Send Us Your Comments

Oracle Transportation Management Data Management Guide, Release 5.5

Part No. B28770-06

Oracle welcomes your comments and suggestions on the quality and usefulness of this publication. Your input is an important part of the information used for revision.

- Did you find any errors?
- Is the information clearly presented?
- Do you need more information? If so, where?
- Are the examples correct? Do you need more examples?
- What features did you like most about this manual?

If you find any errors or have any other suggestions for improvement, please indicate the title and part number of the documentation and the chapter, section, and page number (if available). You can send comments to us in the following ways:

- Electronic mail: otm-doc_us@oracle.com
- FAX: 610-491-9897 Attn: Documentation and Training Manager
- Postal service:

  Documentation and Training Manager
  Oracle Corporation
  1016 W. Ninth Ave.
  Suite 300
  King of Prussia, PA 19406
  USA

If you would like a reply, please give your name, address, telephone number, and electronic mail address (optional).

If you have problems with the software, contact Support at https://metalink.oracle.com or find the Support phone number for your region at http://www.oracle.com/support/contact.html.

Preface

This manual is for members of the Oracle Transportation Management implementation team, who are responsible for maintaining and updating data in Oracle Transportation Management at your site. This manual provides step-by-step instructions for importing and exporting data in CSV and db.xml format.

This manual does not cover the installation of any components required to import or export. See the Administration Guide for for installation and configuration instructions. The latest version of the guide can be found on the OTN website.

> **Note**: This manual provides examples of CSV, XML and schema diagrams. For actual database tables and schema, refer to the latest database schema and the GlogXML schema.

Change History

Date	Document Revision	Summary of Changes
4/21/08	-06	Added Change History table.

1. Introduction

DB.XML

DB.XML (Database-centric XML) is a file format for importing and exporting Oracle Transportation Management data.

A typical db.xml file contains a set of data objects. An example of a data object is a rate_geo object, which includes its child rate_geo_cost_group, rate_geo_cost, and other child records nested within it. When using the replace-children (RC) transaction code, the rate_geo record is updated, and all of its children are deleted and re-inserted. Transaction codes of I and IU are also supported (see page 24-1).

When you edit a DB.XML file remember that:

- The content of a DB.XML file appears within a set of <TRANSACTION_SET> tags.
- Oracle Transportation Management ignores element names that do not correspond to a database table. This allows you to comment your DB.XML file without affecting what is imported.
- Date columns must use the following format: YYYY-MM-DD HH:MM:SS.
- Element and attribute names must be all uppercase.

A complex, nested SQL query defines each data object. The query indicates which tables and columns comprise the data object.

Why do I want to use DB.XML?

Compared to CSV (Comma Separated Values), DB.XML supports manipulation of parent-child records as a unit. This gives DB.XML an advantage compared to CSV when updating, for example, rate information.

How can I use DB.XML?

There are two main python scripts that support db.xml files:

- Sql2xml.py (generates db.xml output from a select statement)
- Xml2sql.py (imports a db.xml file into the database)

These two scripts are located in the glog_deploy.integration.python directory.

There are three ways to use these scripts:

Chapter 2 – **via web-based interface** is the way most users will use the scripts.

Chapter 3 – via ClientUtil.py supports client-side batch jobs that export and import db.xml from a remote Oracle Transportation Management instance.

Chapter 4 - Directly on the DOS/UNIX command line when a local SQL*net connection to the database is available.

CSV

CSVUtil is a utility for importing and exporting data in CSV format in and out of the Oracle Transportation Management database. CSVUtil also exports data as a script of insert statements. This document describes how to use CSVUtil and shows some sample CSV files.

CSV files are compact and enable you to import large amounts of data into Oracle Transportation Management. You typically want to use CSVUtil when importing rates into a fresh installation of Oracle Transportation Management.

There are three ways to use CSVUtil:

- On the DOS/UNIX command line
- Via the Oracle Transportation Management web interface
- Via integration transmissions

A Sample CSV File

Below is a sample CSV file:

```
ICON
ICON_GID,ICON_XID,DESCRIPTION,PATH,DOMAIN_NAME,INSERT_USER,INSERT_DATE,UPDATE_USE
R,UPDATE_DATE
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
"BATCH_GRID","BATCH_GRID","Reports Batch
Grid","/images/icons/reports/batch_grid.jpg","PUBLIC","DBA.ADMIN","20040310091645","DBA.ADMIN
","20040630100834"
```

Line 1 must be the name of the table.

Line 2 must be a comma-separated list of column names. Only the columns being loaded must be specified.

After line 3 may be one or more optional EXEC SQL lines, such as the one shown above, to set the date format.

Subsequent lines include the data. The number of columns of data must correspond to the number of columns specified on line 2. The ordering of the data columns must also correspond to line 2.

Character data may be surrounded with double-quotes, as shown above. If you need to include a double-quote character, use “"” instead. The tools described here to export CSV files automatically convert double-quote characters into “"”.

Numeric data should not be surrounded with double-quotes.

Multi-table CSV Files

The output produced by the xcsvw* commands is in multi-table CSV format. The various CSV import commands recognize this format also

The first record in a multi-format file must be "$HEADER".

The header section contains table names and the names of the columns used in that table.

After the header section comes the body, identified by the $BODY keyword.

Each data record in the $BODY must be preceded by its table name on the prior line.

Here is an example:

```
$HEADER
LOCATION_ROLE_PROFILE
```

```
LOCATION_GID,LOCATION_ROLE_GID,CALENDAR_GID,FIXED_STOP_TIME, etc...
LOCATION_STATUS
LOCATION_GID,STATUS_TYPE_GID,STATUS_VALUE_GID,DOMAIN_NAME,INSERT_USER,INSE
RT_DATE,UPDATE_USER,UPDATE_DATE
LOCATION_CORPORATION
LOCATION_GID,CORPORATION_GID,DOMAIN_NAME,INSERT_DATE,UPDATE_DATE,INSERT_US
ER,UPDATE_USER
LOCATION_ADDRESS
LOCATION_GID,LINE_SEQUENCE,ADDRESS_LINE,DOMAIN_NAME,INSERT_USER,INSERT_DAT
E,UPDATE_USER,UPDATE_DATE
LOCATION_REFNUM
LOCATION_GID,LOCATION_REFNUM_QUAL_GID,LOCATION_REFNUM_VALUE,DOMAIN_NAME,IN
SERT_DATE, etc...
LOCATION
LOCATION_GID,LOCATION_XID,LOCATION_NAME,ADDRESS_LINE1,ADDRESS_LINE2,CITY,e
tc.
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY-MM-DD HH24:MI:SS..'
$BODY
LOCATION
"GUEST.00621918","00621918","00621918",,,,,"TN",,"USA",,,,,"America/New_Yo

International Characters

Import

To be able to send data to Oracle Transportation Management containing characters outside the 7-bit ASCII character set, you must:

- Make sure your database uses an encoding that can handle all the characters you need.
- Always save your files using UTF-8 format.

XML Spy, Textpad and Notepad (Microsoft Windows 2000 or better) can all save in UTF-8 format.

Before you edit your files, you need to ensure that you configure your text editor to use the appropriate font and script (sometimes called subset). A script is a collection of characters such as Western European, Greek or Turkish. For example, if you need to update files containing Czech characters, then you need to select a font that supports an Eastern European script such as Arial or Arial Unicode Ms.

Export

When exporting files, Oracle Transportation Management writes files in UTF-8. Note that when you view data in your browser and then use the view source option to save your data, just save your file without specifying an encoding. Later, when editing your file, use an editor that support UTF-8

2. Updating DB.XML Data via Web Pages

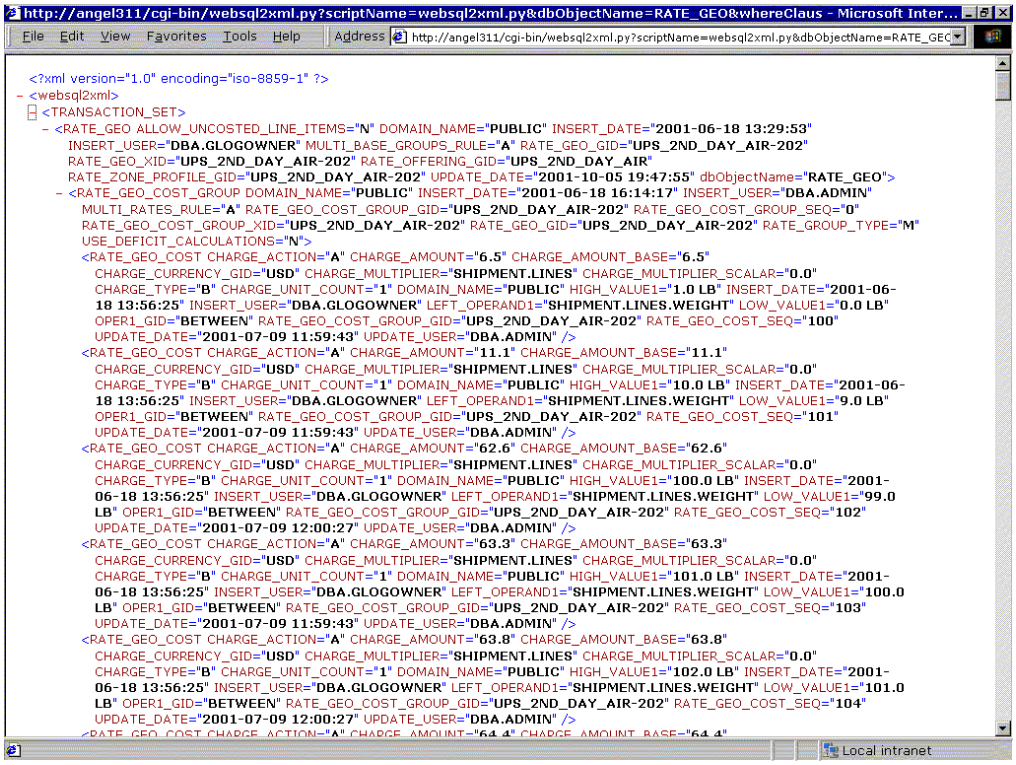
This chapter describes the web-based user interface for exporting and importing db.xml.

Exporting DB.XML

This section describes how to export DB.XML using the web-based user interface.

1. Log into Oracle Transportation Management as DBA.ADMIN.
2. Choose Business Process Automation>Data Export>DB.XML Export and Oracle Transportation Management displays the DB.XML Export page.
3. Choose a **dbObjectName** to export the corresponding database table.
   OR
   Choose a **dbObjectSetName** to export a set.
4. Enter a **whereClause**. For example you can enter DOMAIN_NAME='GUEST' or rownum<3. You can also combine the two like this DOMAIN_NAME='GUEST' and rownum<3.

   Instead of selecting a dbObjectName and entering a whereClause, it is also possible to enter a sqlQuery (for example, *select * from activity*) and a rootName (for example, *ACTIVITY*).
5. Click **Run** and Oracle Transportation Management displays the results page.



In this case, the RATE_GEO data-object consists of a rate_geo record, a rate_geo_cost_group, and two rate_geo_cost records within the rate_geo_cost_group.

Note: Refer to the Oracle Transportation Management Data Dictionary for more information about what the objects can contain.

Note: Oracle Transportation Management does not display elements that are empty in the database.

Saving db.xml Output to a File on Your PC

6. Choose **View** >**Source** in your browser's menu and the browser starts Notepad.
7. Choose **File** >**Save** in Notepad's menu.

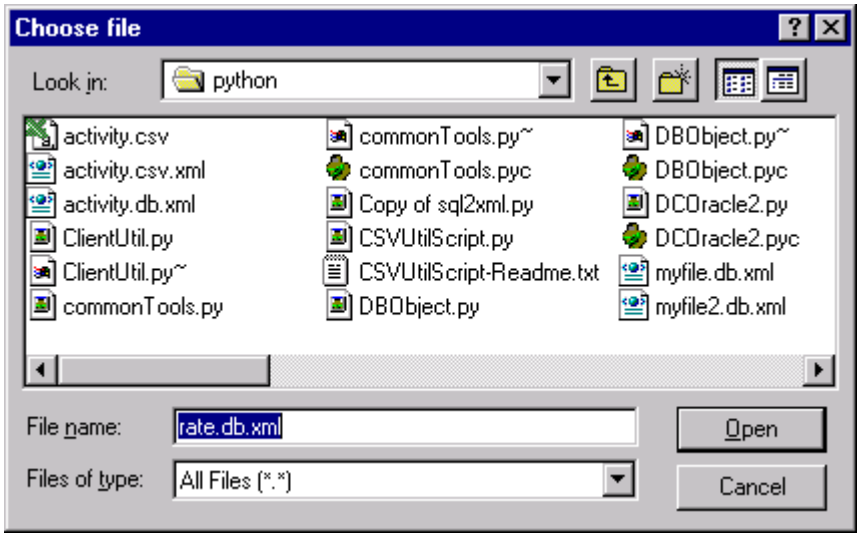
   Note: If your output is too large for Notepad, you need to use ClientUtil.py. See page 3-1.

   Note: Especially if your data contains non-ASCII characters, just save your file as-is and use an editor that supports UTF-8 when editing the file later on.

Importing DB.XML

This section describes how to import a DB.XML file on your PC into a remote Oracle Transportation Management database.

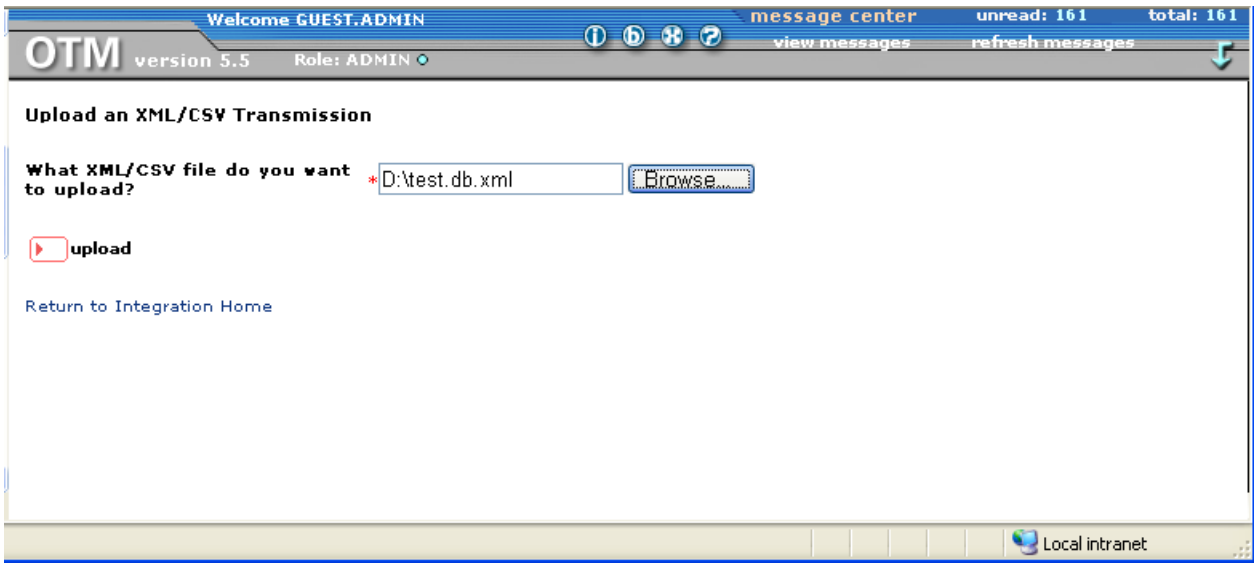
1. Log into Oracle Transportation Management.
2. Choose Business Process Automation >Integration > Integration Manager. Oracle Transportation Management opens the Integration page.
3. Click **Upload an XML/CSV Transmission** and Oracle Transportation Management displays the Upload an XML/CSV Transmission page.
4. Click **Browse** and Oracle Transportation Management displays this window.



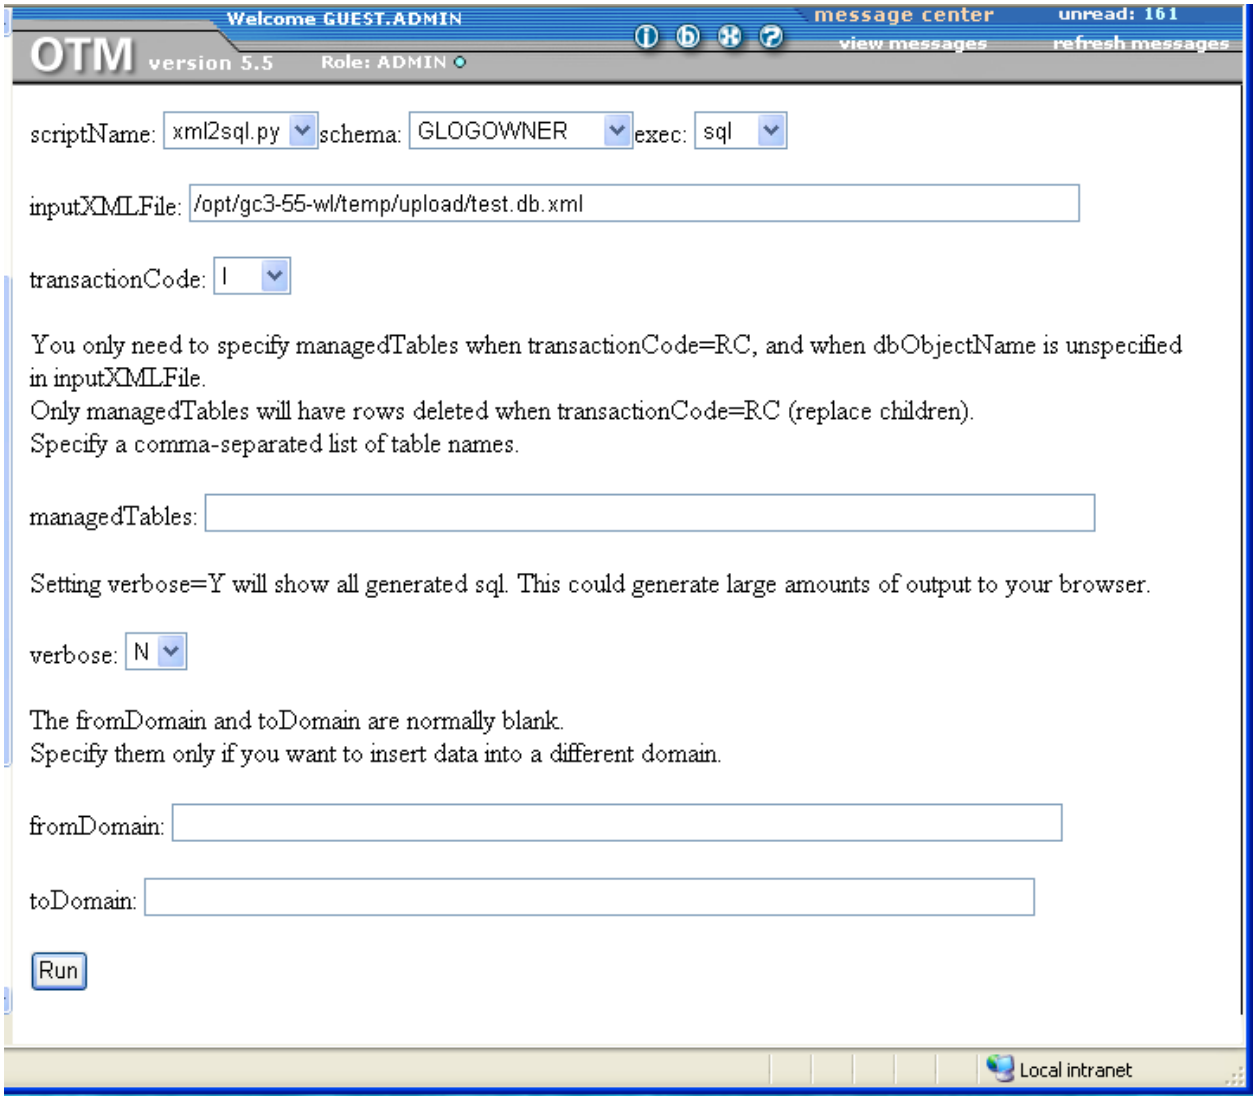
5. Click the db.xml file that you want to import.

   Note: The filename must end in ".db.xml". If it ends in just .xml, but not .db.xml, Oracle Transportation Management processes it as a normal GlogXML file rather than a db.xml file.

6. Click **Open** and Oracle Transportation Management displays this page.



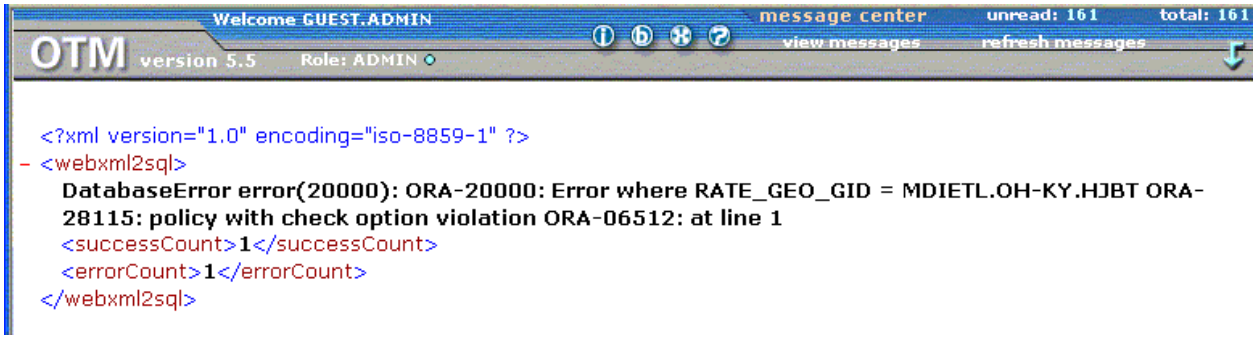
7. Click **Upload** and Oracle Transportation Management uploads your db.xml file to the remote web server and displays this page.



8. Leave the **scriptName** parameter as is since it cannot be changed.
9. Select the **schema** that your data belongs to.

   A database contains a number of tables, indexes, constraints, and so on. Collectively the definition of these items is known as the database's schema.
10. You can set the **exec** parameter to:
    - SQL – Oracle Transportation Management executes SQL directly against the database. This is somewhat faster than running plsql.
    - Plsql – Oracle Transportation Management generates plsql instead of SQL, and executes the plsql against the database.
11. Do not change the **inputXMLFile**. In this case, the file has been uploaded to the d:/temp/upload directory on the webserver.
12. The default **transactionCode** is I (insert). You may change the transactionCode from I to either IU or RC. See page 24-1 for the meaning of the different transactionCodes.

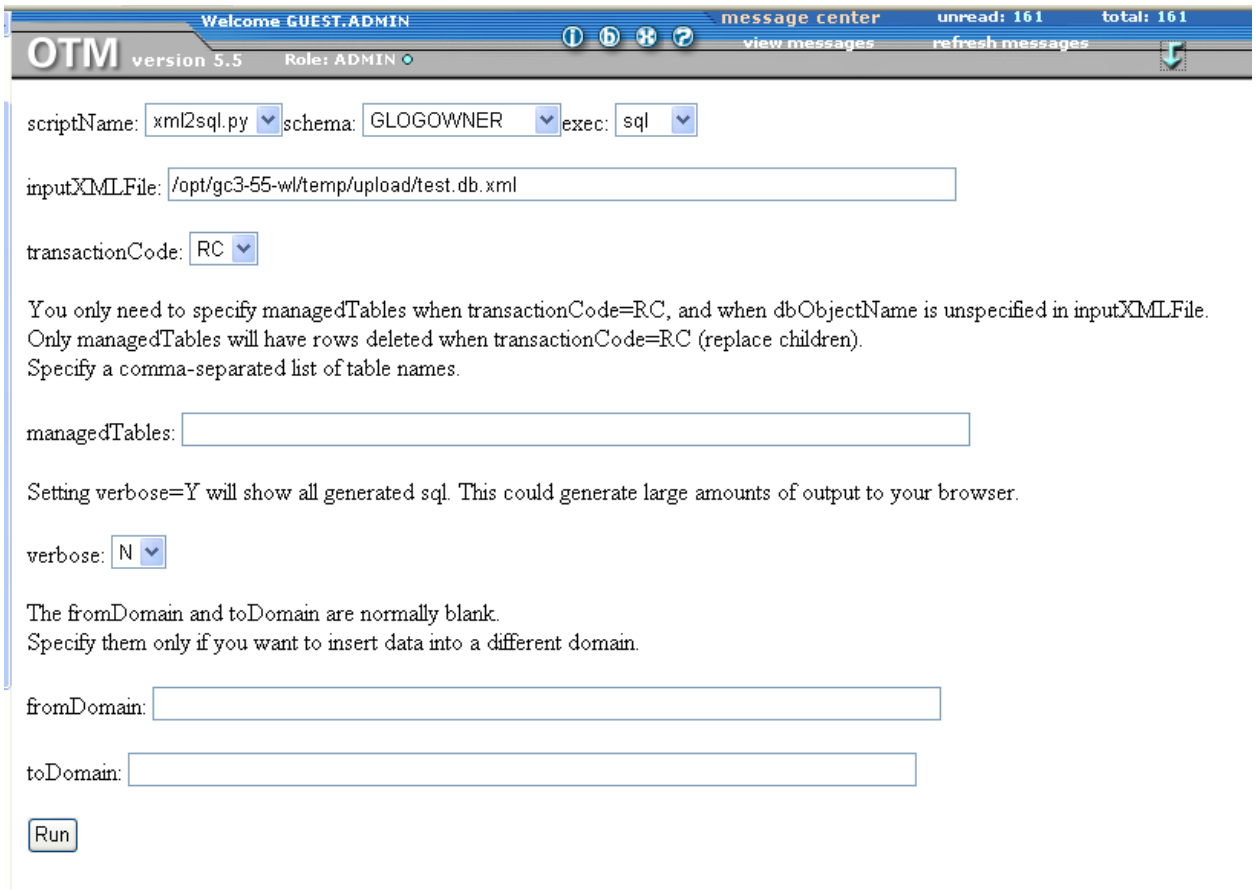
13. You only need to specify **managedTables** when the transactionCode is RC, and the dbObjectName is unspecified in the inputXMLFile. The dbObjectName is unspecified in your db.xml file, if your file was generated using a sqlQuery. To generate a db.xml file with dbObjectName specified, generate the db.xml file by selecting a dbObjectName. See page 2-1 for a procedure on how to do this.
14. The default **verbose** setting is "N". You may change this to "Y", if you wish to see the generated SQL that is executed to persist the XML into the database.
15. Click Run and Oracle Transportation Management displays the following page.



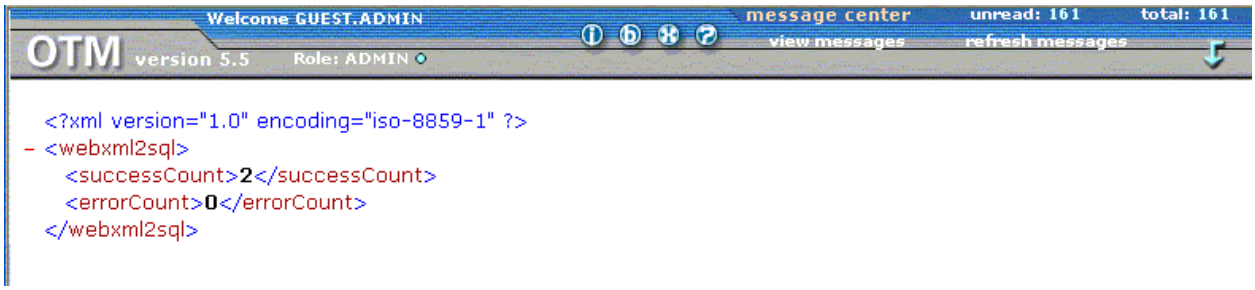
If the data already was persisted in the database, you get a primary key violation like in this example.

16. Repeat steps 2 to 15 and Oracle Transportation Management displays this page again.

    Note: Clicking the Back button in your browser will not work.



17. Select RC in the transactionCode drop-down list.
18. Click Run and Oracle Transportation Management displays this page.

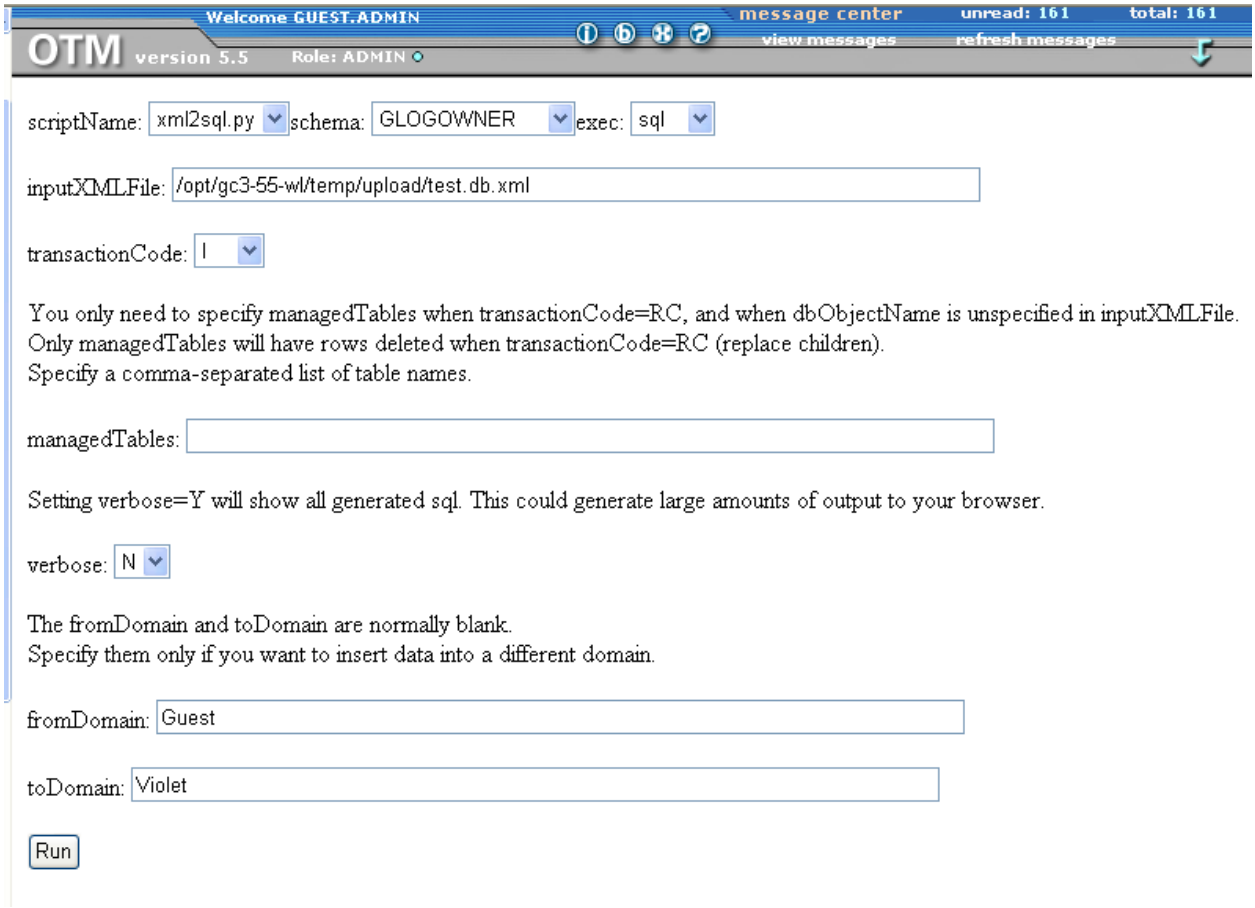


In this case, Oracle Transportation Management displays summary statistics without any error messages. Note that the successCount is 1 greater than the number of data objects. This is correct.

Copying Data between Domains

This section describes how to copy data from one domain to another.

1. Export the data as described on page 2-1.
2. Import the data as described on page 2-2, but specify a **fromDomain** and a **toDomain**, as shown below.



In this example, you are copying data from the GUEST domain to the VIOLET domain.
When copying a table between domains, make sure you copy all dependant tables too. For example, locations might need calendars to work correctly.

3. Updating DB.XML Data in Remote Oracle Transportation Management Databases, ClientUtil

This chapter describes how to use the client-side python script ClientUtil.py to export and import db.xml files from a remote Oracle Transportation Management database. This section assumes you have python installed on your PC. If not, see the Administration Guide on your Oracle Transportation Management CD for installation and configuration instructions.

The main advantage of ClientUtil.py compared to the web-based interface is that it allows you to write client side batch jobs, which pull db.xml data from a remote Oracle Transportation Management instance. This data can be modified as desired, and then imported back to the remote Oracle Transportation Management instance (also using ClientUtil.py).

> **Note:** ClientUtil.py can also export and import CSV files.

Exporting DB.XML

Similar to how it works via the web screen, there are two methods for exporting:

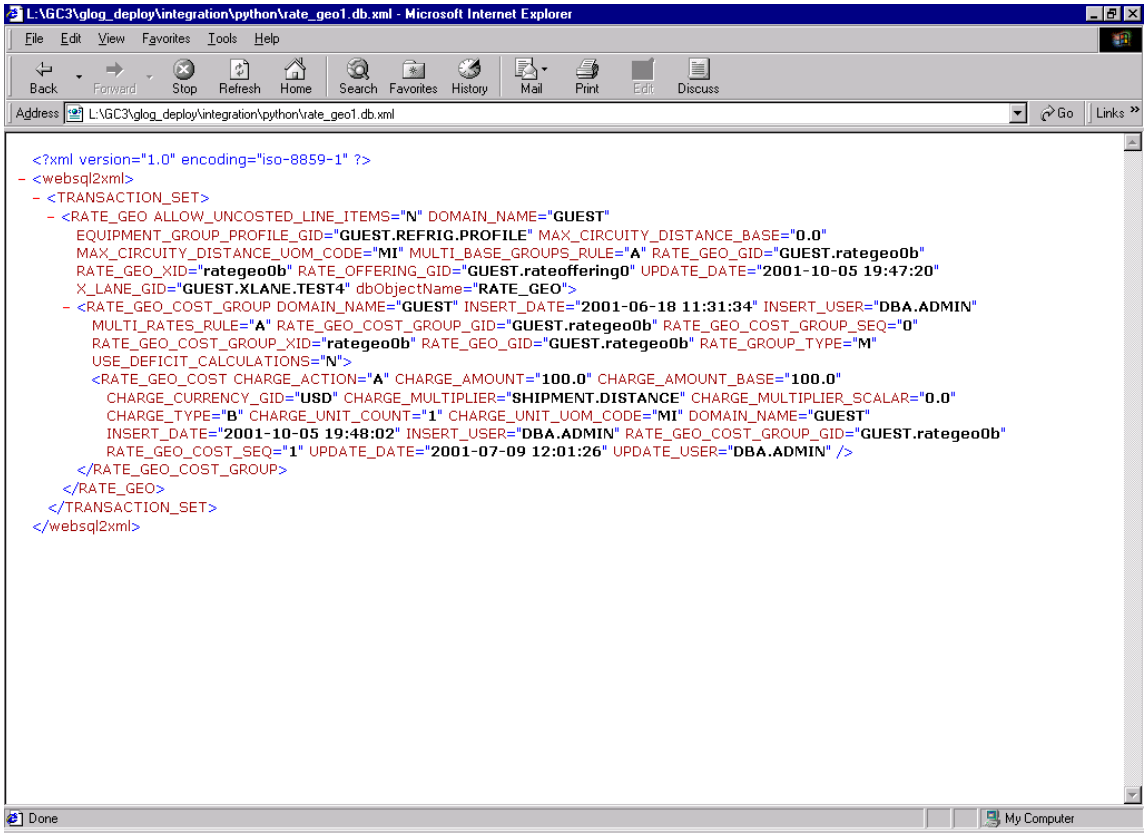
- By specifying a dbObjectName and whereClause, or
- By specifying a sqlQuery and a rootName

Using Pre-Defined Data Objects

Here is the command line for exporting the first RATE_GEO db-object found in the database:

```
python ClientUtil.py -command xmlExport -hostname localhost -username
GUEST.ADMIN -password CHANGEME -dbObjectName RATE_GEO -whereClause "rownum
< 2" -localDir ./ -localFileName rate_geo1.db.xml
```

This example creates the file “rate_geo1.db.xml” in the current working directory. In this case, this file has the following content:



You need to modify the following arguments specific to your situation:

- Hostname (hostname of remote webserver)
- Username (User name used to login to the remote Oracle Transportation Management instance)
- Password (password corresponding to the username)
- WhereClause (SQL whereClause used to limit size of export)
- LocalDir (directory on your PC where output file is written)
- LocalFileName (name of local output file)

What Pre-Defined Data Objects Exist?

Refer to the drop-down list on the xmlexport.xsl page to find out what pre-defined data objects currently exist. At this time, the list contains:

- CORPORATION
- LOCATION
- RATE_GEO
- RATE_OFFERING
- AGENT
- AGENT_ACTION
- AGENT_EVENT
- SAVED_QUERY

- SAVED_CONDITION
- USER_MENU_LAYOUT
- MONITOR_PROFILE
- SHIPMENT
- OB_ORDER_BASE

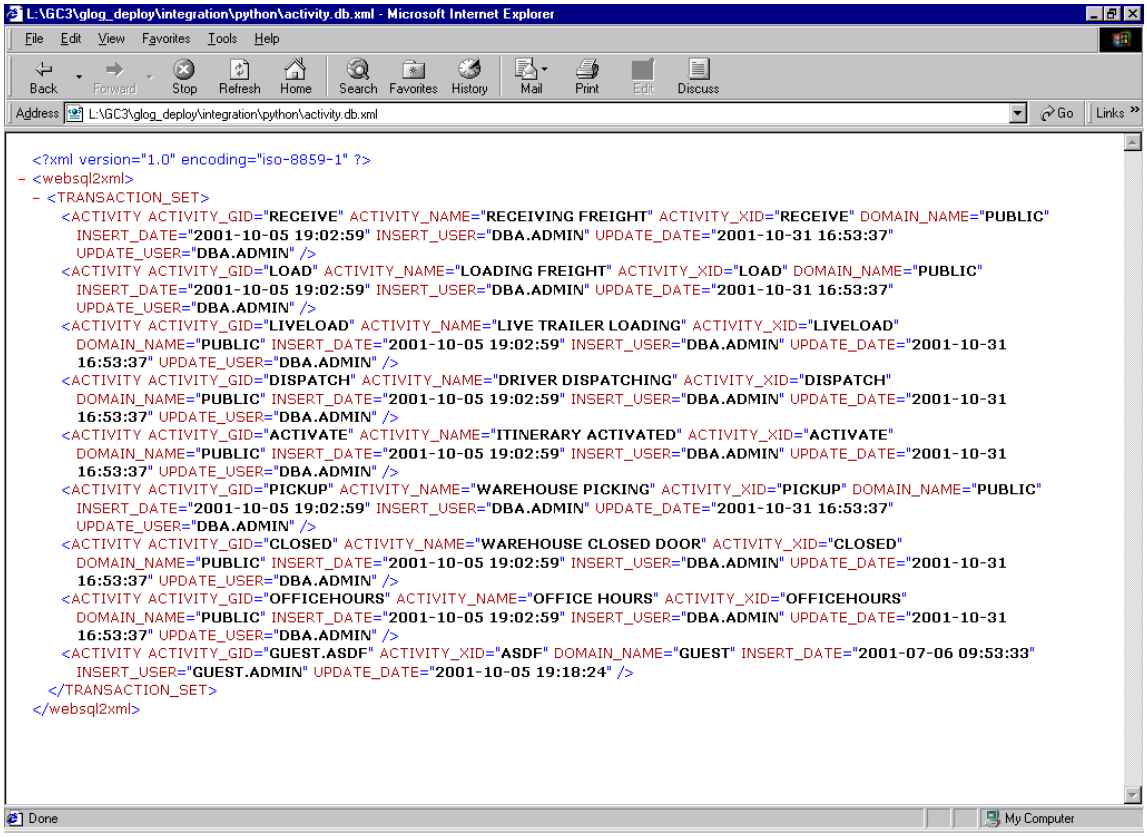
  Note: When exporting the USER_MENU_LAYOUT object, you must specify a whereClause, which includes “Parent_menu_gid is Null”. Otherwise, you will get garbage.

Using a SqlQuery

Here is a sample command line for exporting all the activity records in the database:

```
python ClientUtil.py -command xmlQuery -hostname localhost -username
GUEST.ADMIN -password CHANGEME -sqlQuery "select * from activity"
 -rootName ACTIVITY -localDir ./ -localFileName activity.db.xml
```

The above command creates the activity.db.xml file in the current working directory. In this case, this file has the following content:



You need to modify the following arguments, specific to your situation:

- Hostname
- Username
- Password
- SqlQuery
- RootName

- LocalDir
- LocalFileName

Importing DB.XML

You can use ClientUtil.py to import a client-side db.xml file into a remote Oracle Transportation Management database instance.

Here is an example command line:

```
python ClientUtil.py -command xmlImport -hostname localhost -username
DBA.ADMIN -password CHANGEME -transactionCode IU -localDir ./ -
localFileName rate.db.xml
```

See page 24-1 for possible transactionCodes.

Oracle Transportation Management ignores element names that do not correspond to a database table. This allows you to comment your DB.XML file without affecting what is imported.

Copying Data between Domains

You can use ClientUtil.py to import a client-side db.xml file into a remote Oracle Transportation Management database instance, inserting the data into a different domain than is specified in the db.xml file. For example, if the contents of the db.xml file has data from the GUEST domain, and you want to insert it into your own (MYOWN) domain, you would use the following command:

```
python ClientUtil.py -command xmlImport -hostname localhost -username
DBA.ADMIN -password CHANGEME -transactionCode IU -localDir ./          -
localFileName rate.db.xml -fromDomain GUEST  -toDomain MYOWN
```

4. Updating DB.XML Data in Oracle Transportation Management Databases, Command Line

If you have a SQL*net connection to your database, you can use the sql2xml.py and xml2sql.py scripts directly from your command line.

Exporting DB.XML

There are three methods for exporting DB.XML with sql2xml.py.

- Specify SQL query in a file, and provide file name as input argument
- Specify SQL query directly as input argument
- Specify a pre-defined database object name, such as RATE_GEO

sql2xml has the following syntax and arguments.

```
python sql2xml.py -dbConn <connectString> -sqlFile <sqlFile> -rootName
<rootName>
-or-
python sql2xml.py -dbConn <connectString> -rootName <rootName> -sqlQuery
<queryStringInDoubleQuotes>
-or-
python sql2xml.py -dbConn <connectString> -dbObjectName <dbObjectNameName>
-whereClause <wc>
```

Xml2sql supports the following commands and arguments:

Commands	Arguments
dbConn	Connection to database. Username/password@database
sqlFile	Name of SQL file to specify what should be exported.
rootName	Only used with sqlQuery. Set the XML root element.
sqlQuery	SQL query to specify what should be exported. Use double quotes.
dbObjectName	See page 3-2 for what objects you can refer to.
whereClause	Only used with dbObjectName. SQL where clause to limit what should be exported.

Using SQL Query in a File

Here is a sample command line, which exports db.xml using a SQL query specified in a file:

```
python sql2xml.py -dbConn glogowner/glogowner@localdb -sqlFile myquery.sql
-rootName ACTIVITY
```

The above command writes xml.db output to standard output. You may pipe this output to a file if you like.

Using a SQL Query on Command Line

Here is a sample command line, which exports db.xml using a SQL query specified on the command line:

```
python sql2xml.py -dbConn glogowner/glogowner@localdb -sqlQuery "select *
from activity" -rootName ACTIVITY
```

For a Pre-defined Database-Object

Here is a sample command line, which exports db.xml for the pre-defined RATE_GEO database object:

```
python sql2xml.py -dbConn glogowner/glogowner@localdb -dbObjectName
RATE_GEO -whereClause "rownum < 2"
```

Importing DB.XML

Xml2sql has the following syntax and arguments.

```
python xml2sql.py -schema <schema> -dbConn <dbConn> -inputXMLFile
<filename> -transactionCode <I|IU|RC> -managedTables <mc> -exec
<sql|plsql>
```

Xml2sql supports the following commands and arguments:

Commands	Arguments
schema	Only required when database user is not table owner. If entered, this is typically GLOGOWNER OR REPORTOWNER.
dbConn	Connection to database. Username/password@database
inputXMLFile	Name of DB.XML file to import.
transactionCode	See page 24-1 for possible transactionCodes. Default is IU.
managedTables	This argument specifies what child elements the script should replace. The remaining elements are processed using the IU transaction code. You only need to specify managedTables when the transactionCode is RC, and the dbObjectName is unspecified in your inputXMLFile. The dbObjectName is unspecified in your db.xml file, if your file was generated using the sqlQuery or sqlFile arguments. To generate a db.xml file with dbObjectName specified, export the db.xml file using a dbObjectName.
exec	SQL - the script executes SQL directly against the database. This is somewhat faster than running plsql. Plsql - the script generates plsql instead of SQL, and executes the plsql against the database.

Here is a sample command line, which imports a file called “rate_geo1.db.xml”

```
python xml2sql.py -dbConn glogowner/glogowner@localdb -inputXMLFile
rate_geo1.db.xml
-transactionCode RC -exec SQL
```

The above command converts the rate_geo1.db.xml into SQL statements and executes those SQL statements. If you want to see, but not execute, the generated SQL you can omit the “-exec SQL” option, which causes the SQL to be written to standard output, but not executed. See page 24-1 for possible transactionCodes.

5. Editing DB.XML Files

This section describes how you edit an exported DB.XML file before importing it again.

A Sample DB.XML File

An exported DB.XML file might look like this. Note that the content is wrapped in a pair of <TRANSACTION_SET> tags.

```
<?xml version="1.0" encoding="iso-8859-1" ?>
<websql2xml>
   <TRANSACTION_SET>
   <CORPORATION CORPORATION_GID="ACL" CORPORATION_XID="ACL"
   DOMAIN_NAME="PUBLIC" INSERT_DATE="2001-10-05 19:03:37"
   INSERT_USER="DBA.ADMIN" IS_DOMAIN_MASTER="N" UPDATE_DATE="2001-10-06
   12:43:46" UPDATE_USER="DBA.GLOGLOAD" dbObjectName="CORPORATION" />
   </TRANSACTION_SET>
</websql2xml>
```

You can edit the values and add new objects.

When editing date and time values, be sure to keep the following format: YYYY-MM-DD HH:MM:SS.

If you miss an element in the exported file this is probably because Oracle Transportation Management does not export elements that are empty in the database. This means that you will have to add the tag to the DB.XML file yourself. Refer to the Oracle Transportation Management Data Dictionary for more information about what objects and tables exist.

Oracle Transportation Management ignores element names that do not correspond to the database table. This allows you to comment your DB.XML file without affecting what is imported.

As you edit the file, keep all element and attribute names in uppercase.

6. Loading CSV Data via the Command Line

This chapter describes how to import and export CSV from the command line.

Importing and Exporting on the Server Side

This section describes how to use CSVUtil to export and import data from a local Oracle Transportation Management database.

CSVUtil has the following syntax and arguments.

```
java glog.database.admin.CSVUtil –command
<i|ii|iu|u|uu|d|dd|xcsv|xcsvcd|xcsvpcd|xcsvpd|xsql> -connectionId
<connectionId> -tableName <tableName> -dataDir <dataDirectory> -
dataFileName <dataFileName> -appendFile –runsqlloader -domain_name
<domainName> -useT2 <Y|N> -debug -XMLCSVOutput -sqlQuery <queryString> -
whereClause <whereClause> -clobDir <clobDirectory> –xvalidate <Y|N> -
encoding <encoding>
```

CSVUtil supports the following commands and arguments:

Commands	Arguments
command	i - insert CSV data into the database ii - insert data, while suppressing unique key constraint violations iu - attempts to insert data. If a primary key violation occurs, it updates the data. No delete statements are generated. u - update data in the database uu - update data, while suppressing “no data found” constraint violations d- delete data from the database dd- delete data, while suppressing “no data found” constraint violations xcsv - export a CSV file xcsvcd - export a multi-table CSV file with all subordinate child tables (e.g. shipment_stop, shipment_stop_d etc. for the shipment table). A table set called C.<table_name> controls which tables are considered to be children of a given table. For example, the C.SHIPMENT table set contains the following tables: shipment_stop, shipment_refnum, shipment_remark, etc. Similarly, the C.SHIPMENT_STOP table_set contains the shipment_stop_d table. If you log in as DBA.ADMIN in Oracle Transportation Management, you can use the Table Set Manager to modify the contents of the various C.* table sets. xcsvpcd - export a multi-table CSV file with both parent and child data. xcsvpd - export a multi-table CSV file with all referenced non-public foreign key records (parent data) required to load the record(s) in a foreign database. xsql - export data as a script of insert statements rather than a CSV file

Commands	Arguments
connectionId	The connectionId is a shorthand method for providing an Oracle username, password, and server. For example, if you specify your connectionId as codegen, you need to add the following properties to your glog.properties file: glog.database.codegen.schema=glogowner glog.database.codegen.t2client.driverClassName=oracle.jdbc.driver.OracleDriver glog.database.codegen.t2client.databaseURL=jdbc:oracle:thin:@localhost:1521 glog.database.codegen.user=glogload glog.database.codegen.password=glogload glog.database.codegen.server=dbserver glog.database.codegen.t2client.pool=
tableName	The tableName argument is only specified for the xcsv and xsql commands. This specifies the name of the database table to export. Can be null if sqlQuery is specified. Must be upper case.
dataDir	The dataDir argument specifies the location to either read or write the file specified in the –dataFileName argument. The following glog.property file setting controls the default value of the dataDir argument: glog.database.load.dir=d:\\upload In this case, the default directory has been set to d:\upload. Note that two backslashes are required in glog.properties.
dataFileName	The dataFileName argument specifies the name of the file in the dataDir directory to either read or write. This field is required when importing a file, but is optional when exporting a file. If unspecified for an export, the output is written to System.out.
appendFile	The appendFile argument only applies to the export commands (xcsv and xsql). If specified, CSVUtil will append to the file specified by the dataFileName argument instead of overwriting it.

Commands	Arguments
removeUndefinedColumns	CSVUtil supports, by default, the ability to ignore columns that are not defined in the target table. This is especially useful when exporting from a migrated database with deprecated columns, into a newly created database that does not have the deprecated columns. There is some performance impact for this feature. To deactivate the feature, use the following command line option: -removeUndefinedColumns N This option is only available when running CSVUtil directly on the command line. It is not available using either the web or ClientUtil.
runsqlloader	The runsqlloader argument only applies to import commands. If specified, the oracle sqlloader program will be used to load the CSV file instead of a java procedure. If you have sqlloader installed on your system the sqlloader is faster than the java procedure.
-maxError	By default in CSVUtil, after 50 errors occur, processing stops. You can change this default value to make it higher or lower using the –maxError command line argument. For example: -maxError 20 This parameter is currently only available when running CSVUtil as a java application on the command line.
domain_name	The domain_name argument only applies to the export commands (xcsv and xsql). It specifies that only the data in that domain is to be exported.
useT2	Used to avoid using the T2Connection class, which depends on VPD being already setup correctly. When loading certain Oracle Transportation Management "system" tables, it is necessary to avoid the use of the T2 connection class (it's a chicken or the egg type situation). For normal data loading, using the T2Connection class is correct and desirable.
debug	Used for debugging.
XMLCSVOutput	If true, then output looks like this: <TableName></TableName> or <SqlQuery>...</SqlQuery> <ColumnList></ColumnList> <ExecSQL></ExecSQL> <Row>...</Row> <Row>...</Row>
sqlQuery	If specified, then xcsv command is required and tableName is ignored.

Commands	Arguments
whereClause	Only used when tableName is specified and domainName is omitted.
clobDir	Directory where external CLob files are read. Only used when importing external CLob files and not using sqlloader.
xvalidate	Can be either Y (default) or N. When set to Y, CSVUtil gives you more user-friendly diagnostics messages and hinders missing values in your CSV file to delete an existing value in the database. If you want CSVUtil to allow data to be nulled out, you should specify xvalidate as N when running CSVUtil.
encoding	The encoding of the file you import. Common settings are ISO-8859-1 (default) and UTF-8. You especially need to consider this when you import data containing characters outside the 7-bit ASCII set. Also, consider the encoding of your database.

CLobs in CSV Files

CSVUtil supports inserting, updating, and deleting CLobs. You can:

- Include the CLob in the CSV file (each CLob<1Mb, no newline characters)
- In the CSV file, refer to an external file holding the CLob. (no size restrictions on the CLobs, newline characters allowed)

  Note: CSVUtil can only handle one CLob per record.

Here is a sample CSV file that inserts a CLob using the in-line method:

```
CLOB_TEST
SEQ,DESCR,XML
9,"THIS IS SO COOL",<asdf>blahblah</asdf>
10,"LINE2",<qwerty>yaya</qwerty>
```

In this case, the "XML" column is of type CLob. When using the in-line method, each CLob:

- Must be specified on a single line (no newline characters).
- Must be smaller than 1 megabyte.

Here is a sample CSV file that inserts two CLobs using the external file method:

```
CLOB_TEST
SEQ,DESCR,EXT_FNAME,XML
11,"THIS IS SO COOL",myxmlfile.xml
12,"LINE2",myxmlfile2.xml
```

When using the external file method, you must specify a special "pseudo column" called "EXT_FNAME ". The EXT_FNAME pseudo column must be specified to the left of the CLob column. In this case, you will have an extra column on line 2. So in this case, line 2 has 4 columns, but there are only 3 columns in the data lines.

The external file method must be used when inserting CLobs containing newline characters, or when inserting CLobs greater than 1 megabyte.

Exporting With Parent Data

To export a data record with its parent data, you can do the following:

```
java glog.database.admin.CSVUtil -command xcsvwpd -tableName SHIPMENT -
whereClause "shipment_gid = 'MDIETL.184'" -connectionId angel37
```

The above command exports the record for shipment MDIETL.184, along with all the referenced non-public foreign key records required to successfully load the SHIPMENT record in a foreign database. The generated CSV file is in multi-table format.

> **Note:** All the xcsvw* commands are far more expensive in terms of CPU usage than the plain xcsv command. Using them to export a large data set will take a long time, since many foreign keys must be found. Use the commands with a restrictive where-clause, as shown in the examples, to limit the running time.

Exporting With Child Data

To export a data record with its child data, you can do the following:

```
java glog.database.admin.CSVUtil -command xcsvwcd -tableName SHIPMENT -
whereClause "shipment_gid = 'MDIETL.184'" -connectionId angel37
```

The above command exports the record for shipment MDIETL.184, along with all the subordinate child tables such as shipment_stop, shipment_stop_d etc.

Exporting With Both Parent and Child Data

To export a data record with both its parent and child data, you can do the following:

```
java glog.database.admin.CSVUtil -command xcsvwpcd -tableName SHIPMENT -
whereClause "shipment_gid = 'MDIETL.184'" -connectionId angel37
```

This command should be used with care since it can take while to run.

GL_User Table

CSVUtil supports adding and deleting records in the GL_USER table. This table stores the Oracle Transportation Management users and their passwords.

When the GL_USER table is specified in the header of a CSV file, special processing is done.

If you are an authorized GL_USER, you may add and delete records in the GL_USER table. As an exception for this table, you can only use the commands: i, ii, d, or dd.

> **Note:** The u, uu, and iu commands are not supported when loading the GL_USER table.

Importing on the Client Side

This section describes how to use ClientUtil.py to import data into a remote Oracle Transportation Management database.

> **Note:** ClientUtil does not support the multi-table CSV format.

The following example imports data from d:/temp/rate_geo.csv on your PC into a remote Oracle Transportation Management database. Because xvalidate is set to Y, Oracle Transportation

Management does not null missing values in the CSV file and Oracle Transportation Management also validates the content of the CSV file. If you need to null certain fields, set xvalidate to N.

```
python ClientUtil.py
-command csvImport
-hostname localhost
-username GUEST.ADMIN
-password CHANGEME
-localDir d:/temp
-localFileName rate_geo.csv
-xvalidate Y
```

Note: You can skip password and rely on IP authentication instead.

Exporting on the Client Side

This section describes how to use ClientUtil.py to export data from a remote Oracle Transportation Management database.

Note: ClientUtil does not export child and parent data for the specified records(s).

Exporting a Table

The following example exports all the RATE_GEO records in the GUEST domain from the database that is connected to the Oracle Transportation Management instance running on a host called localhost. ClientUtil writes the CSV file to myfile.csv in the d:/temp directory.

```
python ClientUtil.py
-command csvExport
-hostname localhost
-username GUEST.ADMIN
-password CHANGEME
-tableName RATE_GEO
-whereClause "DOMAIN_NAME='GUEST'"
-localDir d:/temp
-localFileName myfile.csv
```

Note: You can skip password and rely on IP authentication instead.

Exporting Data Based on Any Query

The following example exports a CSV file containing just the shipment_gid column from the shipment table for all records in the GUEST domain. ClientUtil writes the CSV file to d:/temp/myfile.csv on your PC.

```
python ClientUtil.py
-command csvQuery
-hostname localhost
-username GUEST.ADMIN
-password CHANGEME
-sqlQuery "select shipment_gid from shipment where domain_name = 'GUEST'"
-localDir d:/temp
-localFileName myfile.csv
```

7. Loading CSV Data via Web Pages

Running CSVUtil via the command line is only possible if your client environment is configured correctly. If your client environment is not configured, you can still run CSVUtil via the web.

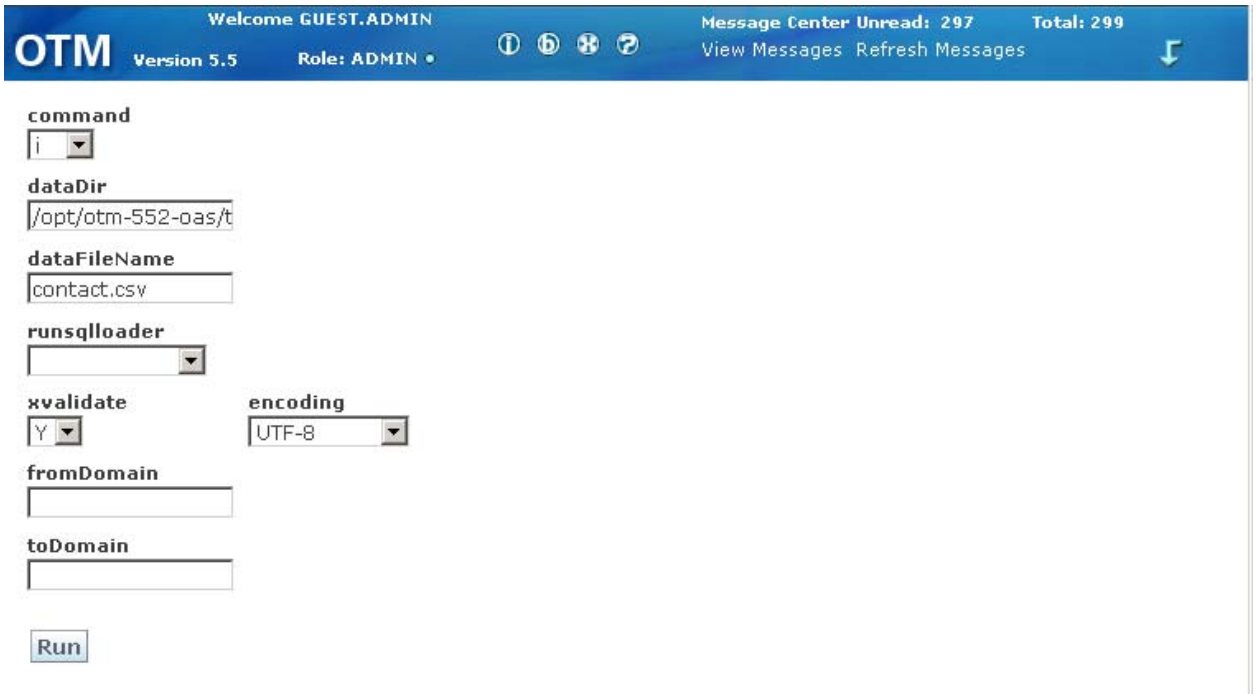
Importing

This section describes how to import a CSV file using Oracle Transportation Management.

1. Log in to Oracle Transportation Management.
2. Choose Business Process Automation > Integration > Integration Manager.
3. Click Upload an XML / CSV Transmission.
4. Select the file to upload. The upload will transfer files from your local machine to the server.

   Note: You must select a .CSV file.

5. Click **Upload** and Oracle Transportation Management displays the page for importing the file. If you select a file other than a .CSV file, a different page will open.



6. If it is not already selected, select i from the **command** list**.**
7. Leave the **dataDir** as is.
8. Leave the **dataFileName** as is.
9. If you are loading a large file, you may specify the **runsqlloader** option. This will only work if sqlloader is installed on the Oracle Transportation Management web server. The following line must be added to the jserv.properties file to make sqlloader run from the web:

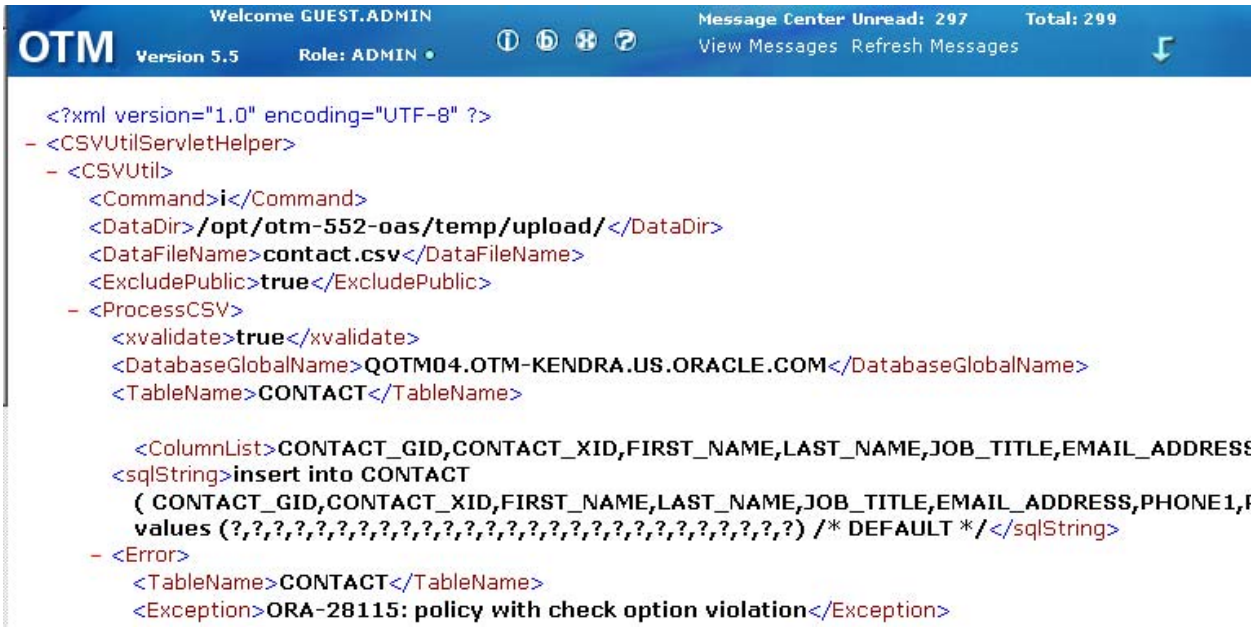
   ```
   wrapper.path = d:/product/oracle/ora81/bin
   ```

   This entry would be different depending on the location of the Oracle bin directory.

10. The **xvalidate** drop-down list allows you to turn off verbose diagnostic messaging. To leave messaging on, the value in the drop down list should be Y, which is the default.

11. In the encoding drop down list, select the appropriate encoding type for your CSV file. If your file contains standard ASCII characters, then it can be encoded as ISO-8859-1. If it contains non-standard, international characters, then it should be encoded as UTF-8.

12. Click **Run** and Oracle Transportation Management displays a results page.



In the above case, no rows were inserted because the user specified in the CSV file, called CORE01.ADMIN, does not exist in the Oracle Transportation Management database. To read more about interpreting error messages, see page 26-1.

8. Loading Rate Data via CSV

This chapter gives you examples of:

- The tables you need to import to set up rates in Oracle Transportation Management.
- How to format the CSV files.
- The order in which you must import tables.

Refer to the Oracle Transportation Management Data Dictionary to learn what data you need and in what order you need to import it.

> **Note:** Any blank columns are not included in the CSV files. See the Data Dictionary for a complete list of columns.

Importing Location Information

This section describes how to import location information in CSV format. A set of sample CSV files is presented. Tables must be loaded in the order presented in this section. Otherwise, foreign key violations occur.

1. Import the LOCATION Table.

   The following example illustrates how you specify LOCATION data in CSV format.

```
LOCATION
LOCATION_GID,LOCATION_XID,LOCATION_NAME,CITY,PROVINCE,PROVINCE_CODE,POS
TAL_CODE,COUNTRY_CODE3_GID,TIME_ZONE_GID,LAT,LON,IS_TEMPORARY,IS_MAKE_A
PPT_BEFORE_PLAN,RATE_CLASSIFICATION_GID,DOMAIN_NAME,IS_SHIPPER_KNOWN,IS
_ADDRESS_VALID,IS_MIXED_FREIGHT_THU_ALLOWED,SLOT_TIME_INTERVAL,SLOT_TIM
E_INTERVAL_UOM_CODE,SLOT_TIME_INTERVAL_BASE,IS_LTL_SPLITABLE
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.YELLOW,YELLOW,YELLOW
LOCATION,PITTSBURGH,,PA,99999,USA,America/New_York,,,N,N,,MYDOMAIN,N,U,
N,,,,Y
MYDOMAIN.MYLOCATION,MYLOCATION,MYLOCATION,PHILADELPHIA,,PA,19001,USA,Am
erica/New_York,40.12726,-75.12881,N,N,COMMERCIAL,MYDOMAIN,N,U,N,0,S,0,Y
MYDOMAIN.MYCORPORATION,MYCORPORATION,MYCORPORATION,PHILADELPHIA,,PA,190
01,USA,America/New_York,40.12726,-
75.12881,N,N,COMMERCIAL,MYDOMAIN,N,U,N,0,S,0,Y
```

2. Import the LOCATION_ADDRESS table

   The following example illustrates how you specify LOCATION_ADDRESS data in CSV format.

```
LOCATION_ADDRESS
LOCATION_GID,LINE_SEQUENCE,ADDRESS_LINE,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.YELLOW,1,432 YELLOW AVE,MYDOMAIN
MYDOMAIN.MYCORPORATION,1,11 EMPEROR AVE,MYDOMAIN
MYDOMAIN.MYLOCATION,1,123 MAPLE STREET,MYDOMAIN
MYDOMAIN.MYLOCATION,2,BUILDING H,MYDOMAIN
MYDOMAIN.MYLOCATION,3,ROOM 100,MYDOMAIN
```

3. Import the CORPORATION Table.

   The following example illustrates how you specify CORPORATION data in CSV format.

Note: Each CORPORATION_GID must correspond to a LOCATION_GID specified in the location table (See example).

```
CORPORATION
CORPORATION_GID,CORPORATION_XID,CORPORATION_NAME,DOMAIN_NAME,IS_DOMAIN_
MASTER,IS_SHIPPING_AGENTS_ACTIVE,IS_ALLOW_HOUSE_COLLECT
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.MYCORPORATION,MYCORPORATION,MYCORP,MYDOMAIN,N,N,N
MYDOMAIN.YELLOW INC,YELLOW INC,YELLOW INCORPORATED,MYDOMAIN,N,N,N
```

4. Import the LOCATION_CORPORATION Table.

   The following example illustrates how you specify LOCATION_CORPORATION data in CSV format. This links a location to a corporation.

   ```
   LOCATION_CORPORATION
   LOCATION_GID,CORPORATION_GID,DOMAIN_NAME
   EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
   MYDOMAIN.MYLOCATION,MYDOMAIN.MYCORPORATION,MYDOMAIN
   MYDOMAIN.MYCORPORATION,MYDOMAIN.MYCORPORATION,MYDOMAIN
   MYDOMAIN.YELLOW,MYDOMAIN.YELLOW INC,MYDOMAIN
   ```

5. Import the SERVPROV Table.

   The following example illustrates how you specify SERVPROV data in CSV format. Each SERVPROV_GID must correspond to a LOCATION_GID specified in the location table (See example).

   ```
   SERVPROV
   SERVPROV_GID,SERVPROV_XID,AUTO_PAYMENT_FLAG,DOMAIN_NAME,IS_DISPATCH_BY_
   REGION,ALLOW_TENDER,IS_ACCEPT_SPOT_BIDS,IS_ACCEPT_BROADCAST_TENDERS,IS_
   LOCALIZE_BROADCAST_CONTACT,DO_CONDITIONAL_ACCEPTS,IS_INTERNAL_NVOCC,IS_
   ACCEPT_BY_SSU_ALLOWED,IS_COPY_INV_DELTA_BACK_TO_SHIP,INVOICING_PROCESS
   EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
   MYDOMAIN.YELLOW,YELLOW,N,MYDOMAIN,N,Y,N,N,N,N,N,N,N,S
   ```

6. Import the LOCATION_ROLE_PROFILE Table.

   The following example illustrates how you specify LOCATION_ROLE_PROFILE data in CSV format. Each location should have at least one row in this table.

   ```
   LOCATION_ROLE_PROFILE
   LOCATION_GID,LOCATION_ROLE_GID,CALENDAR_GID,FIXED_HANDLING_TIME,FIXED_H
   ANDLING_TIME_UOM_CODE,FIXED_HANDLING_TIME_BASE,CREATE_XDOCK_HANDLING_SH
   IPMENT,CREATE_POOL_HANDLING_SHIPMENT,DOMAIN_NAME
   EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
   MYDOMAIN.YELLOW,CARRIER,,0,S,0,N,N,MYDOMAIN
   MYDOMAIN.MYLOCATION,SHIPFROM/SHIPTO,,0,S,0,N,N,MYDOMAIN
   MYDOMAIN.MYCORPORATION,BILL TO,,0,S,0,N,N,MYDOMAIN
   MYDOMAIN.MYCORPORATION,REMIT TO,,0,S,0,N,N,MYDOMAIN
   ```

7. Import the LOCATION_REMARK Table.

   The following example illustrates how you specify LOCATION_REMARK data in CSV format.

   ```
   LOCATION_REMARK
   LOCATION_GID,REMARK_SEQUENCE,REMARK_QUAL_GID,REMARK_TEXT,DOMAIN_NAME
   EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
   MYDOMAIN.MYLOCATION,1,REM,DRIVER CANNOT HAVE A BEARD,MYDOMAIN
   MYDOMAIN.MYLOCATION,2,REM,DRIVER MUST HAVE SAFETY GLASSES,MYDOMAIN
   ```

Importing Service Times

The following example illustrates how you specify SERVICE_TIME data in CSV format.

```
SERVICE_TIME
X_LANE_GID,RATE_SERVICE_GID,SERVICE_TIME_VALUE,SERVICE_DAYS,DOMAIN_NAME,SE
RVICE_TIME_VALUE_UOM_CODE,SERVICE_TIME_VALUE_BASE
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.194-064,MYDOMAIN.VOYAGE-DEFAULT,172800,,MYDOMAIN,S,172800
MYDOMAIN.194-065,MYDOMAIN.VOYAGE-DEFAULT,86400,,MYDOMAIN,S,86400
```

In the above example, note that you must specify SERVICE_DAYS, and leave the SERVICE_TIME_VALUE unspecified. As an alternative, you must specify SERVICE_TIME_VALUE in seconds, and leave the SERVICE_DAYS unspecified. You must never specify both a SERVICE_TIME_VALUE and a SERVICE_DAYS value on the same record.

Importing X_LANE Data for Rates

This section provides an example for loading X_LANE data in CSV format. Typically, the X_LANE tables are loaded prior to the loading of the RATE_GEO and RATE_GEO_COST tables.

X_LANE	
PK	**X_LANE_GID**
	X_LANE_XID
FK7	SOURCE_LOCATION_GID
	SOURCE_CITY
	SOURCE_PROVINCE_CODE
	SOURCE_POSTAL_CODE
FK5	SOURCE_COUNTRY_CODE3_GID
	SOURCE_ZONE4
	SOURCE_ZONE1
	SOURCE_ZONE2
	SOURCE_ZONE3
FK6	SOURCE_GEO_HIERARCHY_GID
FK3	DEST_LOCATION_GID
	DEST_CITY
	DEST_PROVINCE_CODE
	DEST_POSTAL_CODE
FK1	DEST_COUNTRY_CODE3_GID
	DEST_ZONE4
	DEST_ZONE1
	DEST_ZONE2
	DEST_ZONE3
FK2	DEST_GEO_HIERARCHY_GID
FK8	SOURCE_REGION_GID
FK4	DEST_REGION_GID
	LOADED
	DOMAIN_NAME
	INSERT_USER
	INSERT_DATE
	UPDATE_USER
	UPDATE_DATE

The following example illustrates how you specify GEO_HIERARCHY and X_LANE data in CSV format.

```
GEO_HIERARCHY
GEO_HIERARCHY_GID,GEO_HIERARCHY_XID,RANK,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.USZIP4,USZIP4,4,MYDOMAIN

X_LANE
X_LANE_GID,X_LANE_XID,SOURCE_POSTAL_CODE,SOURCE_COUNTRY_CODE3_GID,SOURCE_G
EO_HIERARCHY_GID,DEST_POSTAL_CODE,DEST_COUNTRY_CODE3_GID,DEST_GEO_HIERARCH
Y_GID,DOMAIN_NAME
```

```
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.194-064,194-
064,194,USA,MYDOMAIN.USZIP4,64,USA,MYDOMAIN.USZIP4,MYDOMAIN
MYDOMAIN.194-065,194-
065,194,USA,MYDOMAIN.USZIP4,65,USA,MYDOMAIN.USZIP4,MYDOMAIN
MYDOMAIN.MY LANE,MY LANE,194,,POSTAL_CODE,64,,POSTAL_CODE,MYDOMAIN
```

Importing LTL Rates

This section describes how to specify LTL rates and gives sample CSV files for several scenarios.

The following tables must be loaded (in order):

- RATE_OFFERING (setup manually on Oracle Transportation Management web pages)
- X_LANE (see page 8-3)
- RATE_GEO
- ACCESSORIAL_CODE
- ACCESSORIAL_COST
- RATE_GEO_ACCESSORIAL (*)
- RATE_GEO_COST_GROUP
- RATE_GEO_COST
- RATE_UNIT_BREAK_PROFILE
- RATE_UNIT_BREAK
- RATE_GEO_COST_UNIT_BREAK

Note: (*) RATE_GEO_ ACCESSORIAL must come after RATE_GEO, but is not required before the remaining tables.

Assumptions:

- You have loaded the rate offering table using Oracle Transportation Management web pages
- You have loaded the X_Lane table (see page 8-3)

Simplified ERD for LTL Rates

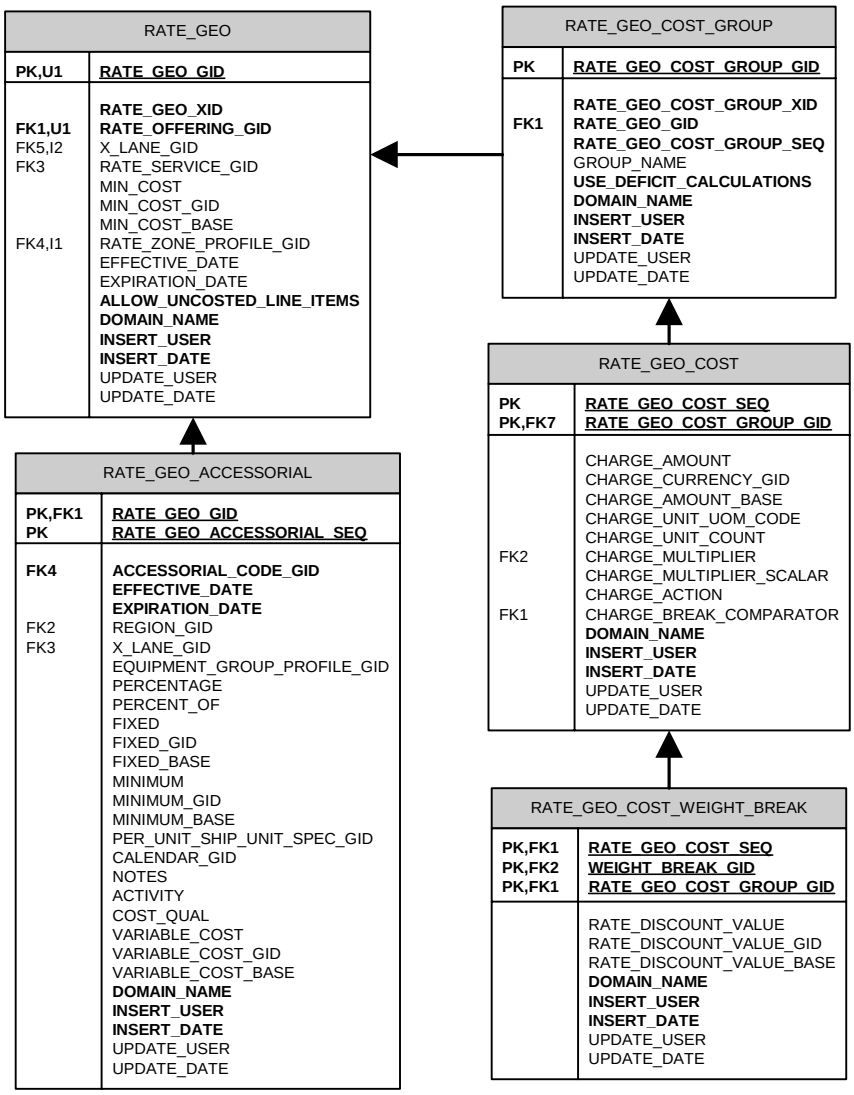


Table Notes:

- RATE_GEO Table

Allow_uncosted_line_items in Y/N (defaults to “N”)

- RATE_GEO_ACCESSORIAL

Left_Operand1 – Basis options define what variable you want to base your conditional charge on.

Oper1_gid – The operand you compare with.

Low_value1 – Depending on the operand you use, you might need only the low_value1 or additionally the high_value1.

- RATE_GEO_COST_GROUP Table

Use_deficit_calculations in Y/N (defaults to “N”)

- RATE_GEO_COST Table

charge_unit_uom_code - unit of measure (e.g. “LB” for pounds, or “MI” for miles)

charge_unit_count - hundredweight, etc.

charge_action – add (A), setmin (M), setmax (X), multiply/discount (D)

charge_break_comparator -identifies data element used to access the break

Scenario–Based on Simple Unit Breaks

This scenario assumes that rates are defined as simple unit breaks.

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,DOMAIN_NAME
"MYDOMAIN.194-064","194-
064","MYDOMAIN.YELLOW",1.0,"USD",1.0,"MYDOMAIN.194-064","MYDOMAIN"
"MYDOMAIN.194-065","194-
065","MYDOMAIN.YELLOW",1.0,"USD",1.0,"MYDOMAIN.194-065","MYDOMAIN"
```

2. Import RATE_GEO_COST_GROUP table.

```
RATE_GEO_COST_GROUP
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_GROUP_XID,RATE_GEO_GID,RATE_GEO_C
OST_GROUP_SEQ,GROUP_NAME,DOMAIN_NAME
"MYDOMAIN.194-064","194-064","MYDOMAIN.194-
064",1,"MY_GROUP_NAME","MYDOMAIN"
"MYDOMAIN.194-065","194-065","MYDOMAIN.194-
065",1,"MY_GROUP_NAME","MYDOMAIN"
```

3. Import RATE_GEO_COST table.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,CHARGE_UNIT_UOM_CODE,CHARGE_U
NIT_COUNT,CHARGE_BREAK_COMPARATOR,DOMAIN_NAME
1,"MYDOMAIN.194-064","LB",100,"SHIPMENT.WEIGHT","MYDOMAIN"
1,"MYDOMAIN.194-065","LB",100,"SHIPMENT.WEIGHT","MYDOMAIN"
```

4. Import RATE_UNIT_BREAK_PROFILE table.

```
RATE_UNIT_BREAK_PROFILE
RATE_UNIT_BREAK_PROFILE_GID,RATE_UNIT_BREAK_PROFILE_XID,DATA_TYPE,LOOKU
P_TYPE,UOM_TYPE,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.LT 1000,LT 1000,U,M,WEIGHT,MYDOMAIN
```

5. Import RATE_UNIT_BREAK table.

```
RATE_UNIT_BREAK
RATE_UNIT_BREAK_GID,RATE_UNIT_BREAK_XID,RATE_UNIT_BREAK_PROFILE_GID,RAT
E_UNIT_BREAK_MAX,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.1000,0-1000,MYDOMAIN.LT 1000,1000 LB,MYDOMAIN
MYDOMAIN.1000-3000,1000-3000,MYDOMAIN.LT 1000,3000 LB,MYDOMAIN
```

6. Import RATE_GEO_COST_UNIT_BREAK table.

```
RATE_GEO_COST_UNIT_BREAK
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_SEQ,RATE_UNIT_BREAK_GID,CHARGE_AM
OUNT,CHARGE_AMOUNT_GID,CHARGE_AMOUNT_BASE,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.194-064,1,MYDOMAIN.1000,48.53,USD,48.53,MYDOMAIN
MYDOMAIN.194-064,1,MYDOMAIN.1000-3000,37.56,USD,37.56,MYDOMAIN
```

Scenario–Based on Cost Per Pound, Surcharge, and Discount

This scenario assumes that:

- Freight cost is $0.07 per lb
- Fuel Surcharge is 3% of Total Cost (Accessorial)
- Discount is 65% of Total Cost
- There is a $50 allowance for loading
- The minimum charge is based on 10,000 lb
- Total Cost = (weight * 0.07 – 50.00) * (65% Discount) * (Accessorial Surcharge of 3%)
- Min Cost = (10,000 * 0.07 – 50.00) * (1 - 0.65) * (1.03) = 234.325
-

Summary

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,DOMAIN_NAME
"MYDOMAIN.194-064-2","194-064-
2","MYDOMAIN.YELLOW",234.325,"USD",234.325,"MYDOMAIN.194-
064","MYDOMAIN"
```

2. Import ACCESSORIAL_COST table.

```
ACCESSORIAL_COST
ACCESSORIAL_COST_GID,ACCESSORIAL_COST_XID,CHARGE_MULTIPLIER,CHARGE_MULT
IPLIER_SCALAR,CHARGE_ACTION,CHARGE_TYPE,USE_DEFAULTS,CHARGE_MULTIPLIER_
OPTION,USES_UNIT_BREAKS,DOMAIN_NAME,IS_FILED_AS_TARIFF
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS,FS,SHIPMENT.COSTS.AMOUNT,1.03,A,B,N,A,N,MYDOMAIN,N
```

3. Import ACCESSORIAL_CODE table.

```
ACCESSORIAL_CODE
ACCESSORIAL_CODE_GID,ACCESSORIAL_CODE_XID,ACCESSORIAL_DESC,APPLY_GLOBAL
LY,DOMAIN_NAME,IS_FLOW_THRU,IS_VAT_EXEMPT
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FUEL_SURCHARGE,FUEL_SURCHARGE,FUEL SURCHARGE,Y,MYDOMAIN,N,N
```

4. Import RATE_GEO_ACCESSORIAL table.

```
RATE_GEO_ACCESSORIAL
ACCESSORIAL_COST_GID,RATE_GEO_GID,ACCESSORIAL_CODE_GID,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS,MYDOMAIN.194-064-2,MYDOMAIN.FUEL_SURCHARGE,MYDOMAIN
```

5. Import RATE_GEO_COST_GROUP table.

```
RATE_GEO_COST_GROUP
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_GROUP_XID,RATE_GEO_GID,RATE_GEO_C
OST_GROUP_SEQ,GROUP_NAME,DOMAIN_NAME
MYDOMAIN.194-064-2,194-064-2,MYDOMAIN.194-064-
2,1,MY_GROUP_NAME_2,MYDOMAIN
```

6. Import RATE_GEO_COST table.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,CHARGE_AMOUNT,CHARGE_CURRENCY
_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_UOM_CODE,CHARGE_UNIT_COUNT,CHARGE_M
ULTIPLIER,CHARGE_MULTIPLIER_SCALAR,CHARGE_ACTION,DOMAIN_NAME
1,"MYDOMAIN.194-064-
2",0.07,"USD",0.07,"LB",1,"SHIPMENT.WEIGHT",,"A","MYDOMAIN"
2,"MYDOMAIN.194-064-2",-50.0,"USD",-50.0,,1,,,"A","MYDOMAIN"
3,"MYDOMAIN.194-064-2",,,,,1,,0.35,"D","MYDOMAIN"
```

Note: An alternative to using the data specified for the RATE_GEO_ACCESSORIAL table above would be to add another Sequence to this table with the following (representing a 3% surcharge of the total value):

```
4,”MYDOMAIN.194-064-2”,,,,,1,,1.03,”D”,”MYDOMAIN”
```

Scenario–Based on Cost Per Pound, Conditional Surcharge, Global Surcharge, and Discount

This scenario assumes that:

- Freight cost is $0.07 per lb
- Unload fee is $10 if the weight > 20000lb (Accessorial)
- Fuel Surcharge is 3% of Total Cost (Accessorial)
- Discount is 65% of Total Cost
- There is a $50 allowance for loading
- The minimum charge is based on 10,000 lb

Summary

- Total Cost = ((weight * 0.07 – 50.00) * (65% Discount) + (if weight>20000lb then Accessorial Surcharge of 10)) * (1.03)
- Min Cost = (10,000 * 0.07 – 50.00) * (1 - 0.65) * (1.03) = 234.325

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,DOMAIN_NAME
MYDOMAIN.194-064-3,194-064-
3,MYDOMAIN.YELLOW,234.325,USD,234.325,MYDOMAIN.194-064,MYDOMAIN
```

2. Import ACCESSORIAL_COST table.

```
ACCESSORIAL_COST
```

```
ACCESSORIAL_COST_GID,ACCESSORIAL_COST_XID,LEFT_OPERAND1,OPER1_GID,LOW_V
ALUE1,AND_OR1,LEFT_OPERAND2,OPER2_GID,LOW_VALUE2,CHARGE_MULTIPLIER,CHAR
GE_AMOUNT,CHARGE_AMOUNT_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_COUNT,CHARGE
_MULTIPLIER_SCALAR,CHARGE_ACTION,CHARGE_TYPE,USE_DEFAULTS,CHARGE_MULTIP
LIER_OPTION,USES_UNIT_BREAKS,DOMAIN_NAME,ROUNDING_TYPE,ROUNDING_FIELDS_
LEVEL,ROUNDING_APPLICATION,IS_FILED_AS_TARIFF
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS,FS,,,,,,,,SHIPMENT.COSTS.AMOUNT,,,,,1.03,A,B,N,A,N,MYDOMAIN
,N,0,A,N
MYDOMAIN.FS-2,FS-
2,SHIPMENT.STOPS.SHIPUNITS.ACTIVITY,EQ,D,S,SHIPMENT.STOPS.WEIGHT,GT,200
00 LB,SHIPMENT,10,USD,10,1,,A,B,N,A,N,MYDOMAIN,,,,N
```

3. Import ACCESSORIAL_CODE table.

```
ACCESSORIAL_CODE
ACCESSORIAL_CODE_GID,ACCESSORIAL_CODE_XID,ACCESSORIAL_DESC,APPLY_GLOBAL
LY,DOMAIN_NAME,IS_FLOW_THRU,IS_VAT_EXEMPT
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FUEL_SURCHARGE,FUEL_SURCHARGE,FUEL SURCHARGE,Y,MYDOMAIN,N,N
```

4. Import RATE_GEO_ACCESSORIAL table.

```
RATE_GEO_ACCESSORIAL
ACCESSORIAL_COST_GID,RATE_GEO_GID,ACCESSORIAL_CODE_GID,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS-2,MYDOMAIN.194-064-3,MYDOMAIN.FUEL_SURCHARGE,MYDOMAIN
MYDOMAIN.FS,MYDOMAIN.194-064-3,MYDOMAIN.FUEL_SURCHARGE,MYDOMAIN
```

5. Import RATE_GEO_COST_GROUP table.

```
RATE_GEO_COST_GROUP
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_GROUP_XID,RATE_GEO_GID,RATE_GEO_C
OST_GROUP_SEQ,GROUP_NAME,DOMAIN_NAME
MYDOMAIN.194-064-3,194-064-3,MYDOMAIN.194-064-
3,1,MY_GROUP_NAME_3,MYDOMAIN
```

6. Import RATE_GEO_COST table.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,CHARGE_AMOUNT,CHARGE_CURRENCY
_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_UOM_CODE,CHARGE_UNIT_COUNT,CHARGE_M
ULTIPLIER,CHARGE_MULTIPLIER_SCALAR,CHARGE_ACTION,DOMAIN_NAME
1,MYDOMAIN.194-064-3,0.07,USD,0.07,LB,1,SHIPMENT.WEIGHT,,A,MYDOMAIN
2,MYDOMAIN.194-064-3,-50,USD,-50,,1,,,A,MYDOMAIN
3,MYDOMAIN.194-064-3,,,,,1,,65,D,MYDOMAIN
```

Importing TL Rates

This section describes how to specify TL rates and gives sample CSV files for several scenarios.

The following tables must be loaded (in order):

- RATE_OFFERING (setup manually on Oracle Transportation Management web pages)
- X_LANE (see page 8-3)
- RATE_GEO

- ACCESSORIAL_CODE
- ACCESSORIAL_COST
- RATE_GEO_ACCESSORIAL (*)
- RATE_GEO_STOPS (*)
- RATE_GEO_COST_GROUP
- RATE_GEO_COST

Note: (*) RATE_GEO_ ACCESSORIAL and RATE_GEO_STOPS must come after RATE_GEO, but are not required before the remaining tables.

Assumptions:

- You have loaded the rate offering table using Oracle Transportation Management web pages
- You have loaded the X_Lane table (see page 8-3).

Simplified ERD for TL Rates

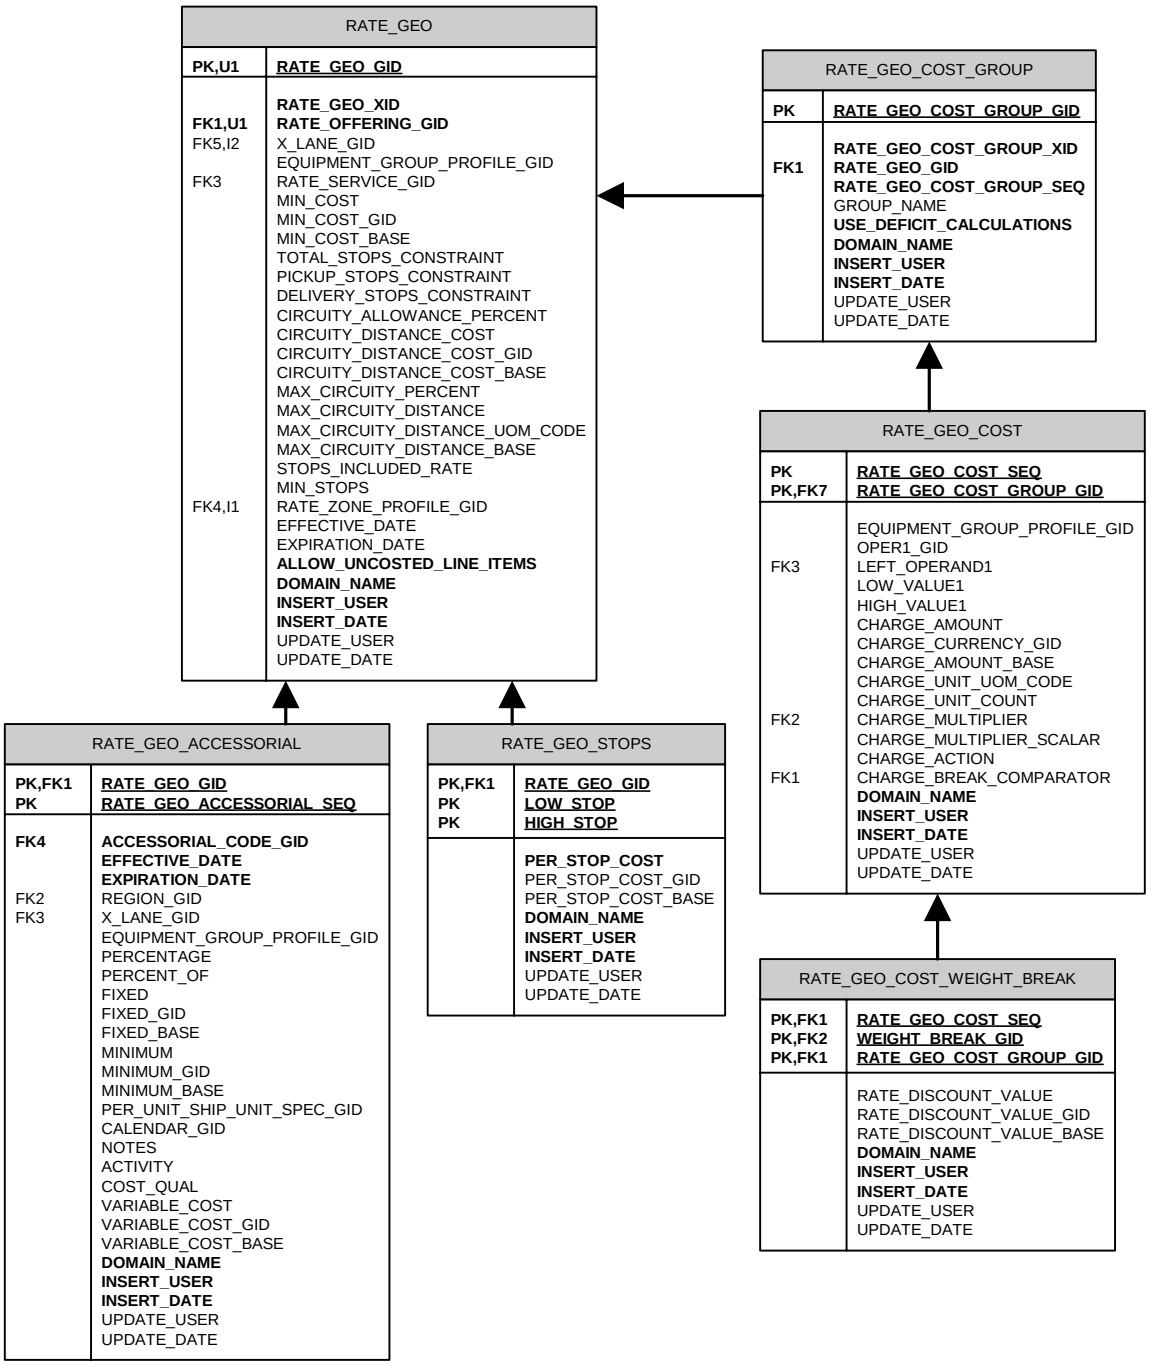

Table Notes

RATE_GEO Table

- Allow_uncosted_line_items in Y/N (defaults to “N”)

RATE_GEO_ACCESSORIAL

- Left_Operand1 – Basis options define what variable you want to base your conditional charge on.
- Oper1_gid – The operand you compare with.
- Low_value1 – Depending on the operand you use, you might need only the low_value1 or additionally the high_value1.

RATE_GEO_COST_GROUP Table

- Use_deficit_calculations in Y/N (defaults to "N")

RATE_GEO_COST Table

- Oper1_gid – field value "BETWEEN" is a shortcut for X > low and X <= high. Other possible values include "<", "<=", ">", ">=", "=", and "<>".
- charge_unit_uom_code - unit of measure (e.g. "LB" for pounds, or "MI" for miles)
- charge_unit_count - hundredweight, etc.
- charge_action – add (A), setmin (M), setmax (X), multiply (D)
- charge_break_comparator -identifies data element used to access the break

Scenario–Based on Distance Bands with Fixed Charges, and Stop Offs

This scenario assumes that:

- TL rates are defined using distance bands, with a flat charge within each band
- For Rate Geo A

If distance between 10 and 100 miles, charge $50

If distance is between 100 and 200 miles, charge $75

- For Rate Geo B

If distance between 10 and 100 miles, charge $80

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,TOTAL_STOPS_CONSTRAINT,STOPS_INCLUDED_RATE,DOMAIN_N
AME
MYDOMAIN.194-064-TL1,194-064-TL1,MYDOMAIN.YELLOW,1,USD,1,MYDOMAIN.194-
064,6,2,MYDOMAIN
MYDOMAIN.194-065-TL1,194-065-TL1,MYDOMAIN.YELLOW,1,USD,1,MYDOMAIN.194-
065,6,2,MYDOMAIN
```

2. Import RATE_GEO_STOPS table.

```
RATE_GEO_STOPS
RATE_GEO_GID,LOW_STOP,HIGH_STOP,PER_STOP_COST,PER_STOP_COST_GID,PER_STO
P_COST_BASE,DOMAIN_NAME
"MYDOMAIN.194-064-TL1",1,2,50.00,"USD",50.00,"MYDOMAIN"
"MYDOMAIN.194-064-TL1",3,4,100.00,"USD",100.00,"MYDOMAIN"
"MYDOMAIN.194-065-TL1",1,2,25.50,"USD",25.50,"MYDOMAIN"
"MYDOMAIN.194-065-TL1",3,4,85.00,"USD",85.00,"MYDOMAIN"
```

3. Import RATE_GEO_COST_GROUP table.

```
RATE_GEO_COST_GROUP
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_GROUP_XID,RATE_GEO_GID,RATE_GEO_C
OST_GROUP_SEQ,GROUP_NAME,DOMAIN_NAME
"MYDOMAIN.194-064-TL1","194-064-TL1","MYDOMAIN.194-064-
TL1",1,"MY_GROUP_NAME_TL","MYDOMAIN"
"MYDOMAIN.194-065-TL1","194-065-TL1","MYDOMAIN.194-065-
TL1",1,"MY_GROUP_NAME_TL","MYDOMAIN"
```

4. Import RATE_GEO_COST table.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,OPER1_GID,LEFT_OPERAND1,LOW_V
ALUE1,HIGH_VALUE1,CHARGE_AMOUNT,CHARGE_CURRENCY_GID,CHARGE_AMOUNT_BASE,
DOMAIN_NAME
1,"MYDOMAIN.194-064-TL1","BETWEEN","SHIPMENT.DISTANCE","10 MI","100
MI",50.00,"USD", 50.00,"MYDOMAIN"
2,"MYDOMAIN.194-064-TL1","BETWEEN","SHIPMENT.DISTANCE","100 MI","200
MI",75.00,"USD", 75.00,"MYDOMAIN"
1,"MYDOMAIN.194-065-TL1","BETWEEN","SHIPMENT.DISTANCE","10 MI","100
MI",80.00,"USD", 80.00,"MYDOMAIN"
```

Scenario–Based on Cost Per Mile, Stop Offs, and Surcharges

This scenario assumes that:

- The freight cost is $1.75 per mile
- Stop Off Charges

Allowed 6 stops total, with 2 stops included in rate

Charge of $50 for 3rd stop, and $65 for subsequent stops

- Fuel Surcharge is $0.02 per mile (Accessorial)
- Minimum charge on transport is $450

Summary

- Total Cost = (distance * 1.75) + stop off charges + (Accessorial of $0.02 per mile)
- Min Transport = (450.00) + stop off charges + (Accessorial of $0.02 per mile)

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,TOTAL_STOPS_CONSTRAINT,STOPS_INCLUDED_RATE,DOMAIN_N
AME
"MYDOMAIN.194-064-TL2","194-064-
TL2","MYDOMAIN.YELLOW",1.0,"USD",1.0,"MYDOMAIN.194-064",6, 2,"MYDOMAIN"
```

2. Import ACCESSORIAL_COST table.

```
ACCESSORIAL_COST
ACCESSORIAL_COST_GID,ACCESSORIAL_COST_XID,CHARGE_MULTIPLIER,CHARGE_AMOU
NT,CHARGE_AMOUNT_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_UOM_CODE,CHARGE_UNI
T_COUNT,CHARGE_ACTION,CHARGE_TYPE,USE_DEFAULTS,CHARGE_MULTIPLIER_OPTION
,USES_UNIT_BREAKS,DOMAIN_NAME,IS_FILED_AS_TARIFF
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS-TL2,FS-
TL2,SHIPMENT.DISTANCE,0.02,USD,0.02,MI,1,A,B,N,A,N,MYDOMAIN,N
```

3. Import ACCESSORIAL_CODE table.

```
ACCESSORIAL_CODE
ACCESSORIAL_CODE_GID,ACCESSORIAL_CODE_XID,ACCESSORIAL_DESC,APPLY_GLOBAL
LY,DOMAIN_NAME,IS_FLOW_THRU,IS_VAT_EXEMPT
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FUEL_SURCHARGE,FUEL_SURCHARGE,FUEL SURCHARGE,Y,MYDOMAIN,N,N
```

4. Import RATE_GEO_ACCESSORIAL table.

```
RATE_GEO_ACCESSORIAL
ACCESSORIAL_COST_GID,RATE_GEO_GID,ACCESSORIAL_CODE_GID,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.FS-TL2,MYDOMAIN.194-064-TL2,MYDOMAIN.FUEL_SURCHARGE,MYDOMAIN
```

5. Import RATE_GEO_STOPS table.

```
RATE_GEO_STOPS
RATE_GEO_GID,LOW_STOP,HIGH_STOP,PER_STOP_COST,PER_STOP_COST_GID,PER_STO
P_COST_BASE,DOMAIN_NAME
MYDOMAIN.194-064-TL2,1,1,50,USD,50,MYDOMAIN
MYDOMAIN.194-064-TL2,2,2,65,USD,65,MYDOMAIN
```

Note: Leaving the HIGH_STOP value empty indicates that the last charge will be applied to all the stops greater than the LOW_STOP value. (i.e. for stops >= 2, charge $65 per stop).

6. Import RATE_GEO_COST_GROUP table.

```
RATE_GEO_COST_GROUP
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_GROUP_XID,RATE_GEO_GID,RATE_GEO_C
OST_GROUP_SEQ,GROUP_NAME,DOMAIN_NAME
MYDOMAIN.194-064-TL2,194-064-TL2,MYDOMAIN.194-064-
TL2,1,MY_GROUP_NAME_TL2,MYDOMAIN
```

7. Import RATE_GEO_COST table.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,CHARGE_AMOUNT,CHARGE_CURRENCY
_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_UOM_CODE,CHARGE_UNIT_COUNT,CHARGE_M
ULTIPLIER,CHARGE_MULTIPLIER_SCALAR,CHARGE_ACTION,DOMAIN_NAME
1,MYDOMAIN.194-064-TL2,1.75,USD,1.75,MI,1,SHIPMENT.DISTANCE,,A,MYDOMAIN
2,MYDOMAIN.194-064-TL2,450,USD,450,,1,,,M,MYDOMAIN
```

Note: Seq#2, with a charge action of “M”, indicates that the minimum of the running calculated cost has to be $450 (i.e. if the calculation from Seq#1 is less than $450, then the new value to be used going forward is $450).

An alternative method of specifying this rate would be to recognize that a minimum of $450 equates to distance of 257.143 miles. A comparison for this distance could be used. This would be the corresponding result.

```
RATE_GEO_COST
RATE_GEO_COST_SEQ,RATE_GEO_COST_GROUP_GID,OPER1_GID,LEFT_OPERAND1,LOW_V
ALUE1,CHARGE_AMOUNT,CHARGE_CURRENCY_GID,CHARGE_AMOUNT_BASE,CHARGE_UNIT_
UOM_CODE,CHARGE_UNIT_COUNT,CHARGE_MULTIPLIER,CHARGE_MULTIPLIER_SCALAR,C
HARGE_ACTION,DOMAIN_NAME
1,"MYDOMAIN.194-064-TL2",">","SHIPMENT.DISTANCE","237.143
MI",1.750,"USD",1.750,"MI",1, "SHIPMENT.DISTANCE",,"A","MYDOMAIN"
2,"MYDOMAIN.194-064-TL2","<=","SHIPMENT.DISTANCE","257.143
MI",450.0,"USD",450.0,,1, ,,"A","MYDOMAIN"
```

Note: An alternative to using the data specified for the RATE_GEO_ACCESSORIAL table above would be to add another Sequence to the RATE_GEO_COST table with the following (representing a surcharge of $0.02 per mile):

```
3,"MYDOMAIN.194-064-
TL2",0.020,"USD",0.020,"MI",1,"SHIPMENT.DISTANCE",,"A","MYDOMAIN"
```

Scenario–Based on Cost per Hundredweight, Unit Breaks, and Surcharges

This scenario assumes that:

- The freight cost is per hundredweight based on unit breaks
- Fuel Surcharge is $0.02 per mile (Accessorial)

Summary

- Total Cost = ((weight/100) * (weight break charge)) + (Accessorial of $0.02 per mile)

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C
OST_BASE,X_LANE_GID,TOTAL_STOPS_CONSTRAINT,STOPS_INCLUDED_RATE,DOMAIN_N
AME
MYDOMAIN.194-064-TL3,194-064-TL3,MYDOMAIN.YELLOW,1,USD,1,MYDOMAIN.194-

```

9. Import RATE_GEO_COST_UNIT_BREAK table.

```
RATE_GEO_COST_UNIT_BREAK
```

```
RATE_GEO_COST_GROUP_GID,RATE_GEO_COST_SEQ,RATE_UNIT_BREAK_GID,CHARGE_AM
OUNT,CHARGE_AMOUNT_GID,CHARGE_AMOUNT_BASE,DOMAIN_NAME
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYYMMDDHH24MISS'
MYDOMAIN.194-064-TL3,1,MYDOMAIN.40000,1.14,USD,1.14,MYDOMAIN
MYDOMAIN.194-064-TL3,1,MYDOMAIN.45000,1.07,USD,1.07,MYDOMAIN
```

Scenario–Based on Cost per Hundredweight, Unit Breaks, and Surcharges

This scenario assumes that:

- The freight cost is per hundredweight based on unit breaks which are based on mileage bands.

	Cost per Weight	
Mileage Band	40000 lbs	45000 lbs
0 – 50	0.85	0.50
51 – 55	0.87	0.82
56 - 60	0.88	0.83

- Weighing charge is $20
- Vacuuming fee is $0.25 per CWT with a $115 minimum

Summary

- Total Cost = ((weight/100) * (unit break charge)) + $20 + (Vacuuming Fee of 0.25 per CWT)
- Note: Min $115 for vacuuming is reached when the weight is at 46,000 lbs

1. Import RATE_GEO table.

```
RATE_GEO
RATE_GEO_GID,RATE_GEO_XID,RATE_OFFERING_GID,MIN_COST,MIN_COST_GID,MIN_C

```

9. Loading CSV Data via the Application Server

Oracle Transportation Management allows importing of CSV files via the application server. This feature is called “AppServer CSV” or AS.CSV.

If you upload a file whose name ends in “as.csv” instead of just “.CSV”, it will be interpreted as an application server CSV file, as opposed to a database-centric CSV file. AppServer CSV files have the following features:

- The first line must be the name of an Entity such as Location, ObOrderBase, OrderRelease, etc. Refer to Example3.java in the chapter titled “Java Integration API” to see how to get a complete list of supported entity names. Entity names are derived from database table names, except they omit the underscores and use mixed case. For example, the entity name for the ob_order_base table is ObOrderBase.
- The second line must be a comma-separated list of attribute names. Attribute names are like database column names, except they omit the underscores and use mixed case. For example, a column called location_gid corresponds to the attribute **locationGid**. Note that the first character is in lower-case for attribute names, but upper case for entity names.
- The third line may be an optional UOM line, which provides UOM values for any UOM attributes. This line may be provided instead of providing UOM qualifiers every time a UOM value occurs.
- The remaining lines are data lines. Each value in a data line must correspond to an attribute name from line2.

Here is small sample file. This example omits the optional UOM line.

```
Location
locationGid,locationXid,countryCode3Gid,domainName,locationName
"GUEST.MYLOC8","MYLOC8","USA","GUEST","myloc8"
```

Here is another small sample file showing how to specify a UOM line.

```
SShipUnit
domainName,unitWidth,sShipUnitGid,isSplitable,unitNetVolume,unitNetWeight,
shipUnitCount,unitWeight,unitVolume,unitHeight,receivedNetVolume,receivedN
etWeight,unitLength,sShipUnitXid
UOM:,,,,CUFT,LB,,LB,,,CUFT,LB,,
GUEST,,GUEST.001,false,0,10,1,10,,,0,0,,001
```

Here is the same sample, but with the UOM line omitted and the units of measure specified with each data attribute instead.

```
SShipUnit
domainName,unitWidth,sShipUnitGid,isSplitable,unitNetVolume,unitNetWeight,
shipUnitCount,unitWeight,unitVolume,unitHeight,receivedNetVolume,receivedN
etWeight,unitLength,sShipUnitXid
GUEST,,GUEST.001,false,0 CUFT,10 LB,1,10 LB,,,0 CUFT,0 LB,,001
```

Here is an example that will result in errors. You cannot specify a UOM line of you also specify UOMs within the data attributes.

> **Note:** The example below represents what not to do. Do NOT copy the example below. The following example would produce an error because a UOM line was specified, but UOMs were also specified in the data attributes. Doing this would cause the system to think that each UOM field has two UOM qualifiers.

```
SShipUnit
```

```
domainName,unitWidth,sShipUnitGid,isSplitable,unitNetVolume,unitNetWeight,
shipUnitCount,unitWeight,unitVolume,unitHeight,receivedNetVolume,receivedN
etWeight,unitLength,sShipUnitXid
UOM:,,,,CUFT,LB,,LB,,,CUFT,LB,,
GUEST,,GUEST.001,false,0 CUFT,10 LB,1,10 LB,,,0 CUFT,0 LB,,001
```

Command-Line API for Importing and Exporting AppServer CSV Files

Here is a command line example for importing an AppServer CSV file:

```
java glog.integration.clientapi.CSVHelper
-command ii
-fileName l:/GC3/glog/integration/clientapi/location.as.csv
-glUserGid GUEST.ADMIN
-glPassword CHANGEME
```

When importing, the valid commands are i, ii, u, uu, d, dd, and iu.

Here is a sample command line for exporting an AppServer CSV file:

```
java glog.integration.clientapi.CSVHelper
-command as.xcsv
-entityName SShipUnit
-glUserGid GUEST.FEWROWS
-glPassword CHANGEME
```

When you export an AppServer CSV file, you should use a special user that has VPD configured to limit the number of rows selected. This is because the underlying Java Integration API does not currently provide a method that allows a where-clause to be specified.

Web Interface for Importing and Exporting AppServer CSV Files

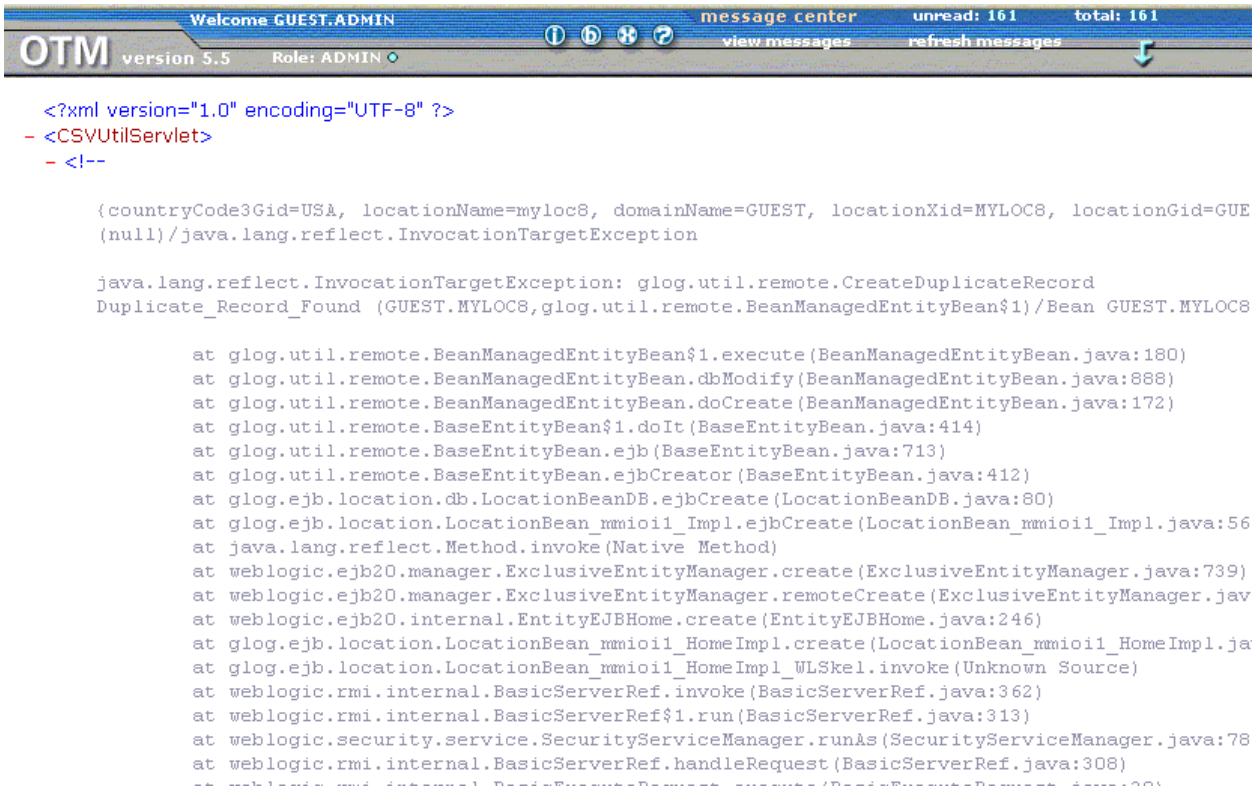
Importing

If you use the Integration Manager to upload a CSV file whose name ends in ".as.csv", Oracle Transportation Management will assume that the content of the file adheres to the rules of AppServer CSV files, and will process it as such. An example of a file name would be "location.as.csv", as opposed to "location.csv".

Each row in the file is processed via the application server instead of directly against the database. This has the benefit of keeping the application server data-cache synchronized with the database.

This page is accessed via **Business Process Automation > Integration > Integration Manager**. See page 7-1 for details about this page.

Errors encountered when importing are reported back to the screen, as shown below:



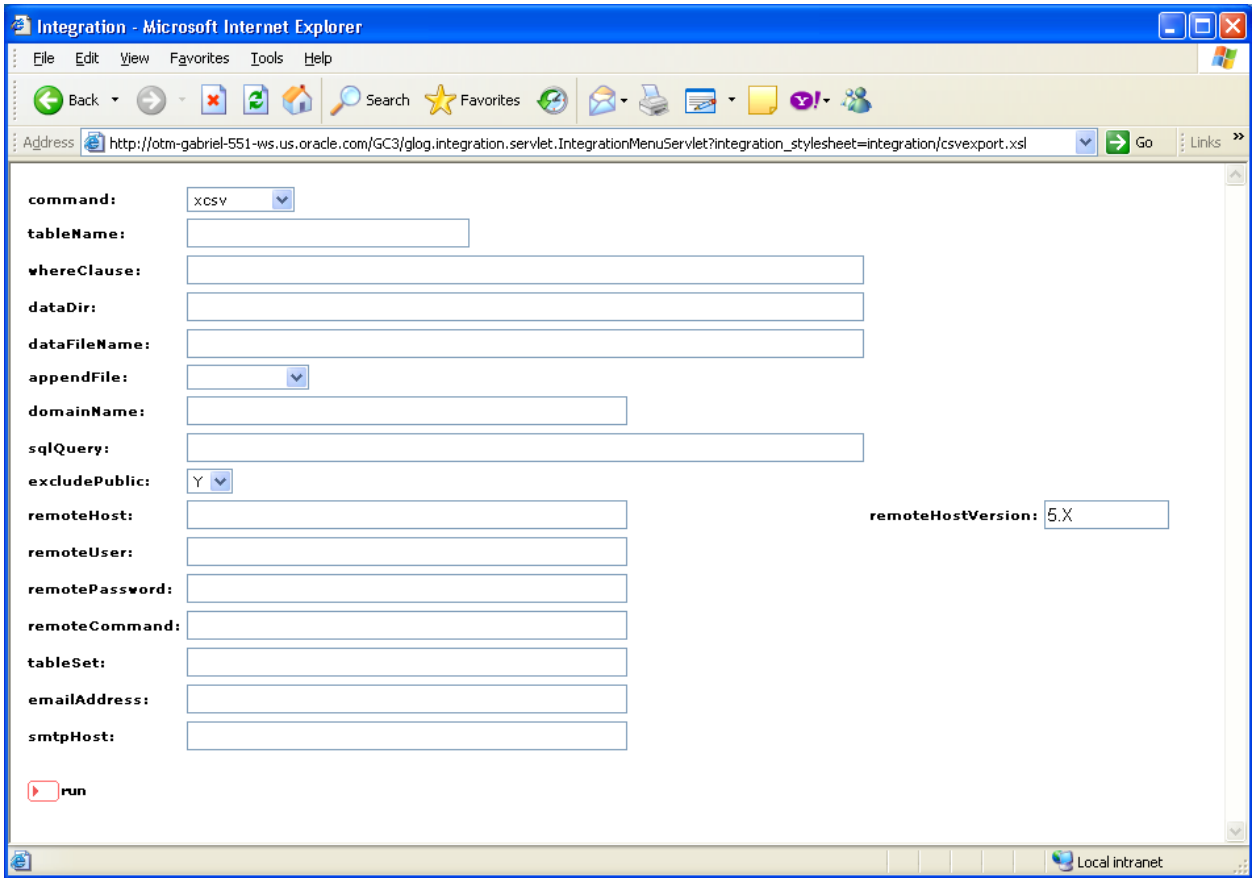
In this case, the location.as.csv file was attempted to be imported more than once using the “i” code. This produced the “CreateDuplicateRecord” error, which is the application server’s version of a duplicate key error.

Exporting

Care must be taken when exporting an AppServer CSV file due to the lack of support for where-clauses. You should be logged in as a user whose vpd_profile limits the number of rows selected from the entity you plan on exporting. Where-clauses will be supported in future releases. In the example below, the user is logged in as “GUEST.FEWROWS”. This user has a vpd_profile which limits the number of rows in the s_ship_unit table.

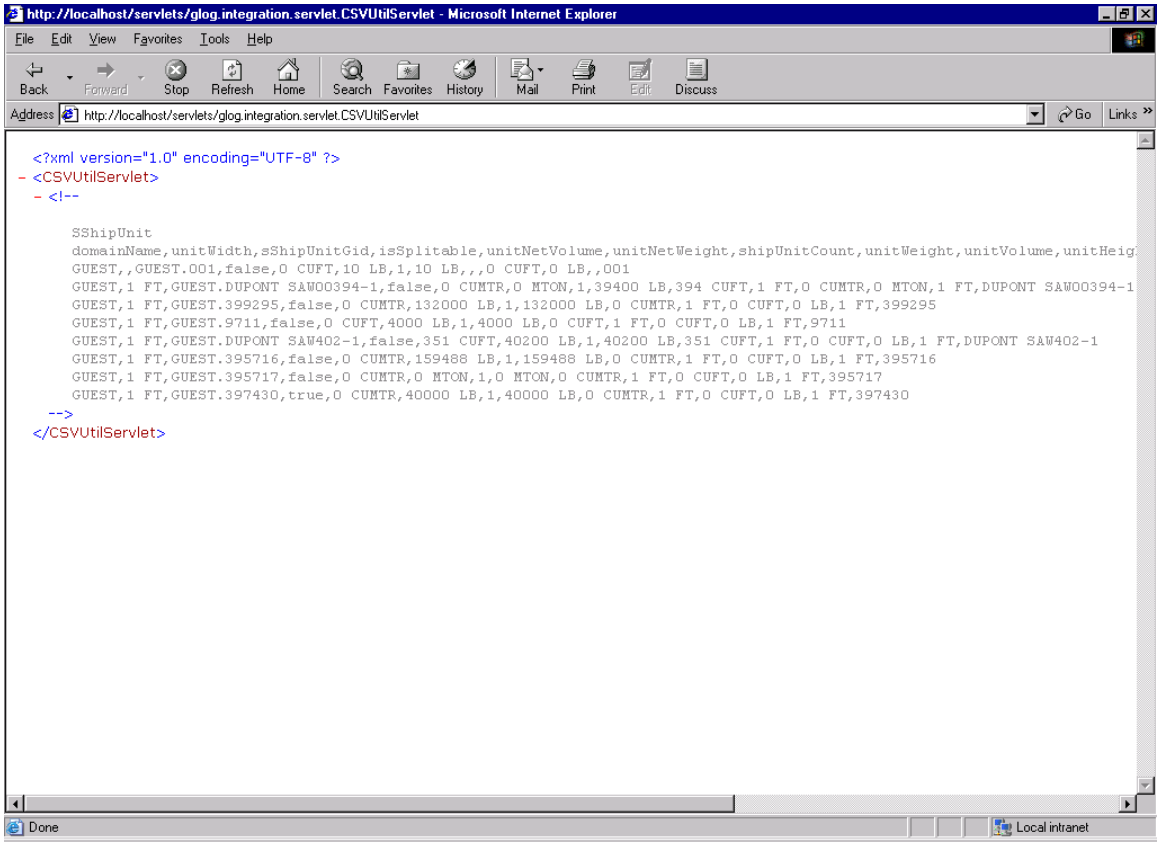
You can use the following URL to export (if it is not on your user menu):

```
http://hostname/servlets/glog.integration.servlet.IntegrationMenuServlet?i
ntegration_stylesheet=integration/csvexport.xsl
```



The above example shows how to do an AppServer CSV export:

1. In the **command** field, select the “as.xcsv” command.
2. In the “**tableName**” field, specify an “EntityName” instead of a table name. In this case, the entity name is “SShipUnit” which differs from the database table name, which would be “S_SHIP_UNIT”.
3. Click the **Run** button. Your output will then appear as follows:



You can then do a “View->Full Screen” in your browser, and select “View Source” (by right-clicking on your mouse). This will place the output in notepad so you can save it to a local file.

Load CSV Files in the Report Owner Directory

Below is the command for loading CSV files in the reportowner directory.

From the application server script8 directory, run the following command.

- ./update_onecsv_rpt.sh REPORT_CONTROL /opt/otm-55-wl/glog/config/dbareportowner

10. Loading CSV Data via Integration

The GlogXML schema lets you embed the contents of multiple CSV files into a Transmission XML document. The contents of the CSV file are contained in the CSVFileContent XML element within the GLogXMLElement. Only one CSV file can be in a single CSVFileContent XML element. Currently, the interface only supports inserts into the database (corresponds to the 'i' command). The implementation of updates and deletes will be provided in a future release. This interface should only be used for setup activities, and is not intended for operational activity.

GlogXML Document Hierarchy

Below you can see the XML document hierarchy. The elements have been indented to show the hierarchy and relationship.

```
<Transmission>
   <TransmissionHeader> . . .
   </TransmissionHeader>
   <TransmissionBody>
   <GLogXMLElement>
         <CSVFileContent>
               ---CSV File Contents---
         </CSVFileContent>
   </GLogXMLElement>
         <GLogXMLElement>
               <CSVFileContent>
                     ---CSV File Contents---
               </CSVFileContent>
   </GLogXMLElement>
   </TransmissionBody>
</Transmission>
```

Below is a sample document that would be used to insert some data into the rate tables:

```
<Transmission>
<TransmissionHeader>
<UserName>DBA.ADMIN</UserName>
</TransmissionHeader>
<TransmissionBody>
<GLogXMLElement>
<CSVFileContent>
X_LANE
X_LANE_GID,X_LANE_XID,SOURCE_POSTAL_CODE,SOURCE_COUNTRY_CODE3_GID,SOURCE_G
EO_HIERARCHY_GID,DEST_POSTAL_CODE,DEST_COUNTRY_CODE3_GID,DEST_GEO_HIERARCH
Y_GID,DOMAIN_NAME
"MYDOMAIN.194-064","194-
064","194","USA","USZIP3","064","USA","USZIP3","MYDOMAIN"
"MYDOMAIN.194-065","194-
065","194","USA","USZIP3","065","USA","USZIP3","MYDOMAIN"
</CSVFileContent>
</GLogXMLElement>
</TransmissionBody>
</Transmission>
```

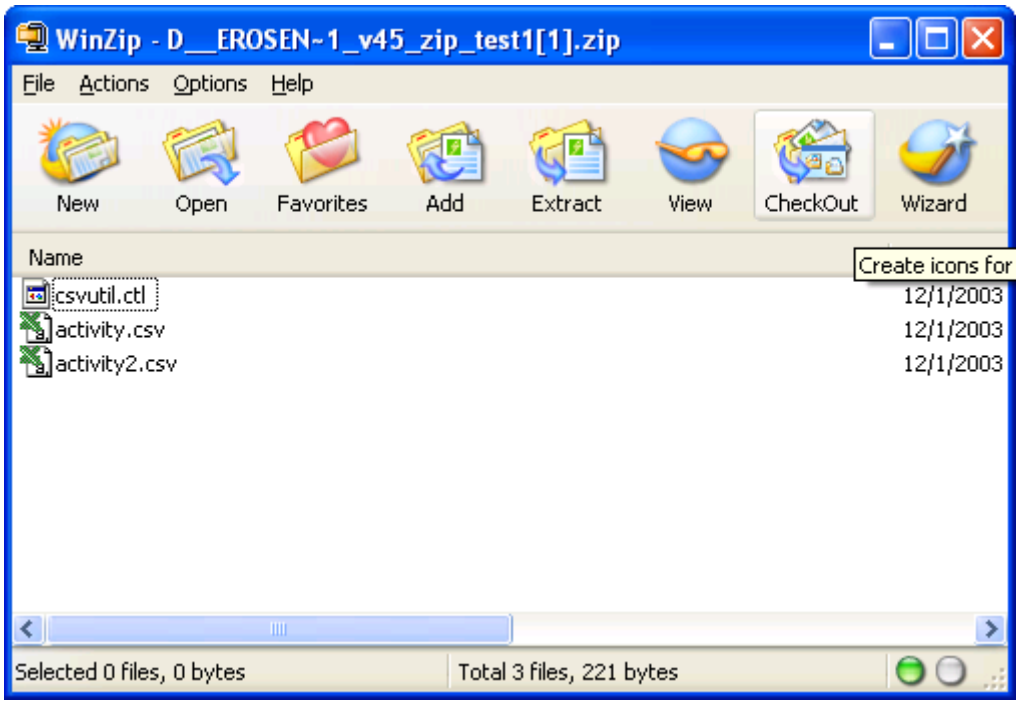
•

11. Loading CSV Files as Zip Files

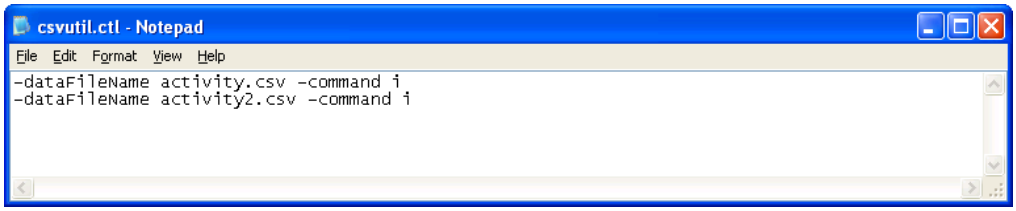
Uploading a Zip File

In addition to the CSV files, your zip file must include a control file called csvutil.ctl to tell Oracle Transportation Management how to process the files. The control file specifies the sequence in which the CSV files should be processed, and specifies the parameters to use when processing each file.

For example, this zip file contains the csvutil.ctl (control) file, and two CSV files:



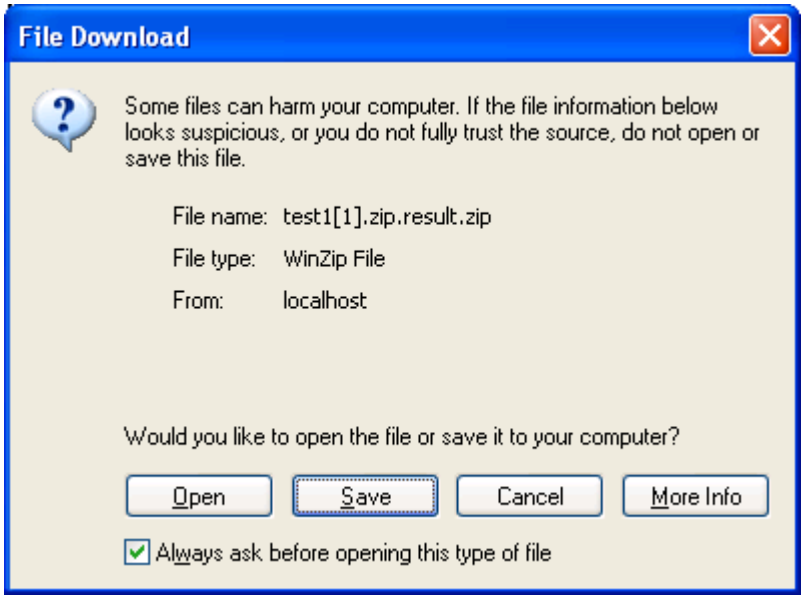
The csvutil.ctl file contains the following command lines:



The above control file says to process the file activity.csv using the insert command, then process the file activity2.csv, also using the insert command.

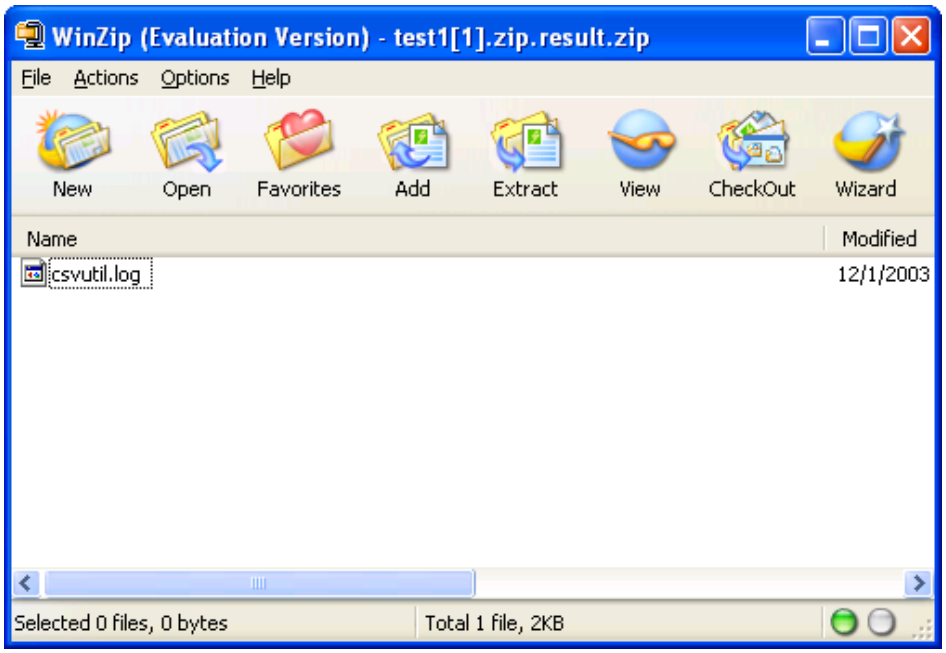
Uploading a zip file is the same as uploading any other file. Use the “Upload an XML/CSV Transmission button accessed via **Business Process Automation > Integration > Integration Manager.**

After uploading your zip file, you are prompted to download a “results” zip file as shown below:

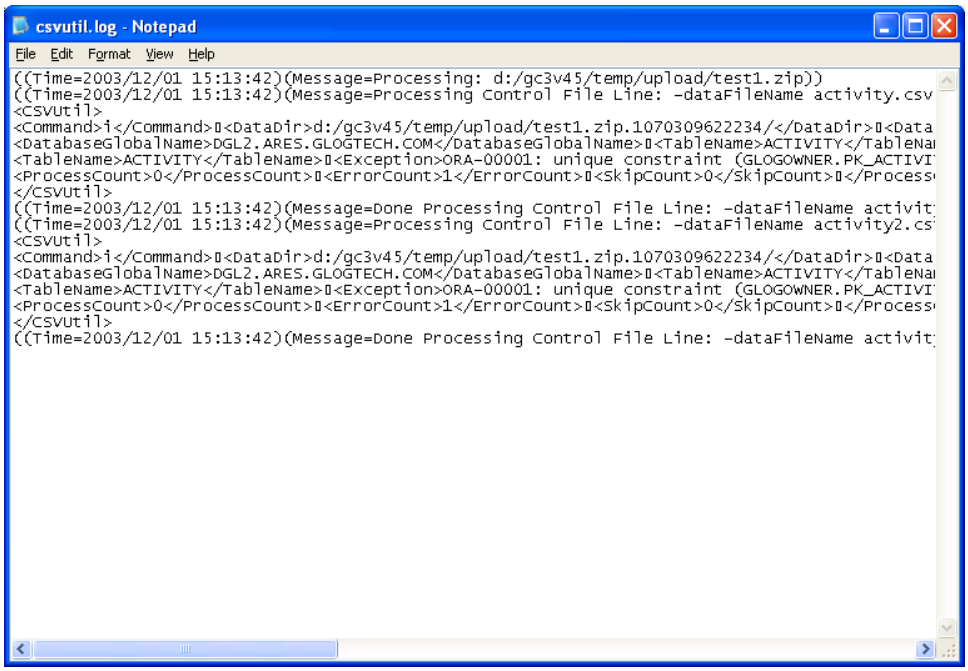


Then click the **Save** button to save the "results" zip file to your local workstation.

Here are the contents of the result zip file in this case:

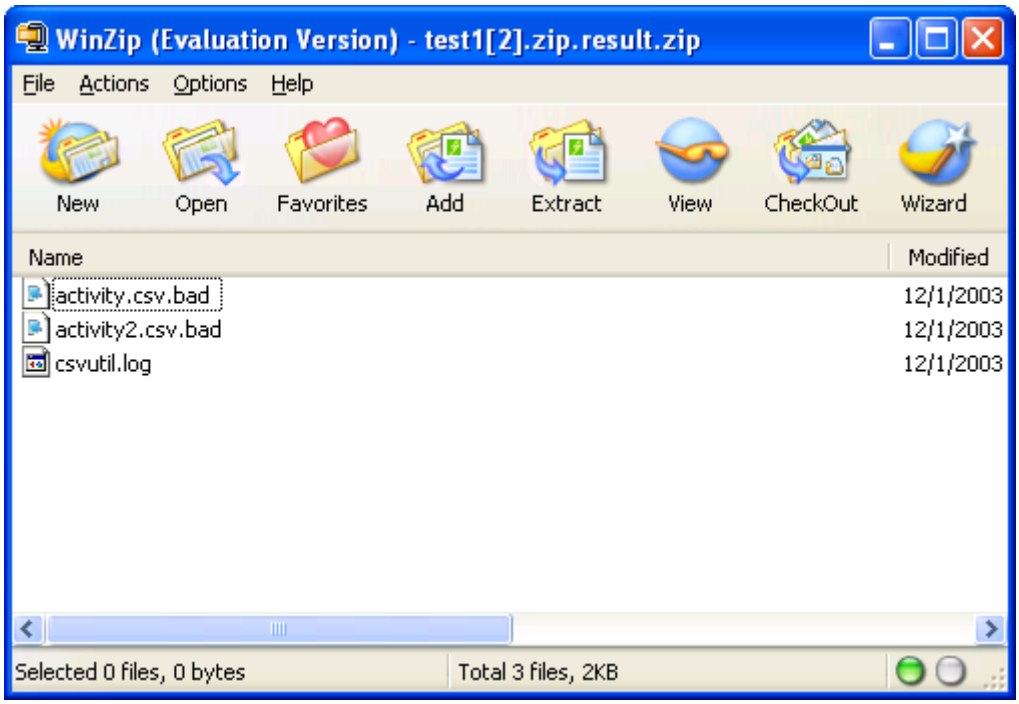


The csvutil.log file in the "result" zip file contains the log from processing all the CSV files in the zip file that you uploaded.



CSV Files that Failed to Load

If any of the records in any of your CSV files fail to load, then your “results” zip file will contain a corresponding “.bad” file containing those records that failed to load. For example:

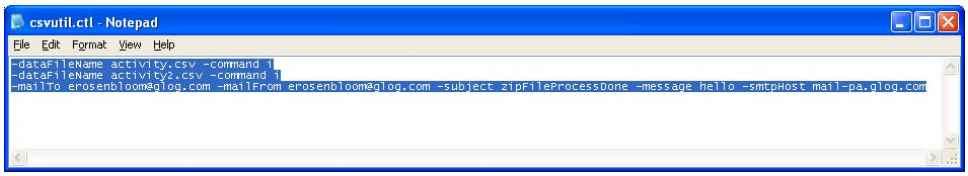


In this case, both of the CSV files contained one of more records that failed to load, so there is a corresponding .bad file for each CSV file.

Background Zip File Processing

If you are uploading a large zip file, you may want to process your zip file in the background and be notified via email when processing completes. You can then pull your "results" zip file using the "ZipFileDownloadServlet".

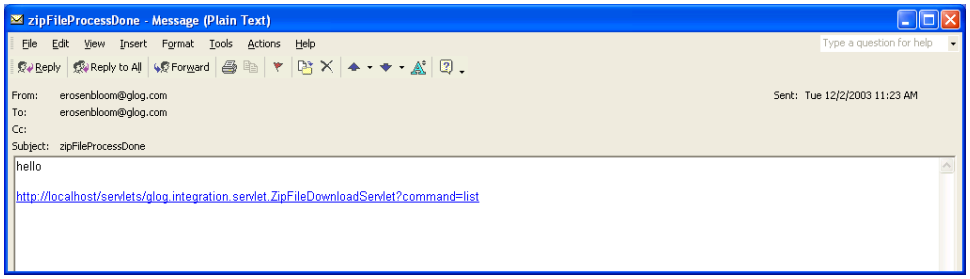
For example, this is a "request" zip file whose name specifies that background processing is desired: *test1.bg.zip*. Notice that the filename ends with "bg.zip" rather than just ".zip". This naming convention indicates that background processing is desired. Here is a sample csvutil.ctl file that illustrates how to have an email sent out when processing completes:



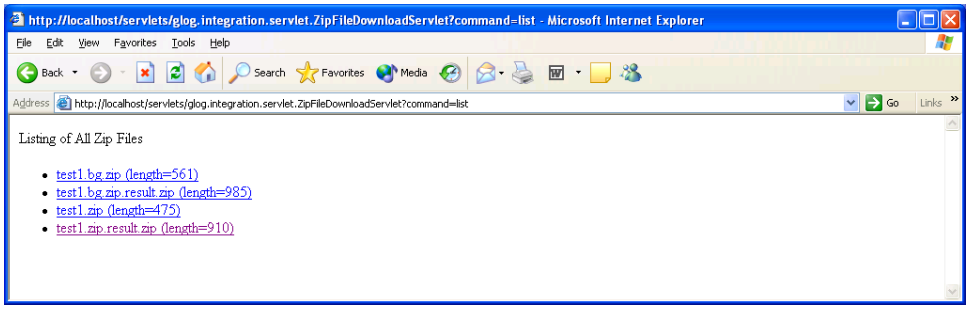
The final "mailto" line looks like:

```
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

Here is the email you will receive when processing completes:



Clicking on the link in the email takes you to a listing of the zip files on the webserver:



You may click on the desired zip file to download it to your local workstation. The zip files ending in "result.zip" are the "results" or "output" zip files.

If things go wrong during background processing, your results zip file will contain a stack trace, which you can read with a text editor rather than WinZip.

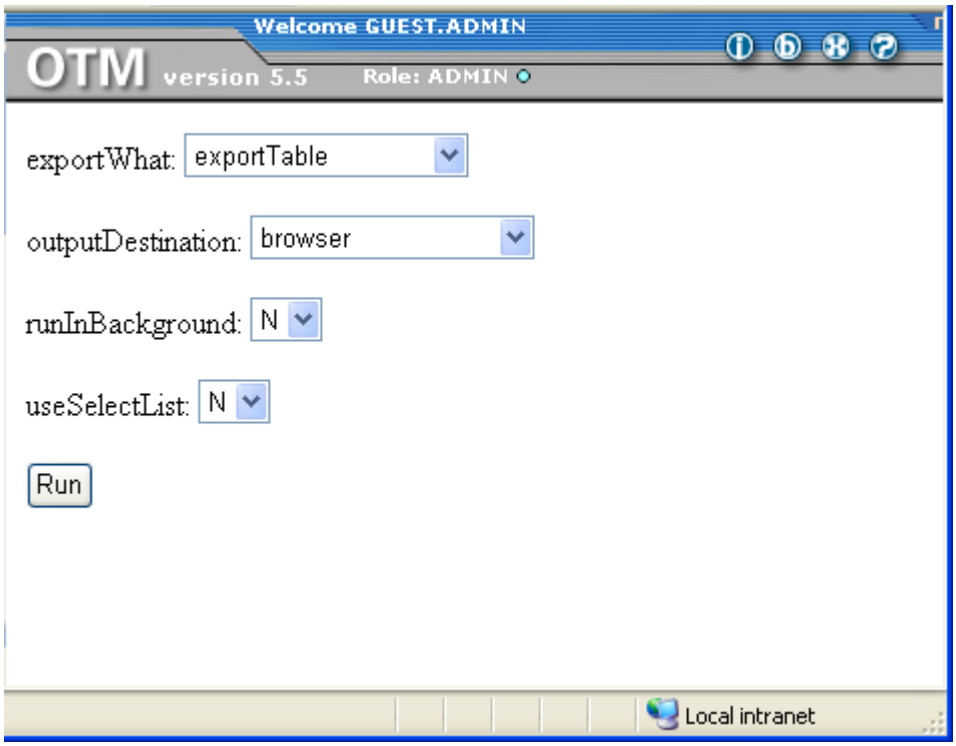
12. Exporting CSV Files via the Interface

CSV Export Screens

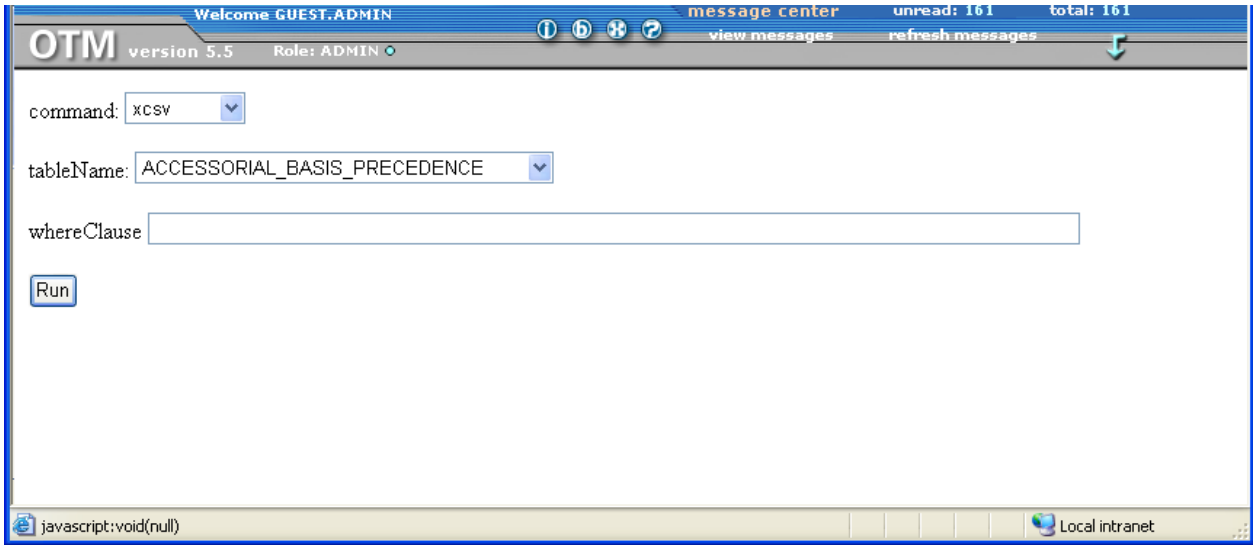
An initial screen prompts for certain information so the system can determine what additional information is required on subsequent screens.

Here is an example.

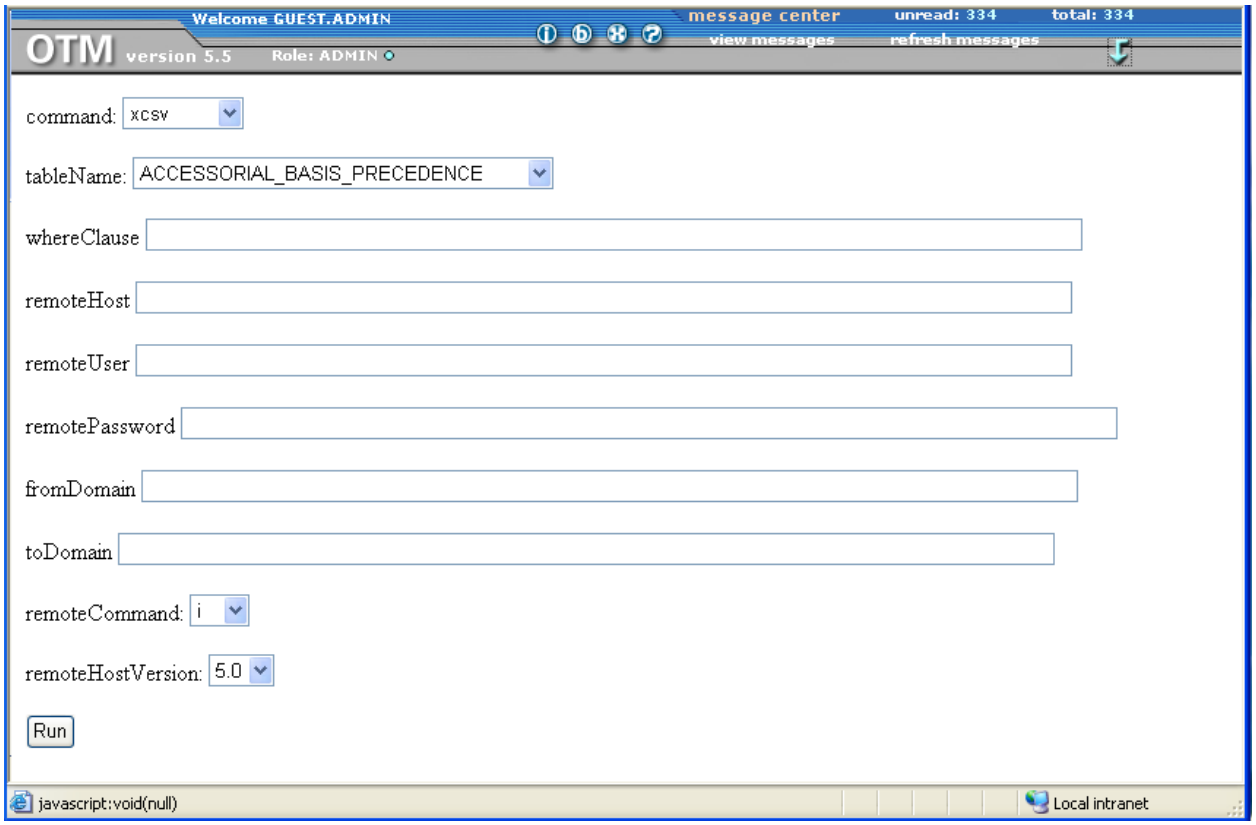
1. Select Business Process Automation->Data Export->CSV Export. The following screen displays:



2. In the **exportWhat** field, you have a choice of selecting one of exportTable, exportTableSet, or exportQueryResults.
3. In the **outputDestination** field, you have a choice of selecting one of browser, remoteGC3Instance (remote Oracle Transportation Management instance), or fileOnWebServer
4. In the **runInBackground** field, you have a choice of selecting either Y or N.
5. In the **useSelectIList** field, you can export specific data that you already selected. An export list can be created from any Finder page by selecting records and clicking **add to export list**.
6. Click the **Run** button. The selections you make on this screen determine the fields that appear on the next screen when you. For example, if you select exportWhat = exportTable, outputDestination = browser, runInBackground = N, and useSelectList=N, the following screen is then displayed:



7. However, if you select outputDestination = remoteGC3Instance, the second screen will be:



8. The second screen is different in this case because more information is required to export data to a remote Oracle Transportation Management instance than to the browser, such as the remoteHost, remoteUser, remotePassword, remoteCommand, and remoteHostVersion. You can also enter From and To Domains.

Exporting Data as a Zip File

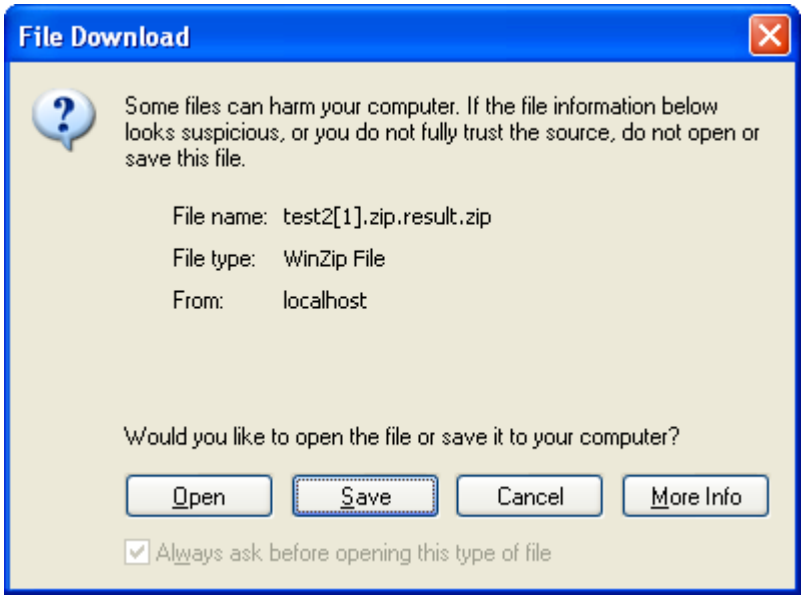
This section illustrates how to export a zip file containing one or more CSV files.

9. First, create a csvutil.ctl file containing the commands for exporting your files.

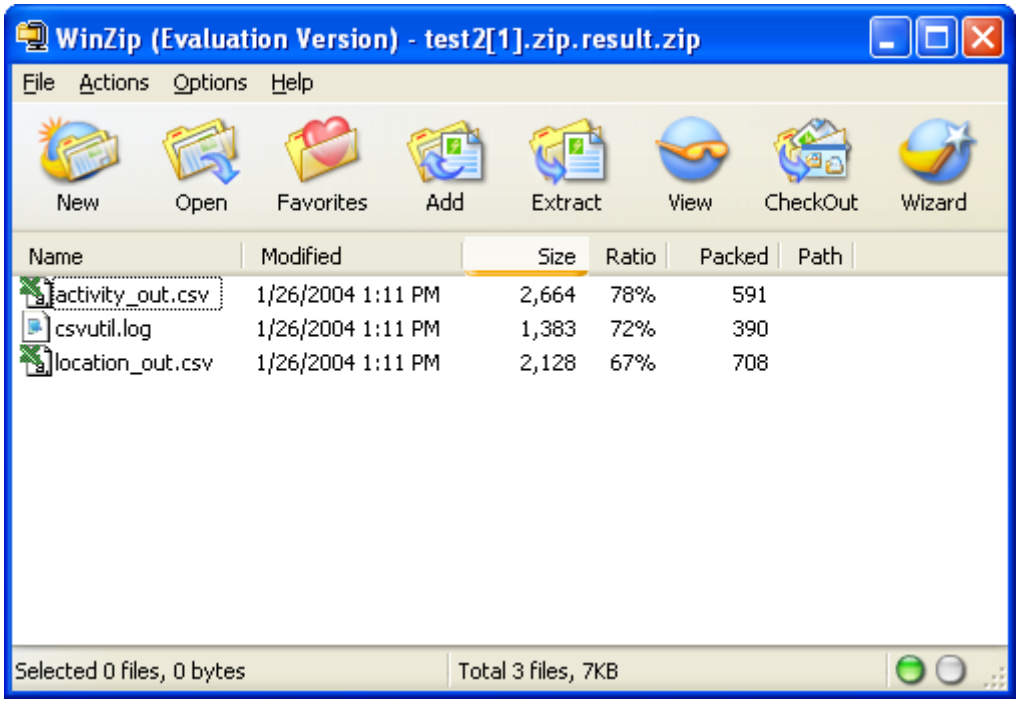
A csvutil.ctl file may contain the following commands:

```
-dataFileName activity_out.csv -command xcsv -tableName ACTIVITY
-dataFileName location_out.csv -command xcsv -tableName LOCATION -
whereClause "rownum < 10"
```

10. Next, create a zip file containing the csvutil.ct file.
11. Once your zip file is created, you can upload the zip file as you would upload any other file to Oracle Transportation Management:
12. Here is the result after uploading the zip file:



13. Press the Save button to save the “results” zip file to your local workstation.
14. Open the zip file to see the following:



15. As you can see, the zip file contains two CSV files in this case, one corresponding to each command in the csvutil.ct file.
16. The zip file also contains a log file containing information regarding the execution(s) of CSVUtil.

Exporting Large Zip Files in the Background

When exporting a large zip file, you may prefer to export it in the background to avoid the browser timing out. Here is a sample request zip file:

Here are the contents of the csvutil.ctl file within test2.bg.zip:

```
-dataFileName activity_out.csv -command xcsv -tableName ACTIVITY
-dataFileName location_out.csv -command xcsv -tableName LOCATION -
whereClause "rownum < 10"
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

Here is another example csvutil.ctl file that exports all the rate_geo records in a given domain, along with all parent and child data, but not public data:

```
-dataFileName rate_geo_out.csv -command xcsvwpcd -tableName RATE_GEO -
whereClause "domain_name = 'MDIETL'"
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

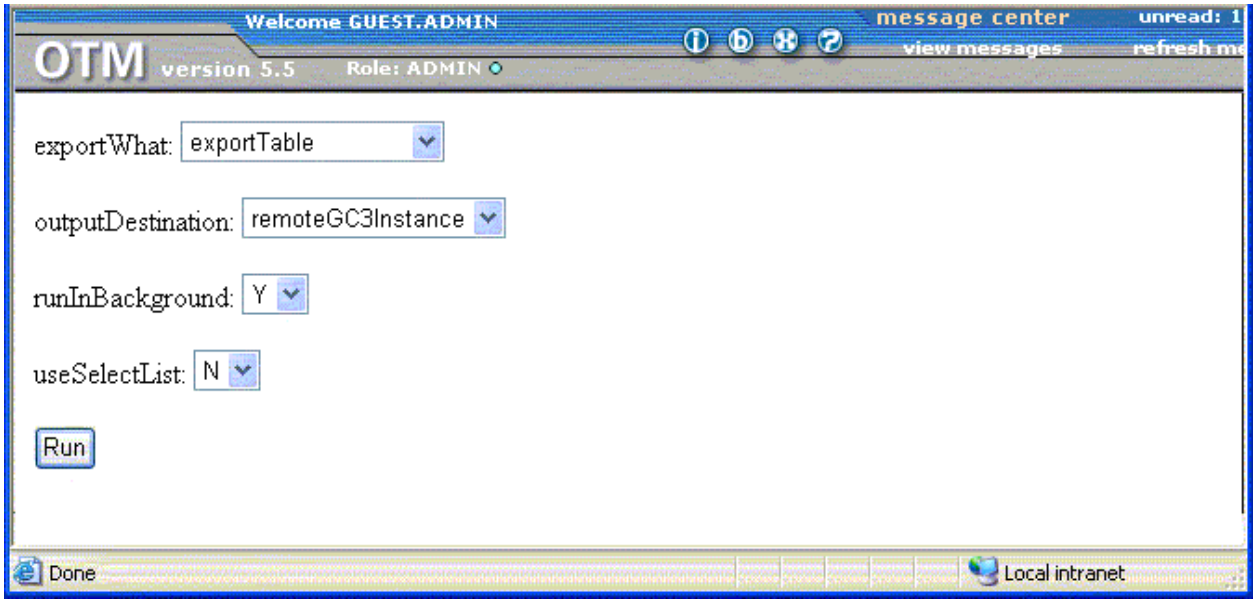
Here is the same example, but this time with referenced public data:

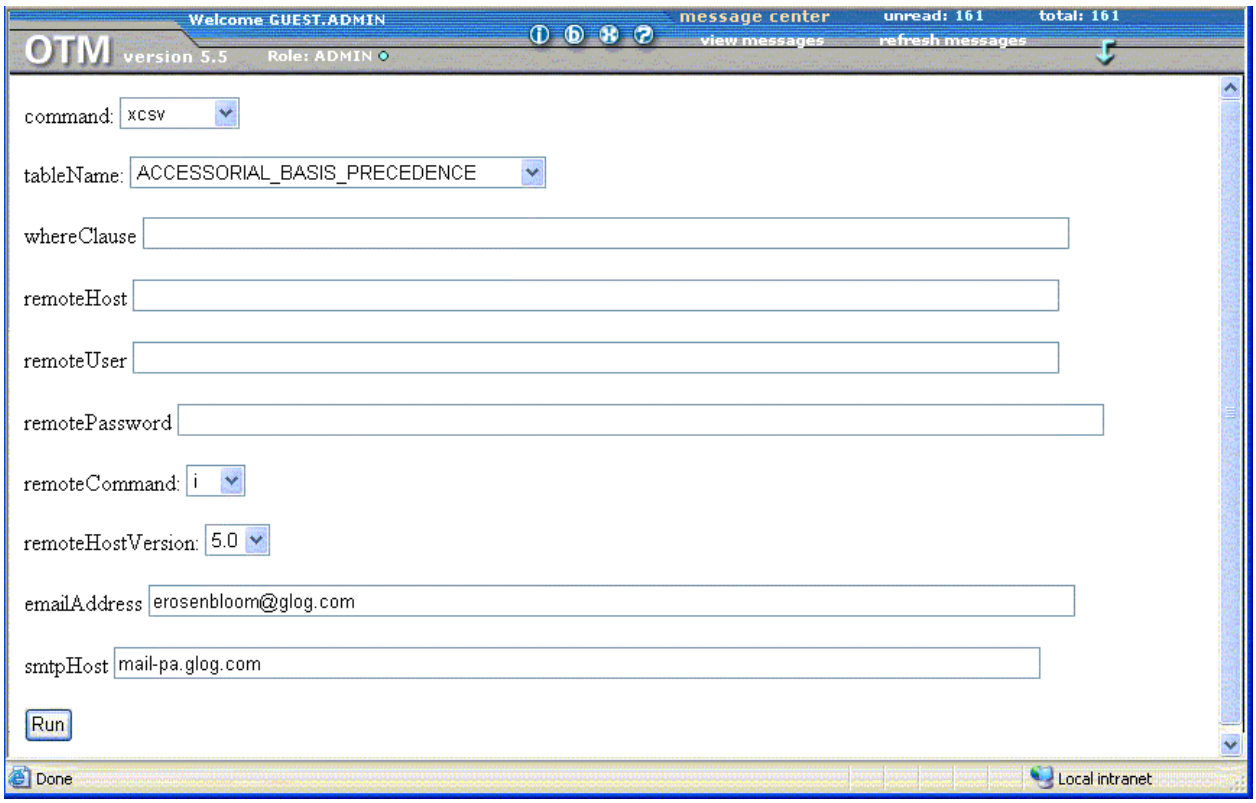
```
-dataFileName rate_geo_out.csv –excludePublic N -command xcsvwpcd -
tableName RATE_GEO -whereClause "domain_name = 'MDIETL'"
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

Note: Exporting with parent and child data is a very time consuming process since the system has to repeatedly chase after foreign key references. Expect the export to run overnight for as long as 8 hours.

Running CSVUtil in the Background

CSVUtil supports running in the background. The following screen shot shows you how:





As shown above, specify your email address and a smtpHost to run in the background. The results will be emailed to you when the background job completes (instead of returning the results to the screen).

In this example, the following content was emailed:

```
<CSVUtil>
<Command>xcsv</Command>
<DataDir>/</DataDir>
<DataFileName>null</DataFileName>
<ExcludePublic>true</ExcludePublic>
<Write>
<DatabaseGlobalName>QGC317.HARMONY.GLOGTECH.COM</DatabaseGlobalName>
<Table>ACTIVITY</Table>
<WhereClause>null</WhereClause>
<DomainName>null</DomainName>
<Sql>null</Sql>
<!--

-->
</Write>
</CSVUtil>
```

Normally, you use background processing when initiating lengthy jobs, such as piping a large table set to a RemoteHost.

13. Exporting Referenced PUBLIC Data during Multi-Table Exports

CSVUtil provides the ability to export referenced PUBLIC data during the multi-table export operations (xcsvwcd, xcsvwpd, xcsvwpcd). This feature is especially important when exporting data from a source database where the PUBLIC data has been modified.

Here is a sample CSVUtil command line for exporting referenced public data:

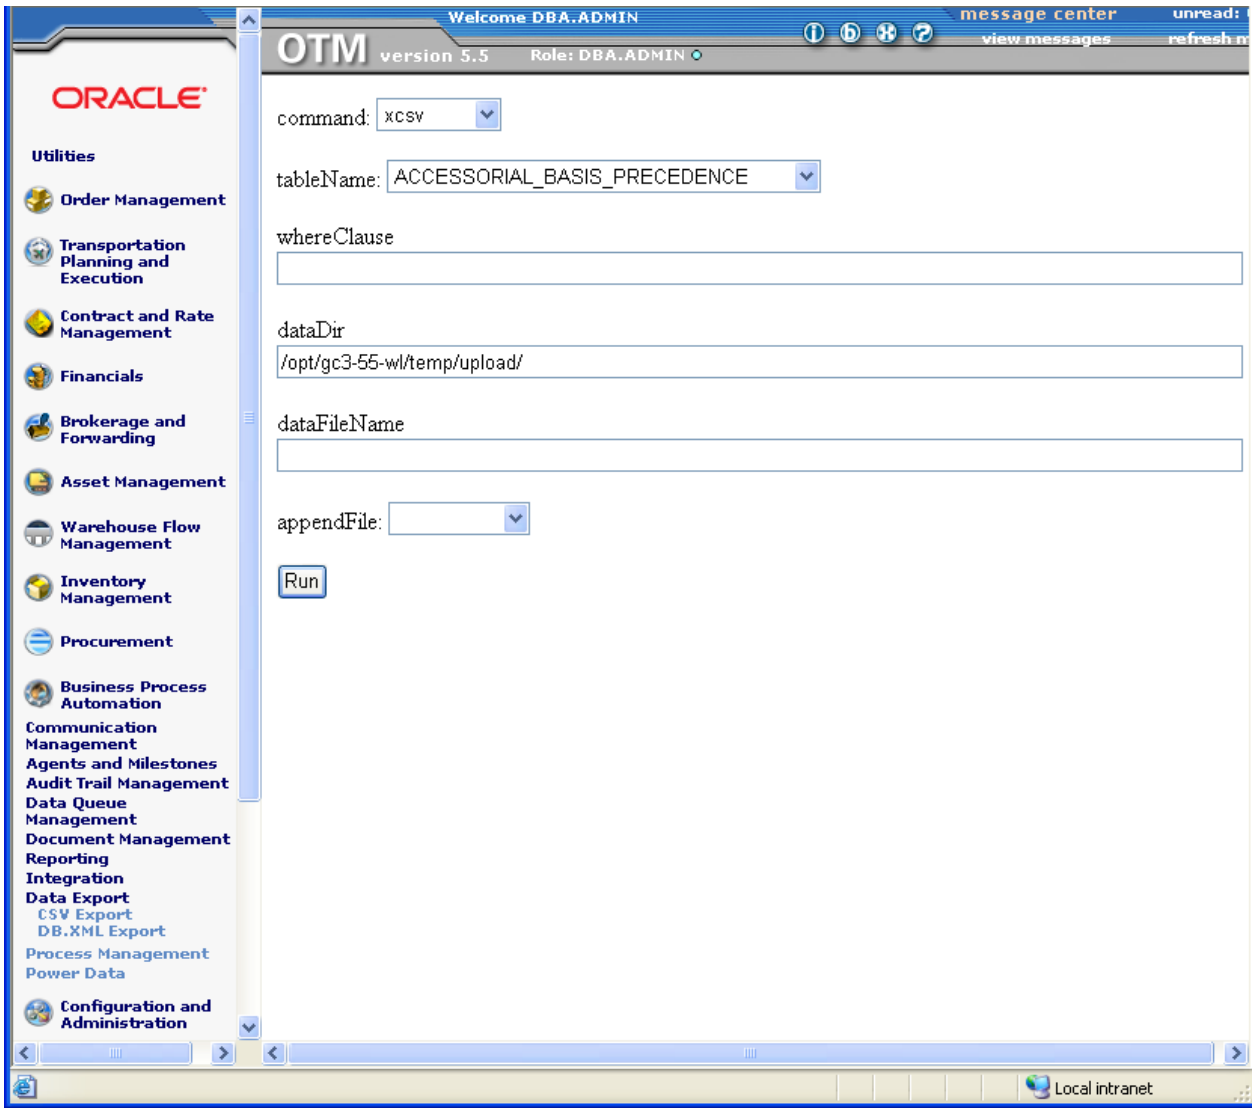
```
java glog.database.admin.CSVUtil -excludePublic N -command xcsvwpcd -
connectionId localdb4 -dataDir . -dataFileName whatever.csv -tableName
RATE_GEO -whereClause "domain_name = 'DGANO'"
```

Notice the –excludePublic option is set to N, meaning that public data should not be excluded (it should be exported, in other words).

Here is a sample ClientUtil command line:

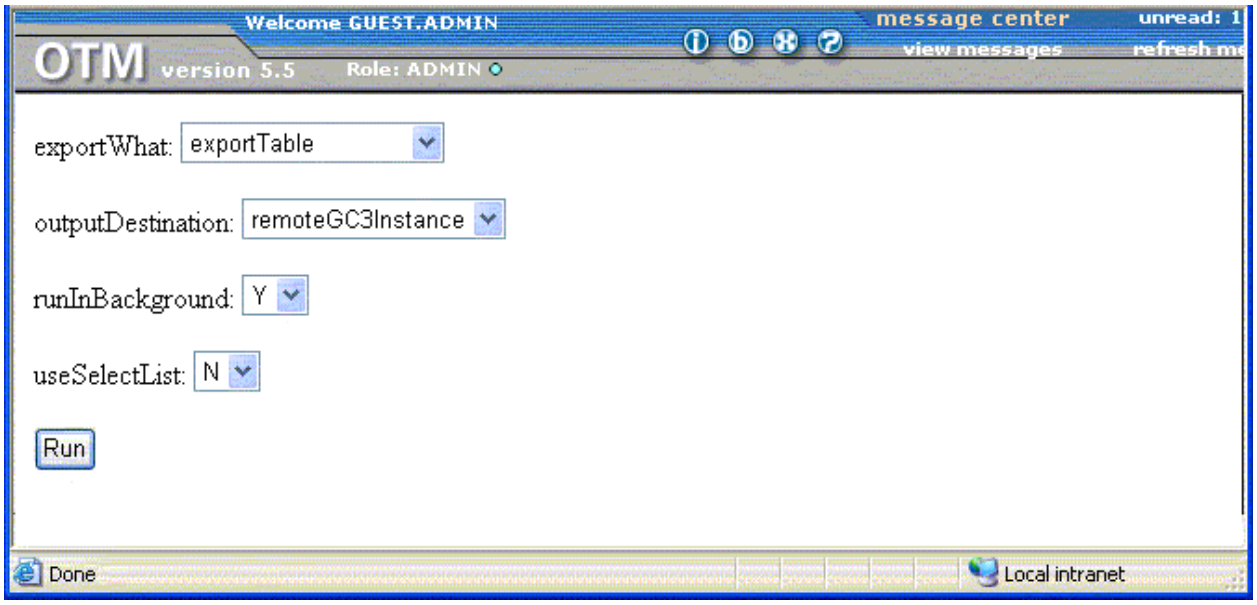
```
python ClientUtil.py -command csvExport -hostname localhost -username
DGANO.ADMIN -password CHANGEME -tableName RATE_GEO  -localDir . -
localFileName myfile.csv -excludePublic N -csvUtilCommand xcsvwpd -
whereClause "domain_name = 'DGANO'"
```

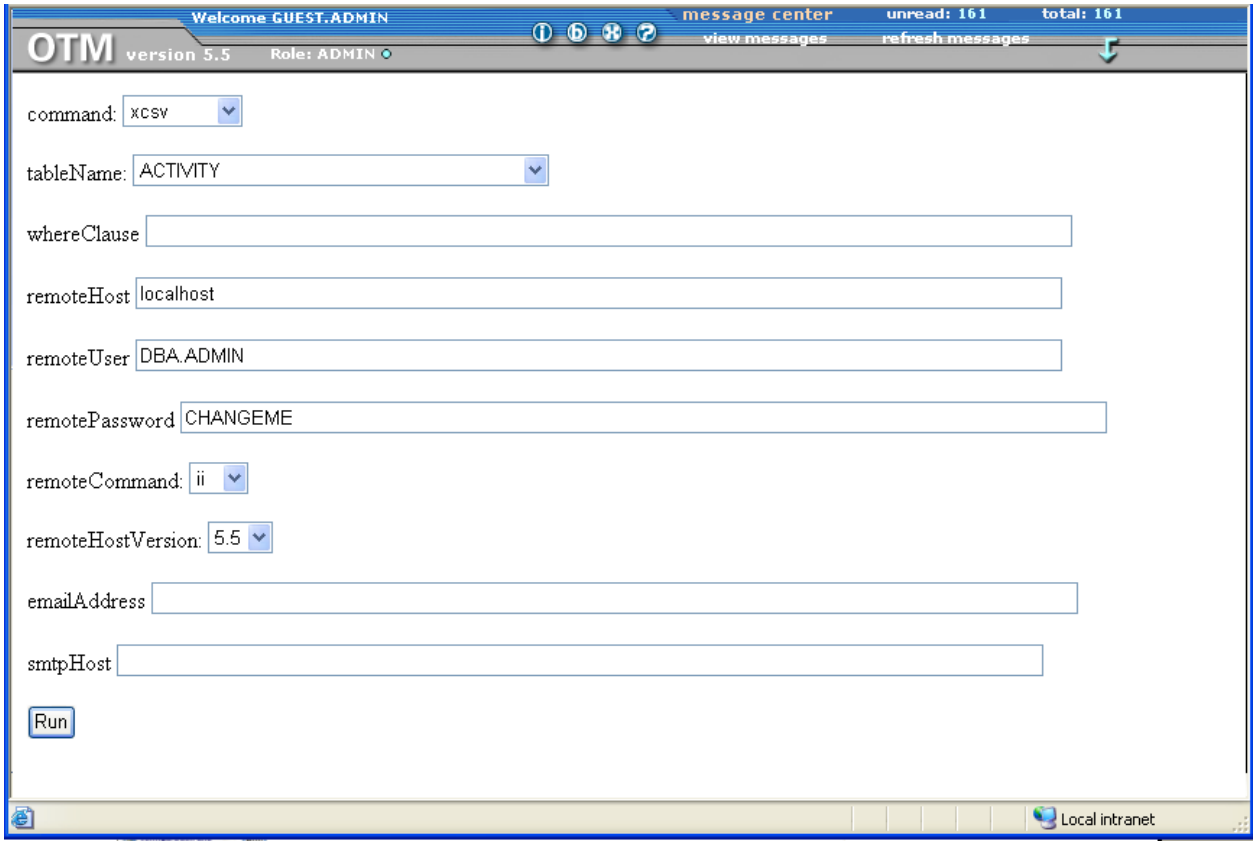
Here is a sample screen shot of the screen when exporting:



14. Piping CSV Output to a Remote Oracle Transportation Management Instance

CSVUtil supports piping CSV Output to a remote Oracle Transportation Management instance. Refer to the screenshots below:





In the above example, the ACTIVITY table is first exported. The results are then immediately sent to the given remoteHost (in this case back to localhost). You must also specify the remoteUser, remotePassword, and remoteCommand (CSVUtil command) to use on the remote host.

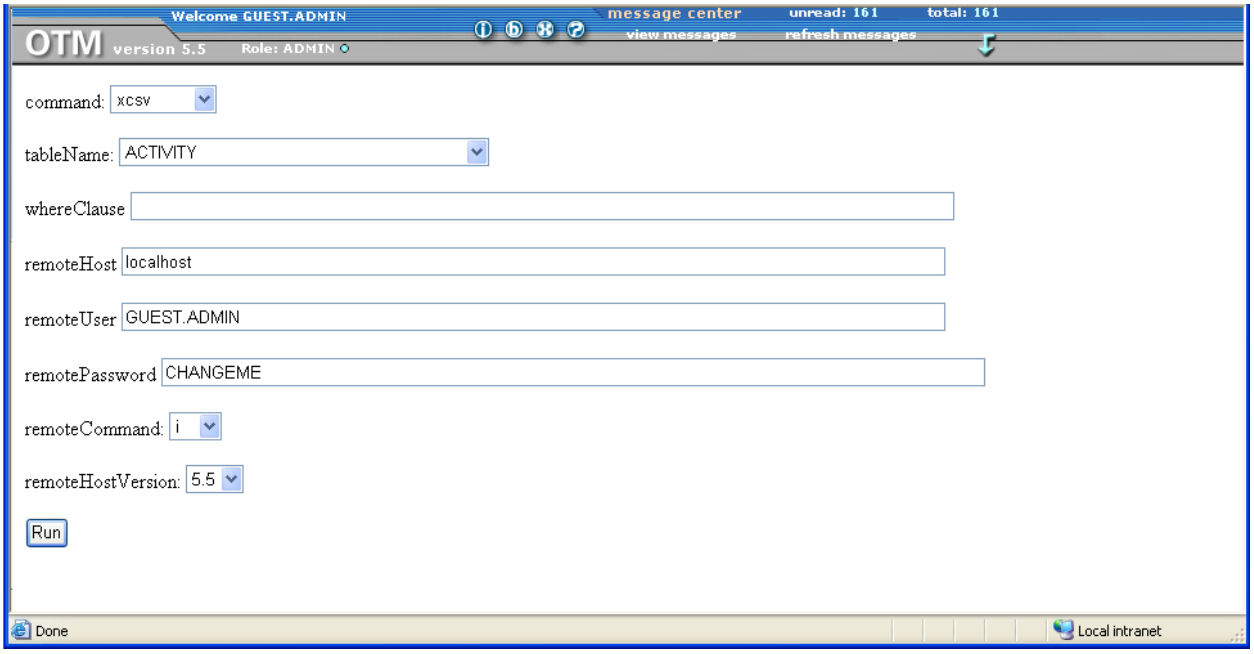
When you click the Run button you will get XML output showing all the processing that occurred – i.e. export the activity table, send the file over to the remote host, then run CSVUtil on the remote host, and get feedback from the remote host.

Synchronizing Data between Different Oracle Transportation Management Versions

CSVUtil supports the ability to extract and push data to a remote Oracle Transportation Management instance whose version is earlier (or later).

When pushing data to the remote instance, CSVUtil queries the data dictionary to determine which columns in the given table exist on the remote system. Columns which do not exist on the remote system are omitted from the CSV file.

When pushing data to a remote system, you must indicate the version of the remote system. This is required because the format of the URL is different between version 4.x and version 5.x of Oracle Transportation Management. A sample screen is shown below in which data is being pushed from a 5.x system to a 4.x system.



15. Exporting Table Sets and Piping to a Remote Instance

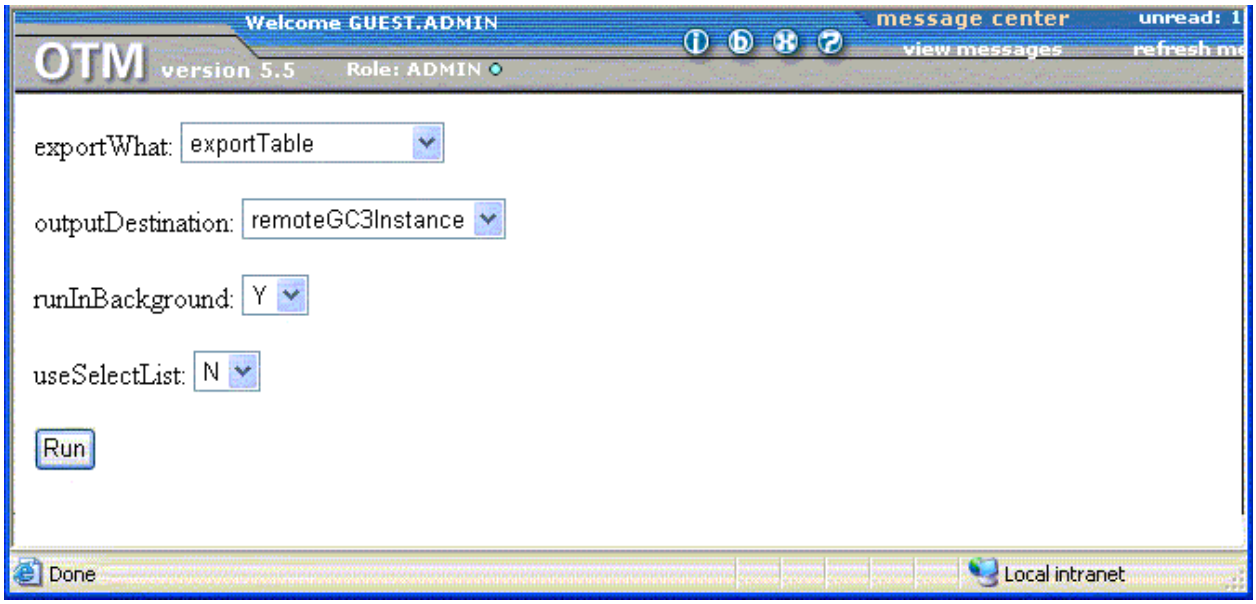
CSVUtil supports exporting ordered table sets. An example of an ordered table set is the EXPORT table set, which lists several hundred tables sorted in foreign key sequence (top-down). Tables in the table_set_detail table may be prefixed by NNNNNNN for the purpose of sequencing the tables. For example:

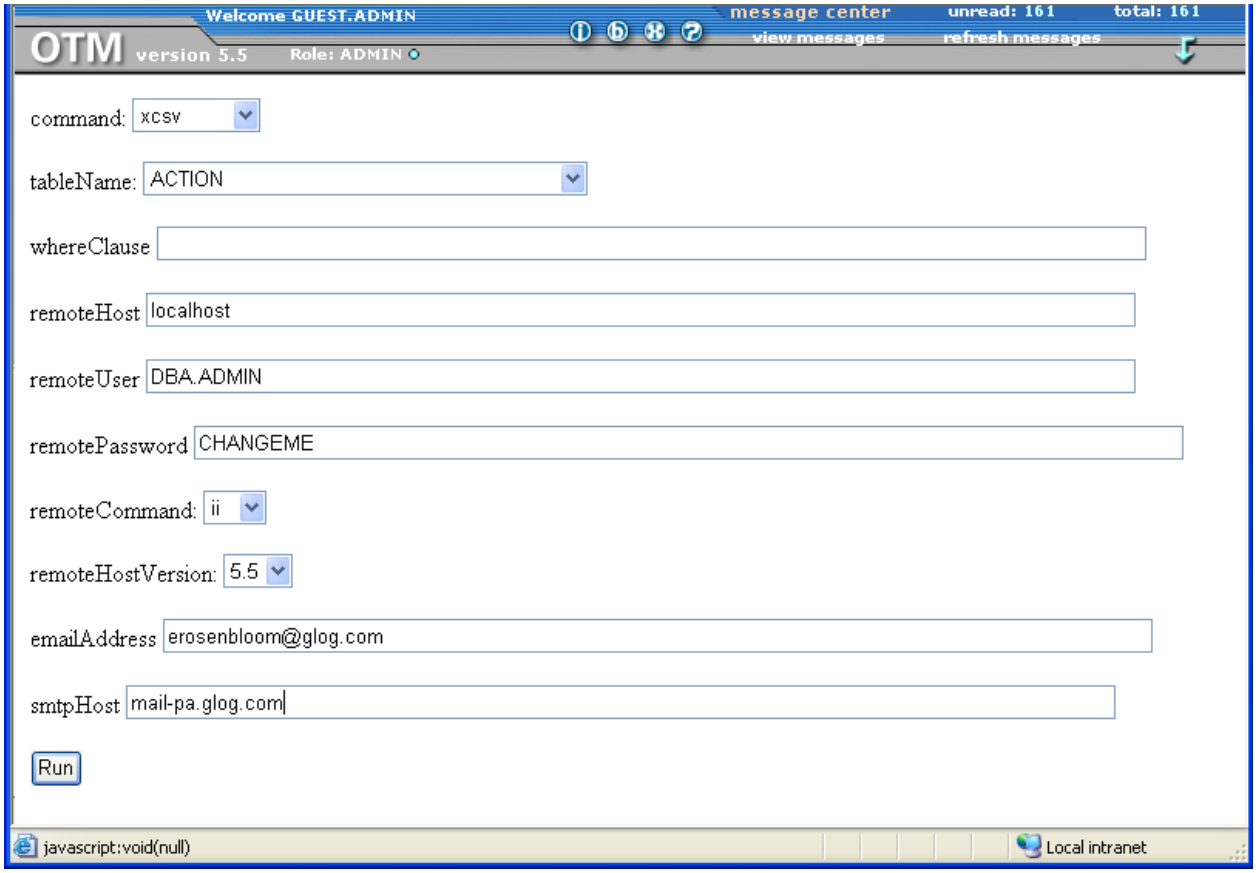
```
SQL> select table_name from table_set_detail where table_set = 'EXPORT'
order by table_name;

TABLE_NAME
----------------------------------------------------------
0000000.RATE_OPERAND
0001000.ACCESSORIAL_BASIS_PRECEDENCE
0002000.ACCESSORIAL_CODE
0003000.RATABLE_OPERATOR
0004000.RATE_GEO_COST_OPERAND
0005000.COUNTRY_ZONE
0006000.COUNTRY_CODE
0007000.CURRENCY
0008000.DIM_RATE_FACTOR
0009000.ACCESSORIAL_COST
0010000.RATE_UNIT_BREAK_PROFILE
```

As you can see, the tables are prefixed by NNNNNNN in order to ensure they are sequenced within the table set. When you export a table set, you normally pipe it to a remote system. If you do not pipe it to a remote system, it will generate a bunch of temporary files on the source system and leave them there.

Here is a sample screen shot showing how you would normally export the EXPORT table set and pipe it to a remote system.





Notice that the above screen requests background processing by specifying an email address and smtpHost.

16. Copying Rates between Databases Using Zip Files

CSVUtil can be used to copy a rate_offering, along with all of its prerequisite parent and child data from one database to another.

Step 1 – Create a csvutil.ctl file (CSVUtil Control File) for Exporting

You create a CSVUtil control file containing commands, and then place it in a zip file whose name ends with .bg.zip; for example: exp_rate_offering.bg.zip. When the zip file name ends with "bg.zip", it knows to run the export job in the background. Here are the contents of the csvutil.ctl file to export an entire rate offering:

```
-dataFileName rate_geo_out.csv -command xcsvwpcd -tableName RATE_GEO -
whereClause "rate_offering_gid = 'MDIETL.ASDF'" –excludePublic N
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

Note: There may only be two lines of text in the above example.

- Place the csvutil.ctl file in a zip file called *name*.bg.zip, where *name* can be anything.
- The xcsvwpcd (export CSV with parent and child data) command will export the rate_geo records, and will recursively export all parent and child records. This can take a while (up to 8 hours).
- The –excludePublic N option means that referenced PUBLIC data will also be exported. If you are sure that your target database has all the required public data, then you can change this to Y, which will save some time on the export.

Step 2 – Use the Integration Upload Screen to Upload the Zip File created in step 1

Use the Integration Upload Screen to upload the exp_rate_offering.bg.zip file. In response to your upload, you immediately receive a message indicating that your export job has been submitted to run in the background. You receive an email when the job completes. The email includes an HTML link to allow you to download the resultant zip file containing your multi-table export.

Step 3 – Download the Zip File Containing the Rate Offering

When you receive the email, download the zip file containing the rate offering, and extract the rate_geo_out.csv file.

Step 4 – Create a csvutil.ctl file for Importing

Similar to step 1, you create another csvutil.ctl file for importing in the background. For example:

```
-dataFileName rate_geo_out.csv -command ii
-mailTo erosenbloom@glog.com -mailFrom erosenbloom@glog.com -subject
zipFileProcessDone -message hello -smtpHost mail-pa.glog.com
```

Step 5 – Create another background zip file

Now create another zip file which will contain the csvutil.ctl file from the previous step, as well as the rate_geo_out.csv file which was exported during step 2. The zip file should again end with "bg.zip".

Step 6 – Upload the zip file from Step 5 to the target instance

To import to the target instance, again use the integration upload screen to upload the background zip file to target instance. You again receive a response indicating that you will get an email when the job completes. The email will again contain a link to allow you to download a results zip file which contains a log file. You will need to examine the log file to see how the import did.

Hint: If you are exporting from a migrated database to a fresh database, use the –removeUndefinedColumns option.

This will tell CSVUtil to ignore deprecated columns.

17. Processing Rate Factors

If you have created rate factors and rate factor rules in Oracle Transportation Management, you can generate accessorial costs in a batch mode fashion. The calculated cost value is placed in the CHARGE_MULTIPLIER_SCALAR column of the Accessorial_Cost table (Charge Discount % field on the Accessorial Cost page).

Using ClientUtil, you can work from a client and access data on the server.

Process Rate Factors from a Client

You can use ClientUtil to process rate factors from a client DOS or UNIX prompt. The following example generates accessorial costs for the specified rate factor source GID.

Command options are:

- python ClientUtil.py -command procRateFactor -hostname <hostname> -username <un> -password <pw> -rateFactorGid <rfg> to process the specified rate factor using associated rate factor rules. The command selects all rules that refer to that Factor Source GID
- python ClientUtil.py -command procRateFactorForRule -hostname <hostname> -username <un> -password <pw> -rateFactorGid <rfg> -ruleGid <rG> to process the specified rate factor using the specified rate factor rule. The command will select the latest rule detail to apply.
- python ClientUtil.py -command procAllRateFactors -hostname <hostname> -username <un> -password <pw> to process all unprocessed rate factors using their associated rate factor rules.
- python ClientUtil.py -command procRateFactorRunGroup -hostname <hostname> -username <un> -password <pw> -runGroup <id> to process all rate factors in the specified run group with their associated rate factor rules.
- python ClientUtil.py -command viewRateFactorResults -hostname <hostname> -username <un> -password <pw> to view the results of processing the rate factors.

Duplicates

The command cannot create duplicates. A duplicate is an accessorial cost with the same Accessorial Code GID and overlapping effective/expiration dates. Take care when setting up the effective and expiration date source logic in the rate factor rule.

Written to Domain

The command generates the accessorial costs in the domain where the rate factor rule exists.

Number of Accessorial Costs

The command generates an accessorial cost for each reference to accessorial default, rate offering, and rate record.

Error Messages

Warning and error messages are logged in the ERROR_LOG table. The following generates errors:

- Inability to calculate the accessorial cost effective/expiration date
- Detected duplicate record

- Unable to calculate accessorial cost value

Undo Changes

There is no specific functionality to undo generated accessorial costs. These tips might help you:

- The way you name your rate factor IDs can help you locate accessorial costs.
- Notes on accessorial costs can help you locate them again. The accessorial cost gets its name according to this template RF_{current date/time}_{first 15 chars of factor source XID}_{effective date of factor value}_{seq num}.
- To delete accessorial costs, you need to first delete them from the Accessorial_Default, Rate_Offering_Accessorial, and Rate_Geo_Accessorial record.

18. Modifying Rates Using the RateMgmt.py Script

The RateMgmt.py Python script provides functionality to modify rates. More specifically, it makes it extremely easy to modify a large number of rate records simultaneously.

The script requires installation of the following Python modules:

- Python 2.1 or higher
- PyXML 0.6.6
- 4Suite 0.12

The RateMgmt.py script assumes that you have exported the rate records from the database using the currently available db.xml scripts. To do this you will use the ClientUtil.py script to export and import db.xml files from and to the database. For more detailed information on the ClientUtil.py script, please see page 3-1.

Below is an example of a command line for exporting the rate records that have been marked for expiration:

```
ClientUtil.py -command xmlExport -hostname SERVERONE -username USER.ADMIN
-password CHANGEME -dbObjectName RATE_GEO -whereClause "expire_mark_id =
'TEST_MARK_1'" -localDir X:\FOLDER -localFileName MARKRATES.xml
```

In this example, you are exporting all the rate records from the RATE_GEO table that have an ExpireMarkId equal to TEST_MARK_1. This assumes you have previously set the Expire Mark ID for the appropriate records to TEST_MARK_1 in the user interface. For more details on doing that, please reference the online help for expiring rate offerings and rate records.

Typical things the RateMgmt.py script will be used for include:

- Copy Rate Offerings from AAA to BBB, with a new version for a new, upcoming time period
- Update records as follows:

Add XX% (i.e., add 10%) to a set of Rate Records

Add $XX (i.e., add $50) to a set of Rate Records

Typically you will be adding either a fixed amount or a relative amount, and be able to specify the where clause.

Currently, the RateMgmt.py script supports twelve different commands. You can use the script itself to see the format of each command and to see a brief description of each. To do this use the following command:

```
python RateMgmt.py -command <command>
```

For example, to see the format and get information on the changeRateGeoXid command, you would use:

```
Python RateMgmt.py –command changeRateGeoXid
```

The following sections describe each of the supported RateMgmt.py commands in detail.

changeRateGeoXid

This is used to change a RateGeoXid. It also automatically updates the RateGeoCostGroupGid for the child records.

The format for the command line is:

```
python RateMgmt.py -command changeRateGeoXid -oldGid <oldGid> -newXid
<xid> -inFile <infile> -outFile <outfile>
```

Here is a sample command line for changing the RateGeoXid:

```
python RateMgmt.py -command changeRateGeoXid -oldGid GUEST.1234A -newXid
1234B -inFile in.xml -outFile out.xml
```

In this example, you are changing the RateGeoXid GUEST.1234A in the input XML file in.xml, to GUEST.1234B in the output XML file out.xml.

In practice, this will often be run before rate records are modified. Since you will most likely need to modify the rates before the old ones actually expire, this will create a rate record with a new ID. That way the rate modifications can be done to the new rate record IDs and the data can be imported back into the database without overriding the current rate records.

changeAllRateGeoXid

This is used to change the suffix of all RateGeoXid(s). It also automatically updates the RateGeoCostGroupGid(s) for the child records.

The format for the command line is:

```
python RateMgmt.py -command changeAllRateGeoXid -numChars <num> -newSuffix
<xidSuffix> -inFile <infile> -outFile <outfile>
```

Here is a sample command line for changing all of the RateGeoXids:

```
python RateMgmt.py -command changeAllRateGeoXid -numChars 5 -newSuffix
_2002 -inFile in.xml -outFile out.xml
```

In this example, you are changing all the rate record IDs in the input XML file in.xml, to include _2002 after what they currently are, and posting the results to the output XML file out.xml. The –numChars argument defines the number of characters in new suffix.

In practice, this will be useful for the same reason as explained under changeRateGeoXid.

changeRateOfferingXid

This is used to change the RateOfferingXid for a rate offering.

The format of the command line is:

```
python RateMgmt.py -command changeRateOfferingXid -oldGid <oldGid> -newXid
<xid> -inFile <infile> -outFile <outfile>
```

Here is a sample command line for changing the RateOfferingXid:

```
python RateMgmt.py -command changeRateOfferingXid -oldGid GUEST.1234A -
newXid 1234B -inFile in.xml -outFile out.xml
```

In this example, you are changing the RateOfferingXid GUEST.1234A in the input XML file in.xml to GUEST.1234B in the output XML file out.xml.

In practice, this can be run before rate offerings or records are modified. Since you will most likely need to modify rate offering or records before old ones actually expire, this will create a rate offering

with a new ID. That way any modifications can be done to the new rate offering IDs and the data can be imported back into the database without overriding the current data.

changeAllRateOfferingXid

This is used to change the suffix of all RateOfferingXid(s).

The format for the command line is:

```
python RateMgmt.py -command changeAllRateOfferingXid -numChars <num> -
newSuffix <xidSuffix> -inFile <infile> -outFile <outfile>
```

Here is a sample command line for changing all the RateOfferingXids:

```
python RateMgmt.py -command changeAllRateOfferingXid -numChars 5 -
newSuffix _2002 -inFile in.xml -outFile out.xml
```

In this example, you are changing all the rate offering IDs in the input XML file in.xml, to include _2002 after what they currently are, in the output XML file out.xml. The –numChars argument defines the number of characters in the new suffix.

In practice, this will be useful for the same reason as explained under changeRateOfferingXid.

removeExpireMarkId

This is used to remove all the data in the EXPIRE_MARK_ID field of the defined records.

The format for the command line is:

```
python RateMgmt.py -command removeExpireMarkId -inFile <infile> -outFile
<outfile>
```

Here is a sample command line for removing the Expire Mark IDs:

```
python RateMgmt.py -command removeExpireMarkId -inFile in.xml -outFile
out.xml
```

In this example, you are removing all the data in the EXPIRE_MARK_ID field for the records in the input XML file in.xml and posting the results in the output XML file out.xml.

In practice, this is helpful for when you modify rate records. A common approach would be to update your rate records, then modify your rates. Since most of the new records have copied information from the original rate records, the new rate records may have expiration mark IDs assigned to them. Since you will not want to have your new, modified rate records marked for expiration, you will use this command to remove their mark IDs.

incRateCostByFactor

This is used to increase your rates by the factor specified. For example, if you need to increase your rates by 10%, you would use this command.

The format for the command line is:

```
python RateMgmt.py -command incRateCostByFactor -factor <increase> [-round
<digits>] [-excBreak Y] [-basis <basis>] -inFile <infile> -outFile
<outfile> [-@table_name.column_name columnValue]
```

Here is a sample command line to increase you rates by 10%:

```
python RateMgmt.py -command incRateCostByFactor -factor 1.10 -inFile
in.xml -outFile out.xml
```

In this example, you are increasing the rates in the input XML file in.xml by 10% and posting the results in the XML output file out.xml. Notice that the -factor argument must be typed as 1.10 for a 10% increase.

This command provides additional arguments to:

- Round the number of digits to a specific value. The value must be an integer greater than or equal to zero. The format of this argument is, -round 2 (which round the rate to the nearest cents in USD).
- Exclude the break (weight or unit) records from being changed. The format of the argument is, -excBreak <xxxxx>
- Specify a filter on the cost basis (e.g. SHIPTMENT, EQUIPMENT, SHIPMENT.DISTANCE (from CHARGE_MULTIPLIER column of RATE_GEO_COST table)). The format of the argument is, -basis <xxxxx>
- Filter for more specific fields. The format of the argument is, -@table_name.column_name columnValue

Here is a sample command line using the -basis argument, as well as a specific field filter:

```
python RateMgmt.py -command incRateCostByFactor -factor 1.10 -basis
SHIPMENT -inFile in.xml -outFile out.xml -@RATE_GEO.X_LANE_GID
GUEST.PHL_NYC
```

This would only increase the rates for those rate records where the RateGeo Domain Name is equal to GUEST, and the X_LANE is equal to GUEST.PHL.NYC.

incRateCostByAmount

This is used to increase your rates by the amount specified. For example, if you needed to increase your rates by $50, then you would use this command.

The format for the command line is:

```
python RateMgmt.py -command incRateCostByAmount -amount <amount> -inFile
<infile> -outFile <outfile>
```

Here is a sample command line to increase all your rates by $50:

```
python RateMgmt.py -command incRateCostByAmount -amount 50.00 -inFile
in.xml -outFile out.xml
```

In this example, you are increasing all the rates in the input XML file in.xml by $50 and posting the results to the output XML file out.xml. The currency of the cost is not considered in the command.

This command provides additional arguments to:

- Exclude the break (weight or unit) records from being changed. The format of the argument is, -excBreak <xxxxx>
- Specify a filter on the cost basis (e.g. SHIPTMENT, EQUIPMENT, SHIPMENT.DISTANCE (from CHARGE_MULTIPLIER column of RATE_GEO_COST table)). The format of the argument is, -basis <xxxxx>

The format for each of these is the same as described in incRateCostByFactor.

addNewCostRecord

This is used to add a fixed amount as a new RateGeoCost record. You would use this to create a new rate record with the defined rate cost.

The format for the command line is:

```
python RateMgmt.py -command addNewCostRecord -amount <amount> [-currency
<currencyCode>] -inFile <infile> -outFile <outfile>
```

Here is a sample command line for changing the rate cost:

```
python RateMgmt.py -command addNewCostRecord -amount 5.00 -currency USD -
inFile in.xml -outFile out.xml
```

In this example, you are adding a new cost record based on everything in the input XML file in.xml, giving it a rate cost of $5.00, and posting the results to the output XML file out.xml.

removeUserDateFields

This is used to remove all the INSERT_USER, INSERT_DATE, UPDATE_USER, and UPDATE_DATE fields.

The format for the command line is:

```
python RateMgmt.py -command removeUserDateFields -inFile <infile> -outFile
<outfile>
```

Here is a sample command line:

```
python RateMgmt.py -command removeUserDateFields -inFile in.xml -outFile
out.xml
```

In this example, you are taking the input XML file in.xml, removing all the data in the fields listed above, and posting the results to the output XML file out.xml.

removeField

This is used to remove a specific field.

The format for the command line is:

```
python RateMgmt.py -command removeField -inFile <infile> -outFile
<outfile> -fieldName <fieldName>
```

Here is a sample command line for removing a specific field:

```
python RateMgmt.py -command removeField -inFile in.xml -outFile out.xml -
fieldName EXPIRATION_DATE
```

In this example, you are taking the input XML file in.xml, removing the field EXPIRATION_DATE and all is contents, and posting the results to the output XML file out.xml.

changeEffDate

This is used to change the value in the effective date field. The newDate must be in the format "YYYY-MM-DD HH24:MI:SS" including quotes.

The format for the command line is:

```
python RateMgmt.py -command changeEffDate -inFile <infile> -outFile
<outfile> -newDate <newDate>
```

Here is a sample command line for changing the effective date field:

```
python RateMgmt.py -command changeEffDate -inFile in.xml -outFile out.xml
-newDate "2003-09-01 08:00:00"
```

In this example, the effective date field in the input XML file in.xml will be changed to 2003-09-01 08:00:00. The results will be posted to the output XML file out.xml.

changeFieldValue

This is used to change the value of a specified field. If the new value has spaces, then it must be in quotes.

The format for the command line is:

```
python RateMgmt.py -command changeFieldValue -inFile <infile> -outFile
<outfile> -fieldName <fieldName> -newValue <newValue>
```

Here is a sample command line for changing the value of a specific field:

```
python RateMgmt.py -command changeFieldValue -inFile in.xml -outFile
out.xml -fieldName EXPIRATION_DATE  -newValue "2003-09-01 08:00:00"
```

In this example, the expiration date in the XML input file in.xml will be changed to 2003-09-01 08:00:00. The results will be posted to the output XML file out.xml.

19. Importing Voyage Schedule Data

You can import ocean schedules from a variety of portals, like ESG, CargoSmart, INTTRA, and GTNexus.

Assuming you want to load data from multiple providers into separate partitions, load the data from the first provider in the staging tables. Once complete, the data should be moved to the database in the first partition. After the first data set is complete, the data from the second provider should be loaded in the staging tables. After that, the data should be moved to the database in the second partition. This would continue until all the data is loaded.

1. Acquire voyage schedule data. While the data from some providers is available in the correct Oracle Transportation Management format, you need to ensure that the format is correct prior to loading it in the staging tables.
2. Setup Mapping of Data Sources and Partition Keys

   This step is optional, but it makes it easier for you to see what partition key goes with what data provider.

   ```
   pkg_voyage.setup_data_source ('PROVIDER1',1)
   ```

   - PROVIDER1 is the name of the data provider
   - 1 is the partition number.

   Repeat this step to assign data from a second data provider to partition 2 and so on.

   There is a maximum of seven partitions available. It is the VOYAGE and VOYLOC tables that are partitioned, not the staging tables. It is possible to combine multiple data source providers in a single partition. This requires you to load data from all data providers in that partition prior to initiating the loading process.

3. Load the Mapping Tables using normal CSV functionality

Table	Description
X_VOY_LOC_MAP	mapping of data source location IDs to Oracle Transportation Management locations GIDs
X_VOY_CAR_MAP	mapping of data source service provider IDs to Oracle Transportation Management Service Provider GIDs

4. Load the Staging Tables using normal CSV functionality

   Load data into the X_VOYAGE and X_VOYLOC tables. The DATA_SOURCE column of the tables should be set to the appropriate data source ID. The data must contain the complete set of voyage data.

5. Delete the current voyage schedules and load the new data set from the staging tables.

   ```
   pkg_voyage.load_schedule (null,200,'Y')
   ```

   - The first parameter is null because the procedure will look up the partition key using the mapping previously setup. If you did not map data sources to partition keys, you need to make sure to load each data provider's data set in a separate partition.
   - 200 defines the batch size in terms of the number of records the database should hold in its buffer before it writes them to the database
   - 'Y' states that errors will be logged to the log file

The Load Schedule procedure takes the new data from the X_VOYAGE and X_VOYLOC tables by cross-referencing service provider IDs with the X_VOY_CAR_MAP table and the location IDs with the X_VOY_LOC_MAP table. Note that if a mapping is missing, the procedure creates a new location using the location ID as the GID, and adds a mapping record to the X_VOY_CAR_MAP or X_VOY_LOC_MAP as needed.

6. View Error Log

```
select * from voyage_err_view
```

If logging was enabled, and there were any problems during the above steps, a message will be posted to the error log.

7. View Data Mappings

```
select * from data_source_partition_view
```

If logging was enabled, the current mapping of data source and partition keys can be viewed by executing the following command using a SQL editor:

Deleting Schedules

pkg_voyage also contains the following:

Purpose	Procedure	Parameters
Delete all the data in a specified partition.	delete_schedule	p_partkey (PLS_INTEGER)
Delete all the data from a specified data provider. Note that the name of this procedure is the same as the preceding one. The parameter, however, is different.	delete_schedule	p_dataSource (VARCHAR2)

20. Java Integration API

Oracle Transportation Management provides a callable Java API to allow external developers to write Java programs that maintain data via the application server. This document describes this API.

This chapter introduces the Java Integration API, taking the perspective of an external developer.

The Java Integration API includes the following methods.

```
package glog.integration.clientapi;
import java.util.Iterator;
public interface ClientAPI
{
   public Iterator getEntityNames () throws ClientAPIException;
   public Iterator describeEntity (String entityName) throws
   ClientAPIException;
   public void insert (ValuesObject rowData) throws ClientAPIException;
   public void insertUpdate (ValuesObject rowData) throws
   ClientAPIException;
   public void update (ValuesObject rowData) throws ClientAPIException;
   public void delete (ValuesObject rowData) throws ClientAPIException;
   public ValuesObject[] execMany (ValuesObject[] commandList) throws
   ClientAPIException;
   public ValuesObject findByPrimaryKey (ValuesObject primaryKey) throws
   ClientAPIException;
   public ValuesObject[] findAll (String entityName) throws
   ClientAPIException;
   public void close() throws ClientAPIException;
}
```

The following table briefly describes the purpose of each method. Code examples are then provided to illustrate the use of each method.

Method	Description
GetEntityNames	Returns an iteration of all supported entity names, such as Location, ObOrderBase, Shipment, etc. Each entity corresponds to an Oracle Transportation Management table, but the name of the entity uses mixed case instead of underscores. See Example3.java
DescribeEntity	Given an entity name, returns an interaction of ValuesObject each of which describes an attribute of the entity. See Example4.java
Insert	Inserts a new row via the application server. See Example1.java
InsertUpdate	Update a row if it exists, otherwise insert a new row. See Example9.java
Update	Updates a row via the application server. See Example2.java
Delete	Deletes a row via the application server. See Example5.java

Method	Description
ExecMany	Process a sequence of operations in a single transaction. See Example7.java
FindByPrimaryKey	Return a ValuesObject corresponding to a given primary key. See Example6.java
FindAll	Return an array of ValuesObjects corresponding to all rows for the given entity. See Example10.java
Close	Close a connection

Example1.java – Insert

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example1
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         ValuesObject rowData = new ValuesObject("Location");
         rowData.put("locationGid","GUEST.MYNEWLOC4");
         rowData.put("locationXid","MYNEWLOC4");
         rowData.put("countryCode3Gid","USA");
         rowData.put("domainName","GUEST");
         rowData.put("isTemporary","true");
         clientAPI.insert(rowData);
   }
}
```

Example2.java – Update

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;

public class Example2
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         ValuesObject rowData = new ValuesObject("Location");
         rowData.put("locationGid","GUEST.MYNEWLOC");
         rowData.put("locationName","Eric Rosenbloom");
         clientAPI.update(rowData);
   }
}
```

Example3.java – GetEntityNames

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
import java.util.Iterator;
public class Example3
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         Iterator i = clientAPI.getEntityNames();
         while (i.hasNext()) {
               System.out.println("EntityName = " + (String) i.next());
         }
   }
}
```

Example4.java – DescribeEntity

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
import java.util.Iterator;
public class Example4
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         Iterator i = clientAPI.getEntityNames();
         while (i.hasNext()) {
               String entityName = (String) i.next();
               System.out.println(entityName);
               Iterator attributeList =
               clientAPI.describeEntity(entityName);
               while (attributeList.hasNext()) {
                     ValuesObject metaData = (ValuesObject)
                     attributeList.next();
                     System.out.println("      " + (String)
                     metaData.get("AttributeName") + " " + (String)
                     metaData.get("DataType"));
               }
         }
   }
}
```

Example5.java – Delete

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
```

```
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example5
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         ValuesObject primaryKey = new ValuesObject("Location");
         primaryKey.put("locationGid", "GUEST.MYNEWLOC");
         clientAPI.delete(primaryKey);
   }
}
```

Example6.java – FindByPrimaryKey

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example6
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("MDIETL.ADMIN","CHANGEME");
         ValuesObject primaryKey = new ValuesObject("Shipment");
         primaryKey.put("shipmentGid", "MDIETL.184");
         ValuesObject rowData = clientAPI.findByPrimaryKey(primaryKey);
         System.out.println("rowData = " + rowData);
   }
}
```

Example7.java – ExecMany

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example7
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");

         // Construct ValuesObject for first update command
         ValuesObject rowData1 = new ValuesObject("Location");
         rowData1.put("locationGid", "GUEST.MYNEWLOC");
         rowData1.put("locationName","My location name");
         ValuesObject update1 = new ValuesObject("update");
         update1.put("rowData", rowData1);

         // Construct ValuesObject for second update command
         ValuesObject rowData2 = new ValuesObject("Location");
         rowData2.put("locationGid", "GUEST.MYNEWLOC2");
```

```
            rowData2.put("locationName","My location name2");
            ValuesObject update2 = new ValuesObject("update");
            update2.put("rowData", rowData2);

            // Now execute both update commands as a single transaction.
            // The method returns the commandList that you passed in, with an
            "status" field
            // added to each element to describe the success or failure of
            each command.
            ValuesObject results[] = clientAPI.execMany(new
            ValuesObject[]{update1, update2});

            // print the status of each command
            for (int i = 0; i < results.length; i++) {
                  ValuesObject command = results[i];
                  String status = (String) command.get("status");
                  if (status != null) {
                        System.out.println("status of command " + i + " = " +
                        status );
                        if (status.equals("error")) {
                              String stackTrace = (String)
                              command.get("stackTrace");
                              System.out.println("stackTrace of failed
                              command = " + stackTrace);
                        }
                  }
            }
      }
}
```

Example9.java – InsertUpdate

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example9
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("GUEST.ADMIN","CHANGEME");
         ValuesObject rowData = new ValuesObject("Location");
         rowData.put("locationGid","GUEST.MYNEWLOC4e");
         rowData.put("locationXid","MYNEWLOC4e");
         rowData.put("countryCode3Gid","USA");
         rowData.put("domainName","GUEST");
         rowData.put("isTemporary","true");
         clientAPI.insertUpdate(rowData);
   }
}
```

Example10.java – FindAll

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
```

```
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
public class Example10
{
   static public void main(String[] args) throws Exception
   {
         ClientAPI clientAPI =
         ClientAPIConnection.connect("MDIETL.ADMIN","CHANGEME");
         ValuesObject[] set = clientAPI.findAll("Shipment");
         for (int i = 0; i < set.length; i++) {
               System.out.println(set[i]);
         }
   }
}
```

Example11.java – Exception Handling

All the ClientAPI methods throw ClientAPIException. This example shows how you may catch a ClientAPIException.

```
package glog_deploy.integration.clientapi;
import glog.integration.clientapi.ValuesObject;
import glog.integration.clientapi.ClientAPIConnection;
import glog.integration.clientapi.ClientAPI;
import glog.integration.clientapi.ClientAPIException;
public class Example11
{
   static public void main(String[] args) throws Exception
   {
         // Catch a bad password
         try {
               ClientAPI clientAPI =
               ClientAPIConnection.connect("GUEST.ADMIN","WRONGPASSWORD");
         }
         catch (ClientAPIException cae) {
               cae.printStackTrace(System.out);
         }
   }
}
```

The ClientAPIConnection Class

The ClientAPIConnection class provides a connect() method which authenticates the client application and returns an instance of a class which implements the ClientAPI.

The ValuesObject Class

The ValuesObject class is a thin wrapper around java.util.HashMap, providing support for a set of attribute/value pairs.

Handling Units of Measure

The output from Example6.java can be used to understand how units of measure are represented within the ValuesObject.

java glog_deploy.integration.clientapi.Example6

```
rowData = {isTemperatureControl=false, domainName=MDIETL,
checkCapacityConstraint=true, itineraryGid=MDIETL.180,
totalActualCost=2880.44 USD, startTime=2002-09-17 17:47:28 UTC,
totalVolume=1000 CUFT, isCostFixed=false, plannedCost=2880.44 USD,
totalWeight=40000 LB, totalWeightedCost=2880.44 USD, totalNetVolume=1000
CUFT, isServiceTimeFixed=false, rateGeoGid=MDIETL.CA-GA.MSCARRIERS,
feasibilityCode=FEASIBLE, rateOfferingGid=MDIETL.MSCARRIERS2000,
endTime=2002-09-22 17:47:28 UTC, totalNetWeight=40000 LB,
isFixedTenderContact=false, isTemplate=false, shipmentAsWork=false,
numStops=2, checkCostConstraint=true, weighCode=A,
isRateOfferingFixed=false, shipmentReleased=true,
sourceLocationGid=MDIETL.CONTAINER MFG - PLANT 1 - LOS ANGELES,
isAutoMergeConsolidate=false, shipmentTypeGid=TRANSPORT, isToBeHeld=false,
parentLegGid=MDIETL.1, isPreferredCarrier=false,
servprovGid=MDIETL.MSCARRIERS, transportModeGid=TL,
destLocationGid=MDIETL.100 INDUSTRIAL ROAD, perspective=B,
shipmentGid=MDIETL.184, totalShipUnitCount=1, shipmentXid=184,
rule7=false, isServprovFixed=false, shipmentName=erosenbloom,
numOrderReleases=1, checkTimeConstraint=true, isPreload=false,
isHazardous=false, isRateGeoFixed=false}
```

The above output illustrates several UOM attributes. For example, the UOM of “totalActualCost” is “USD”, and the UOM of “startTime” is “GMT”. When writing code such as Example1.java, you must specify a unit of measure for any attribute where a unit of measure makes sense. (A Remark would be an example of an attribute where a unit of measure would not make sense).

The valid UOM codes can be determined by querying the UOM table.

Environment Issues

The clientAPIConnection class depends on their being a glog.properties file in the user.home directory. This property file is required to determine which application server to connect to. (Notice that only the username and password is specified when you make the connect call from your java program).

Here are the minimal entries required in the glog.properties file:

```
# application server URL and port
appserver=localhost
appserver.port=7001
```

On an NT machine, the above glog.properties file resides in the default user.home directory:

```
c:/WINNT/Profiles/username/glog.properties
```

You can specify user.home on the java command line, and then CSVHelper will find the glog.properties file in the directory you specify. For example:

```
java -Duser.home=l:/gc3/glog_deploy/app/config
glog_deploy.integration.clientapi.Example1
```

In the above example, you tell the JVM that the user.home directory is l:/gc3/glog_deploy/app/config instead of the default c:/WINNT/Profiles/username.

21. Oracle Advanced Queuing

Oracle Advanced Queuing (OAQ) provides an alternate way of sending and receiving XML transmissions to/from Oracle Transportation Management. The main benefit to using OAQ is the added level of guaranteed message delivery provided by a persistent message queue.

To use the OAQ functionality in Oracle Transportation Management, the following setup steps must be performed.

Step 1 –Create Queue Table(s)

The default implementation for OAQ in Oracle Transportation Management relies on a database table called INTG_QUEUE. The table is a point-to-point (single consumer) queue table. The table should be available with the installation of the Oracle Transportation Management database.

The OAQ functionality is not restricted to a single queue table. Additional queue tables can be created as needed. The following procedure is available to create additional queue tables.

```
procedure create_int_queue_table(p_table_name varchar2,
   p_comment varchar2,
   p_table_space varchar2 default 'data',
   p_multiple_consumers  boolean Default false );
```

The procedure supports creating multi-consumer queue tables using the p_multiple_consumers argument. The only requirement for creating a queue table is inbound queues that Oracle Transportation Management will read from must be created as a point-to-point (single consumer) table.

Example:

```
Sqlplus> execute
pkg_queue_management.create_int_queue_table('queue_test_table',  'This is
for test only');
```

Alternatively, for the multi-consumer:

```
Sqlplus> execute
pkg_queue_management.create_int_queue_table('queue_test_table',  'This is
for test only', 'data', true);
```

The queue tables created use a custom data type called INTG_QUEUE_MESSAGE. The custom data type supports additional fields used for communication. The definition of the INTG_QUEUE_MESSAGE is:

ID	Type	Description
refnum	varchar2(101)	Can be assigned by client system for message referencing.
subject	varchar2(500)	Arbitrary text field definable by the client.
transmission_no	number	Oracle Transportation Management assigned transmission number.

ID	Type	Description
external_system_id	varchar2(101)	Overrides the external system GID in the TransmissionHeader.
user_name	varchar2(128)	Used for user authentication instead of specifying in the TransmissionHeader in the XML.
password	varchar2(128)	Used for user authentication instead of specifying in the TransmissionHeader in the XML.
Xml	clob	Contains the XML transmission.

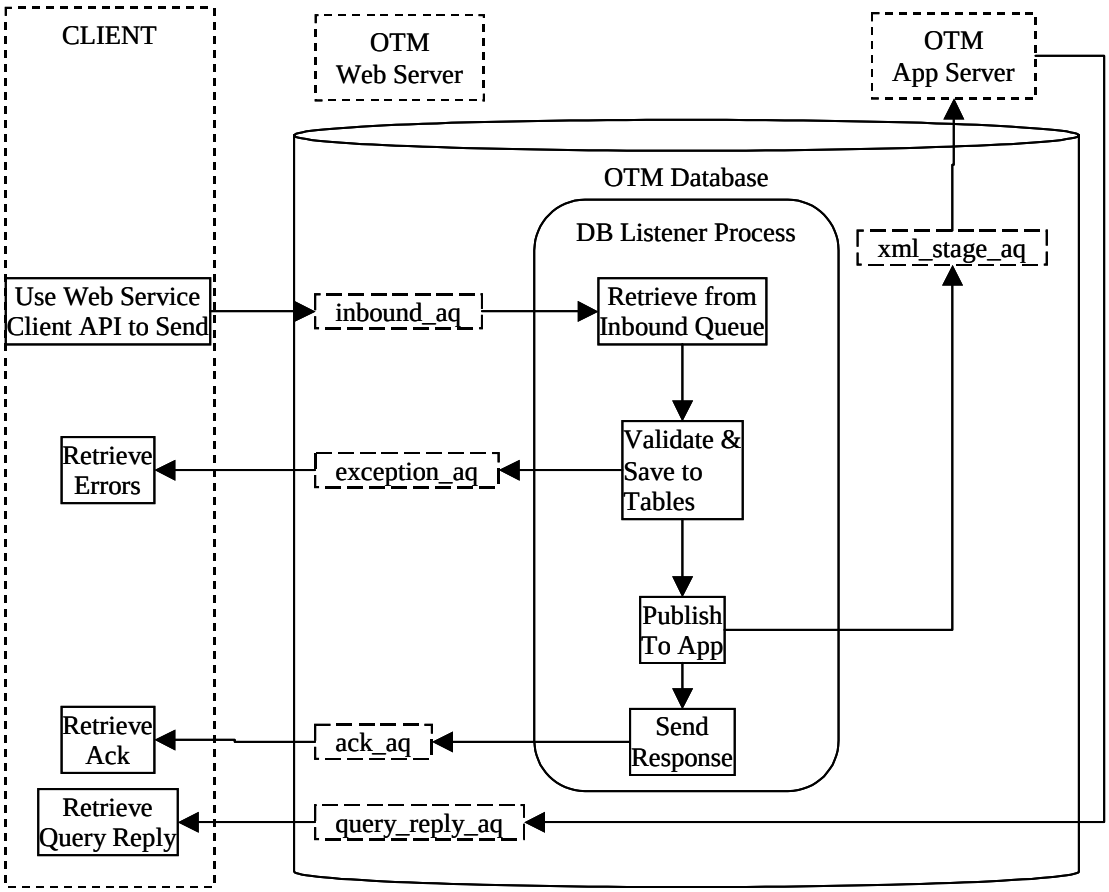
Step 2 – Setup Required Inbound Queues

For inbound processing of the XML, a set of four queues are required. The queues are:

- Inbound Queue (originally defined as inbound_aq in release 4.0)
- XML Topic Queue (originally defined as xml_stage_aq in release 4.0)
- Ack Queue (originally defined as ack_aq in release 4.0)
- Exception Queue (originally defined as exception_aq in release 4.0)

A query_replay_aq is also needed for responding to Remote Query transactions such as Rate Inquiry (RIQ).

The following diagram shows the communication from the client to the database, as well as a high level depiction of the processing in the database.



In the diagram above, the client first sends the XML to the Inbound Queue. The database listener reads from the "Inbound Queue" and stages the data to the i_transmission/i_transaction tables. If staging is successful, the database listener puts the TransmissionAck message in the "Ack Queue" and stages a message to the application server in the "XML Topic Queue" so that the app server can proceed with processing the message. If the Transmission XML is for a RemoteQuery, the query response is placed in the query_reply_aq queue. If an error occurred in the staging, the database listener puts an exception message in the "Exception Queue". The configuration of the application server listener is discussed later. All the queues may or may not be on the same queue table. However, the "Inbound Queue" and "XML Topic Queue" must not be multi-consumer queues. Furthermore, the user is allowed to add multiple sets of inbound and outbound queues in the same queue table.

To create all four queues required for inbound processing on the same queue table, use the following procedure:

```
procedure setup_inbound_queue_system(p_queue_table_name varchar2,
   p_inbound_queue_name varchar2,
   p_xmltopic_queue_name varchar2,
   p_ack_queue varchar2,
   p_exception_queue varchar2)
```

Example:

```
Sqlplus> execute pkg_queue_management.setup_inbound_queue_system
('queue_test_table',
 'another_inbound_aq',
 'raise_xml_topic',
```

```
    'acknowledgement',
    'notify_exception');
```

To create the queues on different queue table(s), use the following procedure:

```
procedure start_queue(p_queue_name varchar2, p_queue_table_name varchar2)
```

Example - to create all the queues in example A above individually, use the following commands:

```
Sqlplus> execute pkg_queue_management.start_queue ('another_inbound_aq',
'queue_test_table');
Sqlplus> execute pkg_queue_management.start_queue( 'raise_xml_topic',
'queue_test_table');
Sqlplus> execute pkg_queue_management.start_queue ( 'acknowledgement',
'queue_test_table');
Sqlplus> execute pkg_queue_management.start_queue ( 'notify_exception',
'queue_test_table');
```

Step 3 – Setup Database Listeners

For each inbound set of queues created above, a database listener should be created in order for the XML to be processed. The following procedure is used to setup the listener:

```
procedure install_queue_listener(p_inbound_queue_name varchar2 ,
   p_xmltopic_queue_name varchar2 ,
   p_ack_queue varchar2 ,
   p_exception_queue varchar2)
```

Example:

```
Sqlplus> execute pkg_queue_management.install_queue_listener  (
'another_inbound_aq',  'raise_xml_topic', 'acknowledgement',
'notify_exception');
```

In this case, the client first sends the XML to the 'another_inbound_aq' queue defined in the first parameter. The database listener reads from this queue and stages the data. If staging is successful, the database listener puts the TransmissionAck message in the 'acknowledgement' queue defined in the third parameter, and stages a message to the application server in the 'raise_xml_topic' queue defined in the second parameter. If an error occurred in the staging, the database listener puts an exception message in the'notify_exception' queue defined in the fourth parameter.

To stop the database listener, execute the following procedure on the "Inbound Queue":

```
Sqlplus> execute
pkg_queue_management.stop_queue_listener('another_inbound_aq');
```

Step 4 – Setup Application Server Listeners

After the database listener successfully stages the XML, it submits a message to the "XML Topic Queue" for the app server to process. The app server requires a listener/thread to be enabled to process the messages in the "XML Topic Queue". The app server listener is set up through properties. The format of property entry is (*note the difference in glog.integration.oaq vs. glog.oaq.integration*):

```
glog.oaq.integration.{the_topic_queue_name}=1
```

For example, the property entry corresponding to the database listener created in (3) should be:

```
glog.oaq.integration.raise_xml_topic=1
```

The value for the property must be a non-zero integer. The integer value determines the total number of threads for the listener. Since the app server listener is very lightweight, one thread should be enough to process the messages. If user desires to set up the value greater than one, a performance test should be done to determine the effects. To turn off the listener, set the value to "0" or remove the property entry. The property only takes effect during the startup.

Auto Startup of Database Listener via Application Server

The app server has the ability to start and stop the database listener when it is being started or shut down. This is enabled through the use of the following property:

```
glog.integration.oaq.controlDbListener=true
```

When the property is true, the app server will also start the database listener when the app is starting, and will also shut down the database listener when the app server is shutting down.

Backward Compatible Application Server Properties

Prior to Oracle Transportation Management Release 5.0, the application server listener was started by setting the property glog.integration.oaq=true. Please note that this property is deprecated. The suggested property is "glog.oaq.integration.xml_stage_aq=1". For backward compatibility, the property "glog.integration.oaq=true" is still supported and correlates to enabling the suggested property "glog.oaq.integration.xml_stage_aq=1".

Step 5 – Create Outbound Queues

Clients specify the queue to use for sending outbound XML from Oracle Transportation Management in the External System Manager in the UI. There are two approaches for creating the outbound queue, which is then used in the External System Manager. The first approach is to create the queue using the stored procedure – this enables the client to specify the queue table to be used for the queue. After the queue is created, the external system can then reference the queue. The second approach is to specify the queue in the external system manager without first creating the queue. If the queue does not exist, the Oracle Transportation Management application would create the queue with the queue table defined in the property entry glog.integration.oaq.outbound.queuetable. By default, the queue table is intg_queue.

Example to create queue from procedure:

```
Sqlplus>  execute pkg_queue_management.start_queue
('outbound_example_queue', 'outbound_queue_table');
```

If the queue table is a multi-consumer queue table, the corresponding queue on the table is multi-consumer. At least one subscriber must be created for the queue, otherwise, Oracle Transportation Management will throw an exception during the enqueue process.

The following procedure will add a subscriber to the multi-consumer queue:

```
Sqlplus>   Pkg_queue_util.add_subscriber('mutlti_consumer_queue',
subscriber_name);
```

Step 6 – Other Queue Management Utilities

To drop a queue:

```
execute pkg_queue_management.drop_queue ('your queue_name');
```

To delete all queue entries for a given queue:

```
execute pkg_queue_management.delete_queue_entries('your queue_name');
```

To remove every entry for all the queues in a given non multi-consumer queue table:

```
execute pkg_queue_management.empty_queue_table(‘queue table name’);
```

To drop all queues in a given table:

```
execute pkg_queue_management.drop_all_queues(‘queue table name’);
```

To drop a queue table as well as the corresponding queues:

```
execute pkg_queue_management.drop_queue_table(‘queue table name’);
```

To stop all database listeners:

```
execute pkg_queue_management.stop_all_queue_listeners;
```

To stop a specific database listener:

```
execute pkg_queue_management.stop_queue_listener(‘inbound queue’);
** The “inbound queue” is the first parameter in install_queue_listener
```

To remove database listeners:

```
execute pkg_queue_management.remove_all_queue_listeners;
```

To remove a specific database listeners:

```
execute pkg_queue_management.remove_queue_listener(‘inbound queue’);
```

Optional Oracle Settings

The following Oracle parameters can be specified in init.ora or spfile. Refer to Oracle database documentation for additional details on these parameters.

- aq_tm_process = 1 (to perform time monitoring on queue messages)
- job_queue_processes = 6 (to set the number of job queue processes started in an instance)

22. Copying Domains

Note: While copying domains, make sure no user accesses the database. You can do this by shutting down the application server.

Note: If you want to copy domain1 that needs data from domain2 and you want domain1 to have access to all data in domain2 in the new target database too, you need to make sure you copy domain2 before domain1.

This chapter describes a set of tools to copy domains. Each of them has its limitations and advantages.

Tool	Advantages	Limitations	Usage

Tool	Advantages	Limitations	Usage
Export/ Import	No physical restrictions on the target and source database servers. For example, they do not need a network link between them.	Tables in your target and source domain must have the same table structure.* Security related tables are not copied. Does not allow you to rename the copied domain name.	Only between databases.
In Schema Copy	Data in CLob and long columns can be copied.	You must rename the copied domain. For tables that have a domain_name column and a numeric primary key, the primary key will increment utilizing sequence numbers. However, its copied child fk column data still points to the old from_domain_name parent.	Only within one database.
Database Link Copy	Preferred tool to build a clean database out of an existing database. Tables in your target and source domain can contain different columns.* You can rename or keep the copied domain name. You can run this script multiple times to insert rows that have been added in the source database since the last database link copy.	Requires that a public database link can be created from the target database to the source database. Allows you to copy CLob and long columns. However, the data types in the local and remote domains must be the same.	Within or between databases.

* Tables might contain different columns if you migrated your source database from an earlier database version and you create your target database with the create_all script. In this case, your migrated database contains obsolete columns since the migration scripts do not generally drop obsolete columns.

Export and Import

This tool exports and imports domain data, child domain data, and referenced domain data. The tool computes the referenced domains from the domain_grant_made table. Furthermore, it copies any table with a domain_name column. You run the domain import/export with two shell scripts.

> **Note:** This tool only works with databases for Oracle Transportation Management version 3.1.1 and later.

> **Note:** Only tables that have a domain_name column can be copied.

Note: It is crucial to create the target domain before copying data into it.

Note: Do not use this tool to copy domains to a production database you plan to go live on. The other tools are better.

What the Objects do

This section describes what each object does.

domain_export.sh

- Calls pkg_domain_export

Searches all the grantor domains that grant read or write access of their domain data to the current domain. However, it does not perform the physical check to see if the current domain does actually reference the grantor domain data. The grantor domain does not include the PUBLIC and SERVPROV domains.

Searches for tables with a domain_name column.

Generates parameter files for export and import

- Calls the Oracle export tool to export the domain data to a dump file.

domain_import.sh

- Calls pkg_domain_export.

Disables some triggers during import.

Disables self-referenced foreign keys during import.

- Calls the Oracle import tool to import the domain data
- Calls pkg_domain_export.

Enables the disabled triggers once the import is completed.

Enables the self-referenced foreign keys once the import is completed.

- Calls pkg_purge and fk_trouble_shooter.

pkg_shipment_purge and fk_trouble_shooter form a backup plan. As mentioned above, PUBLIC and SERVPROV data is not exported. Still, the exported domain might reference PUBLIC or SERVPROV data in the source database leading to foreign key violations. These two packages search for those references and remove them from the target database.

Setup

Compile the packages.

1. Sqlplus> @pkg_shipment_purge.sql
2. Sqlplus> @create_pkg_domain_export.sql
3. Sqlplus> @create_fk_trouble_shooter.sql

Steps to Copy a Domain

Export from source database.

1. Os prompt> `bash domain_export.sh <oracle_sid> <userid> <password> <domainname> <include_reference_domain>`

   Example: bash domain_export.sh localdb glogowner glogowner guest yes

   The last command line argument, include_reference_domain, is either “yes” or “no”. When you enter “yes”, the script exports the grantor domain data along with the specified domain data. This is the preferred scenario. However, you can encounter other situations where you export multiple domains and you have already imported the grantor domain data into the target database. If this is the case, enter “no” as the last argument to skip the grantor domains.
2. Review domainexp.log for error messages. You can safely ignore Oracle errors and messages marked EXP-00081.

Import into target database.

3. Create target domain in Oracle Transportation Management.

   If you do not, you will have problems creating the domain in Oracle Transportation Management afterwards. Even if you do create your target domain in Oracle Transportation Management, you will see a lot of error code –1, which means primary key violation. This is okay. The error messages occur because Oracle Transportation Management creates some table data automatically and the copy then tries to insert the same data.

4. Transfer the files domainexp.dmp and domainimp.par to the target database.
5. Os prompt> bash domain_import.sh <*oracle_sid*> <*userid*> <*password*>

Result

When domain_import.sh is done, it displays the message “ALL FOREIGN KEYS WERE ENABLED SUCCESSFULLY!” on the console. If it does not, examine the error logs in domainimp.log and violated_con.log.

- domainimp.log captures all errors during the import.
- violated_con.log gives you more detailed information about constraints. It summarizes all tables with invalid constraints, as well as parent keys, missing in the target database.

Error Messages

The most common problem encountered while importing is foreign key violations, where a large number of rows are rejected. This can be frustrating since it takes a lot of time to display the error messages on the console. Foreign key violations might occur if you migrated your source database from an earlier database version and you created your target database with the create_all script. In this case, your migrated database contains obsolete columns since the migration scripts do not generally drop obsolete columns. To confirm this, search for ORA-00904 error messages in your domainimp.log file.

In Schema Copy

This tool allows you to copy domains within one database. You can copy domains with or without their child domains. Child domains keep their original child domain names; only the parent domain name part is replaced.

What the Objects do

This tool uses these stored procedures in pkg_novpd_domain_copy:

Procedure	Does This
set_copy_parameters	Stores what “from_domain” to copy into what “to_domain”. You can enter multiple pairs of domains before executing the actual copying.
print_copy_parameters	Displays the list of “from_domain”s and “to_domain”s you have created with set_copy_parameters.
reset_parameters	Clears the list of domains to copy. You might want to do this if you notice a spelling error.

Set-up

Compile the packages.

1. Log in as glogowner.
2. sqlplus>@create_pkg_novpd_inschema_copy.sql to compile the package.
3. `sqlplus>@novpd_domain_copy_script_builder.sql` to generate the domain copy script, novpd_load.sql. In novpd_load.sql, there is a procedure for every table. Each procedure is enclosed by "declare" and a "/". You can remove a procedure from the script if you do not want to copy a certain table.

Copy Domains

1. sqlplus>execute pkg_novpd_domain_copy.set_copy_parameters('from_domain', 'to_domain', copy_child_domains, domain_info) to set your copy parameters.

   Note: You need to execute this command for every domain to be copied.

   Note: You can copy multiple domains with or without renaming them in a single run.

   Note: If domains depend on each other for data and you want to rename at least one of these domains, you must copy all these domains in a single run. This will allow novpd_load.sql to keep all dependencies correct. If you do not, some of the data will be rejected due to foreign key violations.

Parameter	Description
from_domain	Name of the domain to copy.
to_domain	The new name of the domain.
copy_child_domains	true - child domains will be copied false - child domains will not be copied.
domain_info	You must enter "false". This retrieves domain information from the local source database instead of a remote target database.

2. sqlplus>set serverout on size 1000000.
3. sqlplus>execute pkg_novpd_domain_copy.print_copy_parameters to display the parameter values entered.

4. If you notice that any of your parameters are wrong, you can reset all parameters with `execute pkg_novpd_domain_copy.reset_parameters`. If you do execute this statement, you must re-enter all your parameters.
5. sqlplus>`@novpd_load.sql` to copy all domains you have entered parameters for. There is a log file: inschema_domain_copy.log.
6. sqlplus>execute domainman.reset_sequence to reset the Oracle sequence numbers.
7. You need to restart Oracle Transportation Management running against the target database to be able to log in to your newly copied domain. The restart allows Oracle Transportation Management to refresh its caches.

Result of In Schema Copy

After novpd_load.sql has finished it displays the number of data rows that were copied and rejected.

Database Link Copy

This is the preferred tool to build a clean database out of an existing database.

Database Link Copy requires the packages pkg_novpd_domain_copy that depends on pkg_domain_export. It copies tables with the domain_name column as well as the security tables.

The total number of rows copied or rejected is written in the database_link_domain_copy.log file. If an exception happens, the exception code as well as the primary key is also written to the log file. Furthermore, if the exception is a foreign key violation, the log will include the foreign key.

Create Link from Target to Source Database

1. Log in to the **target** database with a DBA level account. You must then navigate to the /glog/oracle/script8/ directory.
2. sqlplus>alter system set global_names=false
3. sqlplus>create public database link "loader.oracle.com" connect to "username_in_source_database" identified by " password_in_source_database" using 'source_database'

   Example: create public database link "loader.oracle.com" connect to "glogowner" identified by "glogowner" using 'hera35'

   Use exact double or single quotes as shown above.

   Later, if you need to change the database link to point to a different database, you must first drop the database link (drop public database link loader.oracle.com) and then recreate it.
4. Sqlplus>select count(1) from `shipment@loader.oracle.com` to confirm that the database link is active.

Generate Script

1. Sqlplus>connect glogowner/password@targetdb
2. Sqlplus>@create_pkg_novpd_inschema_copy.sql
3. Sqlplus>`@database_link_domain_copy_script_builder.sql` to generate the link_load.sql script. link_load.sql contains a stored procedure for every table it will copy. Each procedure is enclosed by "declare" and a "/".

   Note: You can remove a procedure from the link_load.sql script if you do not want to copy a certain table. Note that once you remove a procedure for a table, its child tables are rejected.

Note: Like novpd_load.sql, link_load.sql only contains a stored procedure for tables that the two databases have in common. Furthermore, only data in columns that appear in both the target and source database will be copied. This allows you to copy domains between databases of different releases.

Note: You may encounter some problems
1. When uncopied columns are required and have no default values or triggers.
2. When the same column in both target and source database has different data types such as CLOB and LONG.
3. When data records in your domain point to records in a domain that do not exist in the target domain. You will see error 2291 in your log file (foreign key violation).
4. When the sequence number of your source database is higher than your target database. If any of the records in your copied domain refers to a table with only a sequence number as primary key, the referring record will be rejected.

Copy Domains

Note: During the domain copy, only one commit per table and domain is executed. If you want to copy a large amount of data, be sure to allocate enough rollback tablespace and segments.

1. sqlplus>execute pkg_novpd_domain_copy.set_copy_parameters('from_domain', 'to_domain', copy_child_domains, domain_info) to set your copy parameters.

   Note: You need to execute this command for every domain to be copied.

   Note: You can copy multiple domains with or without renaming them in a single run.

   Note: If domains depend on each other for data and you want to rename at least one of these domains, you must copy all these domains in a single run. This will allow link_load.sql to keep all dependencies correct. If you do not, some of the data will be rejected due to foreign key violations.

Parameter	Description
from_domain	Domain name in source database.
to_domain	Domain name in target database. If it is the same as from_domain, then no renaming is performed. Otherwise, from_domain would be renamed to to_domain during the copying.
copy_child_domains	true - then child domains will be copied false - child domains will not be copied.
domain_info	You must enter "true". This retrieves domain information from the remote source database instead of the local target database.

2. sqlplus>set serverout on size 1000000.
3. sqlplus>execute pkg_novpd_domain_copy.print_copy_parameters to display the parameter values entered.
4. If you notice that any of your parameters are wrong, you can reset all parameters with `execute pkg_novpd_domain_copy.reset_parameters`. If you do execute this statement, you must re-enter all your parameters.
5. sqlplus>`@link_load.sql` to copy all domains you have entered parameters for. There is a log file: database_link_domain_copy.log

6. sqlplus>execute domainman.reset_sequence to reset the Oracle sequence numbers.
7. You need to restart Oracle Transportation Management running against the target database to be able to log in to your newly copied domain. The restart allows Oracle Transportation Management to refresh its caches.

Difference Between Domains

You can find the difference between two domains and list the primary keys.

1. Sqlplus>set serverout on size 1000000
2. sqlplus>execute pkg_domain_export.diff_remote(*remote_domain, local_domain*)

   Note: Differences here, most likely depends on static data missing, in your target database, in a domain like PUBLIC. Also, you might have missed to copy dependant domains in one session.

3. sqlplus>execute pkg_domain_export.diff_table_remote(*remote_domain, local_domain*)

Rerun database link copy

As long as the target database schema has not changed, you can run the link_load.sql script again and again to insert rows that have been added to the source database since the last database link copy. This is also useful to keep PUBLIC domains in two databases synchronized. Note that this does not update existing rows in the target database

Note: If the target database schema has changed, you need to run the `database_link_domain_copy_script_builder.sql` script again to create an updated `link_load.sql` script.

23. Deleting Domains

This chapter describes the steps to delete domains in Oracle Transportation Management.

1. Shut down the Oracle Transportation Management application. This includes WebLogic, Tomcat, Apache, etc.
2. Log in directly to the database using a database management utility such as SQLPLUS. Log into the database as glogowner.
3. Delete a single domain. Enter the following command at the SQLPLUS prompt:

   ```
   Exec domainman.delete_domain('DOMAIN');
   ```

   Note: Substitute the domain name that you want to delete for DOMAIN. Since this does a cascade delete, this may take a significant amount of time. If there is any data cross-referenced between domains, the data referenced will not be deleted. For example, if Shipments in DomainA reference rates in DomainB, and you delete DomainB, rates in DomainB referenced by shipments in DomainA can not be deleted.

4. Delete mutiple domains. Enter the following commands at the SQLPLUS prompt:

   ```
   Exec domainman.mark_domain_for_delete ('DOMAIN',
   including_sub_domains);
   ```

   Note: Substitute the domain name that you want to delete for DOMAIN. Including_sub_domains equals "true" or "false". If it is "true", then the child domains are also marked for deleted. Otherwise, the child domains are not included for deletion. This procedure should be called for each domain to be deleted. Every time the procedure is called, the domain and its child domains are cached in memory. If you make a mistake, you have to log out the session and re-log in.

   ```
   Exec domainman.delete_marked_domains;
   ```

   Note: This procedure iterates through all the domains and child domains marked in the previous step. It deletes one table at a time for the domains and their children. It yields better performance. Futhermore, it can delete cross-referenced data within domains in this transaction.

5. Delete non-existent domain data. Enter the following commands at the SQLPLUS prompt:

   ```
   Set serverout on size 1000000
   Exec domainman.report_unreferenced_domains;
   ```

   Note: This procedure reports all the non-existent domains table by table. The non-existent domains are the ones which are not in domain table. They could be from a bug from previous delete domain procedure or the result from loading a CSV. After reviewing the report generated from the previous step, you can call the next procedure to delete the data in all the tables for the non-existent domains.

   ```
   Exec domainman.delete_unreferenced_domains;
   ```

24. Reference A: DB.XML Transaction Codes

When importing db.xml with any of the methods described in this document, there are three transaction codes currently available:

- I - Insert Mode: Only inserts are performed. If the data already exists in the database, you will get primary key errors.
- IU - Insert/Update Mode: Attempts to insert data. If a primary key violation occurs, it updates the data. No delete statements are generated.
- RC - Replace Children Mode: Deletes all child data corresponding to the top level parent, updates the top level parent, and reinserts the child data. This mode allows for a complete replacement of a data object.

CSVUtil 5.5 supports a “replace children” (rc) command when processing multi-table CSV files. The rc command will recursively delete all child records and re-insert them from the CSV file. This is useful when you want to completely replace the rows that comprise a complex multi-table business object.

The “C.” table sets are used to determine the hierarchical parent/child relationships.

For example:

```
TABLE_SET_DETAIL
TABLE_SET,TABLE_NAME
C.GEO_HIERARCHY,GEO_HIERARCHY_DETAIL
C.GEO_HIERARCHY_DETAIL,HNAME_COMPONENT
```

The C.GEO_HIERARCHY table set indicates that the GEO_HIERARCHY_DETAIL table is a child of geo_hierarchy.

The C.GEO_HIERARCHY_DETAIL table set indicates that the HNAME_COMPONENT table is a child of geo_hierarchy_detail.

Examples:

If you submit the following multi-table CSV file with the “rc” command, all rows in the GEO_HIERARCHY_DETAIL table relating to the GUEST.COUNTRY hierarchy would be deleted (since there are none to replace those records in the CSV file).

```
$HEADER
GEO_HIERARCHY_DETAIL
GEO_HIERARCHY_GID,HNAME_COMPONENT_GID,HLEVEL,DOMAIN_NAME,INSERT_USER,INSER
T_DATE,UPDATE_USER,UPDATE_DATE
GEO_HIERARCHY
GEO_HIERARCHY_GID,GEO_HIERARCHY_XID,RANK,COUNTRY_CODE3_GID,DOMAIN_NAME,INS
ERT_USER,INSERT_DATE,UPDATE_USER,UPDATE_DATE
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY-MM-DD HH24:MI:SS..'
$BODY
GEO_HIERARCHY
"GUEST.COUNTRY","COUNTRY",10,,"GUEST","DBA.ADMIN",2001-08-30
11:01:56.0,"DBA.ADMIN",2005-10-26 14:44:50.0
```

If you submit the following multi-table CSV file with the “rc” command, there will be two records in the geo_hierarchy_detail table relating to the GUEST.COUNTRY hierarchy, regardless of how many rows were there previously.

```
$HEADER
GEO_HIERARCHY_DETAIL
```

```
GEO_HIERARCHY_GID,HNAME_COMPONENT_GID,HLEVEL,DOMAIN_NAME,INSERT_USER,INSER
T_DATE,UPDATE_USER,UPDATE_DATE
GEO_HIERARCHY
GEO_HIERARCHY_GID,GEO_HIERARCHY_XID,RANK,COUNTRY_CODE3_GID,DOMAIN_NAME,INS
ERT_USER,INSERT_DATE,UPDATE_USER,UPDATE_DATE
EXEC SQL ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY-MM-DD HH24:MI:SS..'
$BODY
GEO_HIERARCHY
"COUNTRY","COUNTRY",10,,"PUBLIC","DBA.ADMIN",2001-08-30
11:01:56.0,"DBA.ADMIN",2005-10-26 14:38:33.0
GEO_HIERARCHY_DETAIL
"COUNTRY","COUNTRY_CODE3",1,"PUBLIC","DBA.ADMIN",2001-08-30 11:01:56.0,,
GEO_HIERARCHY_DETAIL
"COUNTRY","CITY",2,"PUBLIC","DBA.ADMIN",2001-08-30 11:01:56.0,,
```

Sample command line:

```
 java glog.database.admin.CSVUtil -command rc -connectionId localdb -
dataDir . -dataFileName geo_hierarchy.csv
```

In version 5.5 and later, the “rc” command is available after you upload a CSV file via the integration manager.

25. Reference B: Specifying Complex Queries

This section shows the SQL query corresponding to the predefined rate_geo database object.

Example of a Complex Query

Use this example to build your own complex queries when no predefined database object exists for the data you want to export.

```
select rate_geo.*,  \
   cursor (select rate_geo_stops.* from rate_geo_stops where
   rate_geo_stops.rate_geo_gid = rate_geo.rate_geo_gid) as rate_geo_stops,
   \
   cursor (select rate_geo_accessorial.* from rate_geo_accessorial where
   rate_geo_accessorial.rate_geo_gid = rate_geo.rate_geo_gid) as
   rate_geo_accessorial,  \
   cursor (select rg_special_service.* from rg_special_service where
   rg_special_service.rate_geo_gid = rate_geo.rate_geo_gid) as
   rg_special_service,  \
   cursor (select rg_special_service_accessorial.* from
   rg_special_service_accessorial where
   rg_special_service_accessorial.rate_geo_gid = rate_geo.rate_geo_gid) as
   rg_special_service_accessorial, \
   cursor (select rate_geo_cost_group.*,   \
               cursor (select rate_geo_cost.* ,   \
               cursor (select rate_geo_cost_weight_break.*  \
               from rate_geo_cost_weight_break  \
               where rate_geo_cost_weight_break.rate_geo_cost_seq =
               rate_geo_cost.rate_geo_cost_seq and
               rate_geo_cost_weight_break.rate_geo_cost_group_gid =
               rate_geo_cost.rate_geo_cost_group_gid) as
               rate_geo_cost_weight_break  \
         from rate_geo_cost   \
         where rate_geo_cost.rate_geo_cost_group_gid =
         rate_geo_cost_group.rate_geo_cost_group_gid ) as rate_geo_cost
         \
   from rate_geo_cost_group   \
   where rate_geo.rate_geo_gid = rate_geo_cost_group.rate_geo_gid) as
   rate_geo_cost_group \
from rate_geo "
```

The main thing to notice is the use of nested cursors to specify a hierarchical query.

26. Reference C: CSVUtil Response Messages

At the completion of processing the command, CSVUtil responds in the form of an XML message. The XML message may contain the following elements:

- Information passed in as input parameters such as the Command, DataDir, and DataFileName
- Information about the contents of the input file such as the TableName and ColumnList
- An Error element identifying the error that was detected.
- Statistics on the success of the message as follows:

ProcessCount – The number of rows that were successfully processed

ErrorCount – The number of rows where an error was detected

Skipcount – The number of rows that were skipped because of duplicate or missing keys. This is only valid when using the ii command which suppresses unique key constraint violations when inserting data, or the uu and dd commands which suppress "no data found" constraint violations when updating/deleting data.

Response Messages with No Errors

Here is an example of a response indicating no errors. In this case, three data rows (based on the ProcessCount element) of the weight_break.csv file were successfully inserted.

```
<CSVUtil>
<Command>i</Command>
<DataDir>.\</DataDir>
<DataFileName>weight_break.csv</DataFileName>
<ProcessCSV>
<TableName>WEIGHT_BREAK</TableName>
<ColumnList>WEIGHT_BREAK_GID,WEIGHT_BREAK_XID,WEIGHT_BREAK_PROFILE_GID,WEI
GHT_BREAK_MAX,WEIGHT_BREAK_MAX_UOM_CODE,WEIGHT_BREAK_MAX_BASE,DOMAIN_NAME<
/ColumnList>
<ProcessCount>3</ProcessCount>
<ErrorCount>0</ErrorCount>
<SkipCount>0</SkipCount>
</ProcessCSV>
</CSVUtil>
```

The following is an example of the response message typically received when exporting data using the xcsv command.

```
<CSVUtil>
<Command>xcsv</Command>
<DataDir>.\</DataDir>
<DataFileName>weight_break.csv</DataFileName>
<Write>
<TableName>WEIGHT_BREAK</TableName>
</Write>
</CSVUtil>
```

Error Messages

After processing a command, CSVUtil displays a response in the form of an XML message (see page 9-1). When an error is detected in the processing, the XML message will contain an Error element with the details. The Error XML element indicates the table name, indicates the type of error detected, and lists the data (or row in file) that was being processed when the error occurred.

Below is the error message that Oracle Transportation Management displayed in the procedure (see page 10-1). The TableName element indicates the table being processed, the Exception element provides the error message, and the Data element indicates the row being processed. In this case, it indicates that the JUNK table does not exist in the database.

```
<Error>
<TableName>JUNK</TableName>
<Exception>ORA-00942: table or view does not exist
</Exception>
<Data>"Data1","Data2","Data3"</Data>
</Error>
```

Import

This topic describes some common error messages while importing. For each error, there is an explanation of when the message occurs and the action needed to correct the error.

Heading	Data
Message:	<Exception> ORA-00942: table or view does not exist
Occurs When:	Table name improperly specified (misspelled or invalid table) on the first line of the CSV file.
Corrective Action:	Verify that the table exists and that the CSV file contains the correct table name.

Heading	Data
Message:	<Exception> ORA-00001: unique constraint (GLOGOWNER.PK_WEIGHT_BREAK) violated
Occurs When:	Inserting data with primary keys that are already in the database.
Corrective Action:	Depending on the action desired, one of the following can be used: • If the data should be skipped or ignored, use the ii command to suppress the message. • If the data is intended to be new, change the keys. • If the data is intended to be an update, use the u or uu command.

Heading	Data
Message:	<Exception>ORA-02292: integrity constraint (GLOGOWNER.FK_RGCWB_WEIGHT_BREAK_GID) violated - child record found
Occurs When:	During a delete when child records in other tables depend on the key being removed.

Heading	Data
Corrective Action:	Delete child records in associated tables before deleting from this table.

Heading	Data
Message:	<Error>There are supposed to be 7 columns of data, but I found 6 columns in this line: ["MYDOMAIN.LT 4500","LT 4500","MYDOMAIN.DEFAULT",4500,"LB","MYDOMAIN"]</Error> <Error> <TableName>WEIGHT_BREAK</TableName> <Exception>ORA-01722: invalid number</Exception> <Data>"MYDOMAIN.LT 4500","LT 4500","MYDOMAIN.DEFAULT",4500,"LB","MYDOMAIN"</Data> </Error>
Occurs When:	Missing a column of data in one of the rows.
Corrective Action:	Verify that the data contains the number of fields as indicated in the ColumnList, and that the field formats (string, numeric, date, etc.) are valid.

Heading	Data
Message:	<Error> <TableName>WEIGHT_BREAK</TableName> <Exception>ORA-01722: invalid number</Exception> <Data>"MYDOMAIN.LT 4500","LT 4500","MYDOMAIN.DEFAULT",4500,"LB","gung ho","MYDOMAIN"</Data> </Error>
Occurs When:	Trying to insert a string in a numeric field.
Corrective Action:	Verify that the data contains the number of fields as indicated in the ColumnList, and that the field formats (string, numeric, date, etc.) are valid.

Heading	Data

Heading	Data
Message:	<Error>There are supposed to be 7 columns of data, but I found 1 columns in this line: []</Error> <Error> <TableName>WEIGHT_BREAK</TableName> <Exception>ORA-01400: cannot insert NULL into ("GLOGOWNER"."WEIGHT_BREAK"."WEIGHT_BREAK_GID") </Exception> <Data></Data> </Error>
Occurs When:	The CSV file contains extra blank lines at the end. Oracle Transportation Management considers each blank line to represent a row of data.
Corrective Action:	Remove any extra blank lines at the end of the file.

Heading	Data
Message:	<Error> <TableName>WEIGHT_BREAK</TableName> <Exception>ORA-01401: inserted value too large for column</Exception> <Data>"MYDOMAIN.LT 4500","LT 4500","MYDOMAIN.DEFAULT",4500,"LB",4500,"MYDOMAIN123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890"</Data> </Error>
Occurs When:	Field length for one of the columns has been exceeded.
Corrective Action:	Limit the length of the input data field value to the appropriate size.

Heading	Data

Heading	Data
Message:	<Error> <TableName>WEIGHT_BREAK</TableName> <RowsProcssed>0</RowsProcssed> <Data>"MYDOMAIN.LT 4500","LT 4500","MYDOMAIN.DEFAULT",4500,"LB",4500,"MYDOMAIN"</Data> </Error>
Occurs When:	Attempted to delete data where the data does not exist in the table.
Corrective Action:	Validate that the keys being used to delete the data are correct. Could use the dd command to suppress the error message.

Export

This topic describes some common error messages while exporting. For each error there is an explanation of when the message occurs and the action needed to correct the error.

Heading	Data
Message:	<CSVUtil> <Command>xcsv</Command> <DataDir>.\</DataDir> <DataFileName>weight_break.csv</DataFileName> <Write> <TableName>WEIGHT_BREAK2</TableName> </Write> </CSVUtil> Caught exception: CSVUtil.SQLException: /CSVUtil.SQLException: (null)/java.sql.SQLException: ORA-00936: missing expression ...
Occurs When:	Attempting to export data from a table that does not exist.

Heading	Data
Corrective Action:	Verify table exists and that the CSV file contains the correct table name.
