have any blanks in it. A single set command may be used to interrogate as well as set a number of variables.

Variables may be initialized at run time by placing set commands (without the **s** prefix) in a **.tiprc** file in one's home directory. The **-v** option makes **tip** display the sets as they are made. Comments preceded by a **#** sign can appear in the **.tiprc** file.

Finally, the variable names must either be completely specified or an abbreviation may be given. The following list details those variables known to **tip**.

beautify

(bool) Discard unprintable characters when a session is being scripted; abbreviated **be**. If the **nb** capability is present, **beautify** is initially set to **off**; otherwise, **beautify** is initially set to **on**.

baudrate

(num) The baud rate at which the connection was established; abbreviated **ba**. If a baud rate was specified on the command line, **baudrate** is initially set to the specified value; otherwise, if the **br** capability is present, **baudrate** is initially set to the value of that capability; otherwise, **baudrate** is set to 300 baud. Once **tip** has been started, **baudrate** can only changed by the super-user.

dialtimeout

(num) When dialing a phone number, the time (in seconds) to wait for a connection to be established; abbreviated **dial**. **dialtimeout** is initially set to 60 seconds, and can only changed by the super-user.

disconnect

(str) The string to send to the remote host to disconnect from it; abbreviated **di**. If the **di** capability is present, **disconnect** is initially set to the value of that capability; otherwise, **disconnect** is set to a null string ("").

echocheck

(bool) Synchronize with the remote host during file transfer by waiting for the echo of the last character transmitted; abbreviated **ec**. If the **ec** capability is present, **echocheck** is initially set to **on**; otherwise, **echocheck** is initially set to **off**.

eofread

(str) The set of characters which signify an end-of-transmission during a ~< file transfer command; abbreviated **eofr**. If the **ie** capability is present, **eofread** is initially set to the value of that capability; otherwise, **eofread** is set to a null string ("").

eofwrite

(str) The string sent to indicate end-of-transmission during a ~> file transfer command; abbreviated **eofw**. If the **oe** capability is present, **eofread** is initially set to the value of that capability; otherwise, **eofread** is set to a null string ("").

- **eol** (str) The set of characters which indicate an end-of-line. **tip** will recognize escape characters only after an end-of-line. If the **el** capability is present, **eol** is initially set to the value of that capability; otherwise, **eol** is set to a null string ("").
- escape (char) The command prefix (escape) character; abbreviated es. If the es capability is present, escape is initially set to the value of that capability; otherwise, escape is set to '~'.

etimeout

(num) The amount of time, in seconds, that **tip** should wait for the echo-check response when **echocheck** is set; abbreviated **et**. If the **et** capability is present, **etimeout** is initially set to the value of that capability; otherwise, **etimeout** is set to 10 seconds.

exceptions

(str) The set of characters which should not be discarded due to the beautification switch; abbreviated **ex**. If the **ex** capability is present, **exceptions** is initially set to the value of that capability; otherwise, **exceptions** is set to $^t n^f b$.

force (char) The character used to force literal data transmission; abbreviated fo. If the fo capability is present, force is initially set to the value of that capability; otherwise, force is set to \377 (which disables it).

framesize

(num) The amount of data (in bytes) to buffer between file system writes when receiving files; abbreviated **fr**. If the **fs** capability is present, **framesize** is initially set to the value of that capability; otherwise, **framesize** is set to 1024.

halfduplex

(bool) Do local echoing because the host is half-duplex; abbreviated hdx. If the hd capability is present, halfduplex is initially set to on; otherwise, halfduplex is initially set to off.

hardwareflow

(bool) Do hardware flow control; abbreviated **hf**. If the **hf** capability is present, **hardwareflow** is initially set to **on**; otherwise, **hardwareflowcontrol** is initially set to **off**.

host (str) The name of the host to which you are connected; abbreviated **ho**. **host** is permanently set to the name given on the command line or in the HOST environment variable.

localecho

(bool) A synonym for **halfduplex**; abbreviated **le**.

log (str) The name of the file to which to log information about outgoing phone calls. log is initially set to /var/adm/aculog, and can only be inspected or changed by the super-user.

parity	(str) The parity to be generated and checked when talking to the remote host;
	abbreviated par . The possible values are:

none

- **zero** Parity is not checked on input, and the parity bit is set to zero on output.
- **one** Parity is not checked on input, and the parity bit is set to one on output.
- even Even parity is checked for on input and generated on output.
- **odd** Odd parity is checked for on input and generated on output.

If the **pa** capability is present, **parity** is initially set to the value of that capability; otherwise, **parity** is set to **none**.

phones

The file in which to find hidden phone numbers. If the environment variable PHONES is set, **phones** is set to the value of PHONES; otherwise, **phones** is set to /**etc/phones**. The value of **phones** cannot be changed from within **tip**.

prompt

(char) The character which indicates an end-of-line on the remote host; abbreviated **pr**. This value is used to synchronize during data transfers. The count of lines transferred during a file transfer command is based on receipt of this character. If the **pr** capability is present, **prompt** is initially set to the value of that capability; otherwise, **prompt** is set to n.

raise (bool) Upper case mapping mode; abbreviated ra. When this mode is enabled, all lower case letters will be mapped to upper case by tip for transmission to the remote machine. If the ra capability is present, raise is initially set to on; otherwise, raise is initially set to off.

raisechar

(char) The input character used to toggle upper case mapping mode; abbreviated **rc**. If the **rc** capability is present, **raisechar** is initially set to the value of that capability; otherwise, **raisechar** is set to **\377** (which disables it).

- rawftp (bool) Send all characters during file transfers; do not filter non-printable characters, and do not do translations like \n to \r. Abbreviated raw. If the rw capability is present, rawftp is initially set to on; otherwise, rawftp is initially set to off.
- **record** (str) The name of the file in which a session script is recorded; abbreviated **rec**. If the **re** capability is present, **record** is initially set to the value of that capability; otherwise, **record** is set to **tip.record**.
- **remote** The file in which to find descriptions of remote systems. If the environment variable REMOTE is set, **remote** is set to the value of REMOTE; otherwise, **remote** is set to /**etc/remote**. The value of **remote** cannot be changed from within **tip**.
- script (bool) Session scripting mode; abbreviated sc. When script is on, tip will record everything transmitted by the remote machine in the script record file specified in record. If the beautify switch is on, only printable ASCII characters will be

	included in the script file (those characters between 040 and 0177). The variable exceptions is used to indicate characters which are an exception to the normal beautification rules. If the sc capability is present, script is initially set to on ; otherwise, script is initially set to off .
	tabexpand
	(bool) Expand TAB characters to SPACE characters during file transfers; abbrevi- ated tab . When tabexpand is on , each tab is expanded to 8 SPACE characters. If the tb capability is present, tabexpand is initially set to on ; otherwise, tabexpand is initially set to off .
	tandem
	(bool) Use XON/XOFF flow control to limit the rate that data is sent by the remote host; abbreviated ta . If the nt capability is present, tandem is initially set to off ; otherwise, tandem is initially set to on .
	verbose
	(bool) Verbose mode; abbreviated verb ; When verbose mode is enabled, tip prints messages while dialing, shows the current number of lines transferred during a file transfer operations, and more. If the nv capability is present, verbose is initially set to off ; otherwise, verbose is initially set to on .
	SHELL (str) The name of the shell to use for the ~! command; default value is /bin/sh, or
	taken from the environment.
	HOME (str) The home directory to use for the ~c command; default value is taken from the environment.
EXAMPLES	An example of the dialogue used to transfer files is given below. arpa% tip monet [connected] (assume we are talking to a UNIX system)
	(assume we are talking to a UNIX system) ucbmonet login: sam
	Password:
	monet% cat > sylvester.c
	~> Filename: sylvester.c
	32 lines transferred in 1 minute 3 seconds
	monet%
	monet% ~< Filename: reply.c List command for remote host: cat reply.c
	65 lines transferred in 2 minutes
	monet%
	(or, equivalently)
	monet% ~p sylvester.c
	(actually echoes as ~[put] sylvester.c)
	32 lines transferred in 1 minute 3 seconds
	monet% monet% ~t reply o
	monet% ~t reply.c (actually echoes as ~[take] reply.c)
	(actually conversion as [take] reply.c/

modified 13 Mar 1994

	65 lines transferred in 2 minutes monet% (to print a file locally) monet% ~ Local command: pr -h sylvester.c lpr List command for remote host: cat sylvester.c monet% ~ D [EOT] (back on the local system)
ENVIRONMENT	The following environment variables are read by tip .
	REMOTE The location of the <i>remote</i> file.
	PHONES The location of the file containing private phone numbers.
	HOST A default host to connect to.
	HOME One's log-in directory (for chdirs).
	SHELL The shell to fork on a '?' escape.
FILES	/etc/phones/etc/remote/var/spool/locks/LCK*lock file to avoid conflicts with UUCP/var/adm/aculogfile in which outgoing calls are logged~/.tiprcinitialization file
SEE ALSO	cu(1C), mail(1), uucp(1C), vi(1), ioctl(2)
BUGS	There are two additional variables chardelay and linedelay that are currently not imple- mented.

NAME	tnfdump – converts binary TNF file to ASCII
SYNOPSIS	tnfdump [-r] <i>tnf_file</i>
AVAILABILITY	SUNWtnfd
DESCRIPTION	tnfdump converts the specified binary TNF trace files to ASCII. The ASCII output can be used to do performance analysis. The default mode (without the -r option) prints all the event records (that were generated by TNF_PROBE (3X)) and the event descriptor records only. It also orders the events by time.
OPTIONS	-r Does a raw conversion of TNF to ASCII. The output is a literal transalation of the binary TNF file and includes all the records in the file. This output is useful only if you have a good understanding of TNF. A sample output is listed in EXAMPLES below.
RETURN VALUES	tnfdump returns 0 on successful exit.
EXAMPLES	To convert the file /tmp/trace-2130 into ASCII use: example% tnfdump /tmp/trace-2130 probe tnf_name: "inloop" tnf_string: "keys cookie main loop;file cookie2.c;line 50;sunw%debug in the loop" probe tnf_name: "end" tnf_string: "keys cookie main end;file cookie2.c;line 41;sunw%debug exiting program"
	Elapsed (ms) Delta (ms) PID LWPID TID CPU Probe Name Data / Description
	0.000000 0.000000 8792 1 0 - inloop loop_count: 0 total_iterations: 0 0.339000 0.339000 8792 1 0 - inloop loop_count: 1 total_iterations: 1 0.350500 0.011500 8792 1 0 - inloop loop_count: 2 total_iterations: 2 0.359500 0.009000 8792 1 0 - inloop loop_count: 3 total_iterations: 3 0.369500 0.010000 8792 1 0 - inloop loop_count: 4 total_iterations: 4 7775.969500 7775.600000 8792 1 0 - inloop loop_count: 1 total_iterations: 5 7776.016000 0.046500 8792 1 0 - inloop loop_count: 2 total_iterations: 6 7776.025000 0.009000 8792 1 0 - inloop loop_count: 3 total_iterations: 7 7776.034000 0.009000 8792 1 0 - inloop loop_count: 4 total_iterations: 9 7776.043000 0.009000 8792 1 0 - inloop loop_count: 5 total_iterations: 10 7776.061000 0.009000 8792<

All probes that are encountered during execution have a description of it printed out. The description is one per line prefixed by the keyword **'probe'**. The name of the probe is in double quotes after the keyword **'tnf_name'**. The description of this probe is in double quotes after the keyword **'tnf_string'**.

modified 14 Oct 1994

A heading is printed after all the description of the probes are printed. The first column gives the elapsed time in milli-seconds since the first event. The second column gives the elapsed time in milli-seconds since the previous event. The next four columns are the process id, lwp id, thread id, and cpu number. The next column is the name of the probe that generated this event. This can be matched to the probe description explained above. The last column is the data that the event contains formatted as **arg_name_n (see TNF_PROBE**(3X)) followed by a colon and the value of that argument. The format of the value depends on its type — **tnf_opaque** arguments are printed in hex, all other integers are printed in decimal, strings are printed in double quotes, and user defined records are enclosed in braces '{}'. The first field of a user defined record indicates its TNF type (see **TNF_DECLARE_RECORD**(3X)) and the rest of the fields are the members of the record.

A '-' in any column indicates that there is no data for that particular column.

To do a raw conversion of the file /tmp/trace-4000 into ASCII use:

example% tnfdump -r /tmp/trace-4000

```
The output will look like the following:
0x10e00 :{
         tnf_tag 0x109c0 tnf_block_header
       generation 1
      bytes_valid 320

modified 14 Oct 1994

The first number is the file offset of the record. The record is enclosed in braces '{ }'. The first column in a record is the slot name (for records whose fields do not have names, it is the type name). The second column in the record is the value of that slot if it is a scalar (only scalars that are of type **tnf_opaque** are printed in hex), or the offset of the record if it is a reference to another record.

The third column in a record is optional. It does not exist for scalar slots of records. If it exists, the third column is a type name with or without angle brackets, or a string in double quotes. Unadorned names indicate a reference to the named metatag record (i.e. a reference to a record with that name in the **tnf_name** field). Type names in angled brackets indicate a reference to a record that is an instance of that type (i.e., a reference to a record with that name in the **tnf_tag** field). The content of strings are printed out in double quotes at the reference site.

Records that are arrays have their array elements follow the header slots, and are numbered 0, 1, 2, etc., except strings where the string is written as the 'chars' (pseudo-name) slot.

Records that are events (generated by **TNF_PROBE**(3X)) will have a slot name of **tnf_tag_arg** as their second field which is a reference to the schedule record. Schedule records describe more information about the event like the thread-id, process-id, and the **time_base**. The **time_delta** of an event can be added to the **time_base** of the schedule record that the event references, to give an absolute time. This time is expressed as nanoseconds since some arbitrary time in the past (see **gethrtime**(3C)).

NAME	tnfxtract – ext	tnfxtract – extract kernel probes output into a trace file				
SYNOPSIS	tnfxtract [-d	dumpfile – n namelist] tnf_file				
AVAILABILITY	SUNWtnfc					
DESCRIPTION	tnfxtract collects kernel trace output from an in-core buffer in the Solaris kernel, or from the memory image of a crashed system, and generates a binary TNF trace file like those produced directly by user programs being traced.					
	trace output is names the file	neither of the $-d$ and $-n$ options must be specified. If neither is specified, extracted from the running kernel. If both are specified, the $-d$ argument containing the (crashed) system memory image, and the $-n$ argument containing the symbol table for the system memory image.				
	essentially a sı active, i.e., wh it generates is	The TNF trace file <i>tnf_file</i> produced is exactly the same size as the in-core buffer; it is essentially a snapshot of that buffer. It is legal to run tnfxtract while kernel tracing is active, i.e., while the in-core buffer is being written. tnfxtract insures that the output file it generates is low-level consistent, i.e., that only whole probes are written out, and that internal data structures in the buffer are not corrupted because the buffer is being con-				
	The TNF trace ASCII file.	file generated is suitable as input to tnfdump (1), which will generate an				
OPTIONS	The following	options are supported:				
	- d dumpfile	Use <i>dumpfile</i> as the system memory image, instead of the running kernel. The <i>dumpfile</i> is normally the path name of a file generated by the savecore utility.				
	– n namelist	Use <i>namelist</i> as the file containing the symbol table information for the given <i>dumpfile</i> .				
OPERANDS	The following	operand is supported:				
	tnf_file	output file generated by tnfxtract based on kernel trace output from an in-core buffer in the Solaris kernel.				
EXAMPLES	# Extract probes from the running kernel into ktrace.out. example% tnfxtract ktrace.out					
	example [®] tnf	es from a kernel crash dump into ktrace.out. xtract –d /var/crash/'uname –n'/vmcore.0 \ r/crash/'uname –n'/unix.0 ktrace.out				
EXIT STATUS	The following 0 >0	exit values are returned: Successful completion. An error occurred.

NAME	touch – change file access and modification times				
SYNOPSIS	touch [-acm] [-r ref_file] file touch [-acm] [-t time] file touch [-acm] [date_time] file				
AVAILABILITY	SUNWcsu				
DESCRIPTION	The touch utility will change the modification times, the access times, or both, of files. The time used can be specified by $-t$ <i>time</i> , by the corresponding time fields of the file referenced by $-\mathbf{r}$ <i>ref_file</i> , or by the <i>date_time</i> operand. If none of these are specified, touch will use the current time (the value returned by the time (2) system call). If neither the $-\mathbf{a}$ nor $-\mathbf{m}$ options were specified, touch will update both the modification and access times.				
OPTIONS	The followi -a -c -m -r ref_file -t time	 ing options are supported: Change the access time of <i>file</i>. Do not change the modification time unless -m is also specified. Do not create a specified <i>file</i> if it does not exist. Do not write any diagnostic messages concerning this condition. Change the modification time of <i>file</i>. Do not change the access time unless -a is also specified. Use the corresponding times of the file named by <i>ref_file</i> instead of the current time. Use the specified <i>time</i> instead of the current time. <i>time</i> will be a decimal number of the form: [[CC]YY]MMDDhhmm[.SS] where each two digits represents the following: MM The month of the year [01-12]. DD The day of the month [01-31]. <i>hh</i> The hour of the day [00-23]. mm The minute of the hour [00-59]. CC The first two digits of the year. YY The second two digits of the year. SS The second of the minute [00-61]. Both CC and YY are optional. If neither is given, the current year will be assumed. If YY is specified, but CC is not, CC will be derived as follows: 			

modified 1 Feb 1995

			If YY is:	CC becomes:			
			69-99	19			
			00-38	20			
			39-68	ERROR			
		The resulting time will be able. If the resulting time immediately with an err January 18, 2038.	ie value pre	cedes the Epoch	, touch will exit		
		The range for SS is (00–61) rather than (00–59) because of leap seconds. If SS is 60 or 61, and the resulting time, as affected by the TZ environment variable, does not refer to a leap second, the resulting time will be one or two seconds after a time where SS is 59. If SS is not given, it is assumed to be 0.					
OPERANDS	The followin	g operands are supported	d:				
	file	A path name of a file wh	nose times a	re to be modified	d.		
	date_time	Use the specified <i>date_time</i> instead of the current time. <i>date_time</i> is a decimal number of the form:					
		MMDDhhmm[yy]					
		where <i>MM</i> , <i>DD</i> , <i>hh</i> , and <i>mm</i> are as described for the <i>time</i> option-argument to the – t option and the optional <i>yy</i> is interpreted as follows:					
		If not specified, the current year will be used. If <i>yy</i> is in the range 69-99, the corresponding year 1969-1999 will be used; if <i>yy</i> is in the range 00-38, the corresponding year 2000-2038 will be used; if <i>yy</i> is in the range 39-68, an error will result.					
		If no – r option is specific are specified, and the fir the first operand will be first operand will be ass	st operand i assumed to	s an eight- or te be a <i>date_time</i> o	n-digit decimal integer,		
RETURN VALUES	touch returns the number of files for which the times could not be successfully modified.						
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of touch : LC_MESSAGES , NLSPATH , and TZ .						
EXIT STATUS	The followin	g exit values are returned	l:				
	0 touch ex	ecuted successfully and	all requested	d changes were i	made.		
	>0 An error	r occurred.					
SEE ALSO	time(2), envi	iron(5)					

1-1082

NOTES Users familiar with the BSD environment will find that the **-f** option is accepted, but ignored. The **-f** option is unnecessary since **touch** will succeed for all files owned by the user regardless of the permissions on the files.

touch(1B)	SunOS/BSD Compatibility Package Commands SunO	OS 5.5
NAME	touch – update the access and modification times of a file	
SYNOPSIS	touch [-c] [-f] filename	
AVAILABILITY	The System V version of this command is available with the <i>System V</i> software instaltion option. Refer to for information on how to install optional software.	lla-
DESCRIPTION	touch sets the access and modification times of each argument to the current time. <i>A</i> is created if it does not already exist.	A file
	touch is valuable when used in conjunction with make (1S), where, for instance, you might want to force a complete rebuild of a program composed of many pieces. In s a case, you might type:	
	example% touch *.c example% make	
	make (1S) would then see that all the .c files were more recent than the corresponding files, and would start the compilation from scratch.	g .o
OPTIONS	-c Do not create <i>filename</i> if it does not exist.	
	- f Attempt to force the touch in spite of read and write permissions on <i>filename</i>).
FILES	usr/ucb/touch BSD touch	
SEE ALSO	make(1S), utimes(2)

NAME	tput – initialize a terminal or query terminfo database					
SYNOPSIS		tput [–Ttype] capname [parm] tput –S <<				
AVAILABILITY	SUNWcsu	1				
DESCRIPTION	tput uses the terminfo database to make the values of terminal-dependent capabilities and information available to the shell (see sh (1)); to clear, initialize or reset the terminal; or to return the long name of the requested terminal type. tput outputs a string if the capability attribute (<i>capname</i>) is of type string, or an integer if the attribute is of type integer. If the attribute is of type boolean, tput simply sets the exit status (0 for TRUE if the terminal has the capability, 1 for FALSE if it does not), and produces no output. Before using a value returned on standard output, the user should test the exit status (\$?, see sh (1)) to be sure it is 0 . See the EXIT STATUS section.					
OPTIONS	–Ttype	Indicates the <i>type</i> of terminal. Normally this option is unnecessary, because the default is taken from the environment variable TERM . If $-\mathbf{T}$ is specified, then the shell variables LINES and COLUMNS and the layer size will not be referenced.				
	- S	Allows more than one capability per invocation of tput . The capabilities must be passed to tput from the standard input instead of from the command line (see the example in the EXAMPLES section). Only one <i>capname</i> is allowed per line. The – S option changes the meaning of the 0 and 1 boolean and string exit statuses (see the EXIT STATUS section).				
OPERANDS	The follow	lowing operands are supported:				
	capname					
		clear Display the clear-screen sequence.				
		init If the terminfo database is present and an entry for the user's terminal exists (see – <i>Ttype</i> , above), the following will occur:				
			(1)	if present, the terminal's initialization strings will be out- put (is1 , is2 , is3 , if , iprog),		
			(2)	any delays (for instance, newline) specified in the entry will be set in the tty driver,		
			(3)	tabs expansion will be turned on or off according to the specification in the entry, and		

			(4)	if tabs are not expanded, standard tabs will be set (every 8 spaces). If an entry does not contain the information needed for any of the four above activities, that activity will silently be skipped.		
		reset	strir strir	ead of putting out initialization strings, the terminal's reset ngs will be output if present (rs1 , rs2 , rs3 , rf). If the reset ngs are not present, but initialization strings are, the initial- ion strings will be output. Otherwise, reset acts identically nit .		
		longname	tern tern first	te terminfo database is present and an entry for the user's ninal exists (see $-Ttype$ above), then the long name of the ninal will be put out. The long name is the last name in the line of the terminal's description in the terminfo database term (5)).		
	parm		into t	a string that takes parameters, the argument <i>parm</i> will be he string. An all numeric argument will be passed to the ber.		
EXAMPLES	This example initializes the terminal according to the type of terminal in the environment variable TERM . This command should be included in everyone's .profile after the environment variable TERM has been exported, as illustrated on the profile (4) manual page.					
	The next ex	mple% tput i 1 ample resets a 1t variable TE F	n ATa	&T 5620 terminal, overriding the type of terminal in the		
	exa	mple% tput –	T5620) reset		
				ne sequence to move the cursor to row 0 , column 0 (the usually known as the "home" cursor position).		
	exa	mple% tput c	up 0 0			
	The next ex	ample echos tl	ne clea	ar-screen sequence for the current terminal.		
		mple% tput c				
		-		number of columns for the current terminal.		
		mple% tput c		the number of columns for the 450 terminal		
		mple% tput –	-	the number of columns for the 450 terminal.		
	Сла	mpie /0 tput –	1 100			

tput(1)

	The next example sets the shell variables bold , to begin stand-out mode sequence, and offbold , to end standout mode sequence, for the current terminal. This might be fol-
	lowed by a prompt:
	echo "\${bold}Please type in your name: \${offbold}\c"
	example% bold='tput smso' example% offbold='tput rmso'
	This example sets the exit status to indicate if the current terminal is a hardcopy terminal.
	example% tput hc
	This next example sends the sequence to move the cursor to row 23, column 4.
	example% tput cup 23 4
	The next command prints the long name from the terminfo database for the type of ter- minal specified in the environment variable TERM .
	example% tput longname
	This last example shows tput processing several capabilities in one invocation. This example clears the screen, moves the cursor to position 10, 10 and turns on bold (extra bright) mode. The list is terminated by an exclamation mark (!) on a line by itself.
	example% tput -S < clear > cup 10 10 > bold > !
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tput : LC_CTYPE, LC_MESSAGES, and NLSPATH.
	TERM Determine the terminal type. If this variable is unset or null, and if the –T option is not specified, an unspecified default terminal type will be used.
EXIT STATUS	The following exit values are returned:
	 If <i>capname</i> is of type boolean and -S is not specified, indicates TRUE. If <i>capname</i> is of type string and -S is not specified, indicates <i>capname</i> is defined for this terminal type. If <i>capname</i> is of type boolean or string and -S is specified, indicates that all lines were successful. <i>capname</i> is of type integer. The requested string was written successfully.
	 If <i>capname</i> is of type boolean and -S is not specified, indicates FALSE. If <i>capname</i> is fo type string and -S is not specified, indicates that <i>capname</i> is not defined for this terminal type.
	2 Usage error.
	3 No information is available about the specified terminal type.
	4 The specified operand is invalid.

NAME	tr – translate characters					
SYNOPSIS	/usr/bin/tr [-cs] string1 string2 /usr/bin/tr -s -d [-c] string1 /usr/bin/tr -ds [-c] string1 string2 /usr/bin/xpg4/tr [-cs] string1 string2 /usr/bin/xpg4/tr -s -d [-c] string1 /usr/bin/xpg4/tr -ds [-c] string1 string2					
AVAILABILITY /usr/bin/tr	SUNWcsu					
/usr/xpg4/bin/tr	SUNWxcu4					
DESCRIPTION	The tr utility copies the standard input to the standard output with substitution or dele- tion of selected characters. The options specified and the <i>string1</i> and <i>string2</i> operands control translations that occur while copying characters and single-character collating ele- ments.					
OPTIONS	The following options are supported:					
	-c Complement the set of characters specified by <i>string1</i> .					
	- d Delete all occurrences of input characters that are specified by <i>string1</i> .					
	-s Replace instances of repeated characters with a single character.					
	When the -d option is not specified:					
	• Each input character found in the array specified by <i>string1</i> is replaced by the character in the same relative position in the array specified by <i>string2</i> . When the array specified by <i>string2</i> is shorter that the one specified by <i>string1</i> , the results are unspecified.					
	• If the -c option is specified, the complements of the characters specified by <i>string1</i> (the set of all characters in the current character set, as defined by the current setting of LC_CTYPE, except for those actually specified in the <i>string1</i> operand) are placed in the array in ascending collation sequence, as defined by the current setting of LC_COLLATE. Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.					
	When the $-\mathbf{d}$ option is specified:					
	• Input characters found in the array specified by <i>string1</i> will be deleted.					
	• When the -c option is specified with -d , all characters except those specified by <i>string1</i> will be deleted.					
	• The contents of <i>string2</i> will be ignored, unless the – s option is also specified.					
I	• The same string cannot be used for both the -d and the -s option; when both options					

modified 30 Mar 1995

	are speci required		ing1 (used for deletion) and <i>string2</i> (used for squeezing) are				
	repeated see character, if operand cor tr -s the last oper in a case cor	quences of the the character itains a charac s ' [:space:] ' rand's array v iversion, as do	option is specified, after any deletions or translations have taken place, uences of the same character will be replaced by one occurrence of the same the character is found in the array specified by the last operand. If the last tains a character class, such as the following example: '[space:]' and's array will contain all of the characters in that character class. However, version, as described previously, such as '[:upper:]' '[:lower:]'				
	the last oper	rand's array v	nd's array will contain only those characters defined as the second charac- f the toupper or tolower character pairs, as appropriate.				
			<i>string1</i> or <i>string2</i> produces undefined results.				
OPERANDS		ng operands a	re supported:				
	string1						
	string2		control strings. Each string represents a set of characters to be nto an array of characters used for the translation.				
		The operands <i>string1</i> and <i>string2</i> (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, tr will exclude, without a diagnostic, those multi-character elements from the resulting array.					
		<i>character</i> Any character not described by one of the conventions below represents itself.					
		∖ octal	Octal sequences can be used to represent characters with specific coded values. An octal sequence consists of a backslash followed by the longest sequence of one-, two- or three-octal-digit characters (01234567). The sequence causes the character whose encoding is represented by the one-, two- or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading \ for each byte.				
		∖ character	The backslash-escape sequences a, b, f, n, r, t , and v are supported. The results of using any other character, other than an octal digit, following the backslash are unspecified.				
/usr/xpg4/bin/tr /usr/bin/tr	c-c [c-c]	inclusive, as	the range of collating elements between the range endpoints, s defined by the current setting of the LC_COLLATE locale he starting endpoint must precede the second endpoint in the ation order.				

modified 30 Mar 1995

The characters or collating elements in the range are placed in the array in ascending collation sequence.

[:class:] Represents all characters belonging to the defined character class, as defined by the current setting of the LC_CTYPE locale category. The following character class names will be accepted when specified in *string1*:

	alnum alpha	_	digit graph		punct space	- I I -
In additio	n, charact	er class ex	pressions	s of the fo	orm [: <i>nam</i> (e:] are recognized

in those locales where the *name* keyword has been given a **charclass** definition in the **LC_CTYPE** category.

When both the –d and –s options are specified, any of the character class names will be accepted in *string2*. Otherwise, only character class names **lower** or **upper** are valid in *string2* and then only if the corresponding character class **upper** and **lower**, respectively, is specified in the same relative position in *string1*. Such a specification is interpreted as a request for case conversion. When [:lower:] appears in *string1* and [:upper:] appears in *string2*, the arrays will contain the characters from the **toupper** mapping in the LC_CTYPE category of the current locale. When [:upper:] appears in *string1* and [:lower:] appears in *string2*, the arrays will contain the characters from the tourent locale. The first character from each mapping pair will be in the array for *string1* and the second character from each mapping pair will be in the array for *string2* in the same relative position.

Except for case conversion, the characters specified by a character class expression are placed in the array in an unspecified order.

If the name specified for *class* does not define a valid character class in the current locale, the behavior is undefined.

- [=equiv=] Represents all characters or collating elements belonging to the same equivalence class as equiv, as defined by the current setting of the LC_COLLATE locale category. An equivalence class expression is allowed only in *string1*, or in *string2* when it is being used by the combined -d and -s options. The characters belonging to the equivalence class are placed in the array in an unspecified order.
- [x*n] Represents *n* repeated occurrences of the character *x*. Because this expression is used to map multiple characters to one, it is only valid when it occurs in *string2*. If *n* is omitted or is **0**, it is interpreted as large enough to extend the *string2*-based sequence to the length of the *string1*-based sequence. If *n* has a leading **0**, it is interpreted as an octal value. Otherwise, it is interpreted as a decimal value.
- **EXAMPLES** 1. The following example creates a list of all words in *file1* one per line in *file2*, where a word is taken to be a maximal string of letters.

modified 30 Mar 1995

	tr -cs "[:alpha:]" "[\n*]" <file1>file2</file1>
	2. The next example translates all lower-case characters in file1 to upper-case and writes the results to standard output.
	tr "[:lower:]" "[:upper:]" <file1< th=""></file1<>
	Note that the caveat expressed in the corresponding example is no longer in effect. This case conversion is now a special case that employs the tolower and toupper classifications, ensuring that proper mapping is accomplished (when the locale is correctly defined).
	3. This example uses an equivalence class to identify accented variants of the base char- acter e in file1 , which are stripped of diacritical marks and written to file2 .
	tr "[=e=]" e <file1>file2</file1>
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tr: LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 All input was processed successfully.
	>0 An error occurred.
SEE ALSO	ed (1), sed (1), sh (1), ascii (5), environ (5)
NOTES	Will not handle ASCII NUL in <i>string1</i> or <i>string2</i> ; always deletes NUL from input.

modified 30 Mar 1995

tr	(1B)
----	---	----	---

NAME	tr – translate characters
SYNOPSIS	/usr/ucb/tr [–cds] [string1 [string2]]
AVAILABILITY	SUNWscpu
DESCRIPTION	tr copies the standard input to the standard output with substitution or deletion of selected characters. The arguments <i>string1</i> and <i>string2</i> are considered sets of characters. Any input character found in <i>string1</i> is mapped into the character in the corresponding position within <i>string2</i> . When <i>string2</i> is short, it is padded to the length of <i>string1</i> by duplicating its last character.
	In either string the notation: a–b
	denotes a range of characters from <i>a</i> to <i>b</i> in increasing ASCII order. The character \backslash , followed by 1, 2 or 3 octal digits stands for the character whose ASCII code is given by those digits. As with the shell, the escape character \backslash , followed by any other character, escapes any special meaning for that character.
OPTIONS	Any combination of the options $-c$, $-d$, or $-s$ may be used:
	-c Complement the set of characters in <i>string1</i> with respect to the universe of characters whose ASCII codes are 01 through 0377 octal.
	-d Delete all input characters in <i>string1</i> .
	- s Squeeze all strings of repeated output characters that are in <i>string2</i> to single characters.
EXAMPLES	The following example creates a list of all the words in <i>filename1</i> one per line in <i>filename2</i> , where a word is taken to be a maximal string of alphabetics. The second string is quoted to protect '\' from the shell. 012 is the ASCII code for NEWLINE. example% tr -cs A-Za-z '\012' < <i>filename1</i> > <i>filename2</i>
SEE ALSO	ed(1), ascii(5)
NOTES	Will not handle ASCII NUL in <i>string1</i> or <i>string2</i> . tr always deletes NUL from input.

modified 26 Sep 1992

NAME	trap, onintr – shell built-in functions to respond to (hardware) signals
SYNOPSIS sh	trap [<i>argument</i> n [<i>n2</i>]]
csh	onintr [– label]
ksh	† trap [<i>arg sig</i> [<i>sig2</i>]]
DESCRIPTION sh	The trap command <i>argument</i> is to be read and executed when the shell receives numeric or symbolic signal(s) (<i>n</i>). (Note: <i>argument</i> is scanned once when the trap is set and once when the trap is taken.) Trap commands are executed in order of signal number or corresponding symbolic names. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. An attempt to trap on signal 11 (memory fault) produces an error. If <i>argument</i> is absent all trap(s) <i>n</i> are reset to their original values. If <i>argument</i> is the null string this signal is ignored by the shell and by the commands it invokes. If <i>n</i> is 0 the command <i>argument</i> is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number.
csh	onintr controls the action of the shell on interrupts. With no arguments, onintr restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the – argument, the shell ignores all interrupts. With a <i>label</i> argument, the shell executes a goto <i>label</i> when an interrupt is received or a child process terminates because it was interrupted.
ksh	trap uses <i>arg</i> as a command to be read and executed when the shell receives signal(s) <i>sig</i> . (Note that <i>arg</i> is scanned once when the trap is set and once when the trap is taken.) Each <i>sig</i> can be given as a number or as the name of the signal. trap commands are executed in order of signal number. Any attempt to set a trap on a signal that was ignored on entry to the current shell is ineffective. If <i>arg</i> is omitted or is \neg , then the trap(s) for each <i>sig</i> are reset to their original values. If <i>arg</i> is the null (the empty string, e.g., "") string then this signal is ignored by the shell and by the commands it invokes. If <i>sig</i> is DEBUG then <i>arg</i> will be executed after each command. If <i>sig</i> is 0 or EXIT and the trap statement is executed inside the body of a function, then the command <i>arg</i> is executed after the function completes. If <i>sig</i> is 0 or EXIT for a trap set outside any function then the command <i>arg</i> is executed on exit from the shell. The trap command with no arguments prints a list of commands associated with each signal number.

modified 15 Apr 1994

On this man page, **ksh**(1) commands that are preceded by one or two † (daggers) are treated specially in the following ways:

- 1. Variable assignment lists preceding the command remain in effect when the command completes.
- 2. I/O redirections are processed after variable assignments.
- 3. Errors cause a script that contains them to abort.
- 4. Words, following a command preceded by *††* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	troff –	typeset or format documents	
SYNOPSIS	troff [-a] [-f] [-Fdir] [-i] [-mname] [-nN] [-olist] [-raN] [-sN] [-Tdest] [-uN] [-z] [filename]		
AVAILABILITY	SUNW	doc	
DESCRIPTION	troff formats text in the <i>filenames</i> for typesetting or laser printing. Input to troff is expected to consist of text interspersed with formatting requests and macros. If no <i>filename</i> argument is present, troff reads standard input. A minus sign (–) as a <i>filenam</i> indicates that standard input should be read at that point in the list of input files.		
	The fol filenam	lowing options may appear in any order, but all must appear before the first e.	
	- a	Send an ASCII approximation of formatted output to standard output.	
	-f	Do not print a trailer after the final page of output or cause the postprocessor to relinquish control of the device.	
	- F dir	Search directory <i>dir</i> for font width or terminal tables instead of the system default directory.	
	—i	Read standard input after all input files are exhausted.	
	– m nam	le	
		Prepend the macro file / usr / share / lib / tmac / <i>name</i> to the input <i>filenames</i> . Note: most references to macro packages include the leading <i>m</i> as part of the name; for example, the man (5) macros reside in / usr / share / lib / tmac / an . The macro direc- tory can be changed by setting the TROFFMACS environment variable to a specific path. Be certain to include the trailing ' / ' (slash) at the end of the path.	
	$-\mathbf{n}N$	Number the first generated page <i>N</i> .	
	-olist	Print only pages whose page numbers appear in the comma-separated <i>list</i> of numbers and ranges. A range $N-M$ means pages N through M ; an initial $-N$ means from the beginning to page N ; and a final N - means from N to the end.	
	$-\mathbf{q}$	Quiet mode in nroff ; ignored in troff .	
	-raN	Set register <i>a</i> (one-character names only) to <i>N</i> .	
	-sN	Stop the phototypesetter every <i>N</i> pages. On some devices, troff produces a trailer so you can change cassettes; resume by pressing the typesetter's start button.	
	–Tdest	Prepare output for typesetter <i>dest</i>. The following values can be supplied for <i>dest</i>:post A PostScript printer; this is the default value.aps Autologic APS-5.	
	$-\mathbf{u}N$	Set the emboldening factor for the font mounted in position 3 to N . If N is missing, then set the emboldening factor to 0.	
	- Z	Suppress formatted output. Only diagnostic messages and messages output using the .tm request are output.

NAME	true, false – provide truth values
SYNOPSIS	true false
AVAILABILITY	SUNWcsu
DESCRIPTION	<pre>true does nothing, successfully. false does nothing, unsuccessfully. They are typically used in a shell script sh as: while true do command done which executes command forever.</pre>
EXIT STATUS	true has exit status 0.
	false always will exit with a non-zero value.
SEE ALSO	sh (1)

	I	
NAME	truss – trace sy	stem calls and signals
SYNOPSIS		[–[tvx] [!]syscall] [–s [!]signal] [–m [!]fault] [–[rw] [!]fd] e] command –p pid
DESCRIPTION	forms, the sign put reports eith return value(s) defines from re	the specified command and produces a trace of the system calls it per- als it receives, and the machine faults it incurs. Each line of the trace out- ner the fault or signal name or the system call name with its arguments and . System call arguments are displayed symbolically when possible using elevant system headers; for any pathname pointer argument, the pointed- olayed. Error returns are reported using the error code names described in
OPTIONS	name all can be begins with a !, trace). Multipl	options are recognized. For those options that take a list argument, the e used as a shorthand to specify all possible members of the list. If the list the meaning of the option is negated (for example, exclude rather than e occurrences of the same option may be specified. For the same name in a t options (those to the right) override previous ones (those to the left).
	- p	Interpret the <i>command</i> arguments to truss as a list of process-ids for existing processes (see ps (1)) rather than as a command to be executed. truss takes control of each process and begins tracing it provided that the userid and groupid of the process match those of the user or that the user is a privileged user. Processes may also be specified by their names in the / proc directory, for example, / proc /12345.
	-f	Follow all children created by fork () or vfork () and include their signals, faults, and system calls in the trace output. Normally, only the first-level command or process is traced. When –f is specified, the process-id is included with each line of trace output to indicate which process executed the system call or received the signal.
	- c	Count traced system calls, faults, and signals rather than displaying the trace line-by-line. A summary report is produced after the traced command terminates or when truss is interrupted. If $-f$ is also specified, the counts include all traced system calls, faults, and signals for child processes.
	-a	Show the argument strings that are passed in each exec () system call.
	- e	Show the environment strings that are passed in each <code>exec()</code> system call.
	- i	Do not display interruptible sleeping system calls. Certain system calls, such as open () and read () on terminal devices or pipes can sleep for indefinite periods and are interruptible. Normally, truss reports such sleeping system calls if they remain asleep for more than one second. The system call is reported again a second time when it completes. The -i option causes such system calls to be reported only once, when they complete.

modified 29 Jul 1991

- l	Include the id of the responsible lightweight process with each line of trace output. If $-\mathbf{f}$ is also specified, both the process-id and the lightweight process id are included.
-t [!] <i>syscall,</i>	System calls to trace or exclude. Those system calls specified in the comma-separated list are traced. If the list begins with a !, the specified system calls are excluded from the trace output. Default is -tall .
− v [!] <i>syscall,</i>	Verbose. Display the contents of any structures passed by address to the specified system calls (if traced). Input values as well as values returned by the operating system are shown. For any field used as both input and output, only the output value is shown. Default is $-v!all$.
− x [!] <i>syscall,</i>	Display the arguments to the specified system calls (if traced) in raw form, usually hexadecimal, rather than symbolically. This is for unredeemed hackers who must see the raw bits to be happy. Default is $-x!all$.
−s [!] <i>signal,</i>	Signals to trace or exclude. Those signals specified in the comma- separated list are traced. The trace output reports the receipt of each specified signal, even if the signal is being ignored (not blocked). (Blocked signals are not received until they are unblocked.) Signals may be specified by name or number (see < sys/signal.h >). If the list begins with a !, the specified signals are excluded from the trace output. Default is - sall .
- m [!] <i>fault,</i>	Machine faults to trace or exclude. Those machine faults specified in the comma-separated list are traced. Faults may be specified by name or number (see <sys b="" fault.h<="">>). If the list begins with a !, the specified faults are excluded from the trace output. Default is -mall -m!fltpage.</sys>
− r [!] <i>fd,</i>	Show the full contents of the I/O buffer for each read () on any of the specified file descriptors. The output is formatted 32 bytes per line and shows each byte as an ascii character (preceded by one blank) or as a 2-character C language escape sequence for control characters such as horizontal tab (\t) and newline (\n). If ascii interpretation is not possible, the byte is shown in 2-character hexadecimal representation. (The first 12 bytes of the I/O buffer for each traced read () are shown even in the absence of -r .) Default is -r!all .
−w [!] <i>fd,</i>	Show the contents of the I/O buffer for each write() on any of the specified file descriptors (see $-\mathbf{r}$). Default is $-\mathbf{w}$!all.
- o outfile	File to be used for the trace output. By default, the output goes to stan- dard error.
	the <i>man Pages(2): System Calls</i> for system call names accepted by the -t , ons. System call numbers are also accepted.

modified 29 Jul 1991

truss	(1)

	If truss is used to initiate and trace a specified command and if the -0 option is used or if standard error is redirected to a non-terminal file, then truss runs with hangup, interrupt, and quit signals ignored. This facilitates tracing of interactive programs that catch interrupt and quit signals from the terminal. If the trace output remains directed to the terminal, or if existing processes are traced (the $-\mathbf{p}$ option), then truss responds to hangup, interrupt, and quit signals by releasing all traced processes and exiting. This enables the user to terminate excessive trace output and to release previously-existing processes. Released processes continue normally, as though they had never been touched.
EXAMPLES	This example produces a trace of the find (1) command on the terminal:
	example% truss find . –print >find.out
	Or, to see only a trace of the open, close, read, and write system calls:
	example% truss –t open,close,read,write find . –print >find.out
	This produces a trace of the spell (1) command on the file truss.out :
	example% truss –f –o truss.out spell document
	spell is a shell script, so the $-\mathbf{f}$ flag is needed to trace not only the shell but also the processes created by the shell. (The spell script runs a pipeline of eight concurrent processes.)
	A particularly boring example is:
	example% truss nroff -mm document >nroff.out
	because 97% of the output reports lseek (), read (), and write () system calls. To abbreviate it:
	example% truss -t !lseek,read,write nroff -mm document >nroff.out
	This example verbosely traces the activity of process #1, init (1M) (if you are a privileged user):
	example% truss –p –v all 1
	Interrupting truss returns init to normal operation.
FILES	/proc/nnnnn process files /proc/process-id
SEE ALSO	intro(2), proc(4)
NOTES	Some of the system calls described in Section 2 differ from the actual operating system interfaces. Do not be surprised by minor deviations of the trace output from the descriptions in Section 2.
	Every machine fault (except a page fault) results in the posting of a signal to the light- weight process that incurred the fault. A report of a received signal will immediately fol- low each report of a machine fault (except a page fault) unless that signal is being blocked.

modified 29 Jul 1991

The operating system enforces certain security restrictions on the tracing of processes. In particular, any command whose object file (**a.out**) cannot be read by a user cannot be traced by that user; set-uid and set-gid commands can be traced only by a privileged user. Unless it is run by a privileged user, **truss** loses control of any process that performs an **exec**() of a set-id or unreadable object file; such processes continue normally, though independently of **truss**, from the point of the **exec**().

To avoid collisions with other controlling processes, **truss** will not trace a process that it detects is being controlled by another process via the /**proc** interface. This allows **truss** to be applied to **proc**(4)-BASED debuggers as well as to another instance of itself.

The trace output contains tab characters under the assumption that standard tab stops are set (every eight positions).

The trace output for multiple processes or for a multithreaded process (one that contains more than one lightweight process) is not produced in strict time order. For example, a **read**() on a pipe may be reported before the corresponding **write**(). For any one lightweight process (a traditional process contains only one), the output is strictly time-ordered.

The system may run out of per-user process slots when tracing of children is requested. When tracing more than one process, **truss** runs as one controlling process for each process being traced. For the example of the **spell** command shown above, **spell** itself uses 9 process slots, one for the shell and 8 for the 8-member pipeline, while **truss** adds another 9 processes, for a total of 18. This is perilously close to the usual system-imposed limit of 25 processes per user.

Not all possible structures passed in all possible system calls are displayed under the $-\mathbf{v}$ option.

modified 29 Jul 1991

NAME	tset, reset – establish or restore terminal characteristics		
SYNOPSIS	tset [–InQrs] [–ec] [–kc] [–m [port –ID [baudrate] : type]] [type]		
	reset $[-] [-ec] [-I] [-kc] [-n] [-Q] [-r] [-s] [-m [indent] [test baudrate]: type] [type]$		
AVAILABILITY	SUNWscpu		
DESCRIPTION	tset sets up your terminal, typically when you first log in. It does terminal dependent processing such as setting erase and kill characters, setting or resetting delays, sending any sequences needed to properly initialized the terminal, and the like. tset first determines the <i>type</i> of terminal involved, and then does necessary initializations and mode settings. If a port is not wired permanently to a specific terminal (not hardwired) it is given an appropriate generic identifier such as dialup .		
	reset clears the terminal settings by turning off CBREAK and RAW modes, output delays and parity checking, turns on NEWLINE translation, echo and TAB expansion, and restores undefined special characters to their default state. It then sets the modes as usual, based on the terminal type (which will probably override some of the above). See stty (1) for more information. All arguments to tset may be used with reset . reset also uses rs = and rf = to reset the initialization string and file. This is useful after a program dies and leaves the terminal in a funny state. Often in this situation, characters will not echo as you type them. You may have to type LINEFEED reset LINEFEED since RETURN may not work.		
	When no arguments are specified, tset reads the terminal type from the TERM environ- ment variable and re-initializes the terminal, and performs initialization of mode, environment and other options at login time to determine the terminal type and set up terminal modes.		
	When used in a startup script (.profile for $sh(1)$ users or .login for $csh(1)$ users) it is desirable to give information about the type of terminal you will usually use on ports that are not hardwired. Any of the alternate generic names given in the file /etc/termcap are possible identifiers. Refer to the $-m$ option below for more information. If no mapping applies and a final <i>type</i> option, not preceded by a $-m$, is given on the command line then that type is used.		
	It is usually desirable to return the terminal type, as finally determined by tset , and information about the terminal's capabilities, to a shell's environment. This can be done using the $-$, $-$ s , or $-$ S options.		

	For the Bourne	shell, put this command in your .profile file:	
	eval `tset -s options`		
	or using the C s	shell, put these commands in your .login file:	
	set nog eval `ts unset r	set –s options…`	
	With the C shell, it is also convenient to make an alias in your .cshrc file:		
	alias ts ´eval `tset –s \!*`´		
	This also allows the command:		
	ts 2621		
	to be invoked at any time to set the terminal and environment. It is not possible to get this aliasing effect with a Bourne shell script, because shell scripts cannot set the environ- ment of their parent. If a process could set its parent's environment, none of this non- sense would be necessary in the first place.		
	involves sendir erase (and optic	nal type is known, tset sets the terminal driver mode. This normally ng an initialization sequence to the terminal, setting the single character onally the line-kill (full line erase)) characters, and setting special character d NEWLINE expansion are turned off during transmission of the terminal quence.	
		hat can backspace but not overstrike (such as a CRT), and when the erase the erase character is changed as if $-e$ had been used.	
OPTIONS	-	The name of the terminal finally decided upon is output on the standard output. This is intended to be captured by the shell and placed in the TERM environment variable.	
	- e <i>c</i>	Set the erase character to be the named character c on all terminals. Default is the BACKSPACE key on the keyboard, usually H (CTRL-H). The character c can either be typed directly, or entered using the circumflex-character notation used here.	
	-ic	Set the interrupt character to be the named character c on all terminals. Default is ^C (CTRL-C). The character c can either be typed directly, or entered using the circumflex-character notation used here.	
	- I	Suppress transmitting terminal-initialization strings.	
	- k c	Set the line kill character to be the named character <i>c</i> on all terminals. Default is U (CTRL-U). The kill character is left alone if $-\mathbf{k}$ is not specified. Control characters can be specified by prefixing the alphabetical character with a circumflex (as in CTRL-U) instead of entering the actual control key itself. This allows you to specify control keys that are currently assigned.	
	- n	Specify that the new tty driver modes should be initialized for this ter- minal. Probably useless since stty new is the default.	

modified 15 Feb 1995

1B-1105

	$-\mathbf{Q}$	Suppress printing the 'Erase set to' and 'Kill set to' messages.
	-r	In addition to other actions, reports the terminal type.
	s	Output commands to set and export TERM. This can be used with set noglob eval `tset -s` unset noglob
		to bring the terminal information into the environment. Doing so makes programs such as vi (1) start up faster. If the SHELL environment vari- able ends with csh , C shell commands are output, otherwise Bourne shell commands are output.
	– m [port-ID [ba	nudrate]: type] Specify (map) a terminal type when connected to a generic port (such as dialup or plugboard) identified by port-ID. The baudrate argument can be used to check the baudrate of the port and set the terminal type accordingly. The target rate is prefixed by any combination of the following operators to specify the conditions under which the mapping is made: > Greater than @ Equals or "at" < Less than ! It is not the case that (negates the above operators) ? Prompt for the terminal type. If no response is given, then type is selected by default.
		In the following example, the terminal type is set to adm3a if the port is a dialup with a speed of greater than 300 or to dw2 if the port is a dialup at 300 baud or less. In the third case, the question mark preceding the terminal type indicates that the user is to verify the type desired. A NULL response indicates that the named type is correct. Otherwise, the user's response is taken to be the type desired.
		tset −m 'dialup>300:adm3a' −m 'dialup:dw2' −m \ 'plugboard:?adm3a'
		To prevent interpretation as metacharacters, the entire argument to $-\mathbf{m}$ should be enclosed in single quotes. When using the C shell, exclamation points should be preceded by a backslash (\).
EXAMPLES	use the –e and –	all use the '-' option. A typical use of tset in a .profile or .login will also .k options, and often the $-\mathbf{n}$ or $-\mathbf{Q}$ options as well. These options have bre to keep the examples short.
	(or .profile for E set n eval	you might put the following sequence of commands in your .login file Bourne shell users). Boglob `tset —s 2621` et noglob

If you have a switch which connects to various ports (making it impractical to identify which port you may be connected to), and use various terminals from time to time, you can select from among those terminals according to the *speed* or baud rate. In the example below, **tset** will prompt you for a terminal type if the baud rate is greater than 1200 (say, 9600 for a terminal connected by an RS-232 line), and use a Wyse® 50 by default. If the baud rate is less than or equal to 1200, it will select a 2621. Note the placement of the question mark, and the quotes to protect the > and ? from interpretation by the shell. **set noglob**

```
eval `tset –s –m 'switch>1200:?wy' –m 'switch<=1200:2621'`
unset noglob
```

The following entry is appropriate if you always dial up, always at the same baud rate, on many different kinds of terminals, and the terminal you use most often is an **adm3a**.

```
set noglob
eval `tset –s ?adm3a`
unset noglob
```

If you want to make the selection based only on the baud rate, you might use the following:

```
set noglob
eval `tset -s -m '>1200:wy' 2621`
unset noglob
```

The following example quietly sets the erase character to BACKSPACE, and kill to CTRL-U. If the port is switched, it selects a Concept[™] 100 for speeds less than or equal to 1200, and asks for the terminal type otherwise (the default in this case is a Wyse 50). If the port is a direct dialup, it selects Concept 100 as the terminal type. If logging in over the ARPANET, the terminal type selected is a Datamedia® 2500 terminal or emulator. Note the backslash escaping the NEWLINE at the end of the first line in the example.

```
set noglob
eval `tset -e -k^U -Q -s -m 'switch<=1200:concept100' -m \
'switch:?wy' -m dialup:concept100 -m arpanet:dm2500`
unset noglob
```

```
FILES .login
.profile
/etc/termcap
```

SEE ALSO | **csh**(1), **sh**(1), **stty**(1), **vi**(1), **environ**(5)

```
NOTES The tset command is one of the first commands a user must master when getting started on a UNIX system. Unfortunately, it is one of the most complex, largely because of the extra effort the user must go through to get the environment of the login shell set. Something needs to be done to make all this simpler, either the login program should do this stuff, or a default shell alias should be made, or a way to set the environment of the parent should exist.
```

modified 15 Feb 1995

1B-1107

This program cannot intuit personal choices for erase, interrupt and line kill characters, so it leaves these set to the local system standards.

It could well be argued that the shell should be responsible for ensuring that the terminal remains in a sane state; this would eliminate the need for the **reset** program.

NAME	tsort – topological sort	
SYNOPSIS	/usr/ccs/bin/tsort [file]	
AVAILABILITY	SUNWbtool	
DESCRIPTION	The tsort command produces on the standard output a totally ordered list of items con- sistent with a partial ordering of items mentioned in the input <i>file</i> . The input consists of pairs of items (nonempty strings) separated by blanks. Pairs of dif- ferent items indicate ordering. Pairs of identical items indicate presence, but not order- ing.	
OPERANDS	The following operand is supported:fileA path name of a text file to order. If no file operand is given, the standard input is used.	
EXAMPLES	The command: tsort < <eof a b c c d e gg fg e f EOF produces the output: a b c d e f g</eof 	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of tsort : LC_CTYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.	
SEE ALSO	lorder(1), environ(5)	
DIAGNOSTICS	Odd data: there are an odd number of fields in the input file.	

modified 1 Feb 1995

NAME	tty – return user's terminal name		
SYNOPSIS	tty [–l] [–s]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The tty utility writes to the standard output the name of the terminal that is open as stan- dard input. The name that is used is equivalent to the string that would be returned by the ttyname (3C) function.		
OPTIONS	The following options are supported:		
	 Prints the synchronous line number to which the user's terminal is connected, if it is on an active synchronous line. 		
	 -s Inhibits printing of the terminal path name, allowing one to test just the exit status. 		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the execution of tty : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Standard input is a terminal.		
	1 Standard input is not a terminal.		
	>1 An error occurred.		
SEE ALSO	<pre>isatty(3C), ttyname(3C), environ(5)</pre>		
DIAGNOSTICS	not on an active synchronous line The standard input is not a synchronous terminal and –1 is specified.		
	not a tty The standard input is not a terminal and -s is not specified.		
NOTES	The $-s$ option is useful only if the exit status is wanted. It does not rely on the ability to form a valid path name. Portable applications should use test $-t$.		

NAME	type – write a description of command type		
SYNOPSIS	type name		
DESCRIPTION	The type utility indicates how each <i>name</i> operand would be interpreted if used as a com- mand. type displays information about each operand identifying the operand as a shell built-in, function, alias, hashed command, or keyword, and where applicable, may display the operand's path name. There is also a shell built-in version of type that is similar to the type utility.		
OPERANDS	The following operand is supported:		
	name A name to be interpreted.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of type: LC_CTYPE , LC_MESSAGES , and NLSPATH .		
	PATH Determine the location of <i>name</i> .		
EXIT STATUS	STATUS The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred.		
SEE ALSO	typeset(1), environ(5)		

modified 1 Feb 1995

typeset, whence – shell built-in functions to set/get attributes and values for shell variables and functions		
<pre>†† typeset [±HLRZfilrtux[n]] [name[=value]]</pre>		
whence [-pv] name		
 whence [-pv] name typeset sets attributes and values for shell variables and functions. When typeset is invoked inside a function, a new instance of the variables name is created. The variables value and type are restored when the function completes. The following list of attributes may be specified: H This flag provides UNIX to host-name file mapping on non-UNIX machines. L Eeft justify and remove leading blanks from value. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off. R Right justify and fill with leading blanks. If n is non-zero it defines the width of the field, otherwise, it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag has not been set. If n is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. F The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u and -x. The flag -t turns on execution tracing for this function. The flag -x allows the function definition to remain in effect across shell procedures invoked by name. Parameter is an integer. This makes arithmetic faster. If n is non-zero it defines the output base. All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off. The given names are marked readonly and these names cannot be changed by subsequent assignment. The given names are marked freadonly and these names cannot be changed by subsequent assignment. 		

The -i attribute can not be specified along with -R, -L, -Z, or -f.

Using + rather than – causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than – keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

For each *name*, **whence** indicates how it would be interpreted if used as a command name.

The –**v** flag produces a more verbose report.

The $-\mathbf{p}$ flag does a path search for *name* even if name is an alias, a function, or a reserved word.

On this man page, $\mathbf{ksh}(1)$ commands that are preceded by one or two \dagger (daggers) are treated specially in the following ways:

- 1. Variable assignment lists preceding the command remain in effect when the command completes.
- 2. I/O redirections are processed after variable assignments.
- 3. Errors cause a script that contains them to abort.
- 4. Words, following a command preceded by *††* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

ucblinks(1B)	SunOS/BSD Compatibility Package Commands Sur		SunOS 5.5
NAME	ucblinks – a	dds /dev entries to give SunOS 4.x compatible names to	SunOS 5.x devices
SYNOPSIS	/usr/ucb/ucblinks [–e rulebase] [–r rootdir]		
AVAILABILITY	SUNWscpu		
DESCRIPTION	ucblinks creates symbolic links under the / dev directory for devices whose SunOS 5.x names differ from their SunOS 4.x names. Where possible, these symbolic links point to the device's SunOS 5.x name rather than to the actual / devices entry.		
	ucblinks does not remove unneeded compatibility links; these must be removed by hand.		
	ucblinks sh SunOS 5.x li	ould be called each time the system is reconfiguration-be nks that are needed have been created, since the reconfig nore compatibility names being needed.	
	4.x compatil nawk rule-b	prior to SunOS 5.4, ucblinks used a nawk rule-base to co ble names. ucblinks no longer uses nawk for the defaul bases can still be specifed with the –e option. The nawk S 5.4 default operation can be found in /usr/ucblib/ucbli	t operation, although rule-base equivalent
OPTIONS	–e rulebase	Specify <i>rulebase</i> as the file containing nawk (1) pattern-a	action statements.
	– r rootdir	Specify <i>rootdir</i> as the directory under which dev and d rather than the standard root directory /.	evices will be found,
FILES	/usr/ucblib/	ucblinks.awk sample rule-base for compatibility links	;

NAME	ul – do underlining		
SYNOPSIS	ul [-i] [-t terminal] [filename]		
AVAILABILITY	SUNWdoc		
DESCRIPTION	ul reads the named <i>filenames</i> (or the standard input if none are given) and translates occurrences of underscores to the sequence which indicates underlining for the terminal in use, as specified by the environment variable TERM . ul uses the / usr/share/lib/terminfo entry to determine the appropriate sequences for underlining. If the terminal is incapable of underlining, but is capable of a standout mode then that is used instead. If the terminal can overstrike, or handles underlining automatically, ul degenerates to cat (1). If the terminal cannot underline, underlining is ignored.		
OPTIONS	 -t terminal Override the terminal kind specified in the environment. If the terminal cannot underline, underlining is ignored. If the terminal name is not found, no underlining is attempted. -i Indicate underlining by a separate line containing appropriate dashes '-'; this is useful when you want to look at the underlining which is present in an nroff(1) 		
	output stream on a CRT-terminal.		
RETURN VALUES	ul returns exit code 1 if the file specified is not found.		
FILES	/usr/share/lib/terminfo/*		
SEE ALSO	cat (1), man (1), nroff (1)		
BUGS	nroff usually generates a series of backspaces and underlines intermixed with the text to indicate underlining. ul makes attempt to optimize the backward motion.		

modified 17 Mar 1994

NAME	umask – get or set the file mode creation mask
SYNOPSIS	/usr/bin/umask [–S] [mask]
sh	umask [000]
csh	umask [000]
ksh	umask [–S] [<i>mask</i>]
DESCRIPTION /usr/bin/umask	The umask utility sets the file mode creation mask of the current shell execution environ- ment to the value specified by the <i>mask</i> operand. This mask affects the initial value of the file permission bits of subsequently created files. If umask is called in a subshell or separate utility execution environment, such as one of the following: (umask 002) nohup umask findexec umask it does not affect the file mode creation mask of the caller's environment. If the <i>mask</i> operand is not specified, the umask utility writes the value of the invoking process's file mode creation mask to standard output.
sh	The user file-creation mode mask is set to <i>ooo</i> . The three octal digits refer to read/write/execute permissions for owner, group, and other, respectively (see chmod (1), chmod (2), and umask (2)). The value of each specified digit is subtracted from the corresponding "digit" specified by the system for the creation of a file (see creat (2)). For example, umask 022 removes write permission for group and other (files normally created with mode 777 become mode 755 ; files created with mode 666 become mode 644). If <i>ooo</i> is omitted, the current value of the mask is printed. umask is recognized and executed by the shell. umask can be included in the user's .profile (see profile (4)) and invoked at login to automatically set the user's permissions on files or directories created.
csh	See the description above for the Bourne shell (sh) umask built-in.
ksh	The user file-creation mask is set to <i>mask</i> . <i>mask</i> can either be an octal number or a symbolic value as described in chmod (1). If a symbolic value is given, the new umask value is the complement of the result of applying <i>mask</i> to the complement of the previous umask value. If <i>mask</i> is omitted, the current value of the mask is printed.
OPTIONS	The following option is supported:
	- S Produce symbolic output.

The default output style is unspecified, but will be recognised on a subsequent invocation of **umask** on the same system as a *mask* operand to restore the previous file mode creation mask.

OPERANDS The following operand is supported:

mask	A string specifying the new file mode creation mask. The string is treated in the
	same way as the <i>mode</i> operand described in the chmod (1) manual page.
	For a <i>symbolic_mode</i> value, the new value of the file mode creation mask is the

logical complement of the file permission bits portion of the file mode specified by the *symbolic_mode* string.

In a *symbolic_mode* value, the permissions *op* characters + and – are interpreted relative to the current file mode creation mask; + causes the of for the indicated permissions to be cleared in the mask; – causes the bits of the indicated permissions to be set in the mask.

The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

The file mode creation mask is set to the resulting numeric value.

The default output of a prior invocation of **umask** on the same system with no operand will also be recognized as a *mask* operand. The use of an operand obtained in this way is not obsolescent, even if it is an octal number.

OUTPUT When the *mask* operand is not specified, the **umask** utility will write a message to standard output that can later be used as a **umask** *mask* operand.

If **-S** is specified, the message will be in the following format: "**u**=%**s**,**g**=%**s**,**o**=%**s****n**", *<owner permissions>*, *<group permissions>*, *<other permissions>* where the three values will be combinations of letters from the set {**r**, **w**, **x**}; the presence of a letter will indicate that the corresponding bit is clear in the file mode creation mask.

If a *mask* operand is specified, there will be no output written to standard output.

EXAMPLES Either of the commands:

umask a=rx,ug+w

umask 002

sets the mode mask so that subsequently created files have their S_IWOTH bit cleared.

After setting the mode mask with either of the above commands, the **umask** command can be used to write the current value of the mode mask:

\$ umask

0002

(The output format is unspecified, but historical implementations use the obsolescent octal integer mode format.)

\$ umask -S 1 u=rwx,g=rwx,o=rx

	Either of these outputs can be used as the mask operand to a subsequent invocation of the umask utility.
	Assuming the mode mask is set as above, the command:
	umask g-w sets the mode mask so that subsequently created files have their S_IWGRP, and S_IWOTH bits cleared.
	The command: umaskw
	sets the mode mask so that subsequently created files have all their write bits cleared. Note that <i>mask</i> operands \mathbf{r} , \mathbf{w} , \mathbf{x} or anything beginning with a hyphen, must be preceded by — to keep it from being interpreted as an option.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of umask : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	The following exit values are returned:
	0 The file mode creation mask was successfully changed, or no <i>mask</i>
	>0 An error occurred.
SEE ALSO	chmod(1), csh(1), ksh(1), sh(1), chmod(2), creat(2), profile(4), environ(5)

NAME	uname – print name of current system		
SYNOPSIS	uname [–aimnprsv] uname [–S system_name]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The uname utility prints information about the current system on the standard output. When options are specified, symbols representing one or more system characteristics will be written to the standard output. If no options are specified, uname prints the current operating system's name. The options print selected information returned by uname (2), sysinfo (2), or both.		
OPTIONS	The following o	ptions are supported:	
	-a	Print all information.	
	i	Print the name of the hardware implementation (platform).	
	- m	Print the machine hardware name (class).	
	-n	Print the nodename (the nodename is the name by which the system is known to a communications network).	
	$-\mathbf{p}$	Print the current host's processor type.	
	-r	Print the operating system release.	
	— s	Print the name of the operating system. This is the default.	
	$-\mathbf{v}$	Print the operating system version.	
	-S system_name	The nodename may be changed by specifying a system name argument. The system name argument is restricted to SYS_NMLN characters. SYS_NMLN is an implementation specific value defined in <sys utsname.h="">. Only the super-user is allowed this capability.</sys>	
EXAMPLES	The following co	ommand:	
	example	e% uname –sr	
	writes the opera	ting system name and release level, separated by one SPACE character.	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uname : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following e	xit values are returned:	
		ted information was successfully written.	
	>0 An error oc	-

NAME	unifdef –	resolve and remove ifdef ed lines from C program source	
SYNOPSIS	unifdef [-clt] [-Dname] [-Uname] [-iDname] [-iUname] [filename]	
DESCRIPTION	unifdef removes ifdef ed lines from a file while otherwise leaving the file alone. It is smart enough to deal with the nested ifdef s, comments, single and double quotes of C syntax, but it does not do any including or interpretation of macros. Neither does it strip out comments, though it recognizes and ignores them. You specify which symbols you want defined with –D options, and which you want undefined with –U options. Lines within those ifdef s will be copied to the output, or removed, as appropriate. Any ifdef , ifndef , else , and endif lines associated with <i>filename</i> will also be removed.		
		olving symbols you do not specify are untouched and copied out along with ciated ifdef , else , and endif lines.	
	If an ifdef <i>X</i> occurs nested inside another ifdef <i>X</i> , then the inside ifdef is treated as if it were an unrecognized symbol. If the same symbol appears in more than one argument, only the first occurrence is significant.		
	unifdef copies its output to the standard output and will take its input from the standard input if no <i>filename</i> argument is given.		
OPTIONS	- c	Complement the normal operation. Lines that would have been removed or blanked are retained, and vice versa.	
	- l	Replace "lines removed" lines with blank lines.	
	-t	Plain text option. unifdef refrains from attempting to recognize comments and single and double quotes.	
	– D name	Lines associated with the defined symbol <i>name</i> .	
	- U name	Lines associated with the undefined symbol <i>name</i> .	
	- iD name	Ignore, but print out, lines associated with the defined symbol <i>name</i> . If you use ifdefs to delimit non-C lines, such as comments or code which is under construction, then you must tell unifdef which symbols are used for that purpose so that it will not try to parse for quotes and comments within them.	
	-iUname	Ignore, but print out, lines associated with the undefined symbol <i>name</i> .	
SEE ALSO	diff (1)		
DIAGNOSTICS	Premature EOF Inappropriate else or endif .		
	Exit status	s is 1 if unifdef encounters problems, and 0 otherwise.	

modified 14 Jan 1992

NAME	uniq – report or filter out repeated lines in a file		
SYNOPSIS	uniq [-c -d -u] [-f fields] [-s char] [input_file [output_file]] uniq [-c -d -u] [-n] [+m] [input_file [output_file]]		
AVAILABILITY	SUNWesu		
DESCRIPTION	The uniq utility will read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines will not be written.		
	Repeated lir	nes in the input will not be detected if they are not adjacent.	
OPTIONS	The followi	ng options are supported:	
	- c	Precede each output line with a count of the number of times the line occurred in the input.	
	-d	Suppress the writing of lines that are not repeated in the input.	
	-f fields	Ignore the first <i>fields</i> fields on each input line when doing comparisons, where <i>fields</i> is a positive decimal integer. A field is the maximal string matched by the basic regular expression:	
		[[:blank:]]*[^[:blank:]]*	
		If <i>fields</i> specifies more fields than appear on an input line, a null string will be used for comparison.	
	–s chars	Ignore the first <i>chars</i> characters when doing comparisons, where <i>chars</i> is a positive decimal integer. If specified in conjunction with the –f option, the first <i>chars</i> characters after the first <i>fields</i> fields will be ignored. If <i>chars</i> specifies more characters than remain on an input line, a null string will be used for comparison.	
	–u	Suppress the writing of lines that are repeated in the input.	
	<i>-n</i>	Equivalent to $-\mathbf{f}$ fields with fields set to n .	
	+ <i>m</i>	Equivalent to $-s$ chars with chars set to m .	
OPERANDS	The following operands are supported:		
	input_file	A path name of the input file. If <i>input_file</i> is not specified, or if the <i>input_file</i> is –, the standard input will be used.	
	output_file	A path name of the output file. If <i>output_file</i> is not specified, the standard output will be used. The results are unspecified if the file named by <i>output_file</i> is the file named by <i>input_file</i> .

NAME	units – converts quantities expressed in standard scales to other scales		
SYNOPSIS	units		
AVAILABILITY	SUNWesu		
DESCRIPTION	units converts quantities expressed in various standard scales to their equivalents in other scales. It works interactively in this fashion:		
	You have: inch You want: cm * 2.540000e+00 / 3.937008e-01 A quantity is specified as a multiplicative combination of units optionally preceded by a		
	numeric multiplier. Powers are indicated by suffixed positive integers, division by the usual sign:		
	You have: 15 lbs force/in2 You want: atm * 1.020689e+00 / 9.797299e-01		
	units only does multiplicative scale changes; thus it can convert Kelvin to Rankine, but not Celsius to Fahrenheit. Most familiar units, abbreviations, and metric prefixes are recognized, together with a generous leavening of exotica and a few constants of nature including:		
	piratio of circumference to diameter,cspeed of light,echarge on an electron,gacceleration of gravity,forcesame as g,moleAvogadro's number,waterpressure head per unit height of water,auastronomical unit.		
	Pound is not recognized as a unit of mass; lb is. Compound names are run together, (for example, lightyear). British units that differ from their U.S. counterparts are prefixed thus: brgallon . For a complete list of units, type: cat /usr/share/lib/unittab		
FILES	/usr/share/lib/unittab		

modified 14 Sep 1992

NAME	unix2dos – convert text file from ISO format to DOS format		
SYNOPSIS	unix2dos [–ascii] [–iso] [–7] originalfile convertedfile		
AVAILABILITY	SUNWesu		
DESCRIPTION	unix2dos converts ISO standard characters to the corresponding characters in the DOS extended character set.		
	This command may be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.		
	If the original file and the converted file are the same, unix2dos will rewrite the original file after converting it.		
OPTIONS	-ascii Adds carriage returns and converts end of file characters in SunOS format text files to conform to DOS requirements.		
	-iso This is the default. Converts ISO standard characters to the corresponding char- acter in the DOS extended character set.		
	-7 Convert 8 bit SunOS characters to 7 bit DOS characters.		
DIAGNOSTICS	File <i>filename</i> not found, or no read permission The input file you specified does not exist, or you do not have read permission (check with the SunOS command ls – l).		
	Bad output filename <i>filename</i> , or no write permission The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.		
	Error while writing to temporary file An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Note that when this error occurs, the origi- nal file remains intact.		
	Could not rename tmpfile to <i>filename</i> . Translated tmpfile name = <i>filename</i> . The program could not perform the final step in converting your file. Your con- verted file is stored under the name indicated on the second line of this message.

NAME	uptime – show how long the system has been up
SYNOPSIS	uptime
AVAILABILITY	SUNWcsu
DESCRIPTION	The uptime command prints the current time, the length of time the system has been up, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. It is, essentially, the first line of a $w(1)$ command.
EXAMPLE	Below is an example of the output uptime provides: example% uptime 10:47am up 27 day(s), 50 mins, 1 user, load average: 0.18, 0.26, 0.20
SEE ALSO	w(1), who(1), whodo(1M)
NOTES	who – b gives the time the system was last booted.

NAME	users – display a compact list of users logged in
SYNOPSIS	/usr/ucb/users [filename]
AVAILABILITY	SUNWscpu
DESCRIPTION	users lists the login names of the users currently on the system in a compact, one-line for- mat.
	Specifying <i>filename</i> , tells users where to find its information; by default it checks / var/adm/utmp .
	Typing <i>users</i> is equivalent to typing who – q .
EXAMPLES	example% users paul george ringo example%
FILES	/var/adm/utmp

NAME	uucp, uulog, uu	ıname – UNIX-to-UNIX system copy	
SYNOPSIS	uucp [-c -C] [-d -f] [-g grade] [-jmr] [-n user] [-s file] [-x debug_level] source-file destination-file		
	uulog [–s sys]	[-f system] [-x] [-number] system	
	uuname [–c -	-1]	
AVAILABILITY	SUNWbnuu		
DESCRIPTION			
uucp	uucp copies file	es named by the <i>source-file</i> arguments to the <i>destination-file</i> argument.	
uulog		log file of uucp or uuxqt transactions in file / var/uucp/.Log/uucico / <i>system</i> og/uuxqt / <i>system</i> .	
uuname	uuname lists th	e names of systems known to uucp .	
OPTIONS			
uucp	The following o	options are supported by uucp :	
	- c	Do not copy local file to the spool directory for transfer to the remote machine (default).	
	- C	Force the copy of local files to the spool directory for transfer.	
	-d	Make all necessary directories for the file copy (default).	
	$-\mathbf{f}$	Do not make intermediate directories for the file copy.	
	− g grade	<i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The uuglist command can determine whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the uuglist command will be a list of service grades that are available, or a message that says to use a single letter or number as a grade of service.	
	-j	Print the uucp job identification string on standard output. This job identification can be used by uustat to obtain the status of a uucp job or to terminate a uucp job. The uucp job is valid as long as the job remains queued on the local system.	
	- m	Send mail to the requester when the copy is complete.	
	–n user	Notify <i>user</i> on the remote system that a file was sent.	
	-r	Do not start the file transfer, just queue the job.	
	– s file	Report status of the transfer to <i>file</i> . This option is accepted for compati- bility, but it is ignored because it is insecure.	
	– x debug_level	Produce debugging output on standard output. <i>debug_level</i> is a number between 0 and 9; as it increases to 9, more detailed debugging	

1C-1127

		information is given. This option may not be available on all systems.		
uulog	The following options cause uulog to print logging information:			
0	-s sys	Print information about file transfer work involving system <i>sys</i> .		
	-f system	Do a " tail $-\mathbf{f}$ " of the file transfer log for <i>system</i> . (You must hit BREAK to exit this function.)		
	Other option	is used in conjunction with the above options are:		
	- x	Look in the uuxqt log file for the given system.		
	-number	Execute a tail command of <i>number</i> lines.		
uuname	The followin	g options are supported by uuname :		
	- c	Display the names of systems known to cu . The two lists are the same, unless your machine is using different Systems files for cu and uucp . See the Sysfiles file.		
	- l	Display the local system name.		
OPERANDS	The source f	ile name may be a path name on your machine, or may have the form:		
	syste	em-name!pathname		
	where <i>system-name</i> is taken from a list of system names that uucp knows about. <i>source_file</i> is restricted to no more than one <i>system-name</i> . The destination <i>system-name</i> may also include a list of system names such as			
	system-name!system-name!!system-name!pathname			
	In this case, an attempt is made to send the file, using the specified route, to the destina- tion. Care should be taken to ensure that intermediate nodes in the route are willing to forward information (see NOTES below for restrictions).			
	For C-Shell users, the "" character must be surrounded by single quotes (), or preceded by a backslash (\).			
	The shell metacharacters ?, * and [] appearing in <i>pathname</i> will be expanded on the appropriate system.			
	Pathnames r	nay be one of the following:		
	(1)	An absolute pathname.		
	(2)	A pathname preceded by <i>~user</i> where <i>user</i> is a login name on the specified system and is replaced by that user's login directory.		
	(3)	A pathname preceded by ~/ <i>destination</i> where <i>destination</i> is appended to / var/spool/uucppublic . (Note: This destination will be treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that the destination is a directory, follow it with a '/'. For example ~/ dan / as the destination will make the directory / var/spool/uucppublic/dan if it does not exist and put the requested file(s) in that directory).		

	Anything else is prefixed by the current directory.		
	If the result is an erroneous path name for the remote system, the copy will fail. If the <i>destination-file</i> is a directory, the last part of the <i>source-file</i> name is used.		
	Invoking uucp with shell wildcard characters as the remote <i>source-file</i> invokes the uux (1C) command to execute the uucp command on the remote machine. The remote uucp command spools the files on the remote machine. After the first session terminates, if the remote machine is configured to transfer the spooled files to the local machine, the remote machine will initiate a call and send the files; otherwise, the user must "call" the remote machine to transfer the files from the spool directory to the local machine. This call can be done manually using Uutry (1M), or as a side effect of another uux (1C) or uucp call.		
	Note that the local machine must have permission to execute the uucp command on the remote machine in order for the remote machine to send the spooled files.		
	uucp removes execute permissions across the transmission and gives 0666 read and write permissions (see chmod (2)).		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uucp : LC_COLLATE , LC_CTYPE , LC_MESSAGES , LC_TIME , TZ , and NLSPATH .		
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
FILES	/etc/uucp/*other data files/var/spool/uucpspool directories/usr/lib/uucp/*other program files/var/spool/uucppublic/*public directory for receiving and sending		
SEE ALSO	mail(1), uuglist(1C), uustat(1C), uux(1C), Uutry(1M), uuxqt(1M), chmod(2)		
NOTES	For security reasons, the domain of remotely accessible files may be severely restricted. You will probably not be able to access files by path name; ask a responsible person on the remote system to send them to you. For the same reasons you will probably not be able to send files to arbitrary path names. As distributed, the remotely accessible files are those whose names begin / var/spool/uucppublic (equivalent to ~/).		
	All files received by uucp will be owned by uucp .		
	The –m option will only work when sending files or receiving a single file. Receiving multiple files specified by special shell characters ? , & , and [] will not activate the –m option.		
	The forwarding of files through other systems may not be compatible with the previous version of uucp . If forwarding is used, all systems in the route must have compatible versions of uucp .		

Protected files and files that are in protected directories that are owned by the requester can be sent by **uucp**. However, if the requester is root, and the directory is not searchable by "other" or the file is not readable by "other", the request will fail.

Strings that are passed to remote systems may not be evaluated in the same locale as the one in use by the process that invoked **uucp** on the local system.

Configuration files must be treated as C (or POSIX) locale text files.

NAME	uuencode, uudecode – encode a binary file, or decode its encoded representation
SYNOPSIS	uuencode [source-file] decode_pathname uudecode [-p] [encoded-file]
AVAILABILITY	SUNWesu
DESCRIPTION uuencode	uuencode converts a binary file into an encoded representation that can be sent using mail (1). It encodes the contents of <i>source-file</i> , or the standard input if no <i>source-file</i> argument is given. The <i>decode_pathname</i> argument is required. The <i>decode_pathname</i> is included in the encoded file's header as the name of the file into which uudecode is to place the binary (decoded) data. uuencode also includes the permission modes of <i>source-file</i> , (except setuid , setgid , and sticky-bits), so that <i>decode_pathname</i> is recreated with those same permission modes.
uudecode	 uudecode reads an <i>encoded-file</i>, strips off any leading and trailing lines added by mailer programs, and recreates the original binary data with the filename and the mode specified in the header. The encoded file is an ordinary portable character set text file; it can be edited by any text editor. It is best only to change the mode or <i>decode_pathname</i> in the header to avoid cor-
	rupting the decoded binary.
OPTIONS uudecode	-p decode <i>encoded-file</i> and send it to standard output. This allows uudecode to be used in a pipeline.
OPERANDS	
uuencode	The following operands are supported by uuencode : decode_pathname The pathname of the file into which the uudecode utility will place the decoded file. If there are characters in decode_pathname that are not in the portable filename character set the results are unspecified. source-file
	A pathname of the file to be encoded.
uudecode	The following operand is supported by uudecode : <i>encoded-file</i> The pathname of a file containing the output of uuencode .
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uuencode and uudecode : LC_CTYPE , LC_MESSAGES , and NLSPATH .

1C-1131

OUTPUT stdout	The standard output is a text file (encoded in the character set of the current locale) that begins with the line:		
	"begin∆%s∆%s\n", < mode >, decode_pathname		
	and ends with the line:		
	end\n		
	In both cases, the lines have no preceding or trailing blank characters.		
	The algorithm that is used for lines in between begin and end takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets are converted to characters by adding a value of 0x20 to each octet, so that each octet is in the range 0x20–0x5f, and then it is assumed to represent a printable character. It then will be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet 0x41, representing A , would be translated to A in the current codeset, such as 0xc1 if it were EBCDIC.)		
	Where the bits of two octets are combined, the least significant bits of the first octet are shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets A, B, C are converted into the four octets:		
	$\begin{array}{llllllllllllllllllllllllllllllllllll$		
	These octets are then translated into the local character set.		
	Each encoded line contains a length character, equal to the number of characters to be decoded plus 0x20 translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line is 45.		
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.		
SEE ALSO	mail (1), mailx (1), uucp (1C), uux (1C)		
NOTES	The encoded file's size is expanded by 35% (3 bytes become 4, plus control information), causing it to take longer to transmit than the equivalent binary.		
	The user on the remote system who is invoking uudecode (typically uucp) must have write permission on the file specified in the <i>decode_pathname</i> .		
	If you uuencode then uudecode a file in the same directory, you will overwrite the original file.		

NAME	uuglist – print the list of service grades that are available on this UNIX system
SYNOPSIS	uuglist [–u]
AVAILABILITY	SUNWbnuu
DESCRIPTION	uuglist prints the list of service grades that are available on the system to use with the $-g$ option of uucp (1C) and uux (1C).
OPTIONS	$-\mathbf{u}$ List the names of the service grades that the user is allowed to use with the $-\mathbf{g}$ option of the uucp and uux commands.
FILES	/etc/uucp/Grades contains the list of service grades
SEE ALSO	uucp(1C), uux(1C)

uustat (1C)		Communication Commands	SunOS 5.5
NAME SYNOPSIS	uustat [– uustat [–	ucp status inquiry and job control m] [–p] [–q] [–kjobid [–n]] [–rjobid [–n]] a] [–ssystem [–j]] [–uuser] [–Sqric] system [–c] [–dnumber]	
AVAILABILITY	SUNWbn	-	
DESCRIPTION	1.) Disp 2.) Prov or a 3.) Prov	nctions in the following three areas: plays the general status of, or cancels, previously specified uucp convides remote system performance information, in terms of average verage queue times. vides general remote system-specific and user-specific status of uuc s to other systems.	transfer rates
OPTIONS General Status		ions obtain general status of, or cancel, previously specified uucp of List all jobs in queue. List the total number of jobs displayed. The – j option can be used tion with the – a or the – s option. Kill the uucp request whose job identification is <i>jobid</i> . The killed must belong to the user issuing the uustat command unless the u super-user or uucp administrator. If the job is killed by the super	d in conjunc- uucp request iser is the
	-m -n	uucp administrator, electronic mail is sent to the user. Report the status of accessibility of all machines. Suppress all standard output, but not standard error. The –n opt conjunction with the –k and –r options.	
	-p -q	Execute the command ps – flp for all the process-ids that are in th List the jobs queued for each machine. If a status file exists for th its date, time and status information are reported. In addition, if appears in parentheses next to the number of C or X files, it is the of the oldest C ./ X . file for that system. The Retry field represents of hours until the next possible call. The Count is the number of attempts. Note: For systems with a moderate number of outstan this could take 30 seconds or more of real-time to execute. An ex- output produced by the – q option is: eagle 3C 04/07-11:07 NO DEVICES AVAILABLE mh3bs3 2C 07/07-10:42 SUCCESSFUL This indicates the number of command files that are waiting for e Each command file may have zero or more files to be sent (zero n the system and see if work is to be done). The date and time refer	e machine, a number e age in days s the number failure ading jobs, ample of the each system. neans to call

	 <i>-rjobid</i> previous interaction with the system followed by the status of the interaction. <i>-rjobid</i> Rejuvenate <i>jobid</i>. The files associated with <i>jobid</i> are touched so that their modification time is set to the current time. This prevents the cleanup daemon from deleting the job until the jobs' modification time reaches the limit imposed by the deemon 	
	imposed by the daemon.	
Remote System Status	These options provide remote system performance information, in terms of average transfer rates or average queue times; the $-c$ and $-d$ options can only be used in conjunction with the $-t$ option:	
	-tsystem Report the average transfer rate or average queue time for the past 60 minutes for the remote <i>system</i> . The following parameters can only be used with this option:	
	 -c Average queue time is calculated when the -c parameter is specified and average transfer rate when -c is not specified. For example, the command: 	
	example% uustat –teagle –d50 –c	
	produces output in the following format:	
	average queue time to eagle for last 50 minutes: 5 seconds	
	The same command without the -c parameter produces output in the follow- ing format:	
	average transfer rate with eagle for last 50 minutes: 2000.88 bytes/sec	
	- d <i>number</i> is specified in minutes. Used to override the 60 minute default used for calculations. These calculations are based on information contained in the optional performance log and therefore may not be available. Calculations can only be made from the time that the performance log was last cleaned up.	
User- or System- Specific Status	These options provide general remote system-specific and user-specific status of uucp connections to other systems. Either or both of the following options can be specified with uustat . The – j option can be used in conjunction with the – s option to list the total number of jobs displayed:	
	-ssystem Report the status of all uucp requests for remote system system.	
	- u <i>user</i> Report the status of all uucp requests issued by <i>user</i> .	
	Output for both the $-s$ and $-u$ options has the following format:	
	eagleN1bd7 4/07-11:07 S eagle dan 522 /home/dan/A	
	eagleC1bd8 4/07-11:07 S eagle dan 59 D.3b2al2ce4924 4/07-11:07 S eagle dan rmail mike	
	With the above two options, the first field is the <i>jobid</i> of the job. This is followed by the date/time. The next field is an S if the job is sending a file or an R if the job is requesting a file. The next field is the machine where the file is to be transferred. This is followed by the user-id of the user who queued the job. The next field contains the size of the file, or in the case of a remote execution (rmail is the command used for remote mail), the name of the command. When the size appears in this field, the file name is also given. This can	

1C-1135

either be the name given by the user or an internal name (for example, **D.3b2alce4924**) that is created for data files associated with remote executions (**rmail** in this example).

	- S <i>qric</i> Report the job state:
	q for queued jobs
	r for running jobs
	i for interrupted jobs
	c for completed jobs
	A job is queued if the transfer has not started. A job is running when the transfer has begun. A job is interrupted if the transfer began but was terminated before the file was completely transferred. A completed job is a job that successfully transferred. The completed state information is maintained in the accounting log, which is optional and therefore may be unavailable. The parameters can be used in any combination, but at least one parameter must be specified. The $-S$ option can also be used with $-s$ and $-u$ options. The output for this option is exactly like the output for $-s$ and $-u$ except that the job states are appended as the last output word. Output for a completed job has the following format:
	eagleC1bd3 completed
	When no options are given, uustat writes to standard output the status of all uucp requests issued by the current user.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uustat : LC_CTYPE, LC_MESSAGES, LC_TIME, TZ, and NLSPATH.
EXIT STATUS	The following exit values are returned:
	0 Successful completion.
	>0 An error occurred.
FILES	/var/spool/uucp/* spool directories /var/uucp/.Admin/account accounting log
	/var/uucp/.Admin/perflog performance log
	real adeptition period period hance log
SEE ALSO	uucp(1C)
DIAGNOSTICS	The –t option produces no message when the data needed for the calculations is not being recorded.
NOTES	
NOTES	After the user has issued the uucp request, if the file to be transferred is moved, deleted or was not copied to the spool directory (–C option) when the uucp request was made, uustat reports a file size of –99999. This job will eventually fail because the file(s) to be transferred can not be found.

NAME	uuto, uupick – p	oublic UNIX-to-UNIX system file copy
SYNOPSIS	uuto [-mp] sou	urce-file destination
	uupick [–s syste	em]
AVAILABILITY	SUNWbnuu	
DESCRIPTION uuto	allows the local	<i>ce-file</i> to <i>destination</i> . uuto uses the uucp (1C) facility to send files, while it system to control the file access. A source-file name is a path name on Destination has the form:
	system[!system] !user
		taken from a list of system names that uucp knows about. <i>User</i> is the omeone on the specified system.
	PUBDIR is a pub	-trees if directories are specified) are sent to PUBDIR on system , where blic directory defined in the uucp source. By default, this directory is public . Specifically the files are sent to
		/receive/user/mysystem/files.
	The recipient is	notified by mail (1) of the arrival of files.
uupick	PUBDIR for files	or rejects the files transmitted to the user. Specifically, uupick searches destined for the user. For each entry (file or directory) found, the folis printed on standard output:
	from sy	stem sysname: [file file-name] [dir dirname] ?
	uupick then rea	ds a line from standard input to determine the disposition of the file:
	<new-line></new-line>	Go to next entry.
	d	Delete the entry.
	m [<i>dir</i>]	Move the entry to named directory <i>dir</i> . If <i>dir</i> is not specified as a complete path name (in which \$HOME is legitimate), a destination relative to the current directory is assumed. If no destination is given, the default is the current directory.
	a [dir]	Same as m above, except it moves all the files sent from system .
	р	Print the content of the file.
	q	Stop.
	EOT (control-d)	Same as q .
	!command	Escape to the shell to do <i>command</i> .
	*	Print a command summary.

1C-1137

OPTIONS uuto	 The following options are supported by uuto: -m Send mail to the sender when the copy is complete. p Copy the source file into the speed directory before transmission 	
	- p Copy the source file into the spool directory before transmission.	
uupick	The following option is supported by uupick : - s system Search only the PUBDIR for files sent from system .	
OPERANDS	The following operands are supported for uuto :	
	destination	
	A string of the form:	
	system-name! user	
	where <i>system-name</i> is taken from a list of system names that uucp knows about; see uuname . The argument <i>user</i> is the login name of someone on the specified system. The destination <i>system-name</i> can also be a list of names such as <i>system-name</i> ! <i>system-name</i> !! <i>system-name</i> ! <i>user</i>	
	in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.	
	<i>source-file</i> A pathname of a file on the local system to be copied to <i>destination</i> .	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uuto and uupick : LC_TYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.	
FILES	PUBDIR /var/spool/uucppublic public directory	
SEE ALSO	mail(1), uucp(1C), uustat(1C), uux(1C), uucleanup(1M)	
NOTES	In order to send files that begin with a dot (for instance, .profile), the files must be qualified with a dot. For example, the following files are correct:	
	.profile .prof* .profil?	
	The following files are incorrect:	
	prof ?profile	

NAME	uux – UNIX-to-UNIX system command execution
SYNOPSIS	uux [–] [–bcCjnprz] [–a name] [–g grade] [–s filename] [–x debug_level] command-string
AVAILABILITY	SUNWbnuu
DESCRIPTION	uux will gather zero or more files from various systems, execute a command on a specified system and then send standard output to a file on a specified system.
	Note: For security reasons, most installations limit the list of commands executable on behalf of an incoming request from uux , permitting only the receipt of mail (see mail (1)). (Remote execution permissions are defined in / etc/uucp/Permissions .)
	The <i>command-string</i> is made up of one or more arguments that look like a shell command line, except that the command and file names may be prefixed by <i>system-name</i> !. A null <i>system-name</i> is interpreted as the local system.
	File names may be one of the following:
	• An absolute path name.
	• A path name preceded by <i>xxx</i> , where <i>xxx</i> is a login name on the specified system and is replaced by that user's login directory.
	Anything else is prefixed by the current directory.
	As an example, the command:
	example% uux "!diff sys1!/home/dan/filename1 sys2!/a4/dan/filename2 > !~/dan/filename.diff"
	will get the <i>filename1</i> and <i>filename2</i> files from the "sys1" and "sys2" machines, execute a diff (1) command and put the results in <i>filename.diff</i> in the local <i>PUBDIR</i> /dan/ directory. <i>PUBDIR</i> is a public directory defined in the uucp source. By default, this directory is /var/spool/uucppublic.
	Any special shell characters such as \langle , \rangle , $;$, $ $ should be quoted either by quoting the entire <i>command-string</i> , or quoting the special characters as individual arguments. The redirection operators \rangle , $\langle <, \rangle $ and \rangle & cannot be used.
	uux will attempt to get all appropriate files to the specified system where they will be processed. For files that are output files, the file name must be escaped using parentheses. For example, the command:
	example% uux "a!cut -f1 b!/usr/filename > c!/usr/filename"
	gets "/ usr/filename " from system " b " and sends it to system " a ", performs a cut command on that file and sends the result of the cut command to system " c ".
	uux will notify you if the requested command on the remote system was disallowed. This notification can be turned off by the $-n$ option. The response comes by remote mail from the remote machine.

1C-1139

OPTIONS	_	The standard input to uux is made the standard input to the <i>command-string</i> .
	– a name	Use <i>name</i> as the user job identification replacing the initiator user-id. (Notification will be returned to user-id <i>name.)</i>
	-b	Return whatever standard input was provided to the uux command if the exit status is non-zero.
	- c	Do not copy local file to the spool directory for transfer to the remote machine (default).
	- C	Force the copy of local files to the spool directory for transfer.
	− g grade	<i>grade</i> can be either a single letter, number, or a string of alphanumeric characters defining a service grade. The uuglist (1C) command determines whether it is appropriate to use the single letter, number, or a string of alphanumeric characters as a service grade. The output from the <i>uuglist</i> command will be a list of service grades that are available or a message that says to use a single letter or number as a grade of service.
	-j	Output the jobid string on the standard output which is the job identification. This job identification can be used by uustat (1C) to obtain the status or terminate a job.
	-n	Do not notify the user if the command fails.
	- p	Same as –: The standard input to uux is made the standard input to the <i>command-string</i> .
	-r	Do not start the file transfer, just queue the job.
	− s filename	Report status of the transfer in <i>filename</i> . This option is accepted for compatibility, but it is ignored because it is insecure.
	– x debug_level	Produce debugging output on the standard output. <i>debug_level</i> is a number between 0 and 9; as it increases to 9, more detailed debugging information is given.
	- Z	Send success notification to the user.
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of uux : LC_CTYPE , LC_MESSAGES , and NLSPATH .	
EXIT STATUS	The following exit values are returned:0Successful completion.>0An error occurred.	
FILES	/etc/uucp/* /etc/uucp/Perm /usr/lib/uucp/* /var/spool/uucj	other programs

1C-1140

SEE ALSO | **cut**(1), **mail**(1), **uucp**(1C), **uuglist**(1C), **uustat**(1C)

NOTES The execution of commands on remote systems takes place in an execution directory known to the **uucp** system.

All files required for the execution will be put into this directory unless they already reside on that machine. Therefore, the simple file name (without path or machine reference) must be unique within the **uux** request. The following command will NOT work:

```
example% uux "a!diff b!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"
```

But the command:

example% uux "a!diff a!/home/dan/xyz c!/home/dan/xyz > !xyz.diff"

will work. (If **diff** is a permitted command.)

Protected files and files that are in protected directories that are owned by the requester can be sent in commands using **uux**. However, if the requester is root, and the directory is not searchable by "other", the request will fail.

The following restrictions apply to the shell pipeline processed by **uux**:

• In gathering files from different systems, pathname expansion in not performed by **uux**. Thus, a request such as

uux "c89 remsys!~/*.c"

would attempt to copy the file named literally *.c to the local system.

- Only the first command of a shell pipeline may have a *system-name*!. All other commands are executed on the system of the first command.
- The use of the shell metacharacter * will probably not do what you want it to do.
- The shell tokens << and >> are not implemented.
- The redirection operators >>, <<, >| and >& cannot be used.
- The reserved word ! cannot be used at the head of the pipeline to modify the exit status.
- Alias substitution is not performed.

NAME	vacation – reply to mail automatically
SYNOPSIS	vacation [–I] vacation [–j] [–a alias] [–tN] username
AVAILABILITY	SUNWcsu
DESCRIPTION	vacation automatically replies to incoming mail.
Installation	The installation consists of an interactive program which sets up vacation 's basic configuration.
	To install vacation , type it with no arguments on the command line. The program creates a .vacation.msg file, which contains the message that is automatically sent to all senders when vacation is enabled, and starts an editor for you to modify the message. (See USAGE section.) Which editor is invoked is determine by the VISUAL or EDITOR environment variable, or vi (1) if neither of those environment variables are set.
	A .forward file is also created if one does not exist in your home directory. Once created, the .forward file will contain a line of the form:
	\username, " /usr/bin/vacation username"
	One copy of an incoming message is sent to the <i>username</i> and another copy is piped into vacation .
	If a .forward file is present in your home directory, it will ask whether you want to remove it, which disables vacation and ends the installation.
	The program automatically creates .vacation.pag and .vacation.dir , which contain a list of senders when vacation is enabled.
Activation and Deactivation	The presence of the .forward file determines whether or not vacation is disabled or enabled. To disable vacation remove the .forward file, or move it to a new name.
Initialization	vacation – I clears the vacation log files, .vacation.pag and .vacation.dir , erasing the list of senders from a previous vacation session. (See OPTIONS section).
Additional Configuration	vacation provides configuration options that are not part of the installation, these being $-j$, $-a$, $-t$. (See OPTIONS section).
OPTIONS	 Initialize the .vacation.pag and .vacation.dir files and enables vacation. If the -I flag is not specified, and a <i>user</i> argument is given, vacation reads the first line from the standard input (for a From: line, no colon). If absent, it produces an error message.

	Options – j , – a , – t are configuration options to be used in conjunction with vacation in the .forward file, not on the command line. For example,			
	\username, " /usr/bin/vacation -t1m username"			
	repeats replies to the sender every minute.			
	-j Do not check whether the recipient appears in the To: or the Cc: line.			
	-a alias Indicate that alias is one of the valid aliases for the user running vacation, so that mail addressed to that alias generates a reply.			
	 -tN Change the interval between repeat replies to the same sender. The default is 1 week. A trailing s, m, h, d, or w scales N to seconds, minutes, hours, days, or weeks respectively. 			
USAGE Files	.vacation.msg should include a header with at least a Subject: line (it should not include a From: or a To: line). For example:			
	Subject: I am on vacation I am on vacation until July 22. If you have something urgent, please contact Joe Jones (jones@fB0). John			
	If the string \$SUBJECT appears in the .vacation.msg file, it is replaced with the subject of the original message when the reply is sent; thus, a .vacation.msg file such as			
	Subject: I am on vacation I am on vacation until July 22. Your mail regarding "\$SUBJECT" will be read when I return. If you have something urgent, please contact Joe Jones (jones@fB0). John			
	will include the subject of the message in the reply.			
	No message is sent if the To : or the Cc : line does not list the user to whom the original message was sent or one of a number of aliases for them, if the initial From line includes the string –REQUEST @, or if a Precedence: bulk or Precedence: junk line is included in the header.			
	vacation will also not respond to mail from either postmaster or Mailer-Daemon.			
FILES	~/.forward ~/.vacation.msg			
	A list of senders is kept in the dbm format files .vacation.pag and .vacation.dir in your home directory. These files are dbm files and cannot be viewed directly with text editors.			
SEE ALSO	vi(1), sendmail(1M), dbm(3B), aliases(4)			

NAME	vc – version co	ntrol		
SYNOPSIS	vc [-a] [-t] [-cchar] [-s] [keyword=value keyword=value]			
DESCRIPTION	This command	is obsolete and will be removed in the next release.		
	trol of its argur the process of J	nd copies lines from the standard input to the standard output under con- nents and of "control statements" encountered in the standard input. In performing the copy operation, user-declared <i>keywords</i> may be replaced by <i>ue</i> when they appear in plain text and/or control statements.		
	 The copying of lines from the standard input to the standard output is conditional, based on tests (in control statements) of keyword values specified in control statements or as vc command arguments. A control statement is a single line beginning with a control character, except as modified by the -t keyletter (see below). The default control character is colon (:), except as modified by the -c keyletter (see below). Input lines beginning with a backslash (\) followed by a control character are not control lines and are copied to the standard output with the backslash removed. Lines beginning with a backslash followed by a non-control character are copied in their entirety. 			
	A keyword is composed of 9 or less alphanumerics; the first must be alphabetic. A value is any ASCII string that can be created with ed ; a numeric value is an unsigned string of digits. Keyword values may not contain blanks or tabs.			
	Replacement of keywords by values is done whenever a keyword surrounded by control characters is encountered on a version control statement. The $-a$ keyletter (see below) forces replacement of keywords in all lines of text. An uninterpreted control character may be included in a value by preceding it with \setminus . If a literal \setminus is desired, then it too must be preceded by \setminus .			
OPTIONS	- a	Forces replacement of keywords surrounded by control characters with their assigned value in all text lines and not just in vc statements.		
	t	All characters from the beginning of a line up to and including the first tab character are ignored for the purpose of detecting a control state- ment. If a control statement is found, all characters up to and including the tab are discarded.		
	–cchar	Specifies a control character to be used in place of the ":" default.		
	- S	Silences warning messages (not error) that are normally printed on the diagnostic output.		
	vc recognizes the following version control statements:			
	:dcl keyword[,, keyword] Declare keywords. All keywords must be declared.			

1-1144

modified 5 Jul 1990

:asg keyword=value

. . .

Assign values to keywords. An **asg** statement overrides the assignment for the corresponding keyword on the **vc** command line and all previous **asg** statements for that keyword. Keywords that are declared but are not assigned values have null values.

```
:if condition
```

:end

Skip lines of the standard input. If the condition is true, all lines between the **if** statement and the matching **end** statement are copied to the standard output. If the condition is false, all intervening lines are discarded, including control statements. Note: Intervening **if** statements and matching **end** statements are recognized solely for the purpose of maintaining the proper **if-end** matching.

The syntax of a condition is:

<cond></cond>	::= ['' not ''] <i><or></or></i>
<0r>	::= <and> / <and> '' '' <or></or></and></and>
<and></and>	::= <exp> <exp> ``&`` <and></and></exp></exp>
<exp></exp>	::= ''('' <or> '')'' <value> <op> <value></value></op></value></or>
<i><op></op></i>	::= ``=`` ``!=`` ``<`` ``>``
<value></value>	::= <arbitrary ascii="" string=""> <numeric string=""></numeric></arbitrary>

The available operators and their meanings are:

=	equal
!=	not equal
&	and
	or
>	greater than
<	less than
()	used for logical groupings
not	may only occur immediately after the if , and when present,
	inverts the value of the entire condition

The > and < operate only on unsigned integer values (for example, : **012** > **12** is false). All other operators take strings as arguments (for example, : **012** != **12** is true).

The precedence of the operators (from highest to lowest) is:

= != > < all of equal precedence
&
</pre>

Parentheses may be used to alter the order of precedence.

Values must be separated from operators or parentheses by at least one blank or tab.

NAME	vgrind – grind nice program listin	gs	
SYNOPSIS	vgrind [–2fntwWx] [–d defs-file] [–Pprinter] [–Toutput-device	[-h header] [-l language] [-s n] [-o pagelist] e] filename	
AVAILABILITY	SUNWdoc		
DESCRIPTION		es named by the <i>filename</i> arguments in a nice style red in italics, keywords in bold face, and as each func- ed on the page margin.	
	vgrind runs in two basic modes, filter mode or regular mode. In filter mode vgrind acts as a filter in a manner similar to tbl (1). The standard input is passed directly to the standard output except for lines bracketed by the troff -like macros:		
	.vS starts processing		
	.vE ends processing		
	These lines are formatted as described above. The output from this filter can be troff for output. There need be no particular ordering with eqn (1) or tbl .		
		put <i>filenames</i> , processes them, and passes them to troff or if the '–' argument is given, vgrind reads from the cified).	
	In both modes vgrind passes any sion.	ines beginning with a decimal point without conver-	
OPTIONS		rguments is important. Some require a SPACE between t, while those that do not have a SPACE below will not	
	point size to 8 (as output to appear	Imm output. Specifying this option changes the default if the $-s8$ option were supplied). It also arranges for in landscape mode, by supplying the $-L$ flag to the for- ging the page height and width accordingly.	
	- f Force filter mode		
	- n Do not make key	words boldface.	
	-w Consider TAB cha usual eight.	aracters to be spaced four columns apart instead of the	
	duced whenever current directory	file in a "pretty" format. The index file itself is pro- vgrind is run with a file called index present in the . The index of function definitions can then be run off the – x option and the file index as argument.	

modified 14 Sep 1992

	-d defs-file	Specify an alternate language definitions file (default is / usr/lib/vgrindefs).		
	-h header	Specify a header to appear in the center of every output page.		
	–llanguage	Specify the language to use. Among the languages currently known are Bourne shell (–lsh), C (–lc, the default), C++ (–lc++), C shell (–lcsh), emacs MLisp, (–lml), FORTRAN (–lf), Icon (–lI), ISP (–i), LDL (–lLDL), Model (–lm), Pascal (–lp), and RATFOR (–lr).	e:	
	-sn	Specify a point size to use on output (exactly the same as the argument of a troff .ps point size request).		
		the following options to the formatter specified by the TROFF environmer NVIRONMENT below.	ıt	
	–t Simila output	r to the same option in troff ; that is, formatted text goes to the standard		
	–W Force	output to the (wide) Versatec printer rather than the (narrow) Varian.		
	–opagelist			
	Print only those pages whose page numbers appear in the comma-separa <i>pagelist</i> of numbers and ranges. A range <i>N</i> – <i>M</i> means pages <i>N</i> through <i>M</i> tial – <i>N</i> means from the beginning to page <i>N</i> ; and a final <i>N</i> – means from end.			
	- P printer Send output to the named printer.			
	- T <i>output-device</i> Format output for the specified <i>output-device</i> .			
ENVIRONMENT	In regular mode vgrind feeds its intermediate output to the text formatter given by the value of the TROFF environment variable, or to troff if this variable is not defined in the environment. This mechanism allows for local variations in troff 's name.			
FILES	index	file where source for index is created		
	/usr/lib/vgrind	lefs language descriptions		
	/usr/lib/vfonte			
	/usr/share/lib/	t mac/tmac.vgrind macro package		
SEE ALSO	troff(1)			
BUGS	vgrind assume	s that a certain programming style is followed:		
	CFunction names can be preceded on a line only by SPACE, TAB, or an asteris The parenthesized arguments must also be on the same line.FORTRANFunction names need to appear on the same line as the keywords function on subroutine.		•	
	MLisp Fu	action names should not appear on the same line as the preceding <i>defun</i> .		
	Model Fu	nction names need to appear on the same line as the keywords is beginproc	•	

modified 14 Sep 1992

Pascal Function names need to appear on the same line as the keywords *function* or *procedure*.

If these conventions are not followed, the indexing and marginal function name comment mechanisms will fail.

More generally, arbitrary formatting styles for programs mostly look bad. The use of SPACE characters to align source code fails miserably; if you plan to **vgrind** your program you should use TAB characters. This is somewhat inevitable since the fonts **vgrind** uses are variable width.

The mechanism of **ctags**(1) in recognizing functions should be used here.

The –w option is a crock, but there is no other way to achieve the desired effect.

The macros defined in **tmac.vgrind** do not coexist gracefully with those of other macro packages, making filter mode difficult to use effectively.

vgrind does not process certain special characters in csh(1) scripts correctly.

The **tmac.vgrind** formatting macros wire in the page height and width used in two column mode, effectively making two column output useless for paper sizes other than the standard American size of 8.5 by 11 inches. For other paper sizes, it is necessary to edit the size values given in **tmac.vgrind**. A better solution would be to create a **troff** output device specification intended specifically for landscape output and record size information there.

NAME	vi, view, vedit	– screen-oriented (visual) display editor based on ex	
SYNOPSIS	/usr/bin/vi [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename		
	/usr/bin/view $[- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename$		
		[- -s][-l][-L][-R][-r[filename]][-t tag][-v][-V][-x][-wn] command $ -c$ command] filename	
		vi [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] -C] [+command -c command] filename	
		view [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] -C] [+command -c command] filename	
		'vedit [- - s] [- l] [- L] [- R] [- r [filename]] [- t tag] [- v] [- V] [- x] - C] [+command - c command] filename	
AVAILABILITY /usr/bin/vi /usr/bin/view /usr/bin/vedit	SUNWcsu		
/usr/xpg4/bin/vi /usr/xpg4/bin/view /usr/xpg4/bin/vedit	SUNWxcu4		
DESCRIPTION	possible to use of vi from wit set options (lik	display-oriented text editor based on an underlying line editor ex . It is the command mode of ex from within vi and to use the command mode hin ex . The visual commands are described on this manual page; how to a automatically numbering lines and automatically starting a new output type carriage return) and all ex line editor commands are described on the bage.	
		i, changes you make to the file are reflected in what you see on your termi- e position of the cursor on the screen indicates the position within the file.	
	The view invo	ocation is the same as vi except that the readonly flag is set.	
	flag is set to 1,	ocation is intended for beginners. It is the same as vi except that the report the showmode and novice flags are set, and magic is turned off. These it easier to learn how to use vi .	
OPTIONS Invocation Options		invocation options are interpreted by vi (previously documented options in the NOTES section of this manual page):	
	- - s	Suppress all interactive user feedback. This is useful when processing editor scripts.	
	- l	Set up for editing LISP programs.	
1-1150		modified 11 Apr 1995	

	$-\mathbf{L}$	List the name of all files saved as the result of an editor or system crash.	
	- R	Readonly mode; the readonly flag is set, preventing accidental overwrit- ing of the file.	
	- r filename	Edit <i>filename</i> after an editor or system crash. (Recovers the version of <i>filename</i> that was in the buffer when the crash occurred.)	
	– t tag	Edit the file containing the <i>tag</i> and position the editor at its definition.	
	$-\mathbf{v}$	Start up in display editing state using vi . You can achieve the same effect by simply typing the – vi command itself.	
	$-\mathbf{V}$	Verbose. Any non-tty input will be echoed on standard error. This may be useful when processing editor commands within shell scripts.	
	- X	Encryption option; when used, vi simulates the X command of ex and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the crypt command. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the -x option.	
	-wn	Set the default window size to <i>n</i> . This is useful when using the editor over a slow speed line.	
	- C	Encryption option; same as the $-x$ option, except that vi simulates the C command of ex . The C command is like the X command of ex , except that all text read in is assumed to have been encrypted.	
	+command -c	 -c command Begin editing by executing the specified editor command (usually a searc or positioning command). 	
/usr/xpg4/bin/vi		ag and the $-c$ command options are given, the $-t$ tag will be processed first. containing the tag is selected by $-t$ and then the command is executed.	
OPERANDS	The following operands are supported:		
	filename	A file to be edited.	
COMMAND SUMMARY vi Modes	Command	Normal and initial mode. Other modes return to command mode upon	
VINUUCS	Communa	completion. ESC (escape) is used to cancel a partial command.	
	Input	Entered by setting any of the following options: a A i I o O c C s S R . Arbitrary text may then be entered. Input mode is normally terminated with ESC character, or, abnormally, with an interrupt.	
	Last line	Reading input for : / ? or !; terminate by typing a carriage return; an interrupt cancels termination.	

Comple commonde	In the decorintion	CD stands for corrigge raturn and ESC stands for the assertation	
Sample commands	In the descriptions, CR stands for carriage return and ESC stands for the escape key.		
	$\leftarrow \downarrow \uparrow \rightarrow$	arrow keys move the cursor	
	hjkl itoutESC	same as arrow keys	
	itextESC	insert <i>text</i>	
	cw <i>new</i> ESC ea <i>s</i> ESC	change word to <i>new</i> pluralize word (end of word; append s ;	
	easesc	escape from input state)	
	X	delete a character	
	dw	delete a word	
	dd	delete a line	
	3dd		
	u	undo previous change	
	ZZ	exit vi , saving changes	
	:q!CR	quit, discarding changes	
	/textCR	search for <i>text</i>	
	^U ^D	scroll up or down	
	:cmdCR	any ex or ed command	
Counts before vi	Numbers may be typed as a prefix to some commands. They are interpreted in one of		
commands	these ways.		
	line/column num scroll amount	ber z G ^D ^U	
	repeat effect	most of the rest	
	Tepeat effect	most of the rest	
Interrupting,	ESC	end insert or incomplete cmd	
canceling	DEL	(delete or rubout) interrupts	
File manipulation	ZZ	if file modified, write and exit; otherwise, exit	
-	:wCR	write back changes	
	:w ! CR	forced write, if permission originally not valid	
	:qCR	quit	
	:q ! CR	quit, discard changes	
	:e nameCR	edit file <i>name</i>	
	:e ! CR	reedit, discard changes	
	:e + nameCR	edit, starting at end	
	:e + nCR	edit starting at line <i>n</i>	
	:e #CR	edit alternate file	
	:e!#CR	edit alternate file, discard changes	
	:w nameCR :w ! nameCR	write file <i>name</i> overwrite file <i>name</i>	
	:w : nameCR :shCR	run shell, then return	
	:! cmdCR	run <i>cmd</i> , then return	
	:nCR	edit next file in arglist	
	:n argsCR	specify new arglist	
	^G	show current file and line	

	:ta tagCR	position cursor to <i>tag</i>	
	In general, any ex or ed command (such as <i>substitute</i> or <i>global</i>) may be typed, preced by a colon and followed by a carriage return.		
Positioning within file	`F `B `D `U <i>n</i> G /pat ?pat n N /pat/+ <i>n</i> ?pat?- <i>n</i>]] [[(forward screen backward screen scroll down half screen go to the beginning of the specified line (end default), where <i>n</i> is a line number next line matching <i>pat</i> previous line matching <i>pat</i> repeat last / or ? command reverse last / or ? command nth line after <i>pat</i> nth line before <i>pat</i> next section/function previous section/function beginning of sentence and of contance

Marking and returning	mx `x `x	move cursor to previous context move cursor to first non-white space in line mark current position with the ASCII lower-case letter <i>x</i> move cursor to mark <i>x</i> move cursor to first non-white space in line marked by <i>x</i>	

Line positioning	Η	top line on screen
	L	last line on screen
	Μ	middle line on screen
	+	next line, at first non-white
	_	previous line, at first non-white
	CR	return, same as +
	↓ or j	next line, same column
	\uparrow or k	previous line, same column
Character positioning	^	first non white-space character
	0	beginning of line
	\$	end of line
	$l \text{ or } \rightarrow$	forward
	$\mathbf{h} \text{ or } \leftarrow$	backward
	ĥΗ	same as \leftarrow (backspace)
	space	same as \rightarrow (space bar)
	fx	find next x
	Fx	find previous x
	tx	move to character prior to next <i>x</i>
	Tx	move to character following previous <i>x</i>
	;	repeat last f, F, t, or T
	,	repeat inverse of last f , F , t , or T
	n	move to column <i>n</i>
	%	find matching ({) or }
Words, sentences,	w	forward a word
paragraphs	b	back a word
	e	end of word
)	to next sentence
	}	to next paragraph
	(back a sentence
	{	back a paragraph
	W	forward a blank-delimited word
	В	back a blank-delimited word
	E	end of a blank-delimited word

Compositions during	^U	arasa last character (hackspace)
Corrections during insert	^H ^W	erase last character (backspace) erase last word
msert	erase	your erase character, same as ^H (backspace)
	kill	your kill character, erase this line of input
		quotes your erase and kill characters
	\ ESC	ends insertion, back to command mode
	CTRL-C	interrupt, suspends insert mode
	^D	backtab one character; reset left margin of <i>autoindent</i>
	^D	caret (^) followed by control-d (^D);
	D	backtab to beginning of line;
		do not reset left margin of <i>autoindent</i>
	0^D	backtab to beginning of line; reset left margin of <i>autoindent</i>
	^V	quote non-printable character
	•	
Insert and replace	а	append after cursor
	Α	append at end of line
	i	insert before cursor
	I	insert before first non-blank
	0	open line below
	0	open above
	rx	replace single char with x
	R text ESC	replace characters
Operators	Operators are follo	wed by a cursor motion, and affect all text that would have been
operators		xample, since w moves over a word, dw deletes the word that would
		puble the operator, for example, dd to affect whole lines.
	d	delete
	с	change
	У	yank lines to buffer
	<	left shift
	>	right shift
	!	filter through command
Miscellaneous	С	change rest of line (c\$)
Operations	D	delete rest of line (d\$)
	s	substitute chars (cl)
	S	substitute lines (cc)
	J	join lines
	X	delete characters (dl)
	X	delete characters before cursor (dh)
	Y	yank lines (yy)

Yank and Put	Put inserts the text most recently deleted or yanked; however, if a buffer is named (using		
		ers $\mathbf{a} - \mathbf{z}$), the text in that buffer is put instead.	
		ik 3 lines	
	•	ık 3 characters	
		back text after cursor	
		back text before cursor	
		from buffer x	
		ik to buffer x	
	'' xd del	ete into buffer <i>x</i>	
Undo, Redo, Retrieve	u une	do last change	
	U res	tore current line	
	. rep	eat last change	
	''dp ret	rieve d'th last delete

Solaris Advanced User's Guide

NOTES Two options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see **intro**(1)). A –**r** option that is not followed with an option-argument has been replaced by –**L** and +*command* has been replaced by –**c** *command*.

The message **file too large to recover with** $-\mathbf{r}$ **option**, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the $-\mathbf{r}$ option will not be possible.

The editing environment defaults to certain configuration options. When an editing session is initiated, **vi** attempts to read the **EXINIT** environment variable. If it exists, the editor uses the values defined in **EXINIT**, otherwise the values set in **\$HOME/.exrc** are used. If **\$HOME/.exrc** does not exist, the default values are used.

To use a copy of **.exrc** located in the current directory other than **\$HOME**, set the *exrc* option in **EXINIT** or **\$HOME/.exrc**. Options set in **EXINIT** can be turned off in a local **.exrc** only if *exrc* is set in **EXINIT** or **\$HOME/.exrc**.

Tampering with entries in /usr/share/lib/terminfo/?/* or /usr/share/lib/terminfo/?/* (for example, changing or removing an entry) can affect programs such as vi that expect the entry to be present and correct. In particular, removing the "dumb" terminal may cause unexpected problems.

Software tabs using **^T** work only immediately after the *autoindent*.

Left and right shifts on intelligent terminals do not make use of insert and delete character operations in the terminal.

The standard Solaris version of **vi** will be replaced by the POSIX.2 conformant version in the future. Scripts which use the **ex** family of addressing and features should use the /usr/xpg4/bin version of these utilities.

NAME	vipw – edit the password file
SYNOPSIS	/usr/ucb/vipw
AVAILABILITY	SUNWscpu
DESCRIPTION	 vipw edits the password file while setting the appropriate locks, and does any necessary processing after the password file is unlocked. If the password file is already being edited, then you will be told to try again later. The vi(1) editor will be used unless the environment variable VISUAL or EDITOR indicates an alternate editor. vipw performs a number of consistency checks on the password entry for root, and will not allow a password file with a "mangled" root entry to be installed. It also checks the /etc/shells file to verify the login shell for root.
FILES	/etc/ptmp /etc/shells
SEE ALSO	passwd(1), vi(1), passwd(4)

modified 14 Sep 1992

NAME	volcancel – cancel user's request for removable media that is not currently in drive		
SYNOPSIS	/usr/lib/vold/volcancel [–n] [volume]		
DESCRIPTION	volcancel cancels a user's request to access a particular floppy or CD-ROM file system. This command is useful when the removable media containing the file system is not currently in the drive. Use the path / vol/rdsk / <i>name_of_volume</i> to specify the volume. If called without a volume		
	name to cancel, volcancel checks for Volume Management running.		
OPTIONS	- n Display the nickname to the device name translation table.		
EXAMPLES	To cancel a request to access an unnamed CD-ROM, use example% /usr/lib/vold/volcancel vol/rdsk/unnamed_cdrom To check if volume management is running, use: example% /usr/lib/vold/volcancel echo volmgmt not running		
SEE ALSO	rmmount(1M), volcheck(1), vold(1M), volmissing(1), rmmount.conf(4), vold.conf(4), volfs(7FS)		

modified 7 Apr 1994

NAME	volcheck – checks for media in a drive and by default checks all floppy media			
SYNOPSIS	volcheck [–v] [–i secs] [–t secs] pathname			
DESCRIPTION	volcheck tells Volume Management to look at each <i>pathname</i> in sequence and determine if new media has been inserted in the drive.			
	The default action is to volcheck all floppy drives pointed to by volume management.			
OPTIONS	–v Verbose.			
	-t secs Check the named device(s) for the next secs seconds. The maximum number of seconds allowed is 28800, which is 8 hours. The frequency of checking is specified by -i. There is no default total time.			
	 -i secs Set the frequency of device checking to secs seconds. The default is 2 seconds. The minimum frequency is 1 second. 			
EXAMPLES	example% volcheck -v /dev/diskette /dev/diskette has media			
	asks Volume Management to examine the floppy drive for new media.			
	example% volcheck -i 2 -t 600 /dev/diskette1 &			
	asks Volume Management if there is a floppy in the floppy drive every 2 seconds for 600 seconds (10 minutes).			
FILES	/dev/volctl Volume Management control port			
SEE ALSO	<pre>eject(1), volcancel(1), volmissing(1) rmmount(1M), vold(1M), rmmount.conf(4), vold.conf(4), volfs(7FS)</pre>			
WARNINGS	Due to a hardware limitation in many floppy drives, the act of checking for media causes mechanical action in the floppy drive. Continuous polling of the floppy drive will cause the drive to wear out. It is recommended that polling the drive only be performed during periods of high use.			

modified 7 Apr 1994

NAME	volmissing – notify user that volume requested is not in the CD-ROM or floppy drive		
SYNOPSIS	/usr/lib/vold/volmissing [-c] [-p] [-s] [-m alias]		
DESCRIPTION	volmissing informs a user when a requested volume is not available. Depending on the option selected, users are notified through their console window, syslogd (1M), or a mail message.		
	mon, whe	en it needs to notify a user	taken by vold (1M), the Volume Management dae- r that the requested volume is not available. If you modify the / etc/vold.conf file. See vold.conf (4).
	configura		ethod for your system by editing the vold.conf new option for volmissing in the notify entry under
OPTIONS	- c		user's console requesting the volume be inserted. To hout inserting the requested volume, use volcancel (1).
	- p	system is running on th	will be handled through a GUI, provided a window he console. If this option is specified, and no window hessages go to the system console.
	— s	Send one message to th	e syslogd (1M).
	– m alias	Send a mail message to	the specified mail alias about the missing volume.
FILES	/etc/vold.		Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes action to be taken when specific criteria is met.
	/usr/lib/v	old/volmissing_popup	Pop-up used when the –p option is supplied and a window system is running.
SEE ALSO		l(1), volcheck(1), rmmour F(4), volfs(7FS)	nt(1M), <pre>syslogd(1M), vold(1M), rmmount.conf(4),</pre>

modified 7 Apr 1994

NAME	vsig – synchronize a co-process with the controlling FMLI application
SYNOPSIS	vsig
AVAILABILITY	SUNWesu
DESCRIPTION	The vsig executable sends a SIGUSR2 signal to the controlling FMLI process. This signal/alarm causes FMLI to execute the FMLI built-in command checkworld which causes all posted objects with a reread descriptor evaluating to TRUE to be reread. vsig takes no arguments.
EXAMPLES	The following is a segment of a shell program:
	echo "Sending this string to an FMLI process" vsig
	The vsig executable will flush the output buffer <i>before</i> it sends the SIGUSR2 signal to make sure the string is actually in the pipe created by the cocreate function.
SEE ALSO	coproc(1F), kill(1), kill(2), signal(3C)
NOTES	Because vsig synchronize with FMLI, it should be used rather than kill to send a SIGUSR2 signal to FMLI.

modified 5 Jul 1990

NAME	w – who is logged in, and what are they doing		
SYNOPSIS	w [-hlsuw] [user]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The w command displays a summary of the current activity on the system, including what each user is doing. The heading line shows the current time, the length of time the system has been up, the number of users logged into the system and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. The fields displayed are: the users login name, the name of the tty the user is on, the time of day the user logged on (in <i>hours:minutes</i>), the idle time—that is, the number of minutes since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), the name and arguments of the current process. If a <i>user</i> name is included, output is restricted to that user.		
OPTIONS			
OPTIONS	 -h Suppress the heading. -l Produce a long form of output, which is the default. 		
	 -s Produce a short form of output. In the short form, the tty is abbreviated, the login time and CPU times are left off, as are the arguments to commands. 		
	 Produces the heading line which shows the current time, the length of time the system has been up, the number of users logged into the system, and the average number of jobs in the run queue over the last 1, 5 and 15 minutes. 		
	-w Produces a long form of output, which is also the same as the default.		
EXAMPLE	example% w 10:54am up 27 day(s), 57 mins, 1 user, load average: 0.28, 0.26, 0.22 User tty login@ idle JCPU PCPU what ralph console 7:10am 1 10:05 4:31 w		
ENVIRONMENT	If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of tar for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to over- ride both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how tar behaves. LC_CTYPE Determines how tar handles characters. When LC_CTYPE is set to a valid value, tar can display and handle text and filenames containing valid characters for that locale. tar can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. tar can also handle EUC		

modified 23 Mar 1994

characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME

Determines how **tar** handles date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

FILES /var/adm/utmp

SEE ALSO ps(1), **who(1)**, **whodo(1M)**, **utmp(4)**

NOTES The notion of the "current process" is muddy. The current algorithm is 'the highest numbered process on the terminal that is not ignoring interrupts, or, if there is none, the highest numbered process on the terminal'. This fails, for example, in critical sections of programs like the shell and editor, or when faulty programs running in the background fork and fail to ignore interrupts. In cases where no process can be found, w prints –.

The CPU time is only an estimate, in particular, if someone leaves a background process running after logging out, the person currently on that terminal is "charged" with the time.

Background processes are not shown, even though they account for much of the load on the system.

Sometimes processes, typically those in the background, are printed with null or garbaged arguments. In these cases, the name of the command is printed in parentheses.

 ${\bf w}$ does not know about the conventions for detecting background jobs. It will sometimes find a background job instead of the right one.

modified 23 Mar 1994

NAME	wait – await process completion
SYNOPSIS sh	wait [n] wait [%jobid]
csh	wait [n]
ksh	wait [<i>pid</i>]
DESCRIPTION sh	 Wait for your background process whose process id is <i>n</i> and report its termination status. If <i>n</i> is omitted, all your shell's currently active background processes are waited for and the return code will be zero. wait accepts a job identifier, when Job Control is enabled, and the argument, <i>jobid</i>, is preceded by a percent-sign. The shell itself executes wait, without creating a new process. If you get the error message cannot fork, too many processes, try using the wait command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.) Not all the processes of a 3- or more-stage pipeline are children of the shell, and thus cannot be waited for. If <i>n</i> is not an active process id, all your shell's currently active background processes are waited for and the return code will be zero.
csh	 Wait for your background process whose process id is <i>n</i> and report its termination status. If <i>n</i> is omitted, all your shell's currently active background processes are waited for and the return code will be zero. The shell itself executes wait, without creating a new process. If you get the error message cannot fork, too many processes, try using the wait command to clean up your background processes. If this doesn't help, the system process table is probably full or you have too many active foreground processes. (There is a limit to the number of process ids associated with your login, and to the number the system can keep track of.) Not all the processes of a 3- or more-stage pipeline are children of the shell, and thus cannot be waited for. If <i>n</i> is not an active process id, all your shell's currently active background processes are waited for and the return code will be zero.
ksh	When an asynchronous list is started by the shell, the process ID of the last command in each element of the asynchronous list becomes known in the current shell execution environment.

modified 28 Mar 1995

If the **wait** utility is invoked with no operands, it will wait until all process IDs known to the invoking shell have terminated and exit with a zero exit status.

If one or more *pid* operands are specified that represent known process IDs, the **wait** utility will wait until all of them have terminated. If one or more *pid* operands are specified that represent unknown process IDs, **wait** will treat them as if they were known process IDs that exited with exit status **127**. The exit status returned by the **wait** utility will be the exit status of the process requested by the last *pid* operand.

The known process IDs are applicable only for invocations of **wait** in the current shell execution environment.

- **OPERANDS** The following operand is supported:
 - *pid* One of the following:
 - 1. The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination. A job control job ID that identifies a background process group to be waited for.
 - 2. The job control job ID notation is applicable only for invocations of **wait** in the current shell execution environment. The exit status of **wait** is determined by the last command in the pipeline.

Note that the job control job ID type of *pid* is available only on systems supporting the job control option.

USAGE On most implementations, **wait** is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

(wait)

nohup wait ...

find . -exec wait ... \;

it will return immediately because there will be no known process IDs to wait for in those environments.

Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while **wait** was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialisation error because the exit status returned was usually zero if the requested process ID was not found. This document requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

j1& p1=\$! j2& wait \$p1 echo Job 1 exited with status \$?

1-1166

modified 28 Mar 1995

wait \$!

echo Job 2 exited with status \$?

	will work without losing status on any of the jobs. The shell is allowed to discard the status of any process that it determines the application cannot get the process ID from the shell. It is also required to remember only number of processes in this way. Since the only way to get the process ID from the shell is by using the ! shell parameter, the shell is allowed to discard the status of an asynchronous list if \$! was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference \$! . If the implementation of the shell is smart enough to determine that a reference to \$! was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to wait with no operands discards the exit status of all asynchronous lists.) If the exit status of wait is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.
EXAMPLES	Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably figure out which signal using kill as shown by the following script:
	sleep 1000&
	pid=\$!
	kill -kill \$pid
	wait \$pid
	echo \$pid was terminated by a SIG\$(kill -l \$?) signal.
	If the following sequence of commands is run in less than 31 seconds:
	sleep 257 sleep 31 &
	jobs -l %%
	either of the following commands will return the exit status of the second sleep in the pipeline:
	wait <pid 31i="" of="" sleep=""></pid>
	wait %%
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of wait : LC_CTYPE , LC_MESSAGES , and NLSPATH .
EXIT STATUS	If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of wait will be the exit status information of the command indicated by the last

modified 28 Mar 1995

operand specified. If the process terminated abnormally due to the receipt of a signal, the exit status will be greater than **128** and will be distinct from the exit status generated by other signals, but the exact value is unspecified. (See the **kill** –**l** option.) Otherwise, the **wait** utility will exit with one of the following values:

- **0** The **wait** utility was invoked with no operands and all process IDs known by the invoking shell have terminated.
- **1–126** The **wait** utility detected an error.
- 127 The command identified by the last *pid* operand specified is unknown.

modified 28 Mar 1995

NAME	wc – display a count of lines, words and characters in a file		
SYNOPSIS	wc [-c -m -C] [-lw] [file]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The wc utility reads one or more input files and, by default, writes the number of newline characters, words and bytes contained in each input file to the standard output. The utility also writes a total count for all named files, if more than one input file is		
	specified.		
	wc considers a <i>word</i> to be a non-zero-length string of characters delimited by white space (for example, SPACE, TAB). See iswspace (3I) or isspace (3C).		
OPTIONS	The following options are supported:		
	-c Count bytes.		
	-m Count characters.		
	$-\mathbf{C}$ Same as $-\mathbf{m}$.		
	-l Count lines.		
	-w Count words delimited by white space characters or new line characters. Delim- iting characters are Extended Unix Code (EUC) characters from any code set defined by iswspace() .		
	If no option is specified the default is $-\mathbf{lwc}$ (count lines, words, and bytes.)		
OPERANDS	The following operand is supported:		
	<i>file</i> A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.		
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of wc : LC_CTYPE , LC_MESSAGES , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Successful completion.		
	>0 An error occurred.		
	(2C) $(2C)$ $(2C)$ $(2C)$ $(2C)$ $(2C)$ $(2C)$ $(2C)$

NAMEwhat – extract SCCS version information from a fileSYNOPSISwhat [-s] filename	C
SYNOPSIS what [-s] filename	Ċ
	p
DESCRIPTION what searches each <i>filename</i> for occurrences of the pattern @(#) that the SCCS get com- mand (see sccs-get(1)) substitutes for the %Z% ID keyword, and prints what follows up to a ", >, NEWLINE, or null character.	
OPTIONS – s Stop after the first occurrence of the pattern.	
EXAMPLES For example, if a C program in file program.c contains	
char sccsid[] = "@(#)identification information ";	
and program.c is compiled to yield program.o and a.out , the command:	
example% what program.c program.o a.out	
produces:	
program.c:	
identification information	
identification information	
a.out: identification information	
SEE ALSO sccs(1), sccs-admin(1), sccs-cdc(1), sccs-comb(1), sccs-delta(1), sccs-get(1), sccs-help(1) sccs-prs(1), sccs-prt(1), sccs-rmdel(1), sccs-sact(1), sccs-sccsdiff(1), sccs-unget(1), sccs-val(1), sccsfile(4)	١,
Programming Utilities Guide	
DIAGNOSTICS Use the SCCS help command for explanations (see sccs-help (1)).	
BUGS There is a remote possibility that a spurious occurrence of the '@(#)' pattern could be found by what .	

modified 5 Oct 1990

NAME	whatis – display a one-line summary about a keyword		
SYNOPSIS	whatis command		
AVAILABILITY	SUNWdoc		
DESCRIPTION	 whatis looks up a given <i>command</i> and displays the header line from the manual section. You can then run the man(1) command to get more information. If the line starts 'name(<i>section</i>)' you can do 'man -s section name' to get the documentation for it. Try 'whatis ed' and then you should do 'man -s 1 ed' to get the manual page for ed(1). whatis is actually just the -f option to the man(1) command. whatis uses the /usr/share/man/windex database. This database is created by catman(1M). If this database does not exist, whatis will fail. 		
FILES	/usr/share/man/windex table of contents and keyword database		
SEE ALSO	apropos(1), man(1), catman(1M)

NAME	where	eis – locate the binary, source, and manual page files for a command		
SYNOPSIS	/usr/u	/usr/ucb/whereis [–bmsu] [–BMS directory –f] filename		
AVAILABILITY	SUNV	SUNWscpu		
DESCRIPTION	whereis locates source/binary and manuals sections for specified files. The supplied names are first stripped of leading pathname components and any (single) trailing extension of the form <i>.ext</i> , for example, <i>.c.</i> Prefixes of s . resulting from use of source code co trol are also dealt with. whereis then attempts to locate the desired program in a list of standard places:			
		/usr/bin /usr/bin /usr/5bin /usr/games /usr/hosts /usr/hosts /usr/include /usr/local /usr/local /usr/lib /usr/share/man /usr/src /usr/ucb		
OPTIONS	- b	Search only for binaries.		
	– m	Search only for manual sections.		
	— s	Search only for sources.		
	- u	Search for unusual entries. A file is said to be unusual if it does not have one entry of each requested type. Thus ' whereis $-\mathbf{m} - \mathbf{u} *$ ' asks for those files in the current directory which have no documentation.		
	- B	Change or otherwise limit the places where whereis searches for binaries.		
	- M	Change or otherwise limit the places where whereis searches for manual sec- tions.		
	- S	Change or otherwise limit the places where whereis searches for sources.		
	- f	Terminate the last directory list and signals the start of file names, and <i>must</i> be used when any of the $-B$, $-M$, or $-S$ options are used.		

1B-1172

modified 14 Sep 1992

EXAMPLES	Find all files in /usr/bin which are not documented in /usr/share/man/man1 with source in /usr/src/cmd: example% cd /usr/ucb example% whereis –u –M /usr/share/man/man1 –S /usr/src/cmd –f *
FILES	/usr/src/* /usr/{doc,man}/* /etc, /usr/{lib,bin,ucb,old,new,local}
SEE ALSO	chdir(2)
BUGS	Since where is uses chdir(2) to run faster, pathnames given with the $-M$, $-S$, or $-B$ must be full; that is, they must begin with a '/'.

1B-1173

NAME	which – locate a command; display its pathname or alias		
SYNOPSIS	which [filename]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	which takes a list of names and looks for the files which would be executed had these names been given as commands. Each argument is expanded if it is aliased, and searched for along the user's path. Both aliases and path are taken from the user's .cshrc file.		
FILES	~/.cshrcsource of aliases and path values/usr/bin/which		
SEE ALSO	csh (1)		
DIAGNOSTICS	A diagnostic is given for names which are aliased to more than a single word, or if an executable file with the argument name was not found in the path.		
NOTES	which is not a shell built-in command; it is the UNIX command, /usr/bin/which		
BUGS	Only aliases and paths from ~/. cshrc are used; importing from the current environment is not attempted. Must be executed by csh (1), since only csh knows about aliases.		
	To compensate for ~ / .cshrc files in which aliases depend upon the prompt variable being set, which sets this variable to NULL. If the ~ / .cshrc produces output or prompts for input when prompt is set, which may produce some strange results.		

modified 26 Sep 1992

NAME	while, until – shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE
SYNOPSIS sh	while [conditions]; do actions ; done until [conditions]; do actions ; done
csh	while (conditions) # do actions end
ksh	while [conditions]; do actions ; done until [conditions]; do actions ; done
DESCRIPTION sh	A while command repeatedly executes the while <i>conditions</i> and, if the exit status of the last command in the <i>conditions</i> list is 0 , executes the do <i>actions</i> ; otherwise the loop terminates. If no commands in the do <i>actions</i> are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test.
csh	While <i>conditions</i> is TRUE (evaluates to nonzero), repeat commands between the while and the matching end statement. The while and end must appear alone on their input lines. If the shell's input is a terminal, it prompts for commands with a question-mark until the end command is entered and then performs the commands in the loop.
ksh	A while command repeatedly executes the while <i>conditions</i> and, if the exit status of the last command in the <i>conditions</i> list is zero, executes the do <i>actions</i> ; otherwise the loop terminates. If no commands in the do <i>actions</i> are executed, then the while command returns a 0 exit status; until may be used in place of while to negate the loop termination test.
loop interrupts	The built-in command continue may be used to terminate the execution of the current iteration of a while or until loop, and the built-in command break may be used to terminate execution of a while or until command.
EXAMPLES sh	In these examples, the user is repeated prompted for a name of a file to be located, until the user chooses to finish the execution by entering an empty line. filename=anything
	while [\$filename] do echo "file?" read filename # read from terminal findname \$filename -print done
	uone

while (1)	User Commands SunOS 5	i.5
	The brackets surrounding Sfilename are necessary for evaluation. (See the test built-in command in the $if(1)$ man page). Additionally, there must be a blank space separating each bracket from any characters within.	
csh	<pre>set filename = anything while ("\$filename" != "") echo "file?" set filename = \$< # read from terminal findname \$filename -print end</pre>	
ksh	Use the same syntax as in the Bourne shell, sh , example above.	
SEE ALSO	break (1), csh (1), if (1), ksh (1), sh (1)	
NOTES	Both the Bourne shell, sh , and the Korn shell, ksh , can use the semicolon and the carriag return interchangeably in their syntax of the if , for , and while built-in commands.	ţe

NAME	who – who is on the system		
SYNOPSIS	/usr/bin/who [–abdHlmpqrstTu] [file] /usr/bin/who –q [–n x] [file] /usr/bin/who am i /usr/bin/who am I		
	/usr/xpg4/bin/who [–abdHlmpqrtTu] [file] /usr/xpg4/bin/who –q [–n x] [file] /usr/xpg4/bin/who –s [–bdHlmpqrtu] [file] /usr/xpg4/bin/who am i /usr/xpg4/bin/who am I		
AVAILABILITY /usr/bin/who	SUNWcsu		
/usr/xpg4/bin/who	SUNWxcu4		
DESCRIPTION	The who command can list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process-ID of the command interpreter (shell) for each current UNIX system user. It examines the /var/adm/utmp file to obtain its informa- tion. If file is given, that file (which must be in utmp(4) format) is examined. Usually, file will be /var/adm/wtmp, which contains a history of all the logins since the file was last created.The general format for output is: name [state] line time [idle] [pid] [comment] [exit]where:nameuser's login name. statecapability of writing to the terminal. linelineime since user's login. idleidletime elapsed since the user's last activity. piduser's process id. commentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentcommentuser's for dead processes.		
OPTIONS	The following options are supported:		
	-a Process /var/adm/utmp or the named <i>file</i> with -b, -d, -l, -p, -r, -t, -T, and -u options turned on.		
	- b Indicate the time and date of the last reboot.		
	 Display all processes that have expired and not been respawned by init. The exit field appears for dead processes and contains the termination and exit values (as returned by wait(3B)), of the dead process. This can be useful in determining why a process terminated. 		

	- H	Output column headings above the regular output.
	-1	List only those lines on which the system is waiting for someone to login. The <i>name</i> field is LOGIN in such cases. Other fields are the same as for user entries except that the <i>state</i> field does not exist.
	- m	Output only information about the current terminal.
	-n x	Take a numeric argument, x , which specifies the number of users to display per line. x must be at least 1. The $-n$ option may only be used with $-q$.
	-p	List any other process which is currently active and has been previously spawned by init . The <i>name</i> field is the name of the program executed by init as found in / sbin/inittab . The <i>state</i> , line , and <i>idle</i> fields have no meaning. The <i>comment</i> field shows the id field of the line from / sbin/inittab that spawned this process. See inittab (4).
	-q	(quick who) display only the names and the number of users currently logged on. When this option is used, all other options are ignored.
	- r	Indicate the current <i>run-level</i> of the init process.
	- s	(default) List only the <i>name</i> , <i>line</i> , and <i>time</i> fields.
/usr/bin/who	- T	Same as the – s option, except that the <i>state idle</i> , <i>pid</i> , and <i>comment</i> , fields are also written. <i>state</i> is one of the following characters:
		 + The terminal allows write access to other users. - The terminal denies write access to other users. ? The terminal write-access state cannot be determined.
/usr/xpg4/bin/who	- T	Same as the – s option, except that the <i>state</i> field is also written. <i>state</i> is one of the characters listed under the / usr/bin/who version of this option.
		If the $-\mathbf{u}$ option is used with $-\mathbf{T}$, the idle time is added to the end of the previous format.
	-t	Indicate the last change to the system clock (via the date command) by root . See su (1M) and date (1).
	-u	List only those users who are currently logged in. The <i>name</i> is the user's login name. The <i>line</i> is the name of the line as found in the directory /dev. The <i>time</i> is the time that the user logged in. The <i>idle</i> column contains the number of hours and minutes since activity last occurred on that particular line. A dot (.) indicates that the terminal has seen activity in the last minute and is there- fore "current". If more than twenty-four hours have elapsed or the line has not been used since boot time, the entry is marked old . This field is useful when trying to determine whether a person is working at the terminal or not. The <i>pid</i> is the process-ID of the user's shell. The <i>comment</i> is the comment field associated with this line as found in /sbin/inittab (see inittab(4)). This can contain information about where the terminal is located, the telephone number of the dataset, type of terminal if hard-wired, and so forth.
	1	

OPERANDS	The following operands are supported:		
	ami		
		locale, limit the output to describing the invoking user, equivalent option. The am and i or I must be separate arguments.	
		bath name of a file to substitute for the database of logged-on users uses by default.	
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of who : LC_CTYPE , LC_MESSAGES , LC_TIME , and NLSPATH .		
EXIT STATUS	The following exit values are returned:		
	0 Successful	completion.	
	>0 An error of	occurred.	
FILES	/sbin/inittab	script for init .	
	/var/adm/utmp	current user and accounting information	
	/var/adm/wtmp	historic user and accounting information	
SEE ALSO	date(1), login(1), mesg(1), init(1M), su(1M), wait(3B), inittab(4), utmp(4), environ(5)		
NOTES	Super-user: After a shutdown to the single-user state, who returns a prompt; since / var/adm/utmp is updated at login time and there is no login in single-user state, who cannot report accurately on this state. who am i , however, returns the correct information.		

modified 1 Feb 1995

whoami(1B)	SunOS/BSD Compatibility Package CommandsSunOS 5.5
NAME SYNOPSIS AVAILABILITY	whoami – display the effective current username / usr/ucb/whoami SUNWscpu
DESCRIPTION	whoami displays the login name corresponding to the current effective user ID. If you have used su to temporarily adopt another user, whoami will report the login name associated with that user ID. whoami gets its information from the geteuid and getpwuid library routines (see getuid and getpwnam (3C), respectively).
FILES	/etc/passwd username data base

modified 14 Sep 1992

NAME	whois – Internet user name directory service		
SYNOPSIS	whois [–h host] identifier		
AVAILABILITY	SUNWcsu		
DESCRIPTION	whois searches for an Internet directory entry for an <i>identifier</i> which is either a name (such as "Smith") or a handle (such as "SRI-NIC"). To force a name-only search, precede the name with a period; to force a handle-only search, precede the handle with an exclamation point.		
	To search for a group or organization entry, precede the argument with * (an asterisk). The entire membership list of the group will be displayed with the record.		
	You may of course use an exclamation point and asterisk, or a period and asterisk together.		
EXAMPLES	The command:		
	example% whois Smith		
	looks for the name or handle SMITH.		
	The command:		
	example% whois !SRI-NIC		
	looks for the handle SRI-NIC only.		
	The command: example% whois .Smith, John looks for the name JOHN SMITH only.		
	Adding to the name or handle argument will match anything from that point; that is, ZU will match ZUL, ZUM, and so on.		

modified 14 Sep 1992

NAME	write – write to another user		
SYNOPSIS	write user [terminal]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The write utility reads lines from the user's standard input and writes them to the termi- nal of another user. When first invoked, it writes the message:		
	Message from sender-login-id (sending-terminal) [date]		
	to <i>user</i> . When it has successfully completed the connection, the sender's terminal will be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.		
	If the recipient wants to reply, this can be accomplished by typing		
	write sender-login-id [sending-terminal]		
upon receipt of the initial message. Whenever a line of input as delimited by a or EOL special character is accumulated while in canonical input mode, the acc data will be written on the other user's terminal. Characters are processed as f			
	 Typing the alert character will write the alert character to the recipient's terminal. Typing the erase and kill characters will affect the sender's terminal in the manner described by the termios(3) interface. Typing the interrupt or end-of-file characters will cause write to write an appropriate message (EOT\n in the "C" locale) to the recipient's terminal and exit. Typing characters from LC_CTYPE classifications print or space will cause those characters to be sent to the recipient's terminal. When and only when the stty iexten local mode is enabled, additional special control characters and multi-byte or single-byte characters are processed as printable characters if their wide character equivalents are printable. Typing other non-printable characters will cause them to be written to the recipient's terminal as follows: control characters will appear as a '' followed by the appropriate ASCII character, and characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as 'C' and '\372' as 'M-z'. To write to a user who is logged in more than once, the <i>terminal</i> argument can be used to indicate which terminal to write to; otherwise, the recipient's terminal is the first writable instance of the user found in /usr/adm/utmp, and the following informational message will be written to the sender's standard output, indicating which terminal was chosen: <i>user</i> is logged on more than one place. You are connected to <i>terminal</i>. 		
	Permission to be a recipient of a write message can be denied or granted by use of the mesg utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The write utility will fail when the user lacks the		
-1182	modified 1 Feb 1995		

	appropriate privileges to perform the requested action.			
	If the character ! is found at the beginning of a line, write calls the shell to execute the rest of the line as a command.			
	write runs setgid() (see setuid(2)) to the group ID tty, in order to have write permissions on other user's terminals.			
	The following protocol is suggested for using write : when you first write to another user, wait for them to write back before starting to send. Each person should end a message with a distinctive signal (that is, (o) for "over") so that the other person knows when to reply. The signal (oo) (for "over and out") is suggested when conversation is to be terminated.			
OPERANDS	The following operands are supported:			
		gin) name of the person to whom the message will be written. This I must be of the form returned by the who (1) utility.		
	terminal Termina	al identification in the same format provided by the who utility.		
ENVIRONMENT		scriptions of the following environment variables that affect the exe- TYPE, LC_MESSAGES, and NLSPATH.		
EXIT STATUS	The following exit values are returned:			
	0 Successful completion.			
	-	ser is not logged on or the addressed user denies permission.		
FILES	/var/adm/utmp /usr/bin/sh	user and accounting information for write Bourne shell executable file

DIAGNOSTICS	user is not logged on	The person you are trying to write to is not logged on.		
	Permission denied	The person you are trying to write to denies that permission (with mesg).		
	Warning: cannot resp	bond, set mesg -y Your terminal is set to mesg n and the recipient cannot respond to you.		
	Can no longer write	to user		
	U	The recipient has denied permission (mesg n) after you had started writing.		

NAME	xargs – construct argument lists and invoke utility		
SYNOPSIS	xargs [-t] [-p] [-e[eofstr]] [-E eofstr] [-I replstr] [-i[replstr]] [-L number] [-l[number]] [-n number [-x]] [-s size] [utility [argument]]		
AVAILABILITY	SUNWcsu		
DESCRIPTION	The xargs utility constructs a command line consisting of the <i>utility</i> and <i>argument</i> operands specified followed by as many arguments read in sequence from standard input as will fit in length and number constraints specified by the options. The xargs utility then invokes the constructed command line and waits for its completion. This sequence is repeated until an end-of-file condition is detected on standard input or an invocation of a constructed command line returns an exit status of 255 . Arguments in the standard input must be separated by unquoted blank characters, or unescaped blank characters or newline characters. A string of zero or more non-double-quote (") and non-newline characters can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe (') and non-newline characters can be escaped by preceding it with a backslash (\). The <i>utility</i> will be executed one or more times until the end-of-file is reached. The results are unspecified if the utility named by <i>utility</i> attempts to read from its standard input. The generated command line length will be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The xargs utility will limit the command line length such that when the command line is invoked, the combined argument and environment lists will not exceed {ARG_MAX}-2048 bytes. Within this constraint, if neither the <i>-n</i> nor the <i>-s</i> option is		
OPTIONS	specified, the default command line length will be at least {LINE_MAX} . The following options are supported:		
	-e[eofstr]	Use <i>eofstr</i> as the logical end-of-file string. Underscore (_) is assumed for the logical EOF string if neither –e nor –E is used. When the –eofstr option-argument is omitted, the logical EOF string capability is disabled and underscores are taken literally. The xargs utility reads standard input until either end-of-file or the logical EOF string is encountered.	
	–E eofstr	Specify a logical end-of-file string to replace the default underscore. The xargs utility reads standard input until either end-of-file or the logical EOF string is encountered.	
	–I replstr	Insert mode. <i>utility</i> will be executed for each line from standard input, taking the entire line as a single argument, inserting it in <i>argument s</i> for each occurrence of <i>replstr</i> . A maximum of five arguments in <i>arguments</i> can each contain one or more instances of <i>replstr</i> . Any blank characters at the beginning of each line are ignored. Constructed arguments cannot grow larger than 255 bytes. Option – x is forced on. The – I and – i	

	options are mutually exclusive; the last one specified takes effect.
-i[replstr]	This option is equivalent to $-I$ <i>replstr</i> . The string {} is assumed for <i>replstr</i> if the option-argument is omitted.
–L number	The <i>utility</i> will be executed for each non-empty <i>number</i> lines of arguments from standard input. The last invocation of <i>utility</i> will be with fewer lines of arguments if fewer than <i>number</i> remain. A line is considered to end with the first newline character unless the last character of the line is a blank character; a trailing blank character signals continuation to the next non-empty line, inclusive. The –L, –l, and –n options are mutually exclusive; the last one specified takes effect.
-l[number]	(The letter ell.) This option is equivalent to $-L$ number. If number is omitted, 1 is assumed. Option $-x$ is forced on.
– n number	Invoke <i>utility</i> using as many standard input arguments as possible, up to <i>number</i> (a positive decimal integer) arguments maximum. Fewer arguments will be used if:
	• The command line length accumulated exceeds the size specified by the -s option (or {LINE_MAX} if there is no -s option), or
	• The last iteration has fewer than <i>number</i> , but not zero, operands remaining.
-p	Prompt mode. The user is asked whether to execute <i>utility</i> at each invo- cation. Trace mode (-t) is turned on to write the command instance to be executed, followed by a prompt to standard error. An affirmative response (specific to the user's locale) read from /dev/tty will execute the command; otherwise, that particular invocation of <i>utility</i> is skipped.
–s size	Invoke <i>utility</i> using as many standard input arguments as possible yielding a command line length less than <i>size</i> (a positive decimal integer) bytes. Fewer arguments will be used if:
	 The total number of arguments exceeds that specified by the –n option, or
	 The total number of lines exceeds that specified by the –L option, or
	• End of file is encountered on standard input before <i>size</i> bytes are accumulated.
	Values of <i>size</i> up to at least {LINE_MAX} bytes are supported, provided that the constraints specified in DESCRIPTION are met. It is not considered an error if a value larger than that supported by the implementation or exceeding the constraints specified in DESCRIPTION is given; xargs will use the largest value it supports within the constraints.
t	Enable trace mode. Each generated command line will be written to standard error just prior to invocation.
- X	Terminate if a command line containing <i>number</i> arguments (see the $-\mathbf{n}$

1-1185

The following utility argument	option above) or <i>number</i> lines (see the -L option above) will not fit in the implied or specified size (see the -s option above). g operands are supported: The name of the utility to be invoked, found by search path using the PATH environment variable; see environ (5). If <i>utility</i> is omitted, the default is the echo (1) utility. If the <i>utility</i> operand names any of the special built-in utilities in shell_builtins (1), the results are undefined. An initial option or operand for the invocation of <i>utility</i> .
utility	The name of the utility to be invoked, found by search path using the PATH environment variable; see environ (5). If <i>utility</i> is omitted, the default is the echo (1) utility. If the <i>utility</i> operand names any of the special built-in utilities in shell_builtins (1), the results are undefined.

xgettext (1)		User Commands	SunOS 5.5
NAME	xgettext – extract g	ettext call strings from C programs	
SYNOPSIS		n [–x exclude-file]] [–c comment-tag] [–d default-domain] [–] [–M suffix] [–p pathname] – filename	- j]
AVAILABILITY	SUNWloc		
DESCRIPTION	tains copies of "C" dard input if '-' is a	automate the creation of portable message files (.po). A .po strings that are found in ANSI C source code in <i>filename</i> or specified on the command line. The .po file can be used as i which produces a binary form of the message file that can b run-time.	the stan- input to the
	messages.po. The	gid strings from gettext (3I) calls in <i>filename</i> to the default out default output file name can be changed by –d option. <i>msg</i> written to the output file <i>domainname</i> . po where <i>domainnam</i> gettext() call.	and strings in
	the same order the	t creates a .po file in the current working directory, and each strings are extracted from <i>filenames</i> . When the $-\mathbf{p}$ option is ed in the <i>pathname</i> directory. An existing .po file is overwrite	specified,
	specified, the .po is	re written to the .po file as comment lines. When the $-s$ opt s sorted by the <i>msgid</i> string, and all duplicated <i>msgids</i> are re the .po file are empty unless the $-m$ option is used.	
OPTIONS	-n	Add comment lines to the output file indicating file name number in the source file where each extracted string is er These lines appear before each <i>msgid</i> in the following form #	ncountered.
		# File : filename, line : line-number	
	- s	Generate output sorted by <i>msgids</i> with all duplicate <i>msgid</i>	ls removed.
	-a	Extract all strings, not just those found in gettext (3I), and calls. Only one .po file is created.	dgettext ()
	–c comment-tag	The comment block beginning with <i>comment-tag</i> as the first the comment block is added to the output .po file as # deli- comments. For multiple domains, xgettext directs commen- messages to the prevailing text domain.	imited
	– d default-domain	Rename default output file from messages.po to default-de	omain .po .
	-j	Join messages with existing message files. If a . po file doe it is created. If a .po file does exist, new messages are app Any duplicate msgids are commented out in the resulting Domain directives in the existing .po file are ignored. Res guaranteed if the existing message file has been edited.	ended. g .po file.

modified 30 Sep 1992

	– m prefix	Fill in the <i>msgstr</i> with <i>prefix</i> . This is useful for debugging purposes. To make <i>msgstr</i> identical to <i>msgid</i> , use an empty string ("") for <i>prefix</i> .
	-M suffix	Fill in the <i>msgstr</i> with <i>suffix</i> . This is useful for debugging purposes.
	– p pathname	Specify the directory where the output files will be placed. This option overrides the current working directory.
	-x exclude-file	Specify a .po file that contains a list of <i>msgids</i> that are not to be extracted from the input files. The format of <i>exclude-file</i> is identical to the .po file. However, only the <i>msgid</i> directive line in <i>exclude-file</i> is used. All other lines are simply ignored. The $-\mathbf{x}$ option can only be used with the $-\mathbf{a}$ option.
	-h	Print a help message on the standard output.
SEE ALSO	msgfmt(1), gettext((31)

NOTES xgettext is not able to extract cast strings, for example ANSI C casts of literal strings to (const char *). This is unnecessary anyway, since the prototypes in libintl.h> already specify this type.

modified 30 Sep 1992

NAME xstr – extract strings from C programs to implement shared strings

SYNOPSISxstr -c filename [-v] [-l array]xstr [-l array]xstr filename [-v] [-l array]

AVAILABILITY SUNWcsu

```
DESCRIPTION
```

xstr maintains a file called **strings** into which strings in component parts of a large program are hashed. These strings are replaced with references to this common area. This serves to implement shared constant strings, which are most useful if they are also readonly.

The command:

example% xstr -c filename

extracts the strings from the C source in name, replacing string references by expressions of the form **&xstr**[*number*] for some number. An appropriate declaration of **xstr** is prepended to the file. The resulting C text is placed in the file **x.c**, to then be compiled. The strings from this file are placed in the **strings** data base if they are not there already. Repeated strings and strings which are suffixes of existing strings do not cause changes to the data base.

After all components of a large program have been compiled, a file declaring the common **xstr** space called **xs.c** can be created by a command of the form:

example% xstr

This **xs.c** file should then be compiled and loaded with the rest of the program. If possible, the array can be made read-only (shared) saving space and swap overhead.

xstr can also be used on a single file. A command:

example% xstr filename

creates files **x.c** and **xs.c** as before, without using or affecting any **strings** file in the same directory.

It may be useful to run **xstr** after the C preprocessor if any macro definitions yield strings or if there is conditional code which contains strings which may not, in fact, be needed. **xstr** reads from the standard input when the argument '–' is given. An appropriate command sequence for running **xstr** after the C preprocessor is:

```
example% cc –E name.c | xstr –c –
example% cc –c x.c
example% mv x.o name.o
```

xstr does not touch the file **strings** unless new items are added; thus **make**(1S) can avoid remaking **xs.o** unless truly necessary.

modified 14 Sep 1992

OPTIONS	-c filename	Take C source text from <i>filename</i> .	
	$-\mathbf{v}$	Verbose: display a progress report indicating where new or duplicate strings were found.	
	–l array	Specify the named <i>array</i> in program references to abstracted strings. The default array name is xstr .	
FILES	strings x.c xs.c /tmp/xs*	data base of strings massaged C source C source for definition of array "xstr*(rq temp file when xstr <i>filename</i> doesn't touch strings	
SEE ALSO	make(1S)		
BUGS		a suffix of another string in the data base, but the shorter string is seen first strings will be placed in the data base, when just placing the longer one there	
NOTES	Be aware that xstr indiscriminately replaces all strings with expressions of the form &xstr [<i>number</i>] regardless of the way the original C code might have used the string. For example, you will encounter a problem with code that uses sizeof() to determine the length of a literal string because xstr will replace the literal string with a pointer that most likely will have a different size than the string's. To circumvent this problem:		
	(ir	<pre>se strlen() instead of sizeof(); note that sizeof() returns the size of the array ncluding the null byte at the end), whereas strlen() doesn't count the null rte. The equivalent of sizeof("xxx") really is (strlen("xxx"))+1.</pre>	
	#d	te #define for operands of sizeof() and use the define 'd version. xstr ignores lefine statements. Make sure you run xstr on <i>filename</i> before you run it on e preprocessor.	
	form	encounter a problem when declaring an initialized character array of the	
	char	$\mathbf{x}[] = "xxx";$	
		ace xxx with an expression of the form &xstr[number] which will not com- umvent this problem, use static char * x = " xxx " instead of static char x[] =

NANGE				
NAME	yacc – yet	yacc – yet another compiler-compiler		
SYNOPSIS		usr/ccs/bin/yacc [-dltVv] [-b file_prefix] [-Q [y n]] [-P parser] [-p sym_prefix] file		
AVAILABILITY	SUNWbto	ol		
DESCRIPTION	The yacc command converts a context-free grammar into a set of tables for a simple maton that executes an LALR(1) parsing algorithm. The grammar may be ambiguo specified precedence rules are used to break ambiguities.			
	yyparse(). well as ma	t file, y.tab.c , must be compiled by the C compiler to produce a function This program must be loaded with the lexical analyzer program, yylex() , as in() and yyerror() , an error handling routine. These routines must be sup- ne user; the lex(1) command is useful for creating lexical analyzers usable by		
OPTIONS	The follow	ving options are supported:		
	- b file_pre	fix		
		Use <i>file_prefix</i> instead of y as the prefix for all output files. The code file y.tab.c , the header file y.tab.h (created when – d is specified), and the description file y.output (created when – v is specified), will be changed to <i>file_prefix</i> . tab.c , <i>file_prefix</i> . tab.h , and <i>file_prefix</i> . output , respectively.		
	-d	Generates the file y.tab.h with the #define statements that associate the yacc user-assigned "token codes" with the user-declared "token names." This association allows source files other than y.tab.c to access the token codes.		
	- l	Specifies that the code produced in y.tab.c will not contain any #line con- structs. This option should only be used after the grammar and the associated actions are fully debugged.		
	–P parser	Allows you to specify the parser of your choice instead of		
/usr/ccs/bin/yaccpar. For example, you can specify:				
		example% yacc –P ~/myparser parser.y		
	- p sym_p	Use <i>sym_prefix</i> instead of yy as the prefix for all external names produced by yacc . The names affected include the functions yyparse() , yylex() and yyer-ror() , and the variables <i>yylval</i> , <i>yychar</i> and <i>yydebug</i> . (In the remainder of this section, the six symbols cited are referenced using their default names only as a notational convenience.) Local names may also be affected by the – p option; however, the – p option does not affect #define symbols generated by yacc .		
	$-\mathbf{Q}[\mathbf{y} \mathbf{n}]$	The $-\mathbf{Q}\mathbf{y}$ option puts the version stamping information in y.tab.c . This allows you to know what version of yacc built the file. The $-\mathbf{Q}\mathbf{n}$ option (the default) writes no version information.		
	t	Compiles runtime debugging code by default. Runtime debugging code is		

SunOS 5.5	User Commands	yacc(1)		
	always generated in y.tab.c under conditional compil default, this code is not included when y.tab.c is comp the –t option is used, the runtime debugging code is u YYDEBUG , a preprocessor symbol. If YYDEBUG has the debugging code is included. If its value is 0 , then included. The size and execution time of a program p runtime debugging code will be smaller and slightly f	piled. Whether or not inder the control of a non-zero value, then the code will not be produced without the		
	-V Prints on the standard error output the version inform	nation for yacc .		
	 -v Prepares the file y.output, which contains a description and a report on conflicts generated by ambiguities in 			
OPERANDS	The following operand is required:			
	<i>file</i> A path name of a file containing instructions for whic created.	h a parser is to be		
EXAMPLES	Access to the yacc library is obtained with library search operand library main , example% cc y.tab.c -ly	ls to cc. To use the yacc		
	Both the lex library and the yacc library contain main . To access	the yacc main ,		
	example% cc y.tab.c lex.yy.c -ly -ll			
	This ensures that the yacc library is searched first, so that its main is used.			
	The historical yacc libraries have contained two simple functions by the application programmer. These library functions are simi	•		
	#include <locale.h> int main(void)</locale.h>			
	{ extern int yyparse();			
	<pre>setlocale(LC_ALL, "");</pre>			
	<pre>/* If the following parser is one created by lex, the application must be careful to ensure that LC_CT and LC_COLLATE are set to the POSIX locale. * (void) yyparse(); return (0); }</pre>			
	<pre>#include <stdio.h></stdio.h></pre>			
	int yyerror(const char *msg) {			
	(void) fprintf(stderr, "%s\n", msg); return (0);			

1-1193

	}
ENVIRONMENT	See environ (5) for descriptions of the following environment variables that affect the exe- cution of yacc : LC_CTYPE , LC_MESSAGES , and NLSPATH .
	yacc can handle characters from EUC primary and supplementary codesets as one-token symbols. EUC codes may only be single character quoted terminal symbols. yacc expects yylex() to return a wide character (wchar_t) value for these one-token symbols.
EXIT STATUS	The following exit values are returned:
	0 Successful completion.
	>0 An error occurred.
FILES	y.outputstate transitions of the generated parsery.tab.csource code of the generated parsery.tab.hheader file for the generated parseryacc.actstemporary fileyacc.debugtemporary fileyacc.tmptemporary fileyaccparparser prototype for C programs
SEE ALSO	cc (1B), lex (1), environ (5) and the yacc chapter in the <i>Programming Utilities Guide</i> manual.
DIAGNOSTICS	The number of reduce-reduce and shift-reduce conflicts is reported on the standard error output; a more detailed report is found in the y.output file. Similarly, if some rules are not reachable from the start symbol, this instance is also reported.
NOTES	Because file names are fixed, at most one yacc process can be active in a given directory at a given time.

NAME	ypcat – print va	alues in a NIS database		
SYNOPSIS	ypcat [-kx] [-	pcat [– kx] [– d ypdomain] mname		
AVAILABILITY	SUNWnisu			
DESCRIPTION	which may be e	mand prints out values in the NIS name service map specified by <i>mname</i> , either a map name or a map nickname. Since ypcat uses the NIS network S server is specified.		
	Refer to ypfiles	s(4) for an overview of the NIS name service.		
OPTIONS	- k	Display the keys for those maps in which the values are null or the key is not part of the value. None of the maps derived from files that have an ASCII version in / etc fall into this class.		
	- d ypdomain	Specify a domain other than the default domain.		
	- x	Display map nicknames.		
SEE ALSO	ypmatch(1), yp	ofiles(4)		

modified 23 Jan 1995

NAME	ypmatch – prin	t the value of one or more keys from a NIS map		
SYNOPSIS	ypmatch [–k]	ypmatch [- k] [- t] [- d domain] key [key] mname		
	ypmatch –x			
AVAILABILITY	SUNWnisu			
DESCRIPTION		ypmatch prints the values associated with one or more keys from the NIS's name services map specified by <i>mname</i> , which may be either a <i>mapname</i> or a map nickname (<i>mnames</i>).		
	must be the san	an be specified; all keys will be searched for in the same map. The keys ne case and length. No pattern matching is available. If a key is not gnostic message is produced.		
OPTIONS	- k	Before printing the value of a key, print the key itself, followed by a ':' (colon).		
	-t	This option inhibits map nickname translation.		
	- d domain	Specify a domain other than the default domain.		
	- x	Display the map nickname table. This lists the nicknames (<i>mnames</i>) the command knows of, and indicates the <i>mapname</i> associated with each nickname.

NAME	yppasswd – change your network password in the NIS database
SYNOPSIS	yppasswd [username]
AVAILABILITY	SUNWcsu
DESCRIPTION	yppasswd changes the network password associated with the user <i>username</i> in the Network Information Service (NIS+) database. If the user has done a keylogin (1), and a publickey/secretkey pair exists for the user in the NIS publickey.byname map, yppasswd also re-encrypts the secretkey with the new password. The NIS password may be different from the local one on your own machine. Use passwd (1) to change the password information on the local machine, and nispasswd (1) to change the password information stored in Network Information Service Plus, Version 3 (NIS+).
	yppasswd prompts for the old NIS password, and then for the new one. You must type in the old password correctly for the change to take effect. The new password must be typed twice, to forestall mistakes.
	New passwords must be at least four characters long, if they use a sufficiently rich alpha- bet, and at least six characters long if monocase. These rules are relaxed if you are insistent enough. Only the owner of the name or the super-user may change a password; in either case you must prove you know the old password.
	The NIS password daemon, rpc.yppasswdd must be running on your NIS server in order for the new password to take effect.
SEE ALSO	keylogin(1), login(1), nispasswd(1), passwd(1), getpwnam(3C), getspnam(3C), secure_rpc(3N), nsswitch.conf(4)
WARNINGS	Even after the user has successfully changed his or her password using this command, the subsequent login (1) using the new password will be successful only if the user's password and shadow information is obtained from NIS, (see getpwnam (3C), getspnam (3C), and nsswitch.conf (4)).
NOTES	The use of yppasswd is discouraged, as it is now only a link to the passwd (1) command, which should be used instead. Using passwd (1) with the –r nis option will achieve the same results, and will be consistent across all the different name services available.
BUGS	The update protocol passes all the information to the server in one RPC call, without ever looking at it. Thus if you type your old password incorrectly, you will not be notified until after you have entered your new password.

NAME	ypwhich – return name of NIS server or map master		
SYNOPSIS	ypwhich [–d ypwhich –x	domain] [[$-\mathbf{t}$] $-\mathbf{m}$ [mname] [$-\mathbf{Vn}$] hostname]	
AVAILABILITY	SUNWnisu		
DESCRIPTION	ypwhich returns the name of the NIS server that supplies the NIS name services to a NIS client, or which is the master for a map. If invoked without arguments, it gives the NIS server for the local machine. If <i>hostname</i> is specified, that machine is queried to find out which NIS master it is using.		
	Refer to ypfiles (4) for an overview of the NIS name services.		
OPTIONS	– d domain	Use <i>domain</i> instead of the default domain.	
	-t	This option inhibits map nickname translation.	
	- m mname	Find the master NIS server for a map. No <i>hostname</i> can be specified with –m . <i>mname</i> can be a mapname, or a nickname for a map. When <i>mname</i> is omitted, produce a list of available maps.	
	- x	Display the map nickname translation table.	
	-Vn	Version of ypbind , V3 is default.

D

decode files - crypt, 1-160 decrypt - crypt, 1-160 define locale environment — localedef, 1-517 dependencies, dynamic of executable files or shared objects — 1dd, 1 - 484deroff - remove nroff, troff, tbl and eqn constructs, 1-205 describe command — whatis, 1-1171 desk calculator - dc, 1-202 devices eject media device from drive — eject, 1-251 df — display status of disk space on file systems, 1B-206 dictionary, system find words — 100k, 1-529 diff — display line-by-line differences between pairs of text files, 1-207 3-way — diff3, 1-210 big — bdiff, 1-73 diff command side-by-side — sdiff, 1-935 diff3 — display line-by-line differences between three text files, 1-210 diffmk — mark differences between versions of a troff input file, 1-212 dircmp — compares contents of directories, 1-213 directories compare contents — dircmp, 1-213 list contents — 1s, 1-553 list contents of — 1s, 1B-558 make — mkdir, 1-631 make link to — ln, 1B-509 print working directory name — pwd, 1-853 remove - rmdir, 1-877 dirname — delivers all but last level of path name, 1-68dirs — shell built-in functions to change the current working directory, 1-85 dis - object code disassembler, 1-214 disable — disable LP printers, 1-254

disassembler object code — dis, 1-214 display a list of all valid user names — dispuid, 1 - 217architecture of current host — arch, 1-42 call-graph profile data — gprof, 1-367 contents of directory - 1s, 1-553 current news - news, 1-673 — date. 1-199 disk usage – du, 1B-224 dynamic dependencies of executable files or shared objects — 1dd, 1-484 effective user name — whoami, 1B-1180 file names — 1s, 1B-558 first few lines of files - head, 1-381 group membership of user — groups, 1B-377, 1 - 376how long the system has been up — uptime, 1-1125 identifier of current host — hostid, 1-390 last commands executed, in reverse order lastcomm, 1-476 list of all valid group names — disgid, 1-216 login and logout information about users and terminals — last, 1-475 name of current host - hostname, 1-391 name of the user running the process — logname, 1-527 printer queue — lpg, 1B-542 process status — ps, 1B-848 processor type of current host — mach, 1-566 selected lines from file - sed, 1B-944 size of page of memory — pagesize, 1-746 status of disk space on file system — df, 1B-206 status of local hosts — ruptime, 1-892 status of network hosts — rup, 1-890 users on system — users, 1B-1126 working directory name — pwd, 1-853 display editor — vi, 1-1150 display or change font information in the RAM of the video card on an x86 system in text mode - loadfont. 1-512 displays package parameter values — pkgparam,

display profile data — prof, 1-838 display the internal versioning information of dynamic objects - pvs, 1-851 document production check nroff/troff files — checknr, 1-88 check spelling — spell, 1-994 create an inverted index to a bibliographic database — indexbib, 1-404 create or extend bibliography — addbib, 1-34 eliminate .so's from nroff input - soelim, 1-986 expand and insert references from a bibliographic database — refer, 1-865 filters reverse line-feeds from two-column nroff text — col, 1-129 find references in a bibliographic database lookbib, 1-530 format and print a bibliographic database roffbib, 1-880 format documents for display or line-printer nroff, 1-734 format tables for nroff or troff — tbl, 1-1043 mark differences between versions of a troff input file — diffmk, 1-212 remove nroff, troff, tbl and eqn constructs — deroff, 1-205 simple text formatters — fmt, 1-313 sort a bibliographic database — sortbib, 1-992 troff postprocessor for PostScript printers dpost, 1-221 typeset mathematics — eqn, 1-256 typeset or format documents — troff, 1-1097 DOS convert text file from DOS format to ISO format — dos2unix, 1-218 convert text file from ISO format to DOS format — unix2dos, 1-1124 dos2unix — convert text file from DOS format to ISO format. 1-218 download — host resident PostScript font downloader, 1-219

dpost — troff postprocessor for PostScript printers,

1-221

- draw graph graph, 1-370
- du display disk usage per directory or file, 1B-224
- dump dump selected parts of an object file, 1-226
 dumpcs show codeset table for the current
 locale, 1-228
- dumpkeys dump keyboard translation tables, 1-514

Ε

echo — (FMLI utility) put string on virtual output, 1F-233. 1-229 echo — echo arguments to standard output, 1B-232 ed - text editor, 1-234 edit - text editor, 1-245 editing text sed — stream editor, 1B-944 egrep — search a file for a pattern using full regular expressions, 1-249 eject — eject media device from drive, 1-251 enable — enable LP printers, 1-254 encode binary file — uuencode, 1C-1131 encode files crypt, 1-160 encryption key, user change — chkey, 1-91 env - obtain or alter environment variables for command execution, 1-255 environment display variables — printenv, 1B-824 set terminal characteristics — tset, 1B-1104 environment variables set or alter for command execution — env. 1 - 255environment variables, global FMLI, 1F-955 eqn remove nroff, troff, tbl and eqn constructs — deroff, 1-205 eqn — mathematical typesetting, 1-256 equations

equations, continued typeset mathematics — eqn, 1-256 error — analyze error messages, 1-260 eval — shell built-in functions to execute other commands, 1-270 ex - text editor, 1-263 exec — shell built-in functions to execute other commands, 1-270 execute a simple command — command, 1-132 execute commands at a later time — at, 1-184, 1-48 batch, 1-184, 1-48 exit — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 1-272 expand — expand TAB characters to SPACE characters, 1-274 export — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents. 1-950 exportfs — translates exportfs options to share/unshare commands, 1B-276 expr — evaluate arguments as an expression, 1-277, 1B-280 expression evaluation - expr, 1B-280 exstr — extract strings from source files, 1-283 extract kernel probes output into a trace file tnfxtract, 1-1079 extract strings from C code — xstr, 1-1190

F

- face executable for the Framed Access Command Environment Interface, 1-286
- factor obtain the prime factors of a number, 1-287
- false provide truth values, 1-1099
- $\begin{array}{l} \texttt{fastboot} \mbox{--} reboot \ system \ without \ checking \ disks, \\ 1B\text{-}288 \end{array}$
- $\begin{array}{l} \texttt{fasthalt} \mbox{--halt system without checking disks,} \\ 1B\text{--288} \end{array}$
- fc shell built-in functions to re-use previous
 command-lines from the current shell, 1-382
 fdformat floppy diskette format

fdformat — floppy diskette format, continued format floppy diskette, 1-289 fg — shell built-in functions to control process execution. 1-410 fgrep — search a file for a character string, 1-293 file — determine file type, 1-295 change ownership — chown, 1B-99 determine type of — file, 1B-297 display names — 1s, 1B-558 files perusal filter for CRTs — pg, 1-777 make link to — ln, 1B-509 print — lpr, 1B-544 strip affixes — basename, 1B-69 sum — sum and count blocks in file, 1B-1021 update last modified date of - touch, 1B-1084 file — get file type, 1B-297 file system display status of disk space — df, 1B-206 make hard or symbolic links to files — ln, 1-506 where am I — pwd, 1-853 file transfer program - ftp, 1-332 files change owner of file — chown, 1-97 change the permissions mode of a file chmod, 1-92 compare two files — cmp, 1-128 compress — compress, 1-135 compress files — pack, 1-743 concatenate and display — cat, 1-81 сору — ср. 1-142 copy archives — cpio, 1-145 crypt — encrypt/decrypt, 1-160 cut out selected fields of each line of a file cut, 1-197 display a count of lines, words and characters in a file — wc, 1-1169 display first few lines — head, 1-381 display last part — tail, 1-1033 display line-by-line differences between pairs of large text files — bdiff, 1-73 display line-by-line differences between pairs of text files — diff, 1-207

display line-by-line differences between three text files — diff3, 1-210 display uncompressed files but leaves compressed files intact — zcat, 1-135 expand compressed files — unpack, 1-743 extract SCCS version information from a file what. 1-1170 — find, 1-299 mark differences between versions of a troff input file — diffmk, 1-212 merge same lines of several files or subsequent lines of one file — paste, 1-752 move — mv, 1-647 print checksum and block count for a file sum, 1-1020 print differences between two files side-by-side - sdiff, 1-935 remove — rm, 1-877 search a file for a character string — fgrep, 1-293 search a file for a pattern — grep, 1-372 search for a pattern using full regular expressions — egrep, 1-249 sort or merge — sort, 1-987 split a file into pieces — split, 1-997 strip affixes from path names — basename, 1-68transfer to and from a remote machine tftp, 1-1060 uncompress — uncompress, 1-135 find — find files, 1-299 floppy diskette format — fdformat, 1-289 fmlcut — (FMLI utility) cut out columns from a table or fields from each line of a file, 1F-306 fmlexpr — (FMLI utility) evaluate arguments as an expression, 1F-308 fmlgrep — (FMLI utility) search afile for a pattern, 1F-310 FMLI cocheck — communicate with a process, 1F-138 cocreate — communicate with a process,

1F-138

codestroy — communicate with a process,

files. continued

1F-138

FMLI, continued coproc — communicate with a process, 1F-138 coreceive — communicate with a process, 1F-138 cosend — communicate with a process, 1F-138 echo - put string on virtual output, 1F-233 fmlcut — cut out columns from a table or fields from each line of a file, 1F-306 fmlexpr — evaluate arguments as an expression, 1F-308 fmlgrep — search afile for a pattern, 1F-310 fmli — invoke fmli, 1-311 getfrm — returns the current frameID number, 1F-352 getitems — returns a list of currently marked menu items, 1F-353 indicator - displays application specific alarms or working indicator, or both, on FMLI banner line, 1F-403 message — puts arguments on FMLI message line, 1F-629 pathconv — converts an alias to its pathname, 1F-761 readfile, longline — reads file, gets longest line, 1F-863 regex — match patterns against a string, 1F-869 reinit — changes the descriptors in the initialization file. 1F-871 reset — (FLMI utility) changes the entry in a field of a form to its default value, 1F-874 run — runs a program, 1F-889 set, unset — set and unset local or global environment variables, 1F-955 setcolor — redefine or create a color, 1F-956 shell — run a command using shell, 1F-977 test - evaluates the expression expression, 1F-1058 vsig — synchronize a co-process with the controlling FMLI application, 1F-1162 fmt — simple text formatters, 1-313 fold — fold long lines, 1-327 fonts

fonts. continued prepends host resident PostScript fonts to files - download, 1-219 for — shell built-in functions to repeatedly execute action(s) for a selected number of times, 1-329 foreach — shell built-in functions to repeatedly execute action(s) for a selected number of times, 1-329 formatters, text — fmt, 1-313 Forms and Menu Language Interpreter, See FMLI FORTRAN create a tags file for use with ex and vi ctags, 1-188 Framed Access Command Environment, see face frameID number (FMLI utility) — getfrm, 1F-352 from — sender of mail messages, 1B-331 ftp — file transfer program, 1-332 function — shell built-in command to define a function which is usable within this shell. 1-341

G

gencat — generate a formatted message catalog, 1-343

generate programs for lexical tasks - lex, 1-487

get configuration values — getconf, 1-346

get locale-specific information — locale, 1-515

getconf — get configuration values, 1-346

getfrm — (FMLI utility) returns the current frameID number, 1F-352

getitems — (FMLI utility) returns a list of currently marked menu items, 1F-353

getopt - parse command options, 1-354, 1-356

- getoptcvt parse command options, 1-356
- getoptcvt parse command options, 1-356, 1-358

gettext — retrieve text string from message database, 1-363, 1-364

glob — shell built-in function to expand a word list, 1-366

goto — shell built-in functions to enable the execution of the shell to advance beyond its sequence

of steps, 1-272 gprof — call-graph profile, 1-367 graph — draw graph, 1-370 graphics interpolate smooth curve — spline, 1-996 graphics filters for plotters — plot, 1B-790, 1-1085 grep search a file for a character string — fgrep, 1 - 293search a file for a pattern — grep, 1-372 search a file for a pattern using full regular expressions — egrep, 1-249 group IDs change real and effective — newgrp, 1-671 change the group ownership of a file chgrp, 1-89 display a list of all valid group names - disgid, 1-216 prompts for group ID — ckgid, 1-102 provides error message for group ID errgid, 1-102 provides help message for group ID - helpgid, 1-102 validates group ID — valgid, 1-102 groups — display group membership, 1B-377, 1-376 grpck — check group database entries, 1B-378

Η

halt system without checking disks — fasthalt, 1B-288
hash — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-379
hashstat — shell built-in functions to evaluate the internal hash table of the contents of directories, 1-379
head — display first few lines of files, 1-381
history — shell built-in functions to re-use previous command-lines from the current shell, 1-382
HOME variable — sh, 1-964
host machines, local

host machines, local, continued show status — ruptime, 1-892 who's logged in — rwho, 1-895 host machines, remote display status of network hosts (RPC version) — rup, 1-890 who's logged in — rusers, 1-894 host resident PostScript font downloader — download, 1-219 hostid — display host ID, 1-390 hostname — display host name, 1-391

I

i386 — get processor type truth value, 1-567 iAPX286 — get processor type truth value, 1-567 if — shell built-in functions to evaluate condition(s) or to make execution of actions dependent upon the evaluation of condition(s), 1-394 IFS variable — sh, 1-964 indicator — (FMLI utility) displays application specific alarms or working indicator, or both, on FMLI banner line, 1F-403 indxbib — create an inverted index to a bibliographic database, 1-404 install — install files, 1B-405 integer prompts for an integer — ckint, 1-104 provides error message for integer — errint, 1 - 104provides help message for integer — helpint, 1 - 104validates an integer — valint, 1-104 integer, range prompts for an integer within a specified range — ckrange, 1-114 provides error message for integer within a specified range — errange, 1-114 provides help message for integer within a specified range — helprange, 1-114 validate an integer within a specified range valrange, 1-114 Internet

Internet, *continued* transfer files to and from a remote machine tftp, 1-1060 transfer of files to and from remote network sites — ftp, 1-332 user name directory service — whois, 1-1181 interprocess communication remove a message queue, semaphore set, or shared memory ID — ipcrm, 1-406 report status — ipcs, 1-407 ipcrm — remove a message queue, semaphore set, or shared memory ID, 1-406 ipcs — report inter-process communication facilities status, 1-407

J

jobs — shell built-in functions to control process execution, 1-410 join — relational database operator, 1-416 jsh — the job control shell command interpreter

K

kbd — manipulate the state of keyboard or display the type of keyboard, 1-419 Kerberos login utility - kinit, 1-428 Kerberos system introduction — Kerberos, 1-421 Kerberos ticket-granting-ticket fetch and store using service key — ksrvtgt, 1-474 **Kerberos tickets** destroy - kdestroy, 1-420 list currently held — klist, 1-429 keyboard load and dump keyboard translation tables loadkeys, dumpkeys, 1-514 manipulate the state of keyboard or display the type of keyboard — kbd, 1-419 keylogin — decrypt and store secret key with keyserv, 1-423 ${\tt keylogout} - delete \ stored \ secret \ key \ with$ keyserv, 1-424

keywords prompts for and validates a keyword ckkeywd, 1-109 kill — terminate a process by default, 1-425 Korn shell commands login command, 1-463 KornShell aliasing — ksh, 1-432 arithmetic evaluation — ksh, 1-446 blank interpretation — ksh, 1-445 command execution — ksh, 1-452 command re-entry — ksh, 1-453 command substitution — ksh, 1-435 commands — ksh, 1-430 comments — ksh, 1-432 conditional expressions — ksh, 1-447 definitions — ksh, 1-430 emacs editing mode — ksh, 1-454 environment — ksh, 1-449 file name generation — ksh, 1-445 functions — ksh, 1-450 I/O - ksh, 1-448 in-line editing options — ksh, 1-453 invocation — ksh, 1-470 jobs — ksh, 1-451, 1-412 parameter substitution — ksh, 1-438 process substitution — ksh, 1-437 prompting — ksh, 1-447 quoting — ksh, 1-446 restricted command and programming language — rksh, 1-430 signals — ksh, 1-452 special commands — ksh, 1-459 tilde substitution — ksh, 1-434 vi editing mode — ksh, 1-456 ksh — KornShell, a standard command and programming language, 1-430

L

languages
 C compiler — cc, 1B-83
 C preprocessor — cpp, 1-151
 C program verifier — lint, 1B-504
 create C error messages — mkstr, 1B-635
 extract strings from C code — xstr, 1-1190

last — display login and logout information about users and terminals, 1-475 lastcomm — display the last commands executed, in reverse order. 1-476 LC ALL variable — sh, 1-965 LC CTYPE variable — sh, 1-965 LC_MESSAGES variable — sh, 1-9651d — link editor for object files, 1-477 1d — link editor, 1B-483 1dd — list dynamic dependencies of executable files or shared objects, 1-484 let — shell built-in function to evaluate one or more arithmetic expressions, 1-486 lex — generate programs for lexical tasks, 1-487 Actions in lex, 1-494 create a tags file for use with ex and vi -ctags, 1-188 Definitions in lex, 1-489 /, 1-488 **Regular Expressions in lex, 1-491** Rules in lex, 1-490 Stderr, 1-488 Stdout, 1-487 User Subroutines in lex. 1-490 library archive find ordering relation for an object or library archive — lorder, 1-531 limit — shell built-in functions to set/get limitations on the system resources available to the current shell and it's descendents.. 1-499 line — read one line from standard input and write to standard output, 1-503 line numbering filter — nl, 1-725 line printer control — lpc link make hard or symbolic links to files — ln, 1 - 506link editor — 1d, 1B-483, 1-477 lint — C program verifier, 1B-504 list contents of directory — ls, 1-553 file names — 1s, 1B-558 list of service grades

list of service grades, continued print — uuglist, 1C-1133 list. sorted find lines — look, 1-529 listusers — list user login information, 1-505 ln — make hard or symbolic links to files, 1-506 loadfont — display or change font information in the RAM of the video card on an x86 system in text mode, 1-512 loadkeys — load keyboard translation tables, 1-514 locale — get locale-specific information, 1-515 localedef — define locale environment, 1-517 log, system add entries — logger, 1-520 logger — add entries to the system log, 1-520, 1B-522 login change login password and password attributes - passwd, 1-747 display effective user name — whoami, 1B-1180 display login and logout information about users and terminals — last, 1-475 get the name of the user running the process logname, 1-527 list user login information — listusers, 1-505 remote — rlogin, 1-875 spawn login to a remote terminal — ct, 1C-186 who is logged in, and what are they doing w. 1-1163 login command, 1-463, 1-971, 1-523 login environment display variables — printenv, 1B-824 set terminal characteristics — tset, 1B-1104 login password change in NIS - yppasswd, 1-1197 logname — get the name of the user running the process, 1-527 logout — shell built-in function to exit from a login session, 1-528

logout — shell built-in function to exit from a login session, *continued* display login and logout information about users and terminals — last, 1-475 look — find words in the system dictionary or lines in a sorted list, 1-529 lookbib — find references in a bibliographic database, 1-530 lorder — find ordering relation for an object or library archive, 1-531 1p — send requests to an LP print service, 1-532 LP print services cancel requests — cancel, 1-532 control line printer — lpc, 1B-539 display printer queue — lpq, 1B-542 generate printer test pattern — lptest, 1B-552 print files — 1p, 1-532 print files (BSD) — lpr, 1B-544 print information about the status — lpstat, 1-549remove print jobs — lprm, 1B-547 lpc — line printer control, 1B-539 lpg — display printer queue, 1B-542 lpr — print files, 1B-544 lprm — remove print jobs, 1B-547 lpstat — print information about the status of the LP print service, 1-549 lptest — generate printer test pattern, 1B-552 ls — list contents of directory, 1-553, 1B-558

Μ

magnetic tape, continued erase — mt, 1-645 forward space files — mt, 1-645 forward space records — mt, 1-645 get unit status — mt, 1-645 manipulate — mt, 1-645 place unit off-line — mt, 1-645 retension - mt, 1-645 rewind — mt, 1-645 skip backward files — mt, 1-645 skip backward records — mt, 1-645 skip forward files — mt, 1-645 skip forward records — mt, 1-645 write EOF mark on - mt, 1-645 mail — read mail or send mail to users automatic replies — vacation, 1-1142 mail services mail notifier — biff, 1B-74 sender of mail messages — from, 1B-331 mail utilities create aliases database — newaliases, 1-667 statistics - mailstats, 1-574 MAIL variable — sh, 1-964 mailbox storage for incoming mail — mailx, 1-575 MAILCHECK variable — sh, 1-964 mailcompat — provide SunOS compatibility for Solaris mailbox format, 1-573 MAIL variable — sh, 1-964 mailstats — mail delivery statistics, 1-574 mailx — interactive message processing system, 1-575, 1-593 mailx commands — !, 1-579 — #, 1-579 — =. 1-579 — ?. 1-579 — |, 1-582 — alias, 1-579 — alternates, 1-579 — cd, 1-579 - chdir, 1-579 — Сору, 1-579 - delete, 1-579

mailx commands, continued - touch, 1-584 — Туре, 1-583, 1-584, 1-582 — unalias, 1-585 - undelete, 1-585 — undiscard, 1-585 — ungroup, 1-585 — unignore, 1-585 — Unread, 1-582, 1-585 — unretain, 1-585 - unset, 1-585 - version, 1-585 - visual, 1-585 - write, 1-585 — xit. 1-585 — z, 1-585 maintain groups of programs - sysV-make make - maintain, update, and regenerate related programs and files Appending to a Macro, 1S-602 **Bourne Shell Constructs**, 1S-615 **Clearing Special Targets, 1S-601 Command Dependencies**, 1S-601 Command Execution, 1S-615 Command Substitutions, 1S-616 Conditional Macro Definitions, 1S-604 Dvnamic Macros. 1S-603 Global, 1S-598 Hidden Dependencies, 1S-601 Implicit Rules, 1S-606 implicit rules, list of make/make.rules, 1S-614 Library Maintenance, 1S-615 Macros, 1S-598, 1S-601 Makefile Target Entries, 1S-597 Pattern Matching Rules, 1S-606 Pattern Replacement Macro References, 1S-602 Predefined Macros, 1S-604 Reading Makefiles and the Environment, 1S-596 Rules, 1S-599 Signals, 1S-616 Special Characters, 1S-598 Special-Function Targets, 1S-600 Special-Purpose Macros, 1S-602 Suffix Replacement Macro References, 1S-602 Suffix Rules, 1S-607

make — maintain, update, and regenerate related programs and files, *continued* System V version of make - sysV-make Targets and Dependencies, 1S-598 The Suffixes List, 1S-614 man — online display of reference pages, 1-621 manual pages accessing — man, 1-621 describe command — whatis, 1-1171 locate — whereis, 1B-1172 matrix display program for PostScript printers postmd, 1-799 mbox storage file for read mail — mailx, 1-575 mconnect — open connection to remote mail server. 1-625 mcs — manipulate the comment section of an object file, 1-626 menu item builds a menu and prompts user to choose one item from menu — ckitem, 1-106 provides error message for menu item -erritem, 1-106 provides help message for menu item - helpitem, 1-106 menu items, FMLI returns a list of - getitems, 1F-353 mesg — permit or deny messages via write, 1-628 message — puts arguments on FMLI message line, 1F-629 messages create message object file — msgfmt, 1-642 creating portable object files - msgfmt, 1-642 display contents of, or search for a text string in, message data bases — srchtxt, 1 - 999display on stderr or system console fmtmsq, 1-315 editing messages - msgfmt, 1-642 extract gettext call strings — xgettext, 1-1188 generate a formatted message catalog - gencat, 1-343 permit or deny messages via write — mesg,

1-628 messages, continued retrieve text string from message database gettext, 1-363 setting the domain — msqfmt, 1-642 setting the message identifier - msgfmt, 1-642 setting the message string — msgfmt, 1-642 mkdir - make directories, 1-631 mkmsgs — create message files for use by gettxt, 1-633 mkstr - create C error messages, 1B-635 modify the Access Control List (ACL) for a file or files — setfacl, 1-957 more — browse through a text file, 1-637 msgfmt — create message object file, 1-642 mt — manipulate magnetic tape, 1-645 my — move files, 1-647

Ν

nawk — pattern scanning and processing language, 1-649/usr/bin/nawk, 1-649 /usr/xcu4/bin/awk, 1-649 /usr/xpg4/bin/awk, 1-649 Actions, 1-649 Arithmetic Functions, 1-649 **Expression Patterns**, 1-649 Expressions in nawk, 1-649 Functions, 1-649 Input/Output and General Functions, 1-649 Output Statements, 1-649 Pattern Ranges, 1-649 Patterns, 1-649 **Regular Expressions**, 1-649 Special Patterns, 1-649 String Functions, 1-649 User-defined Functions, 1-649 Variables and Special Variables, 1-649 negn — mathematical typesetting, 1-256 newaliases — make mail aliases database, 1-667 newform — change the format of a text file, 1-668 newgrp — changes a user's group ID, 1-671 news — print news items, 1-673 NFS, secure

NFS, secure, *continued* decrypt and store secret key with keyserv keylogin, 1-423 delete stored secret key with keyserv- keylogout, 1-424 nice — run a command at low priority, 1-675 change process nice value — renice, 1-872 NIS. See NIS+ change login password in — yppasswd, 1-1197 print the value of one or more keys from a NIS map — ypmatch, 1-1196 print values in a NIS database — ypcat, 1-1195 return name of NIS server or map master ---ypwhich, 1-1198 NIS+ Authentication — nis+, 1-683 Authorization — nis+, 1-683 change access rights on a NIS+ object ---nischmod, 1-694 change password information — nispasswd, 1-712 change the group owner of a NIS+ object nischgrp, 1-692 change the owner of a NIS+ object nischown, 1-696 change the time to live of a NIS+ object nischttl, 1-698 Concatenation Path — nis+, 1-680 create NIS+ directories — nismkdir. 1-710 Directories and Domains — nis+, 1-683 Directory Authorization — nis+, 1-684 display NIS+ defaults - nisdefaults, 1-700 display NIS+ error messages — niserror, 1-702 display tables — niscat, 1-690 Grammar — nis+, 1-679 group administration — nisgrpadm, 1-703 Group Names — nis+, 1-682 Indexed Names — nis+, 1-679 list the contents of a NIS+ directory — nisls, 1-707 Name Expansion — nis+, 1-679 Namespaces — nis+, 1-681

NIS+ Administrative Commands — nis+, 1-686NIS+ Directory Object — nis+, 1-677 NIS+ Files and Directories — nis+, 1-688 NIS+ Group Object — nis+, 1-678 NIS+ Link Object — nis+, 1-678 NIS+ Programming API — nis+, 1-687 NIS+ Table Object — nis+, 1-677 NIS+ User Commands — nis+, 1-686 Principal Names — nis+, 1-681 remove directories — nisrmdir, 1-716 remove objects — nisrm, 1-715 return the state of the NIS+ namespace using a conditional expression — nistest, 1-723 Simple Names — nis+, 1-678 symbolically link NIS+ objects — nisln, 1-705 table administration tool — nistbladm, 1-718 Table Authorization — nis+, 1-685 utilities for searching NIS+ tables nismatch, nisgrep, 1-708 niscat — display NIS+ tables, 1-690 nischgrp — change the group owner of a NIS+ object, 1-692 nischmod — change access rights on a NIS+ object, 1-694 nischown — change the owner of a NIS+ object, 1-696 nischttl — change the time to live of a NIS+ object, 1-698 nisdefaults - display NIS+ defaults, 1-700 niserror — display NIS+ error messages, 1-702 nisgrep — utility for searching NIS+ tables, 1-708 nisgrpadm — NIS+ group administration command. 1-703 nisln — symbolically link NIS+ objects, 1-705 nisls — list the contents of a NIS+ directory, 1-707 nismatch — utility for searching NIS+ tables, 1 - 708

NIS+, continued

- nismkdir create a NIS+ directory, 1-710
- nisrm remove NIS+ objects, 1-715
- nisrmdir remove a NIS+ directory, 1-716

nistbladm — administer NIS+ tables. 1-718 nistest — return the state of the NIS+ namespace using a conditional expression, 1-723 nl — number lines, 1-725 nm — print name list of an object file, 1-728 nohup — run a command immune to hangups, 1-732 notify — shell built-in functions to control process execution. 1-410 notify user that volume requested is not in the CD-ROM or floppy drive — volmissing, 1-1161 nroff - format documents for display or lineprinter, 1-734 nroff utilities check nroff and troff files — checknr, 1-88 eliminate .so's from nroff input - soelim, 1 - 986filters reverse line-feeds from two-column nroff text — col, 1-129 format tables — tbl, 1-1043 remove nroff, troff, tbl and eqn constructs — deroff, 1-205

0

object archive find ordering relation for an object or library archive — lorder, 1-531 object files find printable strings — strings, 1-1005 manipulate the comment section — mcs, 1-626 print section sizes in bytes — size, 1-983 strip symbol table, debugging and line number information — strip, 1-1006 octal dump — od, 1-736 od — octal dump, 1-736 on — execute a command on a remote system, but with the local environment, 1-741 onintr — shell built-in functions to respond to (hardware) signals, 1-1095 online reference pages — man, 1-621

P

pack — compress files, 1-743 page — page through a text file, 1-637 pagesize — display size of a page of memory, 1 - 746Pascal create a tags file for use with ex and vi -ctags, 1-188 passwd — change login password and password attributes. 1-747 password change in NIS — yppasswd, 1-1197 password file edit — vipw, 1B-1158 passwords change login password and password attributes passwd, 1-747 paste — merge same lines of several files or subsequent lines of one file, 1-752 patch — apply changes to files, 1-754 Filename Determination, 1-756 Patch Application, 1-757 Patchfile Format, 1-756 PATH variable — sh, 1-964 pathchk — check path names, 1-758 pathconv — search FMLI criteria for filename, 1F-761 pathname prompts for a pathname — ckpath, 1-111 provides error message for pathname -errpath, 1-111 provides help message for pathname - helppath, 1-111 validates pathname — valpath, 1-111 pattern scanning and processing language — nawk, 1-649pax — portable archive interchange, 1-762 Modes of Operations, 1-762 Standard Error, 1-767 Standard Output, 1-766 pcat — compress files, 1-743 pcmapkeys - set keyboard extended map and scancode translation for the PC console in text

mode, 1-769 pcred — proc tools, 1-836 pdp11 — get processor type truth value, 1-567 performance monitoring display call-graph profile data — gprof, 1-367 resource usage for a command — rusage, 1B-893 time a command; report process data and system activity — timex, 1-1065 pfiles — proc tools, 1-836 pflags — proc tools, 1-836 pg — files perusal filter for CRTs, 1-777 pkginfo — display software package information, 1-781 pkgmk — produce an installable package, 1-783 pkgparam — displays package parameter values, 1-785 pkgproto — generate prototype file entries for input to pkgmk command, 1-786 pkgtrans — translate package format, 1-788 pldd — proc tools, 1-836 plot — graphics filters for plotters, 1B-790 plotters graphics filters — plot, 1B-790, 1-1085 pmap — proc tools, 1-836 popd — shell built-in functions to change the current working directory, 1-85 portable archive interchange — pax, 1-762 postplot — PostScript translator for plot(4B) graphics files, 1-802 postdaisy - PostScript translator for Diablo 630 daisy-wheel files, 1-792 postdmd — PostScript translator for DMD bitmap files, 1-794 postio — serial interface for PostScript printers, 1 - 796postmd — matrix display program for PostScript printers, 1-799 postprint — PostScript translator for text files, 1-804 postprocessors troff for PostScript printers — dpost, 1-221

Index-18

postreverse — reverse the page order in a PostScript file, 1-806 PostScript matrix display program — postmd, 1-799 prepends host resident PostScript fonts to files — download, 1-219 reverse the page order in a PostScript file postreverse, 1-806 serial interface — postio, 1-796 translator for Diablo 630 daisy-wheel files postdaisy, 1-792 translator for DMD bitmap files — postdmd, 1-794 translator for plot(4) graphics files - postplot, 1-802 translator for Tektronix 4014 files — posttek, 1 - 808translator for text files - postprint, 1-804 troff postprocessor for PostScript printers dpost, 1-221 PostScript translator for Diablo 630 daisy-wheel files — postdaisy, 1-792 PostScript translator forMD bitmap files postdmd. 1-794 PostScript translator for Tektronix 4014 files posttek, 1-808 PostScript translator for text files — postprint, 1-804 posttek — PostScript translator for Tektronix 4014 files. 1-808 pr — print files, 1-810 prex — probe external control, 1-814 prime factors obtain for a number — factor, 1-287 print — shell built-in function to output characters to the screen or window, 1-823 formatted output — printf, 1-825 print files — pr, 1-810 print files — lpr, 1B-544 prepends host resident PostScript fonts to files — download, 1-219 printenv — display environment variables, 1B-824 printers

printers, continued cancel requests — cancel, 1-532 control — lpc, 1B-539 display queue — lpg, 1B-542 print information about the status — lpstat, 1-549remove jobs from queue — lprm, 1B-547 send requests — 1p, 1-532 test — lptest, 1B-552 printers, LP - disable, 1-254 — enable, 1-254 printf — print formatted output, 1-825 probe external control — prex, 1-814 proc tools - pcred, 1-836 - pfiles, 1-836 — pflags, 1-836 - pldd, 1-836 - pmap, 1-836 - prun, 1-836 — psig, 1-836 - pstack, 1-836 - pstop, 1-836 - ptime, 1-836 - ptree, 1-836 - pwait, 1-836 — pwdx, 1-836 process accounting search and print files — acctcom, 1-26 time a command; report process data and system activity — timex, 1-1065 process scheduler display or set scheduling parameters of specified process(es) — priocntl, 1-829 process status report — ps, 1-841 process, running change priority — renice, 1-872 processes display status — ps, 1B-848 get core images of running processes gcore, 1-342

processes, continued terminate a process by default — kill, 1-425 processors display type - mach, 1-566 prof — display profile data, 1-838 profile display call-graph — gprof, 1-367 programming languages analyze and disperse compiler error messages — error, 1-260 C compiler — cc, 1B-83 C preprocessor — cpp, 1-151 C program verifier — lint, 1B-504 extract strings from C code — xstr, 1-1190 formats program in nice style using troff vgrind, 1-1147 programming tools arbitrary precision arithmetic language — bc, 1 - 70assembler — as, 1-43 create a tags file for use with ex and vi ctags, 1-188 create C error messages - mkstr, 1B-635 debugger — adb, $1-\overline{28}$ display call-graph profile data — gprof, 1-367 dump selected parts of an object file — dump, 1 - 226find printable strings in an object or binary file - strings, 1-1005 — install. 1B-405 link editor — 1d, 1B-483 link editor for object files — 1d, 1-477 macro processor — m4, 1-561 make — build programs, 1S-594 object code disassembler — dis, 1-214 print name list of an object file — nm, 1-728 print section sizes in bytes of object files size, 1-983 regular expression compile — regcmp, 1-867 resolve and remove ifdef'ed lines from C program source — unifdef, 1-1120 resource usage for a command — rusage, 1B-893 RPC protocol compiler — rpcgen, 1-882 Source Code Control System — sccs, 1-926

programming tools, continued strip symbol table, debugging and line number information from an object file strip, 1-1006 touch — update last modified date of file, 1B-1084prun — proc tools, 1-836 ps — display process status, 1B-848 PS1 variable — sh, 1-964 PS2 variable — sh, 1-964 psig - proc tools, 1-836 pstack - proc tools, 1-836 pstop - proc tools, 1-836 ptime - proc tools, 1-836 ptree - proc tools, 1-836 pushd — shell built-in functions to change the current working directory, 1-85 pvs — display the internal versioning information of dynamic objects, 1-851 pwait - proc tools, 1-836 pwd — print working directory name, 1-853 pwdx - proc tools, 1-836

Q

queue, printer display — lpq, 1B-542 queues display the jobs queued to run at specified times — atq, 1-53 remove jobs spooled by at or batch — atrm, 1-54

R

true — convert archives to random libraries, 1-854
rcp — remote file copy, 1-855
rdist — remote file distribution, 1-857
read — shell built-in function to receive from standard input (keyboard), 1-861
readfile, longline — (FMLI utility) reads file, gets longest line, 1F-863
readonly — shell built-in function to protect the value of the given variable from reassignment, 1-864

Index-20

reboot system without checking disks - fastboot. 1B-288 red — text editor, 1-234 refer — expand and insert references from a bibliographic database, 1-865 regcmp — regular expression compile, 1-867 regenerate groups of programs - sysV-make regenerate programs — make, 1S-594 regex — (FMLI utility) match patterns against a string, 1F-869 rehash — shell built-in functions to evaluate the internal hash table of the contents of directories. 1-379 reinit — (FMLI utility) changes the descriptors in the initialization file, 1F-871 relational database - join, 1-416 reminder services - calendar, 1-77 mail notifier — biff, 1B-74 remote shell — rsh, 1-886 remote system connect — tip, 1-1067 connect to — cu, 1C-191 execute a command on a remote system, but with the local environment — on, 1 - 741file copy — rcp, 1-855 file distribution — rdist, 1-857 remote login — rlogin, 1-875 shell — rsh, 1-886 show status — rup, 1C-891, 1-890 spawn login — ct, 1C-186 system to system command execution — uux, 1C-1139 transfer files to and from — tftp, 1-1060 who's logged in on remote machines rusers, 1-894 renice — alter priority of running processes, 1-872 repeat — shell built-in function to execute a command more than once, 1-329 report or filter out repeated lines in a file — uniq, 1-1121

reset — (FLMI utility) changes the entry in a field of a form to its default value, 1F-874 reset - reset terminal bits, 1B-1104 reset terminal bits - reset, 1B-1104 return — shell built-in functions to enable the execution of the shell to advance beyond its sequence of steps, 1-272 reverse page order PostScript file — postreverse, 1-806 reverse the page order in a PostScript file - postreverse, 1-806 rksh — KornShell, restricted command and programming language, 1-430 rlogin — remote login, 1-875 rm — remove files, 1-877 rmail — only permits sending of mail, 1-569 rmdir — remove directories, 1-877 roffbib — format and print bibliographic database, 1-880 RPC display host status of remote machines — rup, 1C-891 display status of network hosts — rup, 1-890 protocol compiler — rpcgen, 1-882 **RPC** Language RPC protocol compiler — rpcgen, 1-882 RPC, secure decrypt and store secret key with keyserv keylogin, 1-423 delete stored secret key with keyserv ---keylogout, 1-424 rpcgen — RPC protocol compiler, 1-882 rsh — remote shell, 1-886 run — (FMLI utility) runs a program, 1F-889 run a command immune to hangups — nohup, 1-732rup — display status of network hosts, 1C-891, 1 - 890ruptime — display status of local hosts, 1-892 rusage — resource usage for a command, 1B-893 rusers — who's logged in on remote machines, 1-894

rwho - who's logged in on local machines, 1-895

S

sag — system activity graph, 1-896 sar — system activity reporter, 1-898 SCCS extract SCCS version information from a file what, 1-1170 sccs — Source Code Control System, 1-926 SCCS commands admin — create and administer SCCS history files, 1-901 cdc - change the delta commentary of an SCCS delta, 1-905 comb - combine deltas, 1-907 delta — change the delta commentary of an SCCS delta, 1-908 get — retrieve a version of an SCCS file, 1-910 help — help regarding SCCS error or warning messages, 1-915 prt — display delta table information from an SCCS file. 1-919 rmdel — remove a delta from an SCCS file. 1 - 921sact — show editing activity status of an SCCS file, 1-922 sccs-prs — display selected portions of an SCCS history, 1-916 sccsdiff - compare versions of SCCS file, 1-923 unget - unget SCCS file, 1-924 val — validate SCCS file, 1-925 SCCS delta change commentary — sccs-cdc, 1-905 combine - sccs-comb, 1-907 create — delta, 1-908 remove - rmdel, 1-921 SCCS delta table print form an SCCS file — sccs-prt, 1-919 SCCS files compare versions — sccs-sccsdiff, 1-923 retrieve a version of a file — sccs-get. 1-910 show editing activity status — sccs-sact, 1 - 922

SCCS files, continued undo a previous get of an SCCS file - sccsunget, 1-924 validate — sccs-val, 1-925 SCCS help regarding SCCS error or warning messages sccs-help, 1-915 SCCS history display selected portions — sccs-prs, 1-916 SCCS history files create and administer - sccs-admin, 1-901 sccs-admin — create and administer SCCS history files, 1-901 sccs-cdc — change the delta commentary of an SCCS delta, 1-905 sccs-comb — combine deltas, 1-907 sccs-delta — change the delta commentary of an SCCS delta, 1-908 sccs-get — retrieve a version of an SCCS file, 1 - 910sccs-help — help regarding SCCS error or warning messages, 1-915 sccs-prs — display selected portions of an SCCS history, 1-916 sccs-prt — display delta table information from an SCCS file, 1-919 sccs-rmdel — remove delta from SCCS file. 1-921 sccs-sact — show editing activity status of an SCCS file, 1-922 sccs-sccsdiff — compare versions of SCCS file, 1 - 923sccs-unget - unget SCCS file, 1-924 sccs-val — validate SCCS file, 1-925 screen-oriented editor - vi, 1-1150 script — make script of terminal session, 1-934 sdiff - print differences between two files sideby-side, 1-935 sed — stream editor, 1B-944, 1-937 Functions, 1B-945 sed Addresses, 1-938 sed Editing Commands, 1-938 sed Regular Expressions, 1-938 sed Scripts, 1B-944

- select shell built-in functions to choose from among a list of actions, 1-79
- select or reject lines common to two files comm, 1-131
- serial interface for PostScript printers postio, 1-796
- set shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-950

set keyboard extended map and scancode translation for the PC console in text mode — pcmapkeys, 1-769

- set, unset (FLMI utility) set and unset local
 or global environment variables, 1F-955
- setcolor (FMLI utility) redefine or create a
 color, 1F-956
- setenv shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-950
- setfacl modify the Access Control List (ACL)
 for a file or files, 1-957
 acl_entries Syntax, 1-957

shell command interpreter builtin-functions, continued - unsetenv, 1-950 — until, 1-1175 - wait, 1-1165 — whence, 1-1112 - while, 1-1175 shell programming echo arguments — echo, 1-229 read one line from standard input and write to standard output — line, 1-503 shell scripts display size of page memory — pagesize, 1 - 746provide truth values — true, false, 1-1099 SHELL variable — sh, 1-965 shell variables, in Bourne shell shell builtins — shell command interpreter built-in functions, 1-978 shells C shell - cshremote — rsh, 1-886 the job control shell command interpreter jsh, 1-961 the standard shell command interpreter — sh, 1-961 shift — shell built-in function to traverse either a shell's argument list or a list of field-separated words, 1-981 show codeset table for the current locale dumpcs, 1-228 shutdown — shut down multiuser operation, 1B-982 Simple Mail Transfer Protocol connection to remote mailserver — mconnect, 1-625size — print section sizes in bytes of object files, 1-983 sleep — suspend execution for an interval, 1-985 SMPT, See Simple Mail Transfer Protocol soelim — eliminate .so's from nroff input, 1-986 software package, displays package parameter values - pkgparam, 1-785

software package, displays package parameter values - pkgparam, continued display information — pkginfo, 1-781 generate prototype file entries for input to pkgmk command — pkgproto, 1-786 produce an installable package — pkqmk, 1-783translate package format — pkgtrans, 1-788 sort — sort and/or merge files, 1-987 sort, topological items mentioned in input — tsort, 1-1109 sortbib — sort bibliographic database, 1-992 source — shell built-in functions to execute other commands, 1-270 Source Code Control System, See SCCS source files locate — whereis, 1B-1172 sparc — get processor type truth value, 1-567 spell — check spelling, 1-994 spline — interpolate smooth curve, 1-996 split files based on context — csplit, 1-184 split — split a file into pieces, 1-997 srchtxt — display contents of, or search for a text string in, message data bases, 1-999 standard output replicate — tee, 1-1046 statistics collected by sendmail — mailstats, 1-574 stop — shell built-in functions to control process execution, 1-410 strchg — change stream configuration, 1-1002 strconf — query stream configuration, 1-1002 stream editor - sed, 1B-944, 1-937 **STREAMS** change or query stream configuration strchg, strconf, 1-1002 string prompt for defined string answer — ckstr, 1-117 provide an error message for defined string answer — errstr, 1-117 provide an help message for defined string answer - helpstr, 1-117

validate a defined string answer — valstr, 1-117 strings — find printable strings in object or binary file, 1-1005 strip — strip symbol table, debugging and line number information from an object file, 1-1006 stty — set the options for a terminal, 1-1008, 1B-1015 sum — print checksum and block count for a file, 1-1020. 1B-1021 sun — get processor type truth value, 1-567 provide SunOS compatibility for Solaris mailbox format - mailcompat, 1-573 SunOS/BSD Source Compatibility Package - stty, 1B-1015 SunOS/BSD Source Compatibility Package commands — arch, 1-42 basename, 1B-69 - biff, 1B-74 — сс. 1**В-8**3 chown, 1B-99 - df, 1B-206 - du, 1B-224 - echo, 1B-232 - expr, 1B-280 — fastboot, 1B-288 - file, 1B-297 — from, 1B-331 — groups, 1B-377 - grpck, 1B-378 — hostid, 1-390 — hostname. 1-391 — install. 1B-405 — 1d. 1B-483 - lint, 1B-504 — ln, 1B-509

- logger, 1B-522
- lpc, 1B-539
- lpg, 1B-542

string, continued

- lpr, 1B-544
- lprm, 1B-547
- lptest, 1B-552

SunOS/BSD Source Compatibility Package commands, continued - ls. 1B-558 - mach. 1-566 - mkstr. 1B-635 — pagesize, 1-746 - plot, 1B-790 - printenv, 1B-824 - ps, 1B-848 — rusage, 1B-893 — shutdown, 1B-982 — sum. 1B-1021 - test, 1B-1056 - tr. 1B-1094 - tset, 1B-1104 - users, 1B-1126 — vipw, 1B-1158 — whereis. 1B-1172 - whoami, 1B-1180 suspend — shell built-in function to halt the current shell, 1-1022 suspend execution of command - sleep, 1-985 switch — shell built-in functions to choose from among a list of actions, 1-79 symorder — update symbol table ordering, 1-1023 system activity graphical representation — sag, 1-896 reporter — sar, 1-898 time a command; report process data and system activity — timex, 1-1065 system administration — install,1B-405 system call and signals trace — truss, 1-1100 system log add entries — logger, 1-520 system name print — uname, 1-1119 system to system command execution — uux, 1C-1139 system to system copy — uucp, 1C-1127 system to system copy, public — uucp, 1C-1137 system uptime

system uptime, continued display — uptime, 1-1125 sysV-make — maintain, update, and regenerate groups of programs T TAB characters expand to SPACE characters, and vice versa expand _ unexpand 1-274

expand, unexpand, 1-274 tables format for nroff or troff — tbl, 1-1043 tabs - set tabs on a terminal, 1-1030 tail — display last part of file, 1-1033 talk — talk to another user, 1-1035 tape backspace files — mt, 1-645 backspace records — mt, 1-645 erase — mt, 1-645 forward space files - mt, 1-645 forward space records — mt, 1-645 get unit status — mt, 1-645 place unit off-line — mt, 1-645 retension - mt, 1-645 rewind — mt. 1-645 skip backward files — mt, 1-645 skip backward records — mt, 1-645 skip forward files - mt, 1-645 skip forward records — mt, 1-645 write EOF mark on - mt, 1-645 tape archives create — tar, 1-1037 tape, magnetic copy, blocking preserved — tcopy, 1-1045 manipulate — mt, 1-645 scan — tcopy, 1-1045 tar — create tape archives, and add or extract files, 1-1037 tbl — format tables for nroff or troff, 1-1043 remove nroff, troff, tbl and eqn constructs — deroff, 1-205 tcopy — copy a magnetic tape, 1-1045 tee — replicate the standard output, 1-1046 telnet — user interface to a remote system using the TELNET protocol, 1-1047

TELNET protocol user interface to a remote system using the TELNET protocol — telnet, 1-1047 terminal set options - stty, 1-1008 set tabs — tabs, 1-1030 terminal screen — clear, 1-127 terminal session make script - script, 1-934 terminals get name — tty, 1-1110 initialize a terminal or query terminfo database — tput, 1-1086 reset bits - reset, 1B-1104 set characteristics - stty, 1B-1015, 1B-1104 terminate a process by default — kill, 1-425 terminfo database initialize a terminal or query terminfo database - tput, 1-1086 test — (FMLI utility) evaluates the expression expression, 1F-1058, 1-394 test — condition evaluation, 1B-1056 text editing screen-oriented (visual) display editor based on ex — vi, 1-1150 sed - stream editor, 1B-944 stream editor — sed, 1-937 text editor - ed, 1-234 — edit, 1-245 — ex, 1-263 text files browse or page through a text file — more, page, 1-637 change format — newform, 1-668 text formatter format documents for display or line-printer nroff, 1-734 text processing utilities check spelling — spell, 1-994 concatenate and display files — cat, 1-81 display last part of file — tail, 1-1033 pattern scanning and processing language -

awk. text processing utilities, continued 1-63search a file for a character string — fgrep, 1 - 293search a file for a pattern — grep, 1-372 search a file for a pattern using full regular expressions - egrep, 1-249 sort and/or merge files — sort, 1-987 split a file into pieces — split, 1-997 translate characters — tr, 1B-1094, 1-1090 underline text — ul, 1-1115 text retrieval tools create message files for use by gettxt -mkmsgs, 1-633 gettxt, 1-364 tftp — trivial file transfer program, 1-1060 tilde escape commands for mail — mailx. 1-585 time — time a simple command, 1-1062 prompts for time — cktime, 1-121 provides error message for time — errtime, 1-121 provides help message for time — helptime, $1 - 12\overline{1}$ validates time — valtime, 1-121 time a simple command — time, 1-1062 timed event services display the jobs queued to run at specified times — atq, 1-53 reminder service — calendar, 1-77 remove jobs spooled by at or batch atrm, 1-54 user crontab file — crontab, 1-157 times — shell built-in function to report time usages of the current shell, 1-1064 timex — time a command; report process data and system activity, 1-1065 tip — connect to remote system, 1-1067 tnfxtract — extract kernel probes output into a trace file, 1-1079 touch — change file access and modification times, 1-1081, 1-1111

touch — update last modified date of file, 1B-1084 tplot — graphics filters for plotters, 1-1085 tput — initialize a terminal or query terminfo database, 1-1086 tr — translate characters, 1B-1094, 1-1090 translate characters — tr, 1B-1094, 1-1090 translates exportfs options to share/unshare commands - exportfs, 1B-276 trap — shell built-in functions to respond to (hardware) signals, 1-1095 Trivial File Transfer Protocol, See TFTP troff — typeset or format documents, 1-1097 troff utilities check nroff and troff files — checknr. 1-88 eliminate .so's from nroff input - soelim, 1-986 filters reverse line-feeds from two-column nroff text — col, 1-129 format tables — tbl, 1-1043 formats program code — vgrind, 1-1147 postprocessor for PostScript printers — dpost, 1 - 221remove nroff, troff, tbl and eqn constructs — deroff, 1-205 true — provide truth values, 1-1099 truss — trace system calls and signals, 1-1100 tset — set terminal characteristics, 1B-1104 tsort — topological sort of items mentioned in input, 1-1109 ttl — time to live value, nischttl, 1-698 tty, set characteristics — stty, 1B-1015, 1B-1104 set options — stty, 1-1008 tty — get the name of the terminal, 1-1110 typeset — shell built-in functions to set/get attributes and values for shell variables and functions, 1-1112 typeset documents — troff, 1-1097

U

u370 — get processor type truth value, 1-567 u3b — get processor type truth value, 1-567 u3b15 — get processor type truth value, 1-567 u3b2 — get processor type truth value, 1-567 u3b5 — get processor type truth value, 1-567

- ucblinks adds /dev entries to give SunOS 4.x compatible names to SunOS 5.x devices, 1B-1114
- ul underline text, 1-1115
- ulimit shell built-in functions to set/get limitations on the system resources available to the current shell and it's descendents., 1-499

umask — shell built-in function to restrict read/write/execute permissions, 1-1116

- unalias shell built-in functions to create your own pseudonym or shorthand for a command or series of commands, 1-36
- uname print name of current system, 1-1119
- uncompress uncompress files, 1-135
- underline text ul, 1-1115
- unexpand unexpand SPACE characters to TAB characters, 1-274
- unhash shell built-in functions to evaluate the internal hash table of the contents of directories, 1-379
- unifdef resolve and remove ifdef ed lines from C program source, 1-1120
- uniq report or filter out repeated lines in a file, 1-1121
- units converts quantities expressed in standard scales to other scales, 1-1123
- UNIX
 - convert text file from DOS format to ISO format — dos2unix, 1-218
- UNIX-to-UNIX commands uucp — uucp, 1C-1127
 - uulog uucp, 1C-1127
 - uuname uucp, 1C-1127
- unix2dos convert text file from ISO format to DOS format, 1-1124
- unlimit shell built-in functions to set/get limitations on the system resources available to the current shell and it's descendents., 1-499
- unpack expand compressed files, 1-743
- unset shell built-in functions to determine the characteristics for environmental variables of

the current shell and its descendents. 1-950 unseteny — shell built-in functions to determine the characteristics for environmental variables of the current shell and its descendents, 1-950 until — shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE, 1-1175 update groups of programs - sysV-make update last modified date of file - touch, 1B-1084 update programs - make, 1S-594 uptime — show how long the system has been up, 1-1125 user ID change user IDs of files — chown, 1B-99 user IDs display a list of all valid user names dispuid, 1-217 prompts for user ID — ckuid, 1-123 provides error message for user ID — erruid, 1 - 123provides help message for user ID - helpuid. 1-123 validates user ID — valuid, 1-123 users display effective name — whoami, 1B-1180 display group membership — groups, 1-376 display information about local and remote users — finger, 1-304 get the name of the user running the process logname, 1-527 list user login information — listusers. 1 - 505talk to another user — talk, 1-1035 who is logged in, and what are they doing w, 1-1163 who is on the system — who, 1-1177 who's logged in on local machines — rwho, 1 - 895who's logged in on remote machines rusers, 1-894 write to another user — write, 1-1182 users — display users on system, 1B-1126 users, network Internet user name directory service — whois,

1-1181 users, network, continued uucp log — uulog, 1C-1127 uucp status inquiry — uustat, 1C-1134 uucp — UNIX-to-UNIX copy, 1C-1127 uudecode — decode binary file, 1C-1131 uuencode — encode binary file, 1C-1131 uuglist — print list of service grades available, 1C-1133 uulog — UUCP log, 1C-1127 uuname — UUCP list of names, 1C-1127 uupick — public UNIX-to-UNIX copy, 1C-1137 uustat — uucp status inquiry, 1C-1134 uuto — public UNIX-to-UNIX copy, 1C-1137 uux — system to system command execution, 1C-1139

V

vacation — automatic mail replies, 1-1142 vax — get processor type truth value, 1-567 version control - vc. 1-1144 vgrind — formats program in nice style using troff, 1-1147 vi — screen-oriented (visual) display editor based on ex, 1-1150 vipw — edit password file, 1B-1158 volcancel — cancel user's request for removable media that is not currently in drive, 1-1159 volcheck — check for media in a drive, 1-1160 volmissing — notify user that volume requested is not in the CD-ROM or floppy drive, 1-1161 Volume Management cancel user's request for removable media that is not currently in drive — volcancel, 1-1159 check for media in a drive — volcheck, 1 - 1160missing volume notification — volmissing, 1-1161 vsig — synchronize a co-process with the controlling FMLI application, 1F-1162

W

- $\rm w-who$ is logged in, and what are they doing, 1-1163
- wait shell built-in function to wait for other jobs or processes, 1-1165
- wc display a count of lines, words and characters in a file, 1-1169
- what extract SCCS version information from a file, 1-1170
- whatis describe command, 1-1171
- whence shell built-in functions to set/get attributes and values for shell variables and functions, 1-1112
- whereis locate the binary, source and manual page files for a command, 1B-1172
- which locate a command; display its pathname or alias, 1-1174
- while shell built-in functions to repetitively execute a set of actions while/until conditions are evaluated TRUE, 1-1175
- who who is on the system, 1-1177
- who is logged in w, 1-1163
- whoami display effective user name, 1B-1180
- whois Internet user name directory service, 1-1181
- write write to another user, 1-1182
- write file checksums and sizes cksum, 1-119

X

- xargs construct argument lists and invoke utility, 1-1184 xgettext — extract gettext call strings, 1-1188
- xstr extract strings from C code, 1-1190

Y

- yacc yet another compiler-compiler, 1-1192 create a tags file for use with ex and vi ctags, 1-188
- yes/no answer prompts for yes/no answer — ckyorn, 1-125 provides error message for yes/no answer erryorn, 1-125

yes/no answer, *continued* provides help message for yes/no answer helpyorn, 1-125

validates yes/no answer — valyorn, 1-125

- yet another compiler-compiler yacc, 1-1192
- ypcat print values in a NIS database, 1-1195
 ypmatch print the value of one or more keys
- from a NIS map, 1-1196
- yppasswd change your network password in the NIS database, 1-1197
- ypwhich return name of NIS server or map master, 1-1198

Ζ

zcat — displays uncompressed files but leaves compressed files intact, 1-135
