Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to

AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': $A := \text{diag}(R) * A$

EQUED = 'C': $A := A * \text{diag}(C)$

EQUED = 'B': $A := \text{diag}(R) * A * \text{diag}(C)$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by DGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P*L*U$ as computed by DGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the equilibrated matrix A.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').

= 'R': Row equilibration, i.e., A has been premultiplied by diag(R).
= 'C': Column equilibration, i.e., A has been postmultiplied by diag(C).
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag(R)} * A * \text{diag(C)}$.
EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input or output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input or output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by $\text{diag(R)}*B$; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by $\text{diag(C)}*B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(C)) * X$ if TRANSA = 'N' and EQUED = 'C' or 'B', or $\text{inv}(\text{diag}(R)) * X$ if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(4*N) On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
INTEGER*8 M, N, LDA, INFO  
INTEGER*8 IPIV(*)  
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GETF2([M], [N], A, [LDA], IPIV, [INFO])
```

```
INTEGER :: M, N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dgetf2(int m, int n, double *a, int lda, int *ipiv, int
            *info);

void dgetf2_64(long m, long n, double *a, long lda, long
               *ipiv, long *info);

```

PURPOSE

dgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur
if it is used to solve a system of equations.

REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetrf(int m, int n, double *a, int lda, int *ipivot,
            int *info);

void dgetrf_64(long m, long n, double *a, long lda, long
               *ipivot, long *info);
```

PURPOSE

dgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME

dgetri - compute the inverse of a matrix using the LU factorization computed by DGETRF

SYNOPSIS

```
SUBROUTINE DGETRI(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
INTEGER N, LDA, LDWORK, INFO  
INTEGER IPIVOT(*)  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGETRI_64(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
INTEGER*8 N, LDA, LDWORK, INFO  
INTEGER*8 IPIVOT(*)  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: N, LDA, LDWORK, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: N, LDA, LDWORK, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgetri(int n, double *a, int lda, int *ipivot, int
            *info);

void dgetri_64(long n, double *a, long lda, long *ipivot,
               long *info);
```

PURPOSE

dgetri computes the inverse of a matrix using the LU factorization computed by DGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by DGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from DGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)

On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N*\text{NB}$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

```
= 0:  successful exit  
< 0:  if INFO = -i, the i-th argument had an illegal value  
> 0:  if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.
```

void dgetrs_64(char transa, long n, long nrhs, double *a,  
               long lda, long *ipivot, double *b, long ldb, long  
               *info);
```

PURPOSE

dgetrs solves a system of linear equations
 $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A
using the LU factorization computed by DGETRF.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrix B. $NRHS \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by DGETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from DGETRF; for $1 \leq i \leq N$, row i
of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the right hand side matrix B. On exit,
the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE GGBAK_64(JOB, SIDE, [N], ILO, IHI, LSCALE, RSCALE, [M], V,  
                   [LDV], [INFO])
```

```

CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE
REAL(8), DIMENSION(:, :) :: V

```

C INTERFACE

```

#include <sunperf.h>

void dggbak(char job, char side, int n, int ilo, int ihi,
            double *lscale, double *rscale, int m, double *v,
            int ldv, int *info);

void dggbak_64(char job, char side, long n, long ilo, long
               ihi, double *lscale, double *rscale, long m,
               double *v, long ldv, long *info);

```

PURPOSE

dggbak forms the right or left eigenvectors of a real generalized eigenvalue problem $Ax = \lambda Bx$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by DGGBAL.

ARGUMENTS

JOB (input)
 Specifies the type of backward transformation required:
 = 'N': do nothing, return immediately;
 = 'P': do backward transformation for permutation only;
 = 'S': do backward transformation for scaling only;
 = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to DGGBAL.

SIDE (input)
 = 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)
 The integers ILO and IHI determined by DGGBAL. 1
 $\leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

IHI (input)

See the description for ILO.

LSCALE (input)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by DGGBAL.

RSCALE (input)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by DGGBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the matrix V. $LDV \geq \max(1, N)$.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

See R.C. Ward, Balancing the generalized eigenvalue problem, SIAM J. Sci. Stat. Comp. 2 (1981), 141-152.

                   RSCALE, [WORK], [INFO])
```

```

CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL(8), DIMENSION(:, :) :: A, B

```

C INTERFACE

```

#include <sunperf.h>

void dggbal(char job, int n, double *a, int lda, double *b,
            int ldb, int *ilo, int *ihi, double *lscale, double *rscale, int *info);

void dggbal_64(char job, long n, double *a, long lda, double *b,
               long ldb, long *ilo, long *ihi, double *lscale, double *rscale, long *info);

```

PURPOSE

dggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO\$-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $Ax = \lambda Bx$.

ARGUMENTS

JOB (input)
 Specifies the operations to be performed on A and B:
 = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N.
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description for ILO.

LSCALE (input)
Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $LSCALE(j) = D(j)$ for $J = ILO, \dots, IHI$. If JOB = 'N' or 'S', $LSCALE(j) = P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (input)
Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $RSCALE(j) = D(j)$ for $J = ILO, \dots, IHI$. If JOB = 'N' or 'S', $RSCALE(j) = P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK (workspace)
dimension(6*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

```

PURPOSE

dgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver DGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair

(alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
'S': Eigenvalues are ordered (see DELCTG);

DELCTG (input)

LOGICAL FUNCTION of three DOUBLE PRECISION arguments DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j) + \text{ALPHAI}(j)i) / \text{BETA}(j)$ is selected if $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j)) = \text{.TRUE.}$ after ordering. INFO is to be set to N+2 in this case.

N (input) The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

A (input/output)

DOUBLE PRECISION array, dimension(LDA,A) On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA \geq max(1,N).

B (input/output)
DOUBLE PRECISION array, dimension (LDB, N) On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB \geq max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL

≥ 1 , and if `JOBVSL = 'V'`, `LDVSL \geq N`.

VSR (input)
 If `JOBVSR = 'V'`, VSR will contain the right Schur vectors. Not referenced if `JOBVSR = 'N'`.

LDVSR (input)
 The leading dimension of the matrix VSR. `LDVSR \geq 1`, and if `JOBVSR = 'V'`, `LDVSR \geq N`.

WORK (workspace)
 On exit, if `INFO = 0`, `WORK(1)` returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. `LWORK \geq 8*N+16`.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK (workspace)
 dimension(N) Not referenced if `SORT = 'N'`.

INFO (output)
 = 0: successful exit
 < 0: if `INFO = -i`, the i-th argument had an illegal value.
 = 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but `ALPHAR(j)`, `ALPHAI(j)`, and `BETA(j)` should be correct for `j=INFO+1,...,N`.
 > N: =N+1: other than QZ iteration failed in SHGEQZ.
 =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy `DELCTG=.TRUE.` This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

```

PURPOSE

dggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$A,B = ((VSL) S (VSR)^{*}T, (VSL) T (VSR)^{*}T)$$

Optionally, it also orders the eigenvalues so that a

selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α,β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
'S': Eigenvalues are ordered (see DELCTG).

DELCTG (input)

LOGICAL FUNCTION of three DOUBLE PRECISION arguments DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j) + \text{ALPHAI}(j))/\text{BETA}(j)$ is selected if $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of

eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $\text{DELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j)) = \text{.TRUE.}$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
 = 'E' : Computed for average of selected eigenvalues only;
 = 'V' : Computed for selected deflating subspaces only;
 = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N \geq 0.

A (input/output)

DOUBLE PRECISION array, dimension(LDA,N) On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)

The leading dimension of A. LDA \geq max(1,N).

B (input/output)

DOUBLE PRECISION array, dimension(LDB,N) On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)

The leading dimension of B. LDB \geq max(1,N).

SDIM (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)

DOUBLE PRECISION array, dimension(N) On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $\text{ALPHAR}(j) + \text{ALPHAI}(j)*i$ and $\text{BETA}(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-

th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)

DOUBLE PRECISION array, dimension(N) See the description for ALPHAR.

BETA (output)

DOUBLE PRECISION array, dimension(N) See the description for ALPHAR.

VSL (input)

DOUBLE PRECISION array, dimension(LDVSL,N) If $\text{JOBVSL} = 'V'$, VSL will contain the left Schur vectors. Not referenced if $\text{JOBVSL} = 'N'$.

LDVSL (input)

The leading dimension of the matrix VSL. $\text{LDVSL} \geq 1$, and if $\text{JOBVSL} = 'V'$, $\text{LDVSL} \geq N$.

VSR (input)

DOUBLE PRECISION array, dimension(LDVSR,N) If $\text{JOBVSR} = 'V'$, VSR will contain the right Schur vectors. Not referenced if $\text{JOBVSR} = 'N'$.

LDVSR (input)

The leading dimension of the matrix VSR. $\text{LDVSR} \geq 1$, and if $\text{JOBVSR} = 'V'$, $\text{LDVSR} \geq N$.

RCONDE (output)

If $\text{SENSE} = 'E'$ or $'B'$, $\text{RCONDE}(1)$ and $\text{RCONDE}(2)$ contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if $\text{SENSE} = 'N'$ or $'V'$.

RCONDV (output)

If $\text{SENSE} = 'V'$ or $'B'$, $\text{RCONDV}(1)$ and $\text{RCONDV}(2)$ contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if $\text{SENSE} = 'N'$ or $'E'$.

WORK (workspace)

DOUBLE PRECISION array, dimension(LWORK) On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $\text{LWORK} \geq$

8*(N+1)+16. If SENSE = 'E', 'V', or 'B', LWORK >= MAX(8*(N+1)+16, 2*SDIM*(N-SDIM)).

IWORK (workspace)
INTEGER array, dimension(LIWORK) Not referenced if SENSE = 'N'.

LIWORK (input)
The dimension of the array WORK. LIWORK >= N+6.

BWORK (workspace)
LOGICAL array, dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N:
=N+1: other than QZ iteration failed in SHGEQZ
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Further details =====

An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is

$EPS * \text{norm}((A, B)) / RCONDE(1)$.

An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is

$EPS * \text{norm}((A, B)) / RCONDV(2)$.

See LAPACK User's Guide, section 4.11 for more information.

#include <sunperf.h>

void dggev(char jobvl, char jobvr, int n, double *a, int
           lda, double *b, int ldb, double *alphar, double
           *alphai, double *beta, double *vl, int ldvl, dou-
           ble *vr, int ldvr, int *info);
void dggev_64(char jobvl, char jobvr, long n, double *a,
              long lda, double *b, long ldb, double *alphar,
              double *alphai, double *beta, double *vl, long
              ldvl, double *vr, long ldvr, long *info);

```

PURPOSE

dggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^{**H} * A = \lambda(j) * u(j)^{**H} * B.$$

where $u(j)^{**H}$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

```

JOBVL (input)
    = 'N': do not compute the left generalized eigen-
           vectors;
    = 'V': compute the left generalized eigenvectors.

JOBVR (input)
    = 'N': do not compute the right generalized

```

```

eigenvectors;
= 'V': compute the right generalized eigenvec-
tors.

N (input) The order of the matrices A, B, VL, and VR.  N >=
0.

A (input/output)
    On entry, the matrix A in the pair (A,B).  On
    exit, A has been overwritten.

LDA (input)
    The leading dimension of A.  LDA >= max(1,N).

B (input/output)
    On entry, the matrix B in the pair (A,B).  On
    exit, B has been overwritten.

LDB (input)
    The leading dimension of B.  LDB >= max(1,N).

ALPHAR (output)
    On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j),
    j=1,...,N, will be the generalized eigenvalues.
    If ALPHAI(j) is zero, then the j-th eigenvalue is
    real; if positive, then the j-th and (j+1)-st
    eigenvalues are a complex conjugate pair, with
    ALPHAI(j+1) negative.

    Note: the quotients ALPHAR(j)/BETA(j) and
    ALPHAI(j)/BETA(j) may easily over- or underflow,
    and BETA(j) may even be zero.  Thus, the user
    should avoid naively computing the ratio
    alpha/beta.  However, ALPHAR and ALPHAI will be
    always less than and usually comparable with
    norm(A) in magnitude, and BETA always less than
    and usually comparable with norm(B).

ALPHAI (output)
    See the description for ALPHAR.

BETA (output)
    See the description for ALPHAR.

VL (input)
    If JOBVL = 'V', the left eigenvectors u(j) are
    stored one after another in the columns of VL, in
    the same order as their eigenvalues.  If the j-th
    eigenvalue is real, then u(j) = VL(:,j), the j-th
    column of VL.  If the j-th and (j+1)-th eigenvalues
    form a complex conjugate pair, then u(j) =
    VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-
    i*VL(:,j+1).  Each eigenvector will be scaled so

```

the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if `JOBVL = 'N'`.

`LDVL` (input)

The leading dimension of the matrix `VL`. `LDVL` ≥ 1 , and if `JOBVL = 'V'`, `LDVL` $\geq N$.

`VR` (input)

If `JOBVR = 'V'`, the right eigenvectors $v(j)$ are stored one after another in the columns of `VR`, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = \text{VR}(:,j)$, the j -th column of `VR`. If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = \text{VR}(:,j) + i * \text{VR}(:,j+1)$ and $v(j+1) = \text{VR}(:,j) - i * \text{VR}(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if `JOBVR = 'N'`.

`LDVR` (input)

The leading dimension of the matrix `VR`. `LDVR` ≥ 1 , and if `JOBVR = 'V'`, `LDVR` $\geq N$.

`WORK` (workspace)

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LWORK`.

`LWORK` (input)

The dimension of the array `WORK`. `LWORK` $\geq \max(1, 8 * N)$. For good performance, `LWORK` must generally be larger.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

`INFO` (output)

`= 0`: successful exit
`< 0`: if `INFO = -i`, the i -th argument had an illegal value.
`= 1, ..., N`: The QZ iteration failed. No eigenvectors have been calculated, but `ALPHAR(j)`, `ALPHAI(j)`, and `BETA(j)` should be correct for $j = \text{INFO} + 1, \dots, N$.
`> N`: `= N + 1`: other than QZ iteration failed in `SHGEQZ`.
`= N + 2`: error return from `STGEVC`.

```

PURPOSE

dggevz computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j) .$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^{**H} * A = \lambda(j) * u(j)^{**H} * B .$$

where $u(j)^{**H}$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

BALANC (input)

Specifies the balance option to be performed. =
 'N': do not diagonally scale or permute;
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;
 = 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;
 = 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;
 = 'E': computed for eigenvalues only;
 = 'V': computed for eigenvectors only;

= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
 On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA (input)
 The leading dimension of A. LDA >= max(1,N).

B (input/output)
 On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB (input)
 The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
 On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
 See the description of ALPHAR.

BETA (output)
 See the description of ALPHAR.

VL (output)
 If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then $u(j) = \text{VL}(:,j)$, the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then $u(j) =$

$VL(:,j)+i*VL(:,j+1)$ and $u(j+1) = VL(:,j)-i*VL(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $JOBVL = 'N'$.

LDVL (input)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

VR (output)

If $JOBVR = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j)+i*VR(:,j+1)$ and $v(j+1) = VR(:,j)-i*VR(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

LDVR (input)

The leading dimension of the matrix VR. $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

ILO (output)

ILO and IHI are integer values such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If $BALANC = 'N'$ or $'S'$, $ILO = 1$ and $IHI = N$.

IHI (output)

See the description of ILO.

LSCALE (output)

Details of the permutations and scaling factors applied to the left side of A and B. If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then $LSCALE(j) = PL(j)$ for $j = 1, \dots, ILO-1$ and $LSCALE(j) = DL(j)$ for $j = ILO, \dots, IHI$. If $JOBPL = 'V'$, $PL(j) = PL(j)$ for $j = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

RSCALE (output)

Details of the permutations and scaling factors applied to the right side of A and B. If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then $RSCALE(j) = PR(j)$ for $j = 1, \dots, ILO-1$ and $RSCALE(j) = DR(j)$ for $j = ILO, \dots, IHI$. If $JOBPR = 'V'$, $PR(j) = PR(j)$ for $j = IHI+1, \dots, N$. The order in which the inter-

changes are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)

The one-norm of the balanced matrix A.

BBNRM (output)

The one-norm of the balanced matrix B.

RCONDE (output)

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)

If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq \max(1, 6*N)$. If SENSE = 'E', LWORK $\geq 12*N$. If SENSE = 'V' or 'B', LWORK $\geq 2*N*N + 12*N + 16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)

dimension(N+6) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)

dimension(N) If SENSE = 'N', BWORK is not referenced.

```

INFO (output)
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:  The QZ iteration failed.  No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in SHGEQZ.
  =N+2: error return from STGEVC.

```

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{RCONDE}(I)$$

An approximate error bound for the angle between the i-th computed eigenvector $\text{VL}(i)$ or $\text{VR}(i)$ is given by

$$\text{PS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{DIF}(i).$$

For further explanation of the reciprocal condition numbers RCONDE and RCONDV , see section 4.11 of LAPACK User's Guide.

```

C INTERFACE

```
#include <sunperf.h>

void dggglm(int n, int m, int p, double *a, int lda, double
           *b, int ldb, double *d, double *x, double *y, int
           *info);

void dggglm_64(long n, long m, long p, double *a, long lda,
              double *b, long ldb, double *d, double *x, double
              *y, long *info);
```

PURPOSE

dggglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad ||y||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad ||\text{inv}(B)*(d-A*x)||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $0 \leq M \leq N$.

P (input) The number of columns of the matrix B. $P \geq N-M$.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
On exit, X and Y are the solutions of the GLM problem.

Y (output)
See the description of X.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK \geq max(1,N+M+P). For optimum performance, LDWORK \geq M+min(N,P)+max(N,P)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

```

C INTERFACE

```
#include <sunperf.h>
```

```

void dgghrd(char compq, char compz, int n, int ilo, int ihi,
            double *a, int lda, double *b, int ldb, double *q,
            int ldq, double *z, int ldz, int *info);

```

```

void dgghrd_64(char compq, char compz, long n, long ilo,
               long ihi, double *a, long lda, double *b, long
               ldb, double *q, long ldq, double *z, long ldz,
               long *info);

```

PURPOSE

dgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1 * Q) * H * (Z1 * Z)'$$

ARGUMENTS

COMPQ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)

= 'N': do not compute Z;
 = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1*Z is returned.

N (input) The order of the matrices A and B. N >= 0.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input/output)

On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

LDB (input)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

Q (input/output)

If $\text{COMPQ}='N'$: Q is not referenced.
If $\text{COMPQ}='I'$: on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If $\text{COMPQ}='V'$: on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by $Q1*Q$.

LDQ (input)

The leading dimension of the array Q. $\text{LDQ} \geq N$ if $\text{COMPQ}='V'$ or $'I'$; $\text{LDQ} \geq 1$ otherwise.

Z (input/output)

If $\text{COMPZ}='N'$: Z is not referenced.
If $\text{COMPZ}='I'$: on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of the Givens transformations which are applied to A and B on the right. If $\text{COMPZ}='V'$: on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by $Z1*Z$.

LDZ (input)

The leading dimension of the array Z. LDZ \geq N if
COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in Matrix Computations, by Golub and Van Loan (Johns Hopkins Press.)

```

```
SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],  
                   [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO  
REAL(8), DIMENSION(:) :: C, D, X, WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dgglse(int m, int n, int p, double *a, int lda, double
            *b, int ldb, double *c, double *d, double *x, int
            *info);

void dgglse_64(long m, long n, long p, double *a, long lda,
               double *b, long ldb, double *c, double *d, double
               *x, long *info);
```

PURPOSE

dgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } ||c - A*x||_2 \quad \text{subject to} \quad B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that

$P \leq N \leq M+P$, and

$$\text{rank}(B) = P \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

P (input) The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, P)$.

C (input/output)
 On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements $N-P+1$ to M of vector C.

D (input/output)
 On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
 On exit, X is the solution of the LSE problem.

WORK (workspace)
 On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. $LDWORK \geq \max(1, M+N+P)$. For optimum performance $LDWORK \geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit.
 < 0: if $INFO = -i$, the i -th argument had an illegal value.

                    [WORK], [LWORK], [INFO])
```

```
INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, TAUB, WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dggqrf(int n, int m, int p, double *a, int lda, double
           *taua, double *b, int ldb, double *taub, int
           *info);

void dggqrf_64(long n, long m, long p, double *a, long lda,
              double *taua, double *b, long ldb, double *taub,
              long *info);
```

PURPOSE

dggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q \cdot R, \quad B = Q \cdot T \cdot Z,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

$$\begin{array}{l} \text{if } N \geq M, \quad R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} M \\ N-M \end{matrix}, \quad \text{or if } N < M, \quad R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} N \\ M-N \end{matrix} \\ \text{where } R_{11} \text{ is upper triangular, and} \end{array}$$

$$\begin{array}{l} \text{if } N \leq P, \quad T = \begin{pmatrix} 0 & T_{12} \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } N > P, \quad T = \begin{pmatrix} T_{11} & \\ & T_{21} \end{pmatrix} \begin{matrix} P \\ P \end{matrix} \\ \text{where } T_{12} \text{ or } T_{21} \text{ is upper triangular.} \end{array}$$

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B) \cdot A$:

$$\text{inv}(B) \cdot A = Z' \cdot (\text{inv}(T) \cdot R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $M \geq 0$.

P (input) The number of columns of the matrix B. $P \geq 0$.

A (input/output)

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAU A, represent the orthogonal matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

TAU A (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the $(N-P)$ -th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAU B, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

TAU B (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1,N,M,P)$. For optimum performance $LWORK \geq \max(N,M,P) * \max(NB1,NB2,NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of SORMQR.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(n, m).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}a * v * v'$$

where $\text{tau}a$ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i+1:n, i)$, and $\text{tau}a$ in $\text{TAUA}(i)$.

To form Q explicitly, use LAPACK subroutine SORGQR.

To use Q to update another matrix, use LAPACK subroutine SORMQR.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}b * v * v'$$

where $\text{tau}b$ is a real scalar, and v is a real vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(n-k+i, 1:p-k+i-1)$, and $\text{tau}b$ in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine SORGRQ.

To use Z to update another matrix, use LAPACK subroutine SORMRQ.

REAL(8), DIMENSION(:) :: TAU, TAUB, WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dggrqf(int m, int p, int n, double *a, int lda, double
            *taua, double *b, int ldb, double *taub, int
            *info);

void dggrqf_64(long m, long p, long n, double *a, long lda,
               double *taua, double *b, long ldb, double *taub,
               long *info);
```

PURPOSE

dggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

$$\begin{array}{l} \text{if } M \leq N, \quad R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} \begin{matrix} M \\ M-N \end{matrix}, \quad \text{or if } M > N, \quad R = \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix} \begin{matrix} M \\ N \end{matrix} \\ \text{where } R_{12} \text{ or } R_{21} \text{ is upper triangular, and} \end{array}$$

$$\begin{array}{l} \text{if } P \geq N, \quad T = \begin{pmatrix} T_{11} \\ 0 \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } P < N, \quad T = \begin{pmatrix} T_{11} & T_{12} \\ 0 & 0 \end{pmatrix} \begin{matrix} N \\ P \end{matrix} \\ \text{where } T_{11} \text{ is upper triangular.} \end{array}$$

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = (R \cdot \text{inv}(T)) \cdot Z'$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. N

≥ 0 .

A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU A, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU A (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P, N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAU B, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

TAU B (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO= -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}a * v * v'$$

where $\text{tau}a$ is a real scalar, and v is a real vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and $\text{tau}a$ in $\text{TAUA}(i)$. To form Q explicitly, use LAPACK subroutine SORGRQ. To use Q to update another matrix, use LAPACK subroutine SORMRQ.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(p,n).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}b * v * v'$$

where $\text{tau}b$ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i+1:p,i)$, and $\text{tau}b$ in $\text{TAUB}(i)$. To form Z explicitly, use LAPACK subroutine SORGQR. To use Z to update another matrix, use LAPACK subroutine SORMQR.

               *q, long ldq, long *iwork3, long *info);
```

PURPOSE

dggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix}$$

where U, V and Q are orthogonal matrices, and Z' is the transpose of Z. Let K+L = the effective numerical rank of the matrix (A', B')', then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D1 = \begin{matrix} & & K & L \\ & K & \begin{pmatrix} I & 0 \end{pmatrix} \\ & L & \begin{pmatrix} 0 & C \end{pmatrix} \\ M-K-L & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & & K & L \\ & L & \begin{pmatrix} 0 & S \end{pmatrix} \\ P-L & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & & N-K-L & K & L \\ K & \begin{pmatrix} 0 & R11 & R12 \end{pmatrix} \\ L & \begin{pmatrix} 0 & 0 & R22 \end{pmatrix} \end{matrix}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1), ... , BETA(K+L) ),
C**2 + S**2 = I.

```

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If $M-K-L < 0$,

$$\begin{aligned}
 D1 &= \begin{matrix} & K & M-K & K+L-M \\ K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{matrix} \\
 D2 &= \begin{matrix} & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \end{matrix} \\
 \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{matrix} & N-K-L & K & M-K & K+L-M \\ K & (0 & R11 & R12 & R13) \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{matrix}
 \end{aligned}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1), ... , BETA(M) ),
C**2 + S**2 = I.

```

(R11 R12 R13) is stored in A(1:M, N-K-L+1:N), and R33 is stored
 (0 R22 R23)
 in B(M-K+1:L,N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V'.$$

If (A', B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' \cdot A \cdot x = \text{lambda} \cdot B' \cdot B \cdot x.$$

In some literature, the GSVD of A and B is presented in the form

$$U' \cdot A \cdot X = \begin{pmatrix} 0 & D1 \end{pmatrix}, \quad V' \cdot B \cdot X = \begin{pmatrix} 0 & D2 \end{pmatrix}$$

where U and V are orthogonal and X is nonsingular, D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$\begin{aligned}
 X &= Q \cdot \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix} \\
 &\quad \begin{pmatrix} 0 & \text{inv}(R) \end{pmatrix}.
 \end{aligned}$$

ARGUMENTS

JOBV (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in the Purpose section. $K + L =$ effective numerical rank of $(A', B')'$.

L (output)
See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if $M - K - L < 0$. See Purpose for details.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $BETA(1:K) = 0$, and if $M - K - L \geq 0$, $ALPHA(K+1:K+L) = C$,
 $BETA(K+1:K+L) = S$, or if $M - K - L < 0$,
 $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$
 $BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and
 $ALPHA(K+L+1:N) = 0$

BETA(K+L+1:N) = 0

BETA (output)

See the description of ALPHA.

U (output)

If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)

If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)

If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)

dimension (max(3*N,M,P)+N)

IWORK3 (output)

dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

C INTERFACE

```

#include <sunperf.h>

void dggsvp(char jobv, char jobq, int m, int p,
    int n, double *a, int lda, double *b, int ldb,
    double tola, double tol, int *k, int *l, double
    *u, int ldu, double *v, int ldv, double *q, int
    ldq, int *info);

void dggsvp_64(char jobv, char jobq, long m, long
    p, long n, double *a, long lda, double *b, long
    ldb, double tola, double tol, long *k, long *l,
    double *u, long ldu, double *v, long ldv, double
    *q, long ldq, long *info);

```

PURPOSE

dggsvp computes orthogonal matrices U, V and Q such that

$$\begin{array}{c}
 \begin{array}{ccc}
 & L & (\begin{array}{ccc} 0 & 0 & A23 \end{array}) \\
 M-K-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array} \\
 \\
 = \begin{array}{ccc}
 & N-K-L & K & L \\
 K & (\begin{array}{ccc} 0 & A12 & A13 \end{array}) & \text{if } M-K-L < 0; \\
 M-K & (\begin{array}{ccc} 0 & 0 & A23 \end{array})
 \end{array} \\
 \\
 \begin{array}{ccc}
 & N-K-L & K & L \\
 V' * B * Q = & L & (\begin{array}{ccc} 0 & 0 & B13 \end{array}) \\
 P-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array}
 \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L ≥ 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix (A',B')'. Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine DGGSD.

ARGUMENTS

JOBV (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See the description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-

blocks described in Purpose. $K + L$ = effective numerical rank of (A', B') .

L (output)

See the description of K.

U (input) If JOBU = 'U', U contains the orthogonal matrix U.
If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq \max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

V (input) If JOBV = 'V', V contains the orthogonal matrix V.
If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. $LDV \geq \max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

Q (input) If JOBQ = 'Q', Q contains the orthogonal matrix Q.
If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

IWORK (workspace)

dimension(N)

TAU (workspace)

dimension(N)

WORK (workspace)

dimension($\max(3*N, M, P)$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine SGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

- [PURPOSE](#)
- [PARAMETERS](#)

NAME

dgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE DGSSCO ( COND, HANDLE, IER )
```

```
INTEGER          IER
DOUBLE PRECISION COND
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSCO - Condition number estimate.

PARAMETERS

COND - DOUBLE PRECISION

On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, [DGSSFA\(\)](#).

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE\(*\)](#) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-700 : Invalid calling sequence - need to call DGSSFA first.

-710 : Condition number estimate not available (not implemented for this HANDLE's matrix type).

NAME

dgssda - Deallocate working storage for the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSDA ( HANDLE, IER )
```

```
INTEGER                IER  
DOUBLE PRECISION      HANDLE(150)
```

PURPOSE

ZGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

- [PARAMETERS](#)

NAME

dgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE DGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )
```

```
INTEGER          NEQNS, COLSTR(*), ROWIND(*), IER  
DOUBLE PRECISION VALUES(*)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER
On entry, **NEQNS** specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, **COLSTR**(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, **ROWIND**(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array
On entry, **VALUES**(*) is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on

exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-300 : Invalid calling sequence - need to call DGSSOR first.

-301 : Failure to dynamically allocate memory.

-666 : Internal error.

NAME

dgssfs - General sparse solver one call interface.

SYNOPSIS

```
SUBROUTINE DGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,  
                   VALUES, NRHS , RHS , LDRHS , ORDMTHD,  
                   OUTUNT, MSGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,  
                OUTUNT, MSGLVL, IER  
CHARACTER*3      ORDMTHD  
DOUBLE PRECISION VALUES(*), RHS(*)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSFS - General sparse solver one call interface.

PARAMETERS

MTXTYP - CHARACTER*2

On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

```
'sp' or 'SP' - symmetric structure, positive-definite values  
'ss' or 'SS' - symmetric structure, symmetric values  
'su' or 'SU' - symmetric structure, unsymmetric values  
'uu' or 'UU' - unsymmetric structure, unsymmetric values
```

Unchanged on exit.

PIVOT - CHARACTER*1

On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization.
The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one.
Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, *COLSTR*(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, *ROWIND*(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array

On entry, *VALUES*(*) is an array of size COLSTR(NEQNS+1)-1, containing the non-zero numeric values of the sparse matrix to be factored.
Unchanged on exit.

NRHS - INTEGER

On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(*) - DOUBLE PRECISION array

On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER

On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver.
Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see DGSSUO)

Unchanged on exit.

OUTUNT - INTEGER
Output unit. Unchanged on exit.

MSGLVL - INTEGER
Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array of containing
information needed by the solver, and must be passed
unchanged to each sparse solver subroutine.
Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on
exit. If error encountered, it is set to a non-zero
integer. Error numbers set by this subroutine:

- 101 : Failure to dynamically allocate memory.
- 102 : Invalid matrix type.
- 103 : Invalid pivot option.
- 104 : Number of nonzeros is less than NEQNS.
- 105 : NEQNS < 1
- 106 : Invalid matrix structure.
- 201 : Failure to dynamically allocate memory.
- 301 : Failure to dynamically allocate memory.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS
- 666 : Internal error.

Contents

- [NAME](#)
- [SYNOPSIS](#)
- [PURPOSE](#)
- [PARAMETERS](#)

NAME

dgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,  
                  MSGGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGGLVL, IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

 'sp' or 'SP' - symmetric structure, positive-definite values
 'ss' or 'SS' - symmetric structure, symmetric values
 'su' or 'SU' - symmetric structure, unsymmetric values
 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one.
Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, COLSTR(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, ROWIND(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine.
Modified on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGLVL - INTEGER

Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.
-105 : NEQNS < 1
-106 : Invalid matrix structure.

NAME

dgssor - General sparse solver ordering and symbolic factorization.

SYNOPSIS

```
SUBROUTINE DGSSOR ( ORDMTHD, HANDLE, IER )
```

```
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see DGSSUO)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 200 : Invalid calling sequence - need to call DGSSIN first.
- 201 : Failure to dynamically allocate memory.
- 666 : Internal error.

Contents

NAME

dgssps - Print general sparse solver statics.

SYNOPSIS

```
SUBROUTINE DGSSPS ( HANDLE, IER )
```

```
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-800 : Invalid calling sequence - need to call DGSSSL first.
-899 : Printed solver statistics not supported this release.

Contents

NAME

dgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSRP ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call DGSSOR first.

Contents

NAME

dgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )
```

```
INTEGER          NRHS, LDRHS, IER  
DOUBLE PRECISION RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER
On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - DOUBLE PRECISION array
On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call DGSSFA first.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS

Contents

NAME

dgssuo - User supplied permutation for ordering used in the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSUO ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSUO - User supplied permutation for ordering. Must be called after [DGSSIN\(\)](#) (sparse solver initialization) and before [DGSSOR\(\)](#) (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array

On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call DGSSIN first.

INTEGER IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION LOW(*), D(*), UP1(*), UP2(*), WORK(*)
```

```
SUBROUTINE DGICON_64(NORM, N, LOW, D, UP1, UP2, IPIVOT, ANORM,  
                     RCOND, WORK, IWORK2, INFO)
```

```
CHARACTER * 1 NORM  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION LOW(*), D(*), UP1(*), UP2(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GTCON(NORM, [N], LOW, D, UP1, UP2, IPIVOT, ANORM,  
                 RCOND, [WORK], [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND
```

```

REAL(8), DIMENSION(:) :: LOW, D, UP1, UP2, WORK

SUBROUTINE GTCON_64(NORM, [N], LOW, D, UP1, UP2, IPIVOT, ANORM,
                   RCOND, [WORK], [IWORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: LOW, D, UP1, UP2, WORK

```

C INTERFACE

```

#include <sunperf.h>
void dgtcon(char norm, int n, double *low, double *diag,
            double *up1, double *up2, int *ipivot, double
            anorm, double *rcond, int *info);

void dgtcon_64(char norm, long n, double *low, double *diag,
               double *up1, double *up2, long *ipivot, double
               anorm, double *rcond, long *info);

```

PURPOSE

dgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by DGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

LOW (input)
 The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

D (input) The n diagonal elements of the upper triangular

matrix U from the LU factorization of A.

UP1 (input)

The (n-1) elements of the first superdiagonal of U.

UP2 (input)

The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension(2*N)

IWORK2 (workspace)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dgthr - Gathers specified elements from y into x.

SYNOPSIS

```
SUBROUTINE DGTHR(NZ, Y, X, INDX)
```

```
DOUBLE PRECISION Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE DGTHR_64(NZ, Y, X, INDX)
```

```
DOUBLE PRECISION Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE GTHR([NZ], Y, X, INDX)
```

```
  REAL(8), DIMENSION(:) :: Y, X  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE GTHR_64([NZ], Y, X, INDX)
```

```
  REAL(8), DIMENSION(:) :: Y, X  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only

the elements of `y` whose indices are listed in `indx` are referenced.

```
do i = 1, n
    x(i) = y(indx(i))
enddo
```

ARGUMENTS

`NZ (input)` - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

`Y (input)`

Vector in full storage form. Unchanged on exit.

`X (output)`

Vector in compressed form. Contains elements of `y` whose indices are listed in `indx` on exit.

`INDX (input)` - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in `INDX` are distinct and greater than zero. Unchanged on exit.

NAME

dgthrz - Gather and zero.

SYNOPSIS

```
SUBROUTINE DGTHRZ(NZ, Y, X, INDX)
```

```
DOUBLE PRECISION Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE DGTHRZ_64(NZ, Y, X, INDX)
```

```
DOUBLE PRECISION Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE GTHRZ([NZ], Y, X, INDX)
```

```
REAL(8), DIMENSION(:) :: Y, X  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)
```

```
REAL(8), DIMENSION(:) :: Y, X  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The

gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)

Vector in full storage form. Gathered elements are set to zero.

X (output)

Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

    double *b, long ldb, double *x, long ldx, double
    *ferr, double *berr, long *info);

```

PURPOSE

dgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS \geq 0.

LOW (input)
The (n-1) subdiagonal elements of A.

D (input) The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

DF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by DGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution

corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtsv(int n, int nrhs, double *low, double *diag, double *up, double *b, int ldb, int *info);
```

```
void dgtsv_64(long n, long nrhs, double *low, double *diag,
              double *up, double *b, long ldb, long *info);
```

PURPOSE

dgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^*X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

D (input/output)
On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) super-diagonal elements of A.

On exit, UP is overwritten by the (n-1) elements of the first super-diagonal of U.

B (input/output)
On entry, the N by NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N by NRHS
solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, U(i,i) is exactly zero, and the
solution has not been computed. The factorization
has not been completed unless i = N.

```

PURPOSE

dgtsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$, where A is a tridiagonal matrix of order N and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the LU decomposition is used to factor the matrix A

as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

2. If some $U(i,i)=0$, so that U is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision,

$INFO = N+1$ is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form

of A .

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DF, UPF1, UPF2, and IPIVOT contain the factored form of A ; LOW, D, UP, LOWF, DF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DF, and UPF1 and factored.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number

of columns of the matrix B. NRHS ≥ 0 .

LOW (input)

The (n-1) subdiagonal elements of A.

D (input) The n diagonal elements of A.

UP (input/output)

The (n-1) superdiagonal elements of A.

LOWF (input or output)

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by DGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF (input or output)

If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input or output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input or output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by DGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
SUBROUTINE DGTTRF_64(N, LOW, D, UP1, UP2, IPIVOT, INFO)
```

```
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*)  
DOUBLE PRECISION LOW(*), D(*), UP1(*), UP2(*)
```

F95 INTERFACE

```
SUBROUTINE GTTRF([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: LOW, D, UP1, UP2
```

```
SUBROUTINE GTTRF_64([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL(8), DIMENSION(:) :: LOW, D, UP1, UP2
```

C INTERFACE

```
#include <sunperf.h>

void dgttrf(int n, double *low, double *diag, double *up1,
            double *up2, int *ipivot, int *info);

void dgttrf_64(long n, double *low, double *diag, double
               *up1, double *up2, long *ipivot, long *info);
```

PURPOSE

dgttrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D (input/output)

On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or $i+1$; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit
< 0: if INFO = - k , the k -th argument had an illegal value
> 0: if INFO = k , $U(k,k)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

PURPOSE

dgttrs solves one of the systems of equations
 $A * X = B$ or $A' * X = B$, with a tridiagonal matrix A using
the LU factorization computed by DGTTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Trans-
pose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L
from the LU factorization of A.

D (input) The n diagonal elements of the upper triangular
matrix U from the LU factorization of A.

UP1 (input)
 The (n-1) elements of the first super-diagonal of U.

UP2 (input)
 The (n-2) elements of the second super-diagonal of U.

IPIVOT (input)
 The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or $i+1$; IPIVOT(i) = i indicates a row interchange was not required.

B (input/output)
 On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if INFO = - i , the i -th argument had an illegal value

PURPOSE

dhgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal transformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the orthogonal transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

(in) A(in) Z(in)* = Q(out) A(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrixigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

JOB (input)
= 'E': compute only ALPHAR, ALPHAI, and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHAR, ALPHAI, and BETA.

COMPQ (input)
= 'N': do not modify Q.
= 'V': multiply the array Q on the right by the transpose of the orthogonal transformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)
= 'N': do not modify Z.
= 'V': multiply the array Z on the right by the orthogonal transformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. $N \geq 0$.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)
See the description of ILO.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

LDA (input)
The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.) If JOB='S', then on exit A and B will have been simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements

corresponding to diagonal blocks of A will be correct, but the off-diagonal portion will be meaningless.

LDB (input)

The leading dimension of the array B. LDB \geq max(1, N).

ALPHAR (output)

ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=A(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

ALPHAI (output)

ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAI(j)=0. Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

BETA (output)

BETA(1:N) will be set to the (real) diagonal elements of B that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then BETA(j)=B(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB. (Note that BETA(1:N) will always be non-negative, and no BETAI is necessary.)

Q (input/output)

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the transpose of the orthogonal transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)

The leading dimension of the array Q. LDQ >= 1.
If COMPQ='V' or 'I', then LDQ >= N.

Z (input/output)

If COMPZ='N', then Z will not be referenced. If
COMPZ='V' or 'I', then the orthogonal transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1.
If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)

On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

Iteration counters:

JITER -- counts iterations.

IITER -- counts iterations run since ILAST was last changed. This is therefore reset only when a 1-

by-1 or

2-by-2 block deflates off the bottom.

```

PURPOSE

dhsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y .

ARGUMENTS

SIDE (input)

```

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

```

EIGSRC (input)

Specifies the source of eigenvalues supplied in (WR,WI):

```

= 'Q': the eigenvalues were found using DHSEQR;
thus, if H has zero subdiagonal elements, and so
is block-triangular, then the j-th eigenvalue can
be assumed to be an eigenvalue of the block con-
taining the j-th row/column. This property allows
DHSEIN to perform inverse iteration on just one
diagonal block. = 'N': no assumptions are made on

```

the correspondence between eigenvalues and diagonal blocks. In this case, DHSEIN must always perform inverse iteration using the whole matrix H.

INITV (input)

= 'N': no initial vectors are supplied;
= 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT (input/output)

Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to

N (input) The order of the matrix H. $N \geq 0$.

H (input) The upper Hessenberg matrix H.

LDH (input)

The leading dimension of the array H. $LDH \geq \max(1,N)$.

WR (input/output)

On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

WI (input)

See the description of WR.

VL (input/output)

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. $LDVL \geq \max(1,N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ other-

wise.

VR (input/output)

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)

dimension((N+2)*N)

IFAILL (output)

If SIDE = 'L' or 'B', IFAILL(i) = j $>$ 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)

If SIDE = 'R' or 'B', IFAILR(i) = j $>$ 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x|+|y|$.

REAL(8), DIMENSION(:) :: WR, WI, WORK
REAL(8), DIMENSION(:, :) :: H, Z

```

C INTERFACE

```

#include <sunperf.h>

void dhseqr(char job, char compz, int n, int ilo, int ihi,
            double *h, int ldh, double *wr, double *wi, double
            *z, int ldz, int *info);
void dhseqr_64(char job, char compz, long n, long ilo, long
            ihi, double *h, long ldh, double *wr, double *wi,
            double *z, long ldz, long *info);

```

PURPOSE

dhseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q , so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q^*H^*Q^{**T} = (QZ)^*T^*(QZ)^{**T}$.

ARGUMENTS

JOB (input)
 = 'E': compute eigenvalues only;
 = 'S': compute eigenvalues and the Schur form T .

COMPZ (input)
 = 'N': no Schur vectors are computed;
 = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; =
 = 'V': Z must contain an orthogonal matrix Q on entry, and the product Q^*Z is returned.

N (input) The order of the matrix H . $N \geq 0$.

ILO (input)
 It is assumed that H is already upper triangular in rows and columns $1:ILO-1$ and $IHI+1:N$. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output

by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

H (input/output)

On entry, the upper Hessenberg matrix H. On exit, if $\text{JOB} = 'S'$, H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$. If $\text{JOB} = 'E'$, the contents of H are unspecified on exit.

LDH (input)

The leading dimension of the array H. $\text{LDH} \geq \max(1,N)$.

WR (output)

The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with $\text{WI}(i) > 0$ and $\text{WI}(i+1) < 0$. If $\text{JOB} = 'S'$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with $\text{WR}(i) = H(i,i)$ and, if $H(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $\text{WI}(i) = \sqrt{H(i+1,i)*H(i,i+1)}$ and $\text{WI}(i+1) = -\text{WI}(i)$.

WI (output)

See the description of WR.

Z (input) If $\text{COMPZ} = 'N'$: Z is not referenced.

If $\text{COMPZ} = 'I'$: on entry, Z need not be set, and on exit, Z contains the orthogonal matrix Z of the Schur vectors of H. If $\text{COMPZ} = 'V'$: on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the sub-matrix $Z(\text{ILO}:\text{IHI}, \text{ILO}:\text{IHI})$; on exit Z contains $Q*Z$. Normally Q is the orthogonal matrix generated by DORGHR after the call to SGEHRD which formed the Hessenberg matrix H.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq \max(1,N)$ if $\text{COMPZ} = 'I'$ or $'V'$; $\text{LDZ} \geq 1$ otherwise.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, DHSEQR failed to compute all of the eigenvalues in a total of $30 \cdot (\text{IHI} - \text{ILO} + 1)$ iterations; elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed.

int *iperm, double *b, int ldb, double beta, double *c, int
ldb)
```

```
void djadmm_64(long transa, long m, long n, long k, double
alpha, long *descra, double *val, long *indx, long *pntr,
long maxnz, long *iperm, double *b, long ldb, double beta,
double *c, long ldc);
```

DESCRIPTION

djadmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the jagged diagonal format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A.
 VAL can be viewed as a column major ordering of a
 row permutation of the Ellpack representation of A,
 where the Ellpack representation is permuted so that
 the rows are non-increasing in the number of nonzero
 entries. Values added for padding in Ellpack are
 not included in the Jagged-Diagonal format.
 Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column
 indices of the corresponding entries in VAL.
 Unchanged on exit.

PNTR(input) On entry, PNTR is an integer array of length
 MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to
 the location in VAL of the first element
 in the row-permuted Ellpack representation of A.
 Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of
 nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length M
 such that I = IPERM(I'), where row I in the
 original Ellpack representation corresponds
 to row I' in the permuted representation.
 If IPERM(1) = 0, it is assumed by convention that
 IPERM(I) = I. IPERM is used to determine the order
 in which rows of C are updated. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading k by n
 part of the array B must contain the matrix B, otherwise
 the leading m by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n
 part of the array C must contain the matrix C, otherwise

the leading k by n part of the array C must contain the matrix C . On exit, the array C is overwritten by the matrix $(\alpha * \text{op}(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

```
SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                IPERM, [WORK], [LWORK] )
INTEGER TRANSP, M, K, MAXNZ
INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
DOUBLE PRECISION, DIMENSION(:) :: VAL

SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                IPERM, [WORK], [LWORK] )
INTEGER*8 TRANSP, M, K, MAXNZ
INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
DOUBLE PRECISION, DIMENSION(:) :: VAL
```

C INTERFACE

```
#include <sunperf.h>
```

```
void djadrp (int transp, int m, int k, double *val, int
*indx, int *pntr, int maxnz, int *iperm);
```

```
void djadrp_64 (long transp, long m, long k, double *val,
long *indx, long *pntr, long maxnz, long *iperm);
```

DESCRIPTION

djadrp performs one of the matrix-matrix operations

```
A <- A P    or    A <- A P'
                                ( ' indicates matrix transpose)
```

where A is an M-by-K sparse matrix represented in the jagged diagonal format, the permutation matrix P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symmetrically permuted jagged diagonal matrix $P A P'$, one can explicitly permute the columns P A by calling

```
DJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP(input)	TRANSP indicates how to operate with the permutation matrix: 0 : operate with matrix 1 : operate with transpose matrix Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
VAL(input/output)	On entry, VAL is a scalar array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format. On exit, VAL contains non-zero entries of the output permuted jagged diagonal matrix.
INDX(input/output)	On entry, INDX is an integer array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of the column indices of the corresponding entries in VAL. On exit, INDX is overwritten by the column indices of the output permuted jagged diagonal matrix.

PNTR(input) On entry, PNTR is an integer array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length K such that $I = IPERM(I')$. Array IPERM represents a permutation P, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P. For example, if

$$P = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

then IPERM = (3, 1, 2). Unchanged on exit.

WORK(workspace) Scratch array of length LWORK. LWORK should be at least K.

LWORK(input) On entry, LWORK specifies the length of the array WORK. If LWORK=0, the routine is to allocate workspace needed. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

DOUBLE PRECISION, DIMENSION(:, :) :: B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void djadsm (int transa, int m, int n, int unitd, double  
*dv, double alpha, int *descra, double *val, int *indx, int  
*pntr, int maxnz, int *iperm, double *b, int ldb, double  
beta, double *c, int ldc)  
void djadsm_64(long transa, long m, long n, long unitd,  
double *dv, double alpha, long *descra, double *val, long  
*indx, long *pntr, long maxnz, long *iperm, double *b, long  
ldb, double beta, double *c, long ldc);
```

DESCRIPTION

djadsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices,
D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit,
upper or lower triangular matrix represented in the jagged-diagonal format
and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which

the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A.
VAL can be viewed as a column major ordering of a
row permutation of the Ellpack representation of A,
where the Ellpack representation is permuted so that
the rows are non-increasing in the number of nonzero
entries. Values added for padding in Ellpack are
not included in the Jagged-Diagonal format.
Unchanged on exit if UNITD is not equal to 4.

INDX(input) On entry, INDX is an integer array of length
NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column
indices of the corresponding entries in VAL.
Unchanged on exit.

PNTR(input) On entry, PNTR is an integer array of length
MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to
the location in VAL of the first element
in the row-permuted Ellpack representation of A.
Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of
nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length M
such that I = IPERM(I'), where row I in the
original Ellpack representation corresponds
to row I' in the permuted representation.
If IPERM(1) = 0, it is assumed by convention that
IPERM(I) = I. IPERM is used to determine the order
in which rows of C are updated. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B

must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least 2*M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, $LWORK \geq 2 \cdot M \cdot N_{CPUS}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:
<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of the sparse matrix A such that their 2-norms are one. The scaling may

improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = - i` where `i` is the row number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the JAD representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

NAME

dlagtf - factorize the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T - \lambda I = PLU$

SYNOPSIS

```
SUBROUTINE DLAGTF(N, A, LAMBDA, B, C, TOL, D, IN, INFO)
```

```
INTEGER N, INFO
INTEGER IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)
```

```
SUBROUTINE DLAGTF_64(N, A, LAMBDA, B, C, TOL, D, IN, INFO)
```

```
INTEGER*8 N, INFO
INTEGER*8 IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)
```

F95 INTERFACE

```
SUBROUTINE LAGTF([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
```

```
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D
```

```
SUBROUTINE LAGTF_64([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
```

```
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
```

```
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>

void dlagtf(int n, double *a, double lambda, double *b, double
            *c, double tol, double *d, int *in, int
            *info);

void dlagtf_64(long n, double *a, double lambda, double *b,
               double *c, double tol, double *d, long *in, long
               *info);
```

PURPOSE

dlagtf factorizes the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter `LAMBDA` is included in the routine so that `SLAGTF` may be used, in conjunction with `SLAGTS`, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

`N` (input) The order of the matrix T .

`A` (input/output)

On entry, `A` must contain the diagonal elements of T .

On exit, `A` is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .

`LAMBDA` (input)

On entry, the scalar λ .

`B` (input/output)

On entry, `B` must contain the $(n-1)$ super-diagonal

elements of T.

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C (input/output)

On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL (input/output)

On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. TOL should normally be chosen as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5×10^{-4} . If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D (output)

On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN (output)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then $IN(k) = 1$, otherwise $IN(k) = 0$. The element $IN(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}(T - \lambda I)(j) * \text{TOL},$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then $IN(n)$ is returned as zero. If $IN(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \lambda I)$ is singular or nearly singular,

INFO (output)

= 0 : successful exit

```

```
INTEGER(8), DIMENSION(:) :: INDEX
```

```
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dlamrg(int n1, int n2, double *a, int trd1, int trd2,
            int *index);

void dlamrg_64(long n1, long n2, double *a, long trd1, long
               trd2, long *index);
```

PURPOSE

dlamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

N1 (input)
Length of the first sequence to be merged.

N2 (input)
Length of the second sequence to be merged.

A (input) On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

TRD1 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

TRD2 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

INDEX (output)
On exit this array will contain a permutation such that if $B(I) = A(\text{INDEX}(I))$ for $I=1, N1+N2$, then B will be sorted in ascending order.

REAL(8), DIMENSION(:) :: V, WORK  
REAL(8), DIMENSION(:,:) :: C
```

```
SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
```

```
CHARACTER(LEN=1) :: SIDE  
INTEGER(8) :: M, N, L, INCV, LDC  
REAL(8) :: TAU  
REAL(8), DIMENSION(:) :: V, WORK
```

```
REAL(8), DIMENSION(:, :) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlarz(char side, int m, int n, int l, double *v, int  
          incv, double tau, double *c, int ldc);
```

```
void dlarz_64(char side, long m, long n, long l, double *v,  
              long incv, double tau, double *c, long ldc);
```

PURPOSE

dlarz applies a real elementary reflector H to a real M -by- N matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where τ is a real scalar and v is a real vector.

If $\tau = 0$, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

SIDE (input)

= 'L': form $H * C$
= 'R': form $C * H$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) The vector v in the representation of H as returned by STZRZF. V is not used if $\tau = 0$.

INCV (input)

The increment between elements of v . INCV $\neq 0$.

TAU (input)

The value τ in the representation of H .

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix $H * C$ if SIDE = 'L', or $C * H$ if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

```

C INTERFACE

```

#include <sunperf.h>

void dlarzb(char side, char trans, char direct, char storev,
            int m, int n, int k, int l, double *v, int ldv,
            double *t, int ldt, double *c, int ldc, int
            ldwork);

void dlarzb_64(char side, char trans, char direct, char
               storev, long m, long n, long k, long l, double *v,
               long ldv, double *t, long ldt, double *c, long
               ldc, long ldwork);

```

PURPOSE

dlarzb applies a real block reflector H or its transpose H^{*T} to a real distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

SIDE (input)
 = 'L': apply H or H' from the Left
 = 'R': apply H or H' from the Right

TRANS (input)
 = 'N': apply H (No transpose)
 = 'C': apply H' (Transpose)

DIRECT (input)
 Indicates how H is formed from a product of elementary reflectors = 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)
 = 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
 Indicates how the vectors which define the elementary reflectors are stored:
 = 'C': Columnwise (not supported yet)
 = 'R': Rowwise

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', $LDV \geq L$; if STOREV = 'R', $LDV \geq K$.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. $LDT \geq K$.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
 $\text{dimension}(\text{MAX}(M, N), K)$

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', $LDWORK \geq \max(1, N)$; if SIDE = 'R', $LDWORK \geq \max(1, M)$.

```
void dlarzt(char direct, char storev, int n, int k, double  
            *v, int ldv, double *tau, double *t, int ldt);
```

```
void dlarzt_64(char direct, char storev, long n, long k,  
               double *v, long ldv, double *tau, double *t, long  
               ldt);
```

PURPOSE

dlarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If DIRECT = 'B', $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

$$H = I - V * T * V'$$

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

$$H = I - V' * T * V$$

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

= 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)

= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
 Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):
 = 'R': rowwise

N (input) The order of the block reflector H. $N \geq 0$.

K (input) The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R'
 The matrix V. See further details.

LDV (input)
 The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i).

T (input) The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT (input)
 The leading dimension of the array T. $LDT \geq K$.

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and
 STOREV = 'R':

$$\begin{array}{rcl}
 & & \text{-----}V\text{-----} \\
 & (\quad v1 \quad v2 \quad v3 \quad) & / \\
 (\quad v1 \quad v2 \quad v3 \quad) & (\quad v1 \quad v1 \quad v1 \quad v1 \quad v1 \quad . \quad . \quad . \quad 1 \\
) & & \\
 V = (\quad v1 \quad v2 \quad v3 \quad) & (\quad v2 \quad v2 \quad v2 \quad v2 \quad v2 \quad . \\
 . \quad . \quad 1 \quad) & &
 \end{array}$$

<pre> (v1 v2 v3) . 1) (v1 v2 v3) . . . 1 . . 1 . 1 </pre>	<pre> (v3 v3 v3 v3 v3 . </pre>
---	---------------------------------------

DIRECT = 'B' and STOREV = 'C': STOREV = 'R':	DIRECT = 'B' and
---	------------------

<pre> 1 . 1 . . 1 v2 v2 v2) . . . v3 v3 v3) . . . (v1 v2 v3) V = (v1 v2 v3) (v1 v2 v3) </pre>	$\frac{\text{-----}V\text{-----}}{/}$ <pre> (1 v1 v1 v1 v1 v1) (. 1 . . . v2 v2 (. . 1 . . v3 v3 </pre>

dlasrt - the numbers in D in increasing order (if ID = 'I')
or in decreasing order (if ID = 'D')

SYNOPSIS

```
SUBROUTINE DLASRT(ID, N, D, INFO)
```

```
CHARACTER * 1 ID  
INTEGER N, INFO  
DOUBLE PRECISION D(*)
```

```
SUBROUTINE DLASRT_64(ID, N, D, INFO)
```

```
CHARACTER * 1 ID  
INTEGER*8 N, INFO  
DOUBLE PRECISION D(*)
```

F95 INTERFACE

```
SUBROUTINE LASRT(ID, [N], D, [INFO])
```

```
CHARACTER(LEN=1) :: ID  
INTEGER :: N, INFO  
REAL(8), DIMENSION(:) :: D
```

```
SUBROUTINE LASRT_64(ID, [N], D, [INFO])
```

```
CHARACTER(LEN=1) :: ID  
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlasrt(char id, int n, double *d, int *info);  
  
void dlasrt_64(char id, long n, double *d, long *info);
```

PURPOSE

dlasrt the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size ≤ 20 . Dimension of STACK limits N to about 2^{32} .

ARGUMENTS

ID (input)
= 'I': sort D in increasing order;
= 'D': sort D in decreasing order.

N (input) The length of the array D.

D (input/output)
On entry, the array to be sorted. On exit, D has been sorted into increasing order ($D(1) \leq \dots \leq D(N)$) or into decreasing order ($D(1) \geq \dots \geq D(N)$), depending on ID.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
void dlatzm(char side, int m, int n, double *v, int incv,  
            double tau, double *c1, double *c2, int ldc);
```

```
void dlatzm_64(char side, long m, long n, double *v, long  
              incv, double tau, double *c1, double *c2, long  
              ldc);
```

PURPOSE

dlatzm routine is deprecated and has been replaced by routine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a matrix.

Let $P = I - \tau u u'$, $u = \begin{pmatrix} 1 \\ v \end{pmatrix}$,

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals $'L'$, let

$$C = \begin{bmatrix} C1 & 1 \\ C2 & m-1 \end{bmatrix}_n$$

Then C is overwritten by $P * C$.

If $SIDE$ equals $'R'$, let

$$C = \begin{bmatrix} C1 & C2 \end{bmatrix}_{\begin{smallmatrix} m \\ 1 \quad n-1 \end{smallmatrix}}$$

Then C is overwritten by $C * P$.

ARGUMENTS

$SIDE$ (input)

= $'L'$: form $P * C$
= $'R'$: form $C * P$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

V (input) $(1 + (M-1)*abs(INCV))$ if $SIDE = 'L'$ $(1 + (N-1)*abs(INCV))$ if $SIDE = 'R'$ The vector v in the representation of P . V is not used if $TAU = 0$.

$INCV$ (input)

The increment between elements of v. INCV \neq 0

TAU (input)

The value tau in the representation of P.

C1 (input/output)

(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)

The leading dimension of the arrays C1 and C2. LDC \geq (1,M).

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

dnrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DNRM2(N, X, INCX)
```

```
INTEGER N, INCX  
DOUBLE PRECISION X(*)
```

```
DOUBLE PRECISION FUNCTION DNRM2_64(N, X, INCX)
```

```
INTEGER*8 N, INCX  
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2([N], X, [INCX])
```

```
INTEGER :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

```
REAL(8) FUNCTION NRM2_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dnrm2(int n, double *x, int incx);
```

```
double dnrm2_64(long n, double *x, long incx);
```

PURPOSE

dnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. If INCX < 1 then DNRM2 returns 0. Unchanged on exit.

```

```
SUBROUTINE OPGTR_64(UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDQ, INFO  
REAL(8), DIMENSION(:) :: AP, TAU, WORK  
REAL(8), DIMENSION(:, :) :: Q
```

C INTERFACE

```
#include <sunperf.h>

void dopgtr(char uplo, int n, double *ap, double *tau, double *q, int ldq, int *info);

void dopgtr_64(char uplo, long n, double *ap, double *tau, double *q, long ldq, long *info);
```

PURPOSE

dopgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage:

if $UPLO = 'U'$, $Q = H(n-1) \dots H(2) H(1)$,

if $UPLO = 'L'$, $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

N (input) The order of the matrix Q . $N \geq 0$.

AP (input)
The vectors which define the elementary reflectors, as returned by SSPTRD.

TAU (input)
 $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSPTRD.

Q (output)
The N -by- N orthogonal matrix Q .

LDQ (input)
The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

WORK (workspace)
dimension($N-1$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION AP(*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE OPMTR(SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],  
[WORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS  
INTEGER :: M, N, LDC, INFO  
REAL(8), DIMENSION(:) :: AP, TAU, WORK  
REAL(8), DIMENSION(:, :) :: C
```

```
SUBROUTINE OPMTR_64(SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],  
[WORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS  
INTEGER(8) :: M, N, LDC, INFO  
REAL(8), DIMENSION(:) :: AP, TAU, WORK
```

```
REAL(8), DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dopmtr(char side, char uplo, char trans, int m, int n,  
            double *ap, double *tau, double *c, int ldc, int  
            *info);
```

```
void dopmtr_64(char side, char uplo, char trans, long m,  
               long n, double *ap, double *tau, double *c, long  
               ldc, long *info);
```

PURPOSE

dopmtr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by SSPTRD
using packed storage:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

UPLO (input)

= 'U': Upper triangular packed storage used in
previous call to SSPTRD; = 'L': Lower triangular
packed storage used in previous call to SSPTRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

AP (input)

($M*(M+1)/2$) if SIDE = 'L' ($N*(N+1)/2$) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

TAU (input)

or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q*C$ or $Q**T*C$ or $C*Q**T$ or $C*Q$.

LDC (input)

The leading dimension of the array C. LDC $\geq \max(1,M)$.

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

void dorg2l_64(long m, long n, long k, double *a, long lda,
              double *tau, long *info);

```

PURPOSE

dorg2l L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA (input)

The first dimension of the array A. LDA >= max(1,M).

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

```
void dorgbr(char vect, int m, int n, int k, double *a, int  
            lda, double *tau, int *info);
```

```
void dorgbr_64(char vect, long m, long n, long k, double *a,  
               long lda, double *tau, long *info);
```

PURPOSE

dorgbr generates one of the real orthogonal matrices Q or P^{**T} determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and DORGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and DORGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{**T} is of order N :

if $k < n$, $P^{**T} = G(k) \dots G(2) G(1)$ and DORGBR returns the first m rows of P^{**T} , where $n \geq m \geq k$;

if $k \geq n$, $P^{**T} = G(n-1) \dots G(2) G(1)$ and DORGBR returns P^{**T} as an N -by- N matrix.

ARGUMENTS

VECT (input)

Specifies whether the matrix Q or the matrix P^{**T} is required, as defined in the transformation applied by SGEBRD:

= 'Q': generate Q ;

= 'P': generate P^{**T} .

M (input) The number of rows of the matrix Q or P^{**T} to be returned. $M \geq 0$.

N (input) The number of columns of the matrix Q or P^{**T} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M, K)$; if $VECT = 'P'$, $N \geq M \geq \min(N, K)$.

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by SGEBRD. $K \geq 0$.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M-by-N matrix Q or P**T.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)
(min(M,K)) if VECT = 'Q' (min(N,K)) if VECT = 'P'
TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**T, as returned by SGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq \max(1, \min(M, N))$. For optimum performance $LWORK \geq \min(M, N) * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD

SYNOPSIS

```
SUBROUTINE DORGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER N, ILO, IHI, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DORGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],  
[INFO])
```

```
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorghr(int n, int ilo, int ihi, double *a, int lda,  
double *tau, int *info);
```

```
void dorghr_64(long n, long ilo, long ihi, double *a, long
               lda, double *tau, long *info);
```

PURPOSE

dorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

N (input) The order of the matrix Q . $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N -by- N orthogonal matrix Q .

LDA (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

TAU (input)

$\text{TAU}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEHRD.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)

The dimension of the array WORK . $\text{LWORK} \geq \text{IHI} - \text{ILO}$. For optimum performance $\text{LWORK} \geq (\text{IHI} - \text{ILO}) * \text{NB}$, where NB is the optimal blocksize.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

void dorgl2_64(long m, long n, long k, double *a, long lda,
              double *tau, long *info);

```

PURPOSE

dorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q . $M \geq 0$.

N (input) The number of columns of the matrix Q . $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

A (input/output)

On entry, the i-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A. On exit, the m-by-n matrix Q .

LDA (input)

The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGELQF.

WORK (workspace)

dimension(M)

INFO (output)

              double *tau, long *info);
```

PURPOSE

dorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q . $M \geq 0$.

N (input) The number of columns of the matrix Q . $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

A (input/output)

On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A . On exit, the M-by-N matrix Q .

LDA (input)

The first dimension of the array A . $LDA \geq \max(1, M)$.

TAU (input)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGELQF.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The dimension of the array $WORK$. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message

related to LDWORK is issued by XERBLA.

              double *tau, long *info);
```

PURPOSE

dorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $M \geq N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

A (input/output)
On entry, the $(n-k+i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQLF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N \cdot NB$, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```

```
void dorgrq_64(long m, long n, long k, double *a, long lda,
               double *tau, long *info);
```

PURPOSE

dorgrq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q . $M \geq 0$.

N (input) The number of columns of the matrix Q . $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

A (input/output)

On entry, the $(m-k+i)$ -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGERQF in the last k rows of its array argument A . On exit, the M-by-N matrix Q .

LDA (input)

The first dimension of the array A . $LDA \geq \max(1, M)$.

TAU (input)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGERQF.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The dimension of the array $WORK$. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message

related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument has an illegal value

```
SUBROUTINE ORGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dorgtr(char uplo, int n, double *a, int lda, double
            *tau, int *info);

void dorgtr_64(char uplo, long n, double *a, long lda, double
               *tau, long *info);

```

PURPOSE

dorgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by SSYTRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A contains elementary reflectors from SSYTRD; = 'L': Lower triangle of A contains elementary reflectors from SSYTRD.

N (input) The order of the matrix Q . $N \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N -by- N orthogonal matrix Q .

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSYTRD.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, N-1)$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               double *c, long ldc, long *info);
```

PURPOSE

dormbr VECT = 'Q', DORMBR overwrites the general real M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'	TRANS = 'N':
Q * C	C * Q	TRANS = 'T':	Q**T * C
Q**T			C * Q**T

If VECT = 'P', DORMBR overwrites the general real M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'
TRANS = 'N':	P * C	C * P
TRANS = 'T':	P**T * C	C * P**T

Here Q and P**T are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P**T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P**T that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix:

```
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).
```

If VECT = 'P', A is assumed to have been a K-by-NQ matrix:

```
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

VECT (input)

```
= 'Q': apply Q or Q**T;
= 'P': apply P or P**T.
```

SIDE (input)
 = 'L': apply Q, Q**T, P or P**T from the Left;
 = 'R': apply Q, Q**T, P or P**T from the Right.

TRANS (input)
 = 'N': No transpose, apply Q or P;
 = 'T': Transpose, apply Q**T or P**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the original matrix reduced by SGEHRD. If VECT = 'P', the number of rows in the original matrix reduced by SGEHRD. K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q' (LDA,nq) if
 VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by SGEHRD.

LDA (input)
 The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq,K)).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by SGEHRD in the array argument TAUQ or TAUH.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q or P*C or P**T*C or C*P or C*P**T.

LDC (input)
 The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R',

where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8), DIMENSION(:, :) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dormhr(char side, char trans, int m, int n, int ilo,  
            int ihi, double *a, int lda, double *tau, double  
            *c, int ldc, int *info);
```

```
void dormhr_64(char side, char trans, long m, long n, long  
               ilo, long ihi, double *a, long lda, double *tau,  
               double *c, long ldc, long *info);
```

PURPOSE

dormhr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of IHI-ILO elementary reflectors, as returned by
SGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the
previous call of SGEHRD. Q is equal to the unit
matrix except in the submatrix
 $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. If SIDE = 'L', then $1 \leq$
 $\text{ILO} \leq \text{IHI} \leq M$, if $M > 0$, and $\text{ILO} = 1$ and $\text{IHI} =$
0, if $M = 0$; if SIDE = 'R', then $1 \leq \text{ILO} \leq \text{IHI}$
 $\leq N$, if $N > 0$, and $\text{ILO} = 1$ and $\text{IHI} = 0$, if $N = 0$.

IHI (input)
See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,M) if SIDE = 'L'; LDA \geq max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{*T}C$ or CQ^{*T} or CQ .

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               k, double *a, long lda, double *tau, double *c,
               long ldc, long *info);
```

PURPOSE

dormlq overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector H(i), for $i = 1, 2, \dots, k$, as
returned by SGELQF in the first k rows of its
array argument A. A is modified by the routine
but restored on exit.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by $Q \cdot C$ or $Q^T \cdot C$ or $C \cdot Q^T$ or $C \cdot Q$.

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void dormql(char side, char trans, int m, int n, int k, double
            *a, int lda, double *tau, double *c, int ldc,
            int *info);

void dormql_64(char side, char trans, long m, long n, long
               k, double *a, long lda, double *tau, double *c,
               long ldc, long *info);
```

PURPOSE

dormql overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
 The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
 The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>

void dormqr(char side, char trans, int m, int n, int k, double
            *a, int lda, double *tau, double *c, int ldc,
            int *info);

void dormqr_64(char side, char trans, long m, long n, long
               k, double *a, long lda, double *tau, double *c,
               long ldc, long *info);
```

PURPOSE

dormqr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGEQRF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQRF in the first k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or C^*Q^{**T} or C^*Q .

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               long ldc, long *info);
```

PURPOSE

dormrq overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGERQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector H(i), for $i = 1, 2, \dots, k$, as
returned by SGERQF in the last k rows of its array
argument A. A is modified by the routine but
restored on exit.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by $Q \cdot C$ or $Q^* \cdot T \cdot C$ or $C \cdot Q^* \cdot T$ or $C \cdot Q$.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

dormrz overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{**T} * C$ $C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by STZRZF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', M >= K >= 0;
if SIDE = 'R', N >= K >= 0.

L (input) The number of columns of the matrix A containing
the meaningful part of the Householder reflectors.
If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L
>= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The

i-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by STZRZF.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               *c, long ldc, long *info);
```

PURPOSE

dormtr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by
SSYTRD:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

UPLO (input)

= 'U': Upper triangle of A contains elementary
reflectors from SSYTRD; = 'L': Lower triangle of A
contains elementary reflectors from SSYTRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The

vectors which define the elementary reflectors, as returned by SSYTRD.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$ if $SIDE = 'L'$; $LDA \geq \max(1, N)$ if $SIDE = 'R'$.

TAU (input)

$(M-1)$ if $SIDE = 'L'$ $(N-1)$ if $SIDE = 'R'$ TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or CQ^{**T} or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if $SIDE = 'L'$, and $LWORK \geq M \cdot NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

#include <sunperf.h>

void dpbcon(char uplo, int n, int kd, double *a, int lda,
    double anorm, double *rcond, int *info);

void dpbcon_64(char uplo, long n, long kd, double *a, long
    lda, double anorm, double *rcond, long *info);

```

PURPOSE

dpbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by DPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

A (input) The triangular factor U or L from the Cholesky

factorization $A = U^*T^*U$ or $A = L^*L^*T$ of the band matrix A , stored in the first $KD+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

LDA (input)

The leading dimension of the array A . $LDA \geq KD+1$.

ANORM (input)

The 1-norm (or infinity-norm) of the symmetric band matrix A .

RCOND (output)

The reciprocal of the condition number of the matrix A , computed as $RCOND = 1/(ANORM * AINVNM)$, where $AINVNM$ is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

                     INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, LDA, INFO  
DOUBLE PRECISION SCOND, AMAX  
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,  
                [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDA, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE PBEQU_64(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
```

[INFO])

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbequ(char uplo, int n, int kd, double *a, int lda,
            double *scale, double *scond, double *amax, int
            *info);
```

```
void dpbequ_64(char uplo, long n, long kd, double *a, long
               lda, double *scale, double *scond, double *amax,
               long *info);
```

PURPOSE

dpbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)

= 'U': Upper triangular of A is stored;
= 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KD \geq 0$.

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U',

```

A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if
UPLO = 'L', A(1+i-j,j) = A(i,j) for
j<=i<=min(n,j+kd).

```

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

SCALE (output)

If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, the i-th diagonal element is nonpositive.

    ble *berr, long *info);

```

PURPOSE

dpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
The leading dimension of the array A. LDA \geq KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L*L^*T$ of the band matrix A as computed by DPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF \geq KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1, N).

X (input/output)
On entry, the solution matrix X, as computed by DPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1, N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an

exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDAB, INFO  
REAL(8), DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void dpbstf(char uplo, int n, int kd, double *ab, int ldab,
            int *info);

void dpbstf_64(char uplo, long n, long kd, double *ab, long
               ldab, long *info);
```

PURPOSE

dpbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.

The factorization has the form $A = S^*T^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & (M \ L) \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^*T^*S$. See Further Details.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13           )
      (      s22  s23  s24      )
      (           s33  s34      )
      (               s44      )
      (           s53  s54  s55  )
      (               s64  s65  s66 )
      (                   s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

on entry:							on exit:					
*	*	a13	a24	a35	a46	a57	*	*	s13	s24	s53	
s64	s75											
*	a12	a23	a34	a45	a56	a67	*	s12	s23	s34	s54	
s65	s76	a11	a22	a33	a44	a55	a66	a77	s11	s22	s33	
s44	s55	s66	s77									

If UPLO = 'L', the array AB holds:

on entry:							on exit:					
a11	a22	a33	a44	a55	a66	a77	s11	s22	s33	s44	s55	
s66	s77	a21	a32	a43	a54	a65	a76	*	s12	s23	s34	
s54	s65	s76	*	a31	a42	a53	a64	a64	*	*	s13	
s24	s53	s64	s75	*	*							

Array elements marked * are not used by the routine.

[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dpbsv(char uplo, int n, int kd, int nrhs, double *a,
           int lda, double *b, int ldb, int *info);

void dpbsv_64(char uplo, long n, long kd, long nrhs, double
              *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpbsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite band matrix and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if $UPLO = 'U'$, or

$A = L * L^{**T}$, if $UPLO = 'L'$,

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KD \geq 0$.

$NRHS$ (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(KD+1+i-j,j) = A(i,j)$ for $\max(1,j-$

KD)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j)
for j<=i<=min(N,j+KD). See below for further
details.

On exit, if INFO = 0, the triangular factor U or L
from the Cholesky factorization $A = U^*T^*U$ or $A =$
 L^*L^*T of the band matrix A, in the same storage
format as A.

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
On exit, if INFO = 0, the N-by-NRHS solution
matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, the leading minor of order i of
A is not positive definite, so the factorization
could not be completed, and the solution has not
been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following
example, when N = 6, KD = 2, and UPLO = 'U':

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65

On exit:

```
*  
  a31  a42  a53  a64  *    *    131  142  153  164  *  
*
```

Array elements marked * are not used by the routine.

    char equed, double *s, double *b, long ldb, double
    *x, long ldx, double *rcond, double *ferr, double
    *berr, long *info);

```

PURPOSE

dpbsvx uses the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite band matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$
Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} * U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{**T}, \quad \text{if UPLO} = 'L',$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix.

3. If the leading i-by-i principal minor is not positive definite,

then the routine returns with INFO = i. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A. If the reciprocal of the condition number is less than machine

precision, INFO = N+1 is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by

$\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is

factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
 = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

NRHS (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(KD+1+i-j, j) = A(i, j)$ for $\max(1, j-KD) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+KD)$. See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq KD+1$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**T*U$ or $A = L*L**T$ of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from

the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq KD+1.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').

= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S))*X$.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in par-

particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. $= N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A :

a11 a12 a13

```

      a22  a23  a24
      a33  a34  a35
      a44  a45  a46
      a55  a56
(aij=conjg(aji))      a66

```

Band storage of the upper triangle of A:

```

      *      *      a13  a24  a35  a46
      *      a12  a23  a34  a45  a56
a11  a22  a33  a44  a55  a66

```

Similarly, if UPLO = 'L' the format of A is as follows:

```

a11  a22  a33  a44  a55  a66
a21  a32  a43  a54  a65  *
a31  a42  a53  a64  *      *

```

Array elements marked * are not used by the routine.

dpbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE DPBTF2(UPLO, N, KD, AB, LDAB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, KD, LDAB, INFO  
DOUBLE PRECISION AB(LDAB,*)
```

```
SUBROUTINE DPBTF2_64(UPLO, N, KD, AB, LDAB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, LDAB, INFO  
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTF2(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDAB, INFO  
REAL(8), DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBTF2_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDAB, INFO  
REAL(8), DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void dpbtf2(char uplo, int n, int kd, double *ab, int ldab,
            int *info);

void dpbtf2_64(char uplo, long n, long kd, double *ab, long
               ldab, long *info);
```

PURPOSE

dpbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization $A = U^*U$ or $A = L^*L'$ of the band matrix A , in the same storage format as A .

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if $UPLO = 'L'$ the format of A is as follows:

On entry:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65
*												
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*
*												

On exit:

Array elements marked * are not used by the routine.

```

C INTERFACE

```
#include <sunperf.h>

void dpbtrf(char uplo, int n, int kd, double *a, int lda,
            int *info);

void dpbtrf_64(char uplo, long n, long kd, double *a, long
               lda, long *info);
```

PURPOSE

dpbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$A = U^*T * U$, if UPLO = 'U', or

$A = L * L^*T$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

On entry:

On exit:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35	
u46													
	*		a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56													
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66													

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:

On exit:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55	
l66													
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65	
*													
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*	
*													

Array elements marked * are not used by the routine.

```

```
SUBROUTINE PBTRS_64(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dpbtrs(char uplo, int n, int kd, int nrhs, double *a,
            int lda, double *b, int ldb, int *info);

void dpbtrs_64(char uplo, long n, long kd, long nrhs, double
               *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpbtrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by DPBTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky
 factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ of the band
 matrix A, stored in the first $KD+1$ rows of the
 array. The j-th column of U or L is stored in the
 j-th column of the array A as follows: if UPLO
 = 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$
 for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $KD+1$.

B (input/output)
 On entry, the right hand side matrix B. On exit,
 the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

    anorm, double *rcond, int *info);

void dpocon_64(char uplo, long n, double *a, long lda, dou-
    ble anorm, double *rcond, long *info);
```

PURPOSE

dpocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^{*}L^{**T}$ computed by DPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L^{*}L^{**T}$, as computed by DPOTRF.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

ANORM (input)
 The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
 The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$,
where AINVNM is an estimate of the 1-norm of
inv(A) computed in this routine.

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

NAME

dpoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE DPOEQU(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
INTEGER N, LDA, INFO  
DOUBLE PRECISION SCOND, AMAX  
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

```
SUBROUTINE DPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
INTEGER*8 N, LDA, INFO  
DOUBLE PRECISION SCOND, AMAX  
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
INTEGER :: N, LDA, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
INTEGER(8) :: N, LDA, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dpoequ(int n, double *a, int lda, double *scale, double
            *scond, double *amax, int *info);

void dpoequ_64(long n, double *a, long lda, double *scale,
               double *scond, double *amax, long *info);
```

PURPOSE

dpoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input) The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, the i-th diagonal element is nonpositive.

            double *x, long ldx, double *ferr, double *berr,
            long *info);

```

PURPOSE

dporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
 The leading dimension of the array A. LDA >=

max(1,N).

AF (input)
 The triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$, as computed by DPOTRF.

LDAF (input)
 The leading dimension of the array AF. LDAF \geq max(1,N).

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
 On entry, the solution matrix X, as computed by DPOTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
 The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 dimension(3*N)

WORK2 (workspace)
 dimension(N)

NAME

dposv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DPOSV(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, NRHS, LDA, LDB, INFO  
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DPOSV_64(UPLO, N, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, NRHS, LDA, LDB, INFO  
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE POSV(UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE POSV_64(UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dposv(char uplo, int n, int nrhs, double *a, int lda,
           double *b, int ldb, int *info);

void dposv_64(char uplo, long n, long nrhs, double *a, long
              lda, double *b, long ldb, long *info);

```

PURPOSE

dposv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

LDA (input)
 The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

    long ldx, double *rcond, double *ferr, double
    *berr, long *info);

```

PURPOSE

dposvx uses the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} * U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{**T}, \quad \text{if UPLO} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix

A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the fac-

tored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$, in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ of the original matrix A.

If FACT = 'E', then AF is an output argument and

on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF $\geq \max(1,N)$.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S))*X$.

LDX (input)

The leading dimension of the array X. LDX $\geq \max(1,N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by

a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = $-i$, the i -th argument had an illegal value
> 0: if INFO = i , and i is
 <= N : the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. = $N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dpotf2(char uplo, int n, double *a, int lda, int
            *info);

void dpotf2_64(char uplo, long n, double *a, long lda, long
               *info);

```

PURPOSE

dpotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

#include <sunperf.h>
```

```

void dpotrf(char uplo, int n, double *a, int lda, int
            *info);

void dpotrf_64(char uplo, long n, double *a, long lda, long
               *info);

```

PURPOSE

dpotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$A = U^*U$, if UPLO = 'U', or

$A = L L^*$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^*U$ or $A = L L^*$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

               *info);
```

PURPOSE

dpotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$ computed by DPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

A (input/output)
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$, as computed by DPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A , overwriting the input factor U or L .

LDA (input)
 The leading dimension of the array A . $LDA \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value
 > 0: if $INFO = i$, the (i, i) element of the factor U or L is zero, and the inverse could not be computed.

void dpotrs_64(char uplo, long n, long nrhs, double *a, long
               lda, double *b, long ldb, long *info);
```

PURPOSE

dpotrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$ computed by DPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$, as computed by DPOTRF.

LDA (input)
 The leading dimension of the array A . $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)
 The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value

void dppcon(char uplo, int n, double *a, double anorm, double
            *rcond, int *info);
void dppcon_64(char uplo, long n, double *a, double anorm,
               double *rcond, long *info);

```

PURPOSE

dppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by DPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

ANORM (input)
 The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

DOUBLE PRECISION array, WORK (workspace)

```
dimension(3*N)

WORK2 (workspace)
    INTEGER array, dimension(N)
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an illegal value
```

```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: A, SCALE

```

C INTERFACE

```

#include <sunperf.h>

void dppequ(char uplo, int n, double *a, double *scale, double
            *scond, double *amax, int *info);

void dppequ_64(char uplo, long n, double *a, double *scale,
               double *scond, double *amax, long *info);

```

PURPOSE

dppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

SCALE (output) DOUBLE PRECISION array, dimension (N)
 If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
 If INFO = 0, SCALE contains the ratio of the smal-

lest $\text{SCALE}(i)$ to the largest $\text{SCALE}(i)$. If $\text{SCOND} \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by SCALE .

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i -th argument had an illegal value
> 0: if $\text{INFO} = i$, the i -th diagonal element is nonpositive.

void dpprfs(char uplo, int n, int nrhs, double *a, double
    *af, double *b, int ldb, double *x, int ldx, dou-
    ble *ferr, double *berr, int *info);

void dpprfs_64(char uplo, long n, long nrhs, double *a, dou-
    ble *af, double *b, long ldb, double *x, long ldx,
    double *ferr, double *berr, long *info);
```

PURPOSE

dpprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U**T*U$ or $A = L*L**T$, as computed by DPPTRF/ZPPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) DOUBLE PRECISION array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output) DOUBLE PRECISION array, dimension (LDX,NRHS)
On entry, the solution matrix X, as computed by DPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
DOUBLE PRECISION array, dimension(3*N)

WORK2 (workspace)
INTEGER array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void dppsv(char uplo, int n, int nrhs, double *a, double *b,
           int ldb, int *info);

void dppsv_64(char uplo, long n, long nrhs, double *a, double *b, long ldb, long *info);
```

PURPOSE

dppsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$, in the same storage format as A.

B (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B.
On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

    *a, double *af, char equed, double *s, double *b,
    int ldb, double *x, int ldx, double *rcond, double
    *ferr, double *berr, int *info);

void dppsvx_64(char fact, char uplo, long n, long nrhs, dou-
    ble *a, double *af, char equed, double *s, double
    *b, long ldb, double *x, long ldx, double *rcond,
    double *ferr, double *berr, long *info);

```

PURPOSE

dppsvx uses the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A is

overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{**T}, \quad \text{if UPLO} = 'L',$$
 where U is an upper triangular matrix and L is a lower triangular matrix.
3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

$(N*(N+1)/2)$

AF (input or output) DOUBLE PRECISION array, dimension

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$, in the same storage format as A. If EQUED = 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT =

'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output) DOUBLE PRECISION array, dimension (N)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (output) DOUBLE PRECISION array, dimension (LDX,NRHS)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1,N)$.

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

DOUBLE PRECISION array, dimension (3*N)

WORK2 (workspace)

INTEGER array, dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, and i is
 <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is non-singular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A :

```

a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44

```

Packed storage of the upper triangle of A :

$A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]$

CHARACTER * 1 UPLO  
INTEGER*8 N, INFO  
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE PPTRF(UPLO, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
REAL(8), DIMENSION(:) :: A
```

```
SUBROUTINE PPTRF_64(UPLO, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dpptrf(char uplo, int n, double *a, int *info);

void dpptrf_64(char uplo, long n, double *a, long *info);
```

PURPOSE

dpptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, in the same storage format as A.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
      a33 a34    (aij = aji)
        a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

```
#include <sunperf.h>

void dpptri(char uplo, int n, double *a, int *info);

void dpptri_64(char uplo, long n, double *a, long *info);
```

PURPOSE

dpptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$ computed by DPPTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor is stored in A;
 = 'L': Lower triangular factor is stored in A.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

               ble *b, long ldb, long *info);
```

PURPOSE

dpptrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^* T U$ or $A = L^* L^* T$ computed by DPPTRF.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N \cdot (N+1)/2)$

The triangular factor U or L from the Cholesky factorization $A = U^* T U$ or $A = L^* L^* T$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1) \cdot j/2) = U(i, j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1) \cdot (2n-j)/2) = L(i, j)$ for $j \leq i \leq n$.

B (input/output) DOUBLE PRECISION array, dimension $(LDB, NRHS)$

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCON([N], D, E, ANORM, RCOND, [WORK], [INFO])
```

```
INTEGER :: N, INFO  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE PTCON_64([N], D, E, ANORM, RCOND, [WORK], [INFO])
```

```
INTEGER(8) :: N, INFO  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>

void dptcon(int n, double *d, double *e, double anorm, double
            *rcond, int *info);

void dptcon_64(long n, double *d, double *e, double anorm,
               double *rcond, long *info);
```

PURPOSE

dptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L*D*L^T$ or $A = U^T*D*U$ computed by DPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by DPTTRF.

E (input) The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by DPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

```

```
CHARACTER * 1 COMPZ  
INTEGER*8 N, LDZ, INFO  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTEQR(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, INFO
```

```
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dpteqr(char compz, int n, double *d, double *e, double
            *z, int ldz, int *info);

void dpteqr_64(char compz, long n, double *d, double *e,
               double *z, long ldz, long *info);
```

PURPOSE

dpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using DPTTRF, and then calling DBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if DSYTRD, DSPTRD, or DSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
 dimension(4*N)

INFO (output)
 = 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

               *info);

```

PURPOSE

dptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix A.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF (input)
The n diagonal elements of the diagonal matrix D from the factorization computed by DPTTRF.

EF (input)
The (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization computed by DPTTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by DPTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dptsv(int n, int nrhs, double *d, double *e, double *b,
           int ldb, int *info);

void dptsv_64(long n, long nrhs, double *d, double *e, double *b, long ldb, long *info);

```

PURPOSE

dptsv computes the solution to a real system of linear equations $A \cdot X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

A is factored as $A = L \cdot D \cdot L^{**T}$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix D from the factorization $A = L \cdot D \cdot L^{**T}$.

E (input/output)
On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L \cdot D \cdot L^{**T}$ factorization of A . (E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^{**T} \cdot D \cdot U$ factorization of A .)

B (input/output)
On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq$

`max(1,N).`

INFO (output)

`= 0:` successful exit

`< 0:` if INFO = -i, the i-th argument had an illegal value

`> 0:` if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

    ldb, double *x, long ldx, double *rcond, double
    *ferr, double *berr, long *info);

```

PURPOSE

dptsvx uses the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the matrix A is factored as $A = L^*D^*L^{**T}$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^{**T}D^*U$.
2. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix
 - A. If the reciprocal of the condition number is less

than machine
precision, INFO = N+1 is returned as a warning, but the
routine
still goes on to solve for X and compute error bounds as
described below.

3. The system of equations is solved for X using the fac-
tored form
of A.

4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, DF
and EF contain the factored form of A. D, E, DF,
and EF will not be modified. = 'N': The matrix A
will be copied to DF and EF and factored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix
A.

E (input) The (n-1) subdiagonal elements of the tridiagonal
matrix A.

DF (input or output)

If FACT = 'F', then DF is an input argument and on
entry contains the n diagonal elements of the
diagonal matrix D from the $L^*D^*L^*T$ factorization
of A. If FACT = 'N', then DF is an output argu-
ment and on exit contains the n diagonal elements
of the diagonal matrix D from the $L^*D^*L^*T$ factor-
ization of A.

EF (input or output)

If FACT = 'F', then EF is an input argument and on
entry contains the (n-1) subdiagonal elements of

the unit bidiagonal factor L from the $L^*D^*L^{**T}$ factorization of A . If $FACT = 'N'$, then EF is an output argument and on exit contains the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^{**T}$ factorization of A .

B (input) The N -by- $NRHS$ right hand side matrix B .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

X (output)
If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X .

LDX (input)
The leading dimension of the array X . $LDX \geq \max(1, N)$.

$RCOND$ (output)
The reciprocal condition number of the matrix A . If $RCOND$ is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

$FERR$ (output)
The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

$BERR$ (output)
The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

$WORK$ (workspace)
 $\text{dimension}(2*N)$

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 <= N : the leading minor of order i of A is not positive definite, so the factorization could not

be completed, and the solution has not been computed. $RCOND = 0$ is returned. $= N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

NAME

dppttrf - compute the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE DPTTRF(N, D, E, INFO)
```

```
INTEGER N, INFO  
DOUBLE PRECISION D(*), E(*)
```

```
SUBROUTINE DPTTRF_64(N, D, E, INFO)
```

```
INTEGER*8 N, INFO  
DOUBLE PRECISION D(*), E(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRF([N], D, E, [INFO])
```

```
INTEGER :: N, INFO  
REAL(8), DIMENSION(:) :: D, E
```

```
SUBROUTINE PTTRF_64([N], D, E, [INFO])
```

```
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppttrf(int n, double *d, double *e, int *info);
```

```
void dppttrf_64(long n, double *d, double *e, long *info);
```

PURPOSE

dpttrf computes the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U'^*D^*U$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L^*D^*L' factorization of A.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*D^*L' factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U'^*D^*U factorization of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if $k < N$, the factorization could not be completed, while if $k = N$, the factorization was completed, but $D(N) = 0$.

void dpttrs_64(long n, long nrhs, double *d, double *e, double
        *b, long ldb, long *info);

```

PURPOSE

dpttrs solves a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by DPTTRF. D is a diagonal matrix specified in the vector D , L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E , and X and B are N by $NRHS$ matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the $L*D*L'$ factorization of A .

E (input) The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L*D*L'$ factorization of A . E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U'*D*U$.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -k$, the k -th argument had an illegal value

INTEGER :: N, NRHS, LDB
REAL(8), DIMENSION(:) :: D, E
REAL(8), DIMENSION(:, :) :: B

SUBROUTINE DPTTS2_64(N, NRHS, D, E, B, LDB)

INTEGER(8) :: N, NRHS, LDB
REAL(8), DIMENSION(:) :: D, E
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>

void dptts2(int n, int nrhs, double *d, double *e, double
```

```

        *b, int ldb);

void dptts2_64(long n, long nrhs, double *d, double *e, double
        *b, long ldb);

```

PURPOSE

dptts2 solves a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by DPTTRF. D is a diagonal matrix specified in the vector D , L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E , and X and B are N by $NRHS$ matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the $L*D*L'$ factorization of A .

E (input) The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L*D*L'$ factorization of A . E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U'*D*U$.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

NAME

dqdots - compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DQDOTA(N, DB, QC, DX, INCX, DY, INCY)
```

```
INTEGER N, INCX, INCY  
REAL * 16 QC  
DOUBLE PRECISION DB  
DOUBLE PRECISION DX(*), DY(*)
```

```
DOUBLE PRECISION FUNCTION DQDOTA_64(N, DB, QC, DX, INCX, DY, INCY)
```

```
INTEGER*8 N, INCX, INCY  
REAL * 16 QC  
DOUBLE PRECISION DB  
DOUBLE PRECISION DX(*), DY(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DQDOTA(N, DB, QC, DX, INCX, DY, INCY)
```

```
INTEGER :: N, INCX, INCY  
REAL(16) :: QC  
REAL(8) :: DB  
REAL(8), DIMENSION(:) :: DX, DY
```

```
REAL(8) FUNCTION DQDOTA_64(N, DB, QC, DX, INCX, DY, INCY)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(16) :: QC
```

```
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>

double dqdota(int n, double db, long double *qc, double *dx,
              int incx, double *dy, int incy);

double dqdota_64(long n, double db, long double *qc, double
                 *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdota compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If $N \leq 0$ then the function returns the value DB+QC. Unchanged on exit.

DB (input)

On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

QC (input/output)

On entry, the extended precision constant to be added to the dot product. On exit, the extended precision result.

DX (input)

On entry, the incremented array DX must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of DX. Unchanged on exit.

DY (input)

On entry, the incremented array DY must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of DY. Unchanged on exit.

Note:

dqdota does not exist in X86 libraries.

REAL(8) :: DB  
REAL(8), DIMENSION(:) :: DX, DY
```

```
REAL(8) FUNCTION DQDOTI_64(N, DB, QC, DX, INCX, DY, INCY)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(16) :: QC  
REAL(8) :: DB
```

```
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dqdoti(int n, double db, long double *qc, double *dx,  
              int incx, double *dy, int incy);
```

```
double dqdoti_64(long n, double db, long double *qc, double  
                 *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdoti computes a constant plus the double precision dot product of x and y where x and y are double precision n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If $N \leq 0$ then the function returns the value DB. Unchanged on exit.

DB (input)

On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

QC (output)

On exit, the extended precision result.

DX (input)

On entry, the incremented array DX must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of DX. Unchanged on exit.

DY (input)

On entry, the incremented array DY must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of DY. Unchanged on exit.

Note:

dqdoti does not exist in X86 libraries.

```

```
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION C, S  
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
INTEGER :: N, INCX, INCY  
REAL(8) :: C, S  
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(8) :: C, S  
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void drot(int n, double *x, int incx, double *y, int incy,
          double c, double s);

void drot_64(long n, double *x, long incx, double *y, long
             incy, double c, double s);

```

PURPOSE

drot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

N (input)
 On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
 (1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX (input)
 On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)
 (1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
 On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

C (input) On entry, the C rotation value constructed by SROTG. Unchanged on exit.

S (input) On entry, the S rotation value constructed by SROTG. Unchanged on exit.

NAME

drotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE DROTG(A, B, C, S)
```

```
DOUBLE PRECISION A, B, C, S
```

```
SUBROUTINE DROTG_64(A, B, C, S)
```

```
DOUBLE PRECISION A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)
```

```
REAL(8) :: A, B, C, S
```

```
SUBROUTINE ROTG_64(A, B, C, S)
```

```
REAL(8) :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>
```

```
void drotg(double *a, double *b, double *c, double *s);
```

```
void drotg_64(double *a, double *b, double *c, double *s);
```

PURPOSE

drotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input/output)

On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or $1/C$ depending on which of the input values of A and B is larger.

C (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)

See the description of C.

Contents

NAME

`droti` - Apply an indexed Givens rotation.

SYNOPSIS

```
SUBROUTINE DROTI(NZ, X, INDX, Y, C, S)

INTEGER NZ
INTEGER INDX(*)
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DROTI_64(NZ, X, INDX, Y, C, S)

INTEGER*8 NZ
INTEGER*8 INDX(*)
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)

F95 INTERFACE
SUBROUTINE ROTI([NZ], X, INDX, Y, C, S)

INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE ROTI_64([NZ], X, INDX, Y, C, S)

INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y
```

PURPOSE

DROTI - Applies a Givens rotation to a sparse vector x stored in compressed form and another vector y in full storage form

```
do i = 1, n
  temp = -s * x(i) + c * y(indx(i))
  x(i) = c * x(i) + s * y(indx(i))
  y(indx(i)) = temp
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.

Unchanged on exit.

X (input)

Vector containing the values of the compressed form.

INDX (input) - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input/output)

Vector on input which contains the vector Y in full storage form. On exit, only the elements corresponding to the indices in INDX have been modified.

C (input)

Scalar defining the Givens rotation

S (input)

Scalar defining the Givens rotation

```
void drotm(int n, double *x, int incx, double *y, int incy,  
          double *param);
```

```
void drotm_64(long n, double *x, long incx, double *y, long
            incy, double *param);
```

PURPOSE

drotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, X is overwritten by the updated vector x.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

PARAM (input)

On entry, the rotation values constructed by SROTMG. Unchanged on exit.

void drotmg(double d1, double d2, double b1, double b2, double *param);
```

```
void drotmg_64(double d1, double d2, double b1, double b2,
               double *param);
```

PURPOSE

drotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

D1 (input/output)

On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

D2 (input/output)

On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

B1 (input/output)

On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

B2 (input)

On entry, the second element of the vector to which the H matrix is applied. Unchanged on exit.

PARAM (output)

On exit, PARAM(1) describes the form of the rotation matrix H, and PARAM(2..5) contain the H matrix.

If PARAM(1) = -2 then H = I and no elements of PARAM are modified.

If PARAM(1) = -1 then PARAM(2) = h11, PARAM(3) = h21, PARAM(4) = h12, and PARAM(5) = h22.

If PARAM(1) = 0 then h11 = h22 = 1, PARAM(3) = h21, and PARAM(4) = h12.

If PARAM(1) = 1 then h12 = 1, h21 = -1, PARAM(2) = h11, and PARAM(5) = h22.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbev(char jobz, char uplo, int n, int kd, double *a,  
           int lda, double *w, double *z, int ldz, int  
           *info);
```

```
void dsbev_64(char jobz, char uplo, long n, long kd, double  
              *a, long lda, double *w, double *z, long ldz, long  
              *info);
```

PURPOSE

dsbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd) <= i <= j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j <= i <= min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD

and $KD+1$ of A , and if $UPLO = 'L'$, the diagonal and first subdiagonal of T are returned in the first two rows of A .

LDA (input)

The leading dimension of the array A . $LDA \geq KD + 1$.

W (output)

If $INFO = 0$, the eigenvalues in ascending order.

Z (input) If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A , with the i -th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace)

$\text{dimension}(\text{MAX}(1, 3*N-2))$

INFO (output)

$= 0$: successful exit

< 0 : if $INFO = -i$, the i -th argument had an illegal value

> 0 : if $INFO = i$, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

```
CHARACTER(LEN=1) :: JOBZ, UPLO
```

```

INTEGER(8) :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: AB, Z

```

C INTERFACE

```

#include <sunperf.h>

void dsbevd(char jobz, char uplo, int n, int kd, double *ab,
            int ldab, double *w, double *z, int ldz, int
            *info);
void dsbevd_64(char jobz, char uplo, long n, long kd, double
               *ab, long ldab, double *w, double *z, long ldz,
               long *info);

```

PURPOSE

dsbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. KD >= 0.

AB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix A, stored in the first KD+1
 rows of the array. The j-th column of A is stored

in the j-th column of the array AB as follows: if
 UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$
 for $j \leq i \leq \min(n,j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD + 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (output)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 2$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 2$, LWORK must be at least $(1 + 5*N + 2*N**2)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array LIWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ =

'V' and $N > 2$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

    abtol, long *nfound, double *w, double *z, long
    ldz, long *ifail, long *info);

```

PURPOSE

dsbevz computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

```

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

```

RANGE (input)

```

= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval
(VL,VU] will be found; = 'I': the IL-th through
IU-th eigenvalues will be found.

```

UPLO (input)

```

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. N >= 0.

KD (input)

The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KD >= 0.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

LDA (input)

The leading dimension of the array A. LDA >= KD + 1.

Q (output)

If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1, N).

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)

The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension(7*N)

IWORK2 (workspace)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```

C INTERFACE

```

#include <sunperf.h>

void dsbgst(char vect, char uplo, int n, int ka, int kb,
            double *ab, int ldab, double *bb, int ldbb, double
            *x, int ldx, int *info);

void dsbgst_64(char vect, char uplo, long n, long ka, long
              kb, double *ab, long ldab, double *bb, long ldbb,
              double *x, long ldx, long *info);

```

PURPOSE

dsbgst reduces a real symmetric-definite banded generalized eigenproblem $A*x = \lambda B*x$ to standard form $C*y = \lambda y$, such that C has the same bandwidth as A.

B must have been previously factorized as S^*T*S by SPBSTF, using a split Cholesky factorization. A is overwritten by $C = X^*T*A*X$, where $X = S^*(-1)*Q$ and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

ARGUMENTS

VECT (input)
 = 'N': do not form the transformation matrix X;
 = 'V': form X.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq KB \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix X^*TAX , stored in the same format as A .

LDAB (input)

The leading dimension of the array AB . $LDAB \geq KA+1$.

BB (input)

The banded factor S from the split Cholesky factorization of B , as returned by `SPBSTF`, stored in the first $KB+1$ rows of the array.

LDBB (input)

The leading dimension of the array BB . $LDBB \geq KB+1$.

X (output)

If $VECT = 'V'$, the n -by- n matrix X . If $VECT = 'N'$, the array X is not referenced.

LDX (input)

The leading dimension of the array X . $LDX \geq \max(1,N)$ if $VECT = 'V'$; $LDX \geq 1$ otherwise.

WORK (workspace)

$\text{dimension}(2*N)$

INFO (output)

$= 0$: successful exit
 < 0 : if $INFO = -i$, the i -th argument had an illegal value.

REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: AB, BB, Z

```

C INTERFACE

```

#include <sunperf.h>

void dsbgv(char jobz, char uplo, int n, int ka, int kb, double
           *ab, int ldab, double *bb, int ldbb, double
           *w, double *z, int ldz, int *info);
void dsbgv_64(char jobz, char uplo, long n, long ka, long
              kb, double *ab, long ldab, double *bb, long ldbb,
              double *w, double *z, long ldz, long *info);

```

PURPOSE

dsbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KB \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix A, stored in the first $ka+1$

rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB . LDAB \geq KA+1.

BB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix B , stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if $UPLO = 'U'$, $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if $UPLO = 'L'$, $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)

The leading dimension of the array BB . LDBB \geq KB+1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i -th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*T^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z . LDZ \geq 1, and if JOBZ = 'V', LDZ \geq N.

WORK (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i -th argument had an illegal value
 > 0: if INFO = i, and i is:
 <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then SPBSTF returned INFO = i: B is not positive definite.

The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

dsbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. KA >= 0.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. KB >= 0.

AB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix A, stored in the first ka+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array AB as follows: if
 UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-
 ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j)
 for j<=i<=min(n,j+ka).

 On exit, the contents of AB are destroyed.

LDAB (input)
 The leading dimension of the array AB. LDAB >=
 KA+1.

BB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix B, stored in the first kb+1
 rows of the array. The j-th column of B is stored
 in the j-th column of the array BB as follows: if
 UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-
 kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j)
 for j<=i<=min(n,j+kb).

 On exit, the factor S from the split Cholesky fac-
 torization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)
 The leading dimension of the array BB. LDBB >=
 KB+1.

W (output)
 If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the
 matrix Z of eigenvectors, with the i-th column of
 Z holding the eigenvector associated with W(i).
 The eigenvectors are normalized so $Z^*T^*B^*Z = I$.
 If JOBZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1,
 and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 3*N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 5*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
 On exit, if LIWORK > 0 , IWORK(1) returns the optimal LIWORK.

LIWORK (input)
 The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, and i is:
 <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then SPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

    long *info);

```

PURPOSE

dsbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $Ax = (\lambda)Bx$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

JOBZ (input)
    = 'N': Compute eigenvalues only;
    = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
    = 'A': all eigenvalues will be found.

```

= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

KB (input)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KA+1$.

BB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)

The leading dimension of the array BB. $LDBB \geq KB+1$.

Q (output)

If JOBZ = 'V', the n-by-n matrix used in the reduction of $A*x = (\lambda)B*x$ to standard form, i.e. $C*x = (\lambda)x$, and consequently C to triangular form. If JOBZ = 'N', the array Q is not

referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with INFO > 0, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input)

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i).

The eigenvectors are normalized so $Z^T B Z = I$.
If `JOBZ = 'N'`, then `Z` is not referenced.

`LDZ` (input)

The leading dimension of the array `Z`. `LDZ` ≥ 1 ,
and if `JOBZ = 'V'`, `LDZ` $\geq \max(1, N)$.

`WORK` (workspace)

dimension($7 \cdot N$)

`IWORK` (workspace/output)

dimension($5 \cdot N$)

`IFAIL` (input)

If `JOBZ = 'V'`, then if `INFO = 0`, the first `M` elements of `IFAIL` are zero. If `INFO > 0`, then `IFAIL` contains the indices of the eigenvalues that failed to converge. If `JOBZ = 'N'`, then `IFAIL` is not referenced.

`INFO` (output)

= 0 : successful exit

< 0 : if `INFO = -i`, the `i`-th argument had an illegal value

<= `N`: if `INFO = i`, then `i` eigenvectors failed to converge. Their indices are stored in `IFAIL`.

> `N` : `SPBSTF` returned an error code; i.e., if `INFO = N + i`, for $1 \leq i \leq N$, then the leading minor of order `i` of `B` is not positive definite. The factorization of `B` could not be completed and no eigenvalues or eigenvectors were computed.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbmv(char uplo, int n, int k, double alpha, double *a,  
           int lda, double *x, int incx, double beta, double  
           *y, int incy);  
void dsbmv_64(char uplo, long n, long k, double alpha, dou-  
ble *a, long lda, double *x, long incx, double  
beta, double *y, long incy);
```

PURPOSE

dsbmv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

K (input)

On entry, K specifies the number of super-diagonals of the matrix A . $K \geq 0$. Unchanged on

exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading ($k + 1$) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row ($k + 1$) of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading ($k + 1$) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

X (input)
(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

NAME

dsbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE DSBTRD(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK,  
                  INFO)
```

```
CHARACTER * 1 VECT, UPLO  
INTEGER N, KD, LDAB, LDQ, INFO  
DOUBLE PRECISION AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)
```

```
SUBROUTINE DSBTRD_64(VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK,  
                     INFO)
```

```
CHARACTER * 1 VECT, UPLO  
INTEGER*8 N, KD, LDAB, LDQ, INFO  
DOUBLE PRECISION AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBTRD(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
                [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER :: N, KD, LDAB, LDQ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:,:) :: AB, Q
```

```
SUBROUTINE SBTRD_64(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
                   [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO
```

```

INTEGER(8) :: N, KD, LDAB, LDQ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: AB, Q

```

C INTERFACE

```
#include <sunperf.h>
```

```

void dsbtrd(char vect, char uplo, int n, int kd, double *ab,
            int ldab, double *d, double *e, double *q, int
            ldq, int *info);

```

```

void dsbtrd_64(char vect, char uplo, long n, long kd, double
               *ab, long ldab, double *d, double *e, double *q,
               long ldq, long *info);

```

PURPOSE

dsbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

VECT (input)

```

= 'N': do not form Q;
= 'V': form Q;
= 'U': update a matrix X, by forming X*Q.

```

UPLO (input)

```

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the

elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

D (output)

The diagonal elements of the tridiagonal matrix T.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i, i+1)$ if UPLO = 'U'; $E(i) = T(i+1, i)$ if UPLO = 'L'.

Q (input/output)

On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product $X*Q$; if VECT = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1, and LDQ \geq N if VECT = 'V' or 'U'.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE DSCAL(N, ALPHA, Y, INCY)
```

```
INTEGER N, INCY  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION Y(*)
```

```
SUBROUTINE DSCAL_64(N, ALPHA, Y, INCY)
```

```
INTEGER*8 N, INCY  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION Y(*)
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
INTEGER :: N, INCY  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: Y
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
INTEGER(8) :: N, INCY  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dscal(int n, double alpha, double *y, int incy);

void dscal_64(long n, double alpha, double *y, long incy);
```

PURPOSE

dscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{INCY}$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y. This routine returns immediately if INCY is less than or equal to zero. Unchanged on exit.

NAME

dsctr - Scatters elements from x into y.

SYNOPSIS

```
SUBROUTINE DSCTR(NZ, X, INDX, Y)
```

```
DOUBLE PRECISION X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE DSCTR_64(NZ, X, INDX, Y)
```

```
DOUBLE PRECISION X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE SCTR([NZ], X, INDX, Y)
```

```
  REAL(8), DIMENSION(:) :: X, Y  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE SCTR_64([NZ], X, INDX, Y)
```

```
  REAL(8), DIMENSION(:) :: X, Y  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

DSCTR - Scatters the components of a sparse vector x stored in compressed form into specified components of a vector y

in full storage form.

```
do i = 1, n
  y(indx(i)) = x(i)
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector containing the values to be scattered from
compressed form into full storage form. Unchanged
on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector whose elements specified by indx have been
set to the corresponding entries of x. Only the
elements corresponding to the indices in indx have
been modified.

NAME

`dsdot` - compute the double precision dot product of two single precision vectors `x` and `y`.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DSDOT(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
REAL X(*), Y(*)
```

```
DOUBLE PRECISION FUNCTION DSDOT_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
REAL X(*), Y(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DSDOT(N, X, INCX, Y, INCY)
```

```
INTEGER :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

```
REAL(8) FUNCTION DSDOT_64(N, X, INCX, Y, INCY)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dsdot(int n, float *x, int incx, float *y, int incy);
```

```
double dsdot_64(long n, float *x, long incx, float *y, long
```

```
incy);
```

PURPOSE

dsdot compute the double precision dot product of `x` and `y` where `x` and `y` are single precision `n`-vectors.

ARGUMENTS

`N` (input)

On entry, `N` specifies the number of elements in the vector. If `N` is not positive then the function returns the value 0.0. Unchanged on exit.

`X` (input)

(1 + (`n` - 1) * abs(`INCX`)). On entry, the incremented array `X` must contain the vector `x`. Unchanged on exit.

`INCX` (input)

On entry, `INCX` specifies the increment for the elements of `X`. `INCX` must not be zero. Unchanged on exit.

`Y` (input)

(1 + (`n` - 1) * abs(`INCY`)). On entry, the incremented array `Y` must contain the vector `y`. Unchanged on exit.

`INCY` (input)

On entry, `INCY` specifies the increment for the elements of `Y`. `INCY` must not be zero. Unchanged on exit.

NAME

dsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINC operations are unnormalized inverses of themselves, so a call to SINC followed by a call to SINQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DSINQB(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINQB_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQB_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqb(int n, double *x, double *wsave);
```

```
void dsingb_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine synthesis of the input.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

dsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The Sinq operations are unnormalized inverses of themselves, so a call to Sinqf followed by a call to Sinqb will multiply the input sequence by 4 * N.

SYNOPSIS

```
SUBROUTINE DSINQF(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINQF_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQF_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqf(int n, double *x, double *wsave);
```

```
void dsinqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine transform of the input.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

Contents

- [NAME](#)
- [SYNOPSIS](#)
 - [F95 INTERFACE](#)
 - [C INTERFACE](#)
- [ARGUMENTS](#)

NAME

dsinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

SYNOPSIS

```
SUBROUTINE DSINQI(N, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE DSINQI_64(N, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQI(N, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINQI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsinqi(int n, double *wsave);
```

```
void dsinqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)

On entry, an array of dimension $(3 * N + 15)$ or greater. SINQI needs to be called only once to initialize WSAVE before calling SINQF and/or SINQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

```
SUBROUTINE SINT([N], X, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE SINT_64([N], X, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsint(int n, double *x, double *wsave);
```

```
void dsint_64(long n, double *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the sine transform of the input.

WSAVE (input/output)

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by SINTI.

NAME

dsinti - initialize the array WSAVE, which is used in sub-routine SINT.

SYNOPSIS

```
SUBROUTINE DSINTI(N, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE DSINTI_64(N, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINTI(N, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsinti(int n, double *wsave);
```

```
void dsinti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input/output)

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

#include <sunperf.h>
void dskymm (int transa, int m, int n, int k, double alpha,
int *descra, double *val, int *pntr, double *b, int ldb,
double beta, double *c, int ldc);

void dskymm_64 (long transa, long m, long n, long k,
double alpha, long *descra, double *val, long *pntr,
double *b, long ldb, double beta, double *c, long ldc);

```

DESCRIPTION

dskymm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the skyline format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, integer K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general (NOT SUPPORTED) 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array consisting of
                  the nonzeros of A in skyline profile form.
                  Row-oriented if DESCRA(2) = 1 (lower triangular),
                  column oriented if DESCRA(2) = 2 (upper triangular).
                  Unchanged on exit.

PNTR (input)     On entry, INDX is an integer array of length
                  M+1 (lower triangular) or K+1 (upper triangular)
                  such that PNTR(I)-PNTR(1)+1 points to the
                  location in VAL of the first element of the skyline
                  profile in row (column) I. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading k by n
                  part of the array B must contain the matrix B,  otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading m by n
                  part of the array C must contain the matrix C,  otherwise
                  the leading k by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

```

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

The SKY data structure is not supported for a general matrix structure (*DESCRA*(1)=0).

Also not supported:

1. lower triangular matrix A of size m by n where $m > n$
2. upper triangular matrix A of size m by n where $m < n$

C INTERFACE

```
#include <sunperf.h>
```

```
void dskysm (int transa, int m, int n, int unitd, double
*dv, double alpha, int *descra, double *val, int *pntr,
double *b, int ldb, double beta, double *c, int ldc);
void dskysm_64 (long transa, long m, long n, long unitd,
double *dv, double alpha, long *descra, double *val, long
*pntr, double *b, long ldb, double beta, double *c, long
ldc);
```

DESCRIPTION

dskysm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the skyline format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row or column scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the scaling matrix D.

If UNITD is 4, DV contains diagonal matrix by which the rows (columns) have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array.

DESCRA(1) matrix structure

- 0 : general (NOT SUPPORTED)
- 1 : symmetric ($A=A'$)
- 2 : Hermitian ($A= \text{CONJG}(A')$)
- 3 : Triangular
- 4 : Skew(Anti)-Symmetric ($A=-A'$)
- 5 : Diagonal
- 6 : Skew-Hermitian ($A= -\text{CONJG}(A')$)

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL(input) On entry, VAL contains the nonzeros of A in skyline profile form. Row-oriented if DESCRA(2) = 1 (lower triangular), column oriented if DESCRA(2) = 2 (upper triangular). Unchanged on exit if UNITD is not 4. Otherwise, VAL contains entries of $D*A$ or $A*D$ (see section NOTES for further details).

PNTR (input) On entry, INDX is an integer array of length M+1 such that $\text{PNTR}(I)-\text{PNTR}(1)+1$ points to the location in VAL of the first element of the skyline profile in row (column) I. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK

should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M \times N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A if `DESCRA(2)=1` (lower triangular), and the columns of A if `DESCRA(2)=2` (upper triangular) such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On exit, DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if `DESCRA(2)=1` and UNITD=3 if `DESCRA(2)=2` should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = -i` where i is the row (column) number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the skyline representation of a sparse matrix don't need to be referenced in this usage but they need to be 1.0 if they are referenced. However if UNITD=4, the unit diagonal elements with the mathematical value 1

MUST be referenced in the skyline representation.

```

C INTERFACE

```
#include <sunperf.h>
void dspcon(char uplo, int n, double *a, int *ipivot, double
    anorm, double *rcond, int *info);

void dspcon_64(char uplo, long n, double *a, long *ipivot,
    double anorm, double *rcond, long *info);
```

PURPOSE

dspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U^T$ or $A = L*D*L^T$ computed by DSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^T$;
= 'L': Lower triangular, form is $A = L*D*L^T$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) Double precision array, dimension $(N*(N+1)/2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A , computed as $RCOND = 1/(ANORM * AINVNM)$, where $AINVNM$ is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)

Double precision array, dimension(2*N)

IWORK2 (workspace)

Integer array, dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

```
SUBROUTINE DSPEV_64(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDZ, INFO  
DOUBLE PRECISION AP(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEV(JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: AP, W, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE SPEV_64(JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: AP, W, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dspev(char jobz, char uplo, int n, double *ap, double
           *w, double *z, int ldz, int *info);

void dspev_64(char jobz, char uplo, long n, double *ap, double
              *w, double *z, long ldz, long *info);
```

PURPOSE

dspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)
 Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)
 Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonor-

mal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

Double precision array, dimension(3*N)

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```

#include <sunperf.h>

void dspevd(char jobz, char uplo, int n, double *ap, double
            *w, double *z, int ldz, int *info);
void dspevd_64(char jobz, char uplo, long n, double *ap,
               double *w, double *z, long ldz, long *info);

```

PURPOSE

dspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated

during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)

Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (input) Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Real array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6*N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

PURPOSE

dspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found;
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the sym-

metric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,"

by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

Double precision array, dimension (N) If $\text{INFO} = 0$, the selected eigenvalues in ascending order.

Z (output)

Double precision array, dimension (LDZ, $\max(1, M)$)
If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

Double precision array, dimension(8*N)

IWORK2 (workspace)

Integer array, dimension(5*N)

IFAIL (output)

Integer array, dimension(N) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```

```
CHARACTER * 1 UPLO  
INTEGER*8 ITYPE, N, INFO  
DOUBLE PRECISION AP(*), BP(*)
```

F95 INTERFACE

```
SUBROUTINE SPGST(ITYPE, UPLO, [N], AP, BP, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: ITYPE, N, INFO  
REAL(8), DIMENSION(:) :: AP, BP
```

```
SUBROUTINE SPGST_64(ITYPE, UPLO, [N], AP, BP, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: ITYPE, N, INFO  
REAL(8), DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dspgst(int itype, char uplo, int n, double *ap, double
            *bp, int *info);

void dspgst_64(long itype, char uplo, long n, double *ap,
               double *bp, long *info);

```

PURPOSE

dspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is $Ax = \lambda Bx$, and A is overwritten by $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$.
 If ITYPE = 2 or 3, the problem is $A * B * x = \lambda x$ or $B * A * x = \lambda x$, and A is overwritten by $U * A * U^{**T}$ or $L^{**T} * A * L$.

B must have been previously factorized as $U^{**T} * U$ or $L * L^{**T}$ by SPPTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$;
 = 2 or 3: compute $U * A * U^{**T}$ or $L^{**T} * A * L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**T} * U$; = 'L': Lower triangle of A is stored and B is factored as $L * L^{**T}$.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N * (N + 1) / 2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j - 1) * j / 2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j - 1) * (2n - j) / 2) = A(i, j)$ for $j \leq i \leq n$.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)

Double precision array, dimension $(N*(N+1)/2)$ The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPSTRF.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

    ble *ap, double *bp, double *w, double *z, long  
    ldz, long *info);
```

PURPOSE

dspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)*B*x$
- = 2: $A*B*x = (\lambda)*x$
- = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

- = 'U': Upper triangles of A and B are stored;
- = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

BP (input/output)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

W (output)

Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)

Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**T*B*Z = I$; if ITYPE = 3, $Z**T*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace)

Double precision array, dimension(3*N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: DPPTRF or DSPEV returned an error code:
 <= N: if INFO = i, DSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

#include <sunperf.h>
```

```
void dspgvd(int itype, char jobz, char uplo, int n, double
            *ap, double *bp, double *w, double *z, int ldz,
            int *info);
```

```
void dspgvd_64(long itype, char jobz, char uplo, long n,
               double *ap, double *bp, double *w, double *z, long
               ldz, long *info);
```

PURPOSE

dspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

```
= 1:  A*x = (lambda)*B*x
= 2:  A*B*x = (lambda)*x
= 3:  B*A*x = (lambda)*x
```

JOBZ (input)

```
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.
```

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$, in the same storage format as B.

W (output)
 Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)
 Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*T*B*Z = I$; if ITYPE = 3, $Z^*T*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace/output)
 Double precision array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If $N \leq 1$,

LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: DPPTRF or DSPEVD returned an error code:
<= N: if INFO = i, DSPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

PURPOSE

dspgvx computes selected eigenvalues, and optionally, eigen-
vectors of a real generalized symmetric-definite eigenprob-
lem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or
 $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric,
stored in packed storage, and B is also positive definite.
Eigenvalues and eigenvectors can be selected by specifying
either a range of values or a range of indices for the
desired eigenvalues.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)*B*x$
- = 2: $A*B*x = (\lambda)*x$
- = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.

= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangle of A and B are stored;
= 'L': Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B). $N \geq 0$.

AP (input/output)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$, in the same storage format as B.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged

when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$\text{ABSTOL} + \text{EPS} * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * \text{SLAMCH}('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = \text{IU} - \text{IL} + 1$.

W (output)

Double precision array, dimension (N) On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (output)

Double precision array, dimension (LDZ, $\max(1, M)$) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $\text{INFO} = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $\text{ITYPE} = 1$ or 2 , $Z^* T^* B^* Z = I$; if $\text{ITYPE} = 3$, $Z^* T^* \text{inv}(B)^* Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

Double precision array, dimension(8*N)

IWORK (workspace)

Integer array, dimension(5*N)

IFAIL (output)

Integer array, dimension (N) If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: DPPTRF or DSPEVX returned an error code:
 <= N: if INFO = i, DSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL.
 > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

dspmv - perform the matrix-vector operation $y := \alpha A x + \beta y$

SYNOPSIS

```
SUBROUTINE DSPMV(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER N, INCX, INCY  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(*), X(*), Y(*)
```

```
SUBROUTINE DSPMV_64(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SPMV(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INCX, INCY  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:) :: A, X, Y
```

```
SUBROUTINE SPMV_64(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX, INCY  
REAL(8) :: ALPHA, BETA
```

```
REAL(8), DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspmv(char uplo, int n, double alpha, double *a, double  
           *x, int incx, double beta, double *y, int incy);
```

```
void dspmv_64(char uplo, long n, double alpha, double *a,  
              double *x, long incx, double beta, double *y, long  
              incy);
```

PURPOSE

dspmv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

A (input)

(($n * (n + 1) / 2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$

contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. Before entry with $UPLO = 'L'$ or $'l'$, the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar β . When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

INTEGER(8) :: N, INCX  
REAL(8) :: ALPHA
```

```
REAL(8), DIMENSION(:) :: X, A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspr(char uplo, int n, double alpha, double *x, int  
          incx, double *a);
```

```
void dspr_64(char uplo, long n, double alpha, double *x,  
             long incx, double *a);
```

PURPOSE

dspr performs the symmetric rank 1 operation $A := \alpha x x^T + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX, INCY  
REAL(8) :: ALPHA
```

```
REAL(8), DIMENSION(:) :: X, Y, AP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspr2(char uplo, int n, double alpha, double *x, int  
          incx, double *y, int incy, double *ap);
```

```
void dspr2_64(char uplo, long n, double alpha, double *x,  
             long incx, double *y, long incy, double *ap);
```

PURPOSE

dspr2 performs the symmetric rank 2 operation $A := \alpha x y' + \alpha y x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

X (input)

Double precision array, dimension $(1 + (n - 1) * \text{abs}(\text{INCX}))$ Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

Y (input)

Double precision array, dimension $(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

AP (input/output)

Double precision array, dimension $((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

```

C INTERFACE

```

#include <sunperf.h>
void dsprfs(char uplo, int n, int nrhs, double *ap, double
            *af, int *ipivot, double *b, int ldb, double *x,
            int ldx, double *ferr, double *berr, int *info);

void dsprfs_64(char uplo, long n, long nrhs, double *ap,
               double *af, long *ipivot, double *b, long ldb,
               double *x, long ldx, double *ferr, double *berr,
               long *info);

```

PURPOSE

dsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

AP (input)
 Double precision array, dimension $(N*(N+1)/2)$ The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

AF (input)
 Double precision array, dimension $(N*(N+1)/2)$ The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by DSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

B (input) Double precision array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
 Double precision array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by DSPTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
 Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 Double precision array, dimension(3*N)

WORK2 (workspace)
 Integer array, dimension(N)

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

```

```

INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: A
REAL(8), DIMENSION(:, :) :: B

```

C INTERFACE

```

#include <sunperf.h>

void dspsv(char uplo, int n, int nrhs, double *a, int
           *ipivot, double *b, int ldb, int *info);

void dspsv_64(char uplo, long n, long nrhs, double *a, long
              *ipivot, double *b, long ldb, long *info);

```

PURPOSE

dspsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear

array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by `DSPTRF`, stored as a packed triangular matrix in the same storage format as A .

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D , as determined by `DSPTRF`. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

Double precision array, dimension $(LDB, NRHS)$ On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value
 > 0: if $INFO = i$, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = aji)
            a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

    ble *a, double *af, long *ipivot, double *b, long
    ldb, double *x, long ldx, double *rcond, double
    *ferr, double *berr, long *info);

```

PURPOSE

DSPSVX uses the diagonal pivoting factorization $A = U^*D U^{**T}$ or $A = L^*D L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$$A = U * D * U^{**T}, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * D * L^{**T}, \text{ if } UPLO = 'L',$$
 where U (or L) is a product of permutation and unit upper (lower) triangular matrices and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine

precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.

3. The system of equations is solved for X using the factored form
of A.
4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, AF
and IPIVOT contain the factored form of A. AP, AF
and IPIVOT will not be modified. = 'N': The
matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

AP (input)
Double precision array, dimension $(N*(N+1)/2)$ The
upper or lower triangle of the symmetric matrix A,
packed columnwise in a linear array. The j-th
column of A is stored in the array AP as follows:
if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for
 $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) =$
 $A(i,j)$ for $j \leq i \leq n$. See below for further
details.

AF (input or output)
Double precision array, dimension $(N*(N+1)/2)$ If
FACT = 'F', then AF is an input argument and on
entry contains the block diagonal matrix D and the
multipliers used to obtain the factor U or L from
the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as
computed by DSPTRF, stored as a packed triangular
matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by DSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSPTRF.

B (input) Double precision array, dimension (LDB, NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

Double precision array, dimension (LDX, NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution

corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

Double precision array, dimension(3*N)

WORK2 (workspace)

Integer array, dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: $D(i,i)$ is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. = N+1: D is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = aji)
            a44
```

Packed storage of the upper triangle of A:

AP = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: AP, D, E, TAU
```

C INTERFACE

```
#include <sunperf.h>

void dsptrd(char uplo, int n, double *ap, double *d, double
            *e, double *tau, int *info);

void dsptrd_64(char uplo, long n, double *ap, double *d,
               double *e, double *tau, long *info);
```

PURPOSE

dsptrd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input)

Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D (output)

Double precision array, dimension (N) The diagonal elements of the tridiagonal matrix T: $D(i) =$

$A(i,i)$.

E (output)

Double precision array, dimension (N-1) The off-diagonal elements of the tridiagonal matrix T:
 $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)

Double precision array, dimension (N-1) The scalar factors of the elementary reflectors (see Further Details).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in AP, overwriting $A(1:i-1,i+1)$, and τ is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in AP, overwriting $A(i+2:n,i)$, and τ is stored in TAU(i).

REAL(8), DIMENSION(:) :: AP
```

```
SUBROUTINE SPTRF_64(UPLO, [N], AP, IPIVOT, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: AP

```

C INTERFACE

```

#include <sunperf.h>

void dsptrf(char uplo, int n, double *ap, int *ipivot, int
            *info);

void dsptrf_64(char uplo, long n, double *ap, long *ipivot,
               long *info);

```

PURPOSE

dsptrf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double precision array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,
i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L * D * L'$, where

$$L = P(1) * L(1) * \dots * P(k) * L(k) * \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \\ & & & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \\ k-1 \quad s \quad n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

               long *info);
```

PURPOSE

dsptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by DSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U^*D^*U^{**T}$;
= 'L': Lower triangular, form is $A = L^*D^*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
Double precision array, dimension $(N*(N+1)/2)$ On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = inv(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

WORK (workspace)
Double precision array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

void dspttrs_64(char uplo, long n, long nrhs, double *ap,
                long *ipivot, double *b, long ldb, long *info);

```

PURPOSE

dspttrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by DSPTRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
 = 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

AP (input)
 Double precision array, dimension $(N \cdot (N+1) / 2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

B (input/output)
 Double precision array, dimension $(LDB, NRHS)$ On entry, the right hand side matrix B . On exit, the

solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void dstebz(char range, char order, int n, double vl, double
            vu, int il, int iu, double abstol, double *d,
            double *e, int *m, int *nsplit, double *w, int
            *iblock, int *isplit, int *info);

void dstebz_64(char range, char order, long n, double vl,
               double vu, long il, long iu, double abstol, double
               *d, double *e, long *m, long *nsplit, double *w,
               long *iblock, long *isplit, long *info);

```

PURPOSE

dstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $\text{overflow}^{1/2}$ * $\text{underflow}^{1/4}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

RANGE (input)

- = 'A': ("All") all eigenvalues will be found.
- = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found.
- = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER (input)

- = 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT)

and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N (input) The order of the tridiagonal matrix T. $N \geq 0$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then $ULP*|T|$ will be used, where $|T|$ means the 1-norm of T.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) off-diagonal elements of the tridiagonal matrix T.

M (output)

The actual number of eigenvalues found. $0 \leq M \leq N$. (See also the description of INFO=2,3.)

NSPLIT (output)

The number of diagonal blocks in the matrix T. $1 \leq NSPLIT \leq N$.

W (output)

On exit, the first M elements of W will contain the eigenvalues. (DSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK (output)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (DSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT (output)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK (workspace)

dimension(4*N)

IWORK (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: some or all of the eigenvalues failed to converge or were not computed:

=1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found.

Effect: $M < IU + 1 - IL$

Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

```

```
SUBROUTINE STEDC_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
                   [LIWORK], [INFO])
```

```

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: Z

```

C INTERFACE

```

#include <sunperf.h>

void dstedc(char compz, int n, double *d, double *e, double
            *z, int ldz, int *info);
void dstedc_64(char compz, long n, double *d, double *e,
               double *z, long ldz, long *info);

```

PURPOSE

dstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)

- = 'N': Compute eigenvalues only.
- = 'I': Compute eigenvectors of tridiagonal matrix also.
- = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.
N >= 0.

D (input/output)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
 On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1.
 If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
 dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If COMPZ = 'N' or $N \leq 1$ then LWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LWORK must be at least $(1 + 3*N + 2*N*\lg N + 3*N**2)$, where $\lg(N)$ = smallest integer k such that $2**k \geq N$. If COMPZ = 'I' and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
 On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
 The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$ then LIWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LIWORK must be at least $(6 + 6*N + 5*N*\lg N)$. If COMPZ = 'I' and $N > 1$ then LIWORK must be at least $(3 + 5*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

```

PURPOSE

dstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,

(c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),

(d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently DSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine DSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. DSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : DSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of DSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 See the description of VL.

IL (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
 See the description of IL.

ABSTOL (input)
 The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq \max(1, 18*N)$
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. $LIWORK \geq \max(1, 10*N)$
If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if
INFO = 2, internal error in SLARRV.

REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dstein(int n, double *d, double *e, int m, double *w,
            int *iblock, int *isplit, double *z, int ldz, int
            *ifail, int *info);

void dstein_64(long n, double *d, double *e, long m, double
               *w, long *iblock, long *isplit, double *z, long
               ldz, long *ifail, long *info);
```

PURPOSE

dstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from DSTEBZ with ORDER = 'B' is expected here.)

IBLOCK (input)
The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix

from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from DSTEBZ is expected here.)

ISPLIT (input)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from DSTEBZ is expected here.)

Z (output)

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ (input)

The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)

dimension(5*N)

IWORK (workspace)

dimension(N)

IFAIL (output)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

NAME

dsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE DSTEQR(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
INTEGER N, LDZ, INFO  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE DSTEQR_64(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
INTEGER*8 N, LDZ, INFO  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEQR_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dsteqr(char compz, int n, double *d, double *e, double
            *z, int ldz, int *info);

void dsteqr_64(char compz, long n, double *d, double *e,
               double *z, long ldz, long *info);
```

PURPOSE

dsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I',

Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if eigenvectors are desired, then LDZ \geq max(1,N).

WORK (workspace)

dimension(max(1,2*N-2)) If COMPZ = 'N', then WORK is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: the algorithm has failed to find all the eigenvalues in a total of 30*N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

```
SUBROUTINE STERF([N], D, E, [INFO])
```

```
INTEGER :: N, INFO  
REAL(8), DIMENSION(:) :: D, E
```

```
SUBROUTINE STERF_64([N], D, E, [INFO])
```

```
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsterf(int n, double *d, double *e, int *info);
```

```
void dsterf_64(long n, double *d, double *e, long *info);
```

PURPOSE

dsterf computes all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm.

ARGUMENTS

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: the algorithm failed to find all of the eigenvalues in a total of $30 \cdot N$ iterations; if INFO = i, then i elements of E have not converged to zero.

REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEV_64(JOBZ, N, D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ  
INTEGER(8) :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dstev(char jobz, int n, double *d, double *e, double
           *z, int ldz, int *info);

void dstev_64(char jobz, long n, double *d, double *e, double
              *z, long ldz, long *info);
```

PURPOSE

dstev computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E; E(N) need not be set, but is used by the routine. On exit, the contents of E are destroyed.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)
If JOBZ = 'N', WORK is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

NAME

dstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

SYNOPSIS

```
SUBROUTINE DSTEVD(JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK,  
INFO)
```

```
CHARACTER * 1 JOBZ  
INTEGER N, LDZ, LWORK, LIWORK, INFO  
INTEGER IWORK(*)  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE DSTEVD_64(JOBZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
LIWORK, INFO)
```

```
CHARACTER * 1 JOBZ  
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEVD(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
[LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEVD_64(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
[LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ
```

```

INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: Z

```

C INTERFACE

```

#include <sunperf.h>

void dstevd(char jobz, int n, double *d, double *e, double
            *z, int ldz, int *info);
void dstevd_64(char jobz, long n, double *d, double *e, dou-
               ble *z, long ldz, long *info);

```

PURPOSE

dstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E; E(N) need not be set, but is used by the routine. On exit, the contents of E are destroyed.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associ-

ated with $D(i)$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension (LWORK) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $JOBZ = 'N'$ or $N \leq 1$ then LWORK must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $JOBZ = 'N'$ or $N \leq 1$ then LIWORK must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then LIWORK must be at least $3+5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

               ldz, long *isuppz, long *info);

```

PURPOSE

dstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, DSTEVR calls DSTEGR to compute the eigenspectrum using Relatively Robust Representations. DSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T ,

(a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$

is a relatively robust representation,

(b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high

relative accuracy by the dqds algorithm,

(c) If there is a cluster of close eigenvalues, "choose" σ_i

close to the cluster, and go to step (a),

(d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$,

compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by

Note 1 : DSTEVR calls DSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. DSTEVR calls DSTEGBZ and DSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of DSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E; E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$\text{ABSTOL} + \text{EPS} * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = \text{IU} - \text{IL} + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z , i.e., the indices indicating the nonzero elements in Z . The i -th eigenvector is nonzero only in elements $ISUPPZ(2*i-1)$ through $ISUPPZ(2*i)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal (and minimal) $LWORK$.

LWORK (input)

The dimension of the array WORK. $LWORK \geq 20*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal (and minimal) $LIWORK$.

LIWORK (input)

The dimension of the array IWORK. $LIWORK \geq 10*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: Internal error

```

PURPOSE

dstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a

constant factor chosen to avoid over/underflow in computing the eigenvalues.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E; E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge ($\text{INFO} > 0$), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL . If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

dimension($5 \cdot N$)

IWORK2 (workspace)

IFAIL (output)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, then i eigenvectors failed to converge. Their indices are stored in array IFAIL .

INTEGER(8), DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:) :: L, D, SUBL  
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>

void dstsv(int n, int nrhs, double *l, double *d, double
           *subl, double *b, int ldb, int *ipiv, int *info);

void dstsv_64(long n, long nrhs, double *l, double *d, double
              *subl, double *b, long ldb, long *ipiv, long
              *info);
```

PURPOSE

dstsv computes the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix.

ARGUMENTS

N (input) INTEGER
 The order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides in B.

L (input/output)
 REAL array, dimension (N-1)
 On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
 REAL array, dimension (N)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
 REAL array, dimension (N-2)
 On exit, part of the factorization of A.

B (input/output)
 The columns of B contain the right hand sides.

LDB (input)
 The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)
 INTEGER array, dimension (N)
 On exit, the pivot indices of the factorization.

INFO (output)

INTEGER

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

```
SUBROUTINE STTRF_64([N], L, D, SUBL, IPIV, [INFO])
```

```
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL(8), DIMENSION(:) :: L, D, SUBL
```

C INTERFACE

```
#include <sunperf.h>

void dsttrf(int n, double *l, double *d, double *subl, int
            *ipiv, int *info);

void dsttrf_64(long n, double *l, double *d, double *subl,
               long *ipiv, long *info);
```

PURPOSE

dsttrf computes the L^*D^*L' factorization of a real symmetric tridiagonal matrix A using the Bunch-Kaufman diagonal pivoting method.

ARGUMENTS

N (input) INTEGER
 The order of the matrix A. $N \geq 0$.

L (input/output)
 REAL array, dimension (N-1)
 On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
 REAL array, dimension (N)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the $L^*D^*L^{**H}$ factorization of A.

SUBL (output)
 REAL array, dimension (N-2)
 On exit, part of the factorization of A.

IPIV (output)
 INTEGER array, dimension (N)
 On exit, the pivot indices of the factorization.

INFO (output)
 INTEGER
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block

diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:) :: L, D, SUBL
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>

void dsttrs(int n, int nrhs, double *l, double *d, double
            *subl, double *b, int ldb, int *ipiv, int *info);

void dsttrs_64(long n, long nrhs, double *l, double *d, double
               *subl, double *b, long ldb, long *ipiv, long
               *info);
```

PURPOSE

dsttrs computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

NRHS (input)
 INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

L (input) REAL array, dimension (N-1)
On entry, the subdiagonal elements of L.

D (input) REAL array, dimension (N)
On entry, the diagonal elements of D.

SUBL (input)
 REAL array, dimension (N-2)
On entry, the second subdiagonal elements of L.

B (input/output)
 REAL array, dimension
(LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 INTEGER
The leading dimension of the array B. $LDB \geq \max(1, N)$

IPIV (output)
 INTEGER array, dimension (N)
Details of the interchanges and block pivot. If

IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1
an interchange done; If IPIV(K) < 0, 2 by 2
pivot, no interchange required.

INFO (output)

INTEGER
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an ille-
gal value

NAME

dswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE DSWAP(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DSWAP_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SWAP([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dswap(int n, double *x, int incx, double *y, int incy);
```

```
void dswap_64(long n, double *x, long incx, double *y, long  
               incy);
```

PURPOSE

dswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

INTEGER IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DSYCON_64(UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,  
                    IWORK2, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, LDA, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYCON(UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND, [WORK],  
                [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYCON_64(UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
    [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dsycon(char uplo, int n, double *a, int lda, int
    *ipivot, double anorm, double *rcond, int *info);

void dsycon_64(char uplo, long n, double *a, long lda, long
    *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dsycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by DSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U*D*U^{**T}$;
 = 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by DSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dsyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE DSYEV(JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

```
SUBROUTINE DSYEV_64(JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDA, LDWORK, INFO  
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEV(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYEV_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDA, LDWORK, INFO  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsyev(char jobz, char uplo, int n, double *a, int lda,
           double *w, int *info);

void dsyev_64(char jobz, char uplo, long n, double *a, long
              lda, double *w, long *info);
```

PURPOSE

dsyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

W (output)
 If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK \geq max(1,3*N-1). For optimal efficiency, LDWORK \geq (NB+2)*N, where NB is the blocksize for DSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

INTEGER*8 N, LDA, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
DOUBLE PRECISION A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEVD(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK], [IWORK],  
                [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDA, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYEVD_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],  
                   [IWORK], [LIWORK], [INFO])
```

```

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void dsyevd(char jobz, char uplo, int n, double *a, int lda,
            double *w, int *info);
void dsyevd_64(char jobz, char uplo, long n, double *a, long
               lda, double *w, long *info);

```

PURPOSE

dsyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, DSYEVD needs N^2 more workspace than DSYEVX.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if

INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

               il, long iu, double abstol, long *m, double *w,
               double *z, long ldz, long *isuppz, long *info);
```

PURPOSE

dsyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, DSYEVR calls DSTEGR to compute the eigenspectrum using Relatively Robust Representations. DSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : DSYEVR calls DSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. DSYEVR calls DSTEBZ and DSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of DSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval $(VL, VU]$ will be found.
- = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of

M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq \max(1, 26*N)$. For optimal efficiency, LWORK $\geq (NB+6)*N$, where NB is the max of the blocksize for DSYTRD and DORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK $\geq \max(1, 10*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: Internal error

```

PURPOSE

dsyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
- = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,"

by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. $\text{LDWORK} \geq \max(1, 8*N)$. For optimal efficiency, $\text{LDWORK} \geq (\text{NB} + 3)*N$, where NB is the max of the blocksize for DSYTRD and DORMTR returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)

IFAIL (output)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value
> 0:  if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.
```

REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dsygs2(int itype, char uplo, int n, double *a, int lda,
            double *b, int ldb, int *info);

void dsygs2_64(long itype, char uplo, long n, double *a,
               long lda, double *b, long ldb, long *info);

```

PURPOSE

dsygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $Ax = \lambda Bx$, and A is overwritten by $\text{inv}(U')A\text{inv}(U)$ or $\text{inv}(L)A\text{inv}(L')$. If ITYPE = 2 or 3, the problem is $ABx = \lambda x$ or $B^*Ax = \lambda x$, and A is overwritten by U^*AU' or L'^*AL .

B must have been previously factorized as U^*U or L^*L' by SPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U')A\text{inv}(U)$ or $\text{inv}(L)A\text{inv}(L')$;
 = 2 or 3: compute U^*AU' or L'^*AL .

UPLO (input)
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular
 = 'L': Lower triangular

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

```

```
SUBROUTINE SYGST_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO  
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dsygst(int itype, char uplo, int n, double *a, int lda,
            double *b, int ldb, int *info);

void dsygst_64(long itype, char uplo, long n, double *a,
               long lda, double *b, long ldb, long *info);

```

PURPOSE

dsygst reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $Ax = \lambda Bx$, and A is overwritten by $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$.
 If ITYPE = 2 or 3, the problem is $A * B * x = \lambda x$ or $B * A * x = \lambda x$, and A is overwritten by $U * A * U^{**T}$ or $L^{**T} * A * L$.

B must have been previously factorized as $U^{**T} * U$ or $L * L^{**T}$ by SPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$;
 = 2 or 3: compute $U * A * U^{**T}$ or $L^{**T} * A * L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**T} * U$; = 'L': Lower triangle of A is stored and B is factored as $L * L^{**T}$.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,

stored in the same format as A.

LDA (input)

The leading dimension of the array A. LDA \geq
max(1,N).

B (input) The triangular factor from the Cholesky factoriza-
tion of B, as returned by SPOTRF.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: ITYPE, N, LDA, LDB, LDWORK, INFO  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:,:) :: A, B
```

```
SUBROUTINE SYGV_64(ITYPE, JOBZ, UPLO, N, A, [LDA], B, [LDB], W, [WORK],  
                  [LDWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: ITYPE, N, LDA, LDB, LDWORK, INFO
```

```
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dsygv(int itype, char jobz, char uplo, int n, double
           *a, int lda, double *b, int ldb, double *w, int
           *info);

void dsygv_64(long itype, char jobz, char uplo, long n, dou-
              ble *a, long lda, double *b, long ldb, double *w,
              long *info);
```

PURPOSE

dsygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also positive definite.

ARGUMENTS

ITYPE (input)
Specifies the problem type to be solved:
= 1: $A*x = (\lambda)*B*x$
= 2: $A*B*x = (\lambda)*x$
= 3: $B*A*x = (\lambda)*x$

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvec-

tors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{**T}B*Z = I$; if $ITYPE = 3$, $Z^{**T}inv(B)*Z = I$. If $JOBZ = 'N'$, then on exit the upper triangle (if $UPLO='U'$) or the lower triangle (if $UPLO='L'$) of A , including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1,N)$.

B (input/output)

On entry, the symmetric positive definite matrix B . If $UPLO = 'U'$, the leading N -by- N upper triangular part of B contains the upper triangular part of the matrix B . If $UPLO = 'L'$, the leading N -by- N lower triangular part of B contains the lower triangular part of the matrix B .

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^{**T}U$ or $B = L*L^{**T}$.

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

W (output)

If $INFO = 0$, the eigenvalues in ascending order.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of the array $WORK$. $LDWORK \geq \max(1,3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for $DSYTRD$ returned by $ILAENV$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

INFO (output)

$= 0$: successful exit
 < 0 : if $INFO = -i$, the i -th argument had an illegal value
 > 0 : $DPOTRF$ or $DSYEV$ returned an error code:
 $\leq N$: if $INFO = i$, $DSYEV$ failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;
 $> N$: if $INFO = N + i$, for $1 \leq i \leq N$, then the leading

minor of order i of B is not positive definite.
The factorization of B could not be completed and
no eigenvalues or eigenvectors were computed.

               *w, long *info);
```

PURPOSE

dsygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^T B Z = I$; if ITYPE = 3, $Z^T \text{inv}(B) Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T U$ or $B = L L^T$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N^2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: DPOTRF or DSYEVD returned an error code:
<= N: if INFO = i, DSYEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

    double vl, double vu, long il, long iu, double
    abstol, long *m, double *w, double *z, long ldz,
    long *ifail, long *info);

```

PURPOSE

dsygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $Ax = (\lambda)Bx$, $ABx = (\lambda)x$, or $B^*Ax = (\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

ITYPE (input)
    Specifies the problem type to be solved:
    = 1:  $Ax = (\lambda)Bx$ 
    = 2:  $ABx = (\lambda)x$ 
    = 3:  $B^*Ax = (\lambda)x$ 

JOBZ (input)
    = 'N': Compute eigenvalues only;

```

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A and B are stored;
 = 'L': Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B). $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

 On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

 On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * DLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'N', then Z is not referenced. If JOBZ

= 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^* T * B * Z = I$; if $ITYPE = 3$, $Z^* T * \text{inv}(B) * Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
 The leading dimension of the array Z. LDZ ≥ 1 ,
 and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal
 LWORK.

LWORK (input)
 The length of the array WORK. LWORK \geq
 $\max(1, 8*N)$. For optimal efficiency, LWORK \geq
 $(NB+3)*N$, where NB is the blocksize for DSYTRD
 returned by ILAENV.

If LWORK = -1, then a workspace query is assumed;
 the routine only calculates the optimal size of
 the WORK array, returns this value as the first
 entry of the WORK array, and no error message
 related to LWORK is issued by XERBLA.

IWORK (workspace)
 dimension(5*N)

IFAIL (output)
 If JOBZ = 'V', then if INFO = 0, the first M ele-
 ments of IFAIL are zero. If INFO > 0, then IFAIL
 contains the indices of the eigenvectors that
 failed to converge. If JOBZ = 'N', then IFAIL is
 not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: DPOTRF or DSYEVX returned an error code:
 <= N: if INFO = i, DSYEVX failed to converge; i
 eigenvectors failed to converge. Their indices
 are stored in array IFAIL. > N: if INFO = N +
 i, for 1 <= i <= N, then the leading minor of
 order i of B is not positive definite. The fac-
 torization of B could not be completed and no
 eigenvalues or eigenvectors were computed.

```

C INTERFACE

```

#include <sunperf.h>

void dsymm(char side, char uplo, int m, int n, double alpha,
           double *a, int lda, double *b, int ldb, double
           beta, double *c, int ldc);

void dsymm_64(char side, char uplo, long m, long n, double
             alpha, double *a, long lda, double *b, long ldb,
             double beta, double *c, long ldc);

```

PURPOSE

dsymm performs one of the matrix-matrix operations $C := \alpha A^*B + \beta C$ or $C := \alpha B^*A + \beta C$ where α and β are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha A^*B + \beta C$,

SIDE = 'R' or 'r' $C := \alpha B^*A + \beta C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

B (input)

DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on

exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB \geq max(1, m). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC \geq max(1, m). Unchanged on exit.

NAME

dsymv - perform the matrix-vector operation $y := \alpha A x + \beta y$

SYNOPSIS

```
SUBROUTINE DSVMV(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER N, LDA, INCX, INCY  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

```
SUBROUTINE DSVMV_64(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, LDA, INCX, INCY  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SYMV(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INCX, INCY  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:) :: X, Y  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYMV_64(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INCX, INCY  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:) :: X, Y
```

```
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsymv(char uplo, int n, double alpha, double *a, int  
          lda, double *x, int incx, double beta, double *y,  
          int incy);
```

```
void dsymv_64(char uplo, long n, double alpha, double *a,  
              long lda, double *x, long incx, double beta, dou-  
              ble *y, long incy);
```

PURPOSE

dsymv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly

upper triangular part of A is not referenced.
Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

dsyr - perform the symmetric rank 1 operation $A := \alpha x x' + A$

SYNOPSIS

```
SUBROUTINE DSyr(UPLO, N, ALPHA, X, INCX, A, LDA)
```

```
CHARACTER * 1 UPLO  
INTEGER N, INCX, LDA  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), A(LDA,*)
```

```
SUBROUTINE DSyr_64(UPLO, N, ALPHA, X, INCX, A, LDA)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, INCX, LDA  
DOUBLE PRECISION ALPHA  
DOUBLE PRECISION X(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYr(UPLO, [N], ALPHA, X, [INCX], A, [LDA])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INCX, LDA  
REAL(8) :: ALPHA  
REAL(8), DIMENSION(:) :: X  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYr_64(UPLO, [N], ALPHA, X, [INCX], A, [LDA])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX, LDA
```

```

REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X
REAL(8), DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void dsyr(char uplo, int n, double alpha, double *x, int
          incx, double *a, int lda);

void dsyr_64(char uplo, long n, double alpha, double *x,
             long incx, double *a, long lda);

```

PURPOSE

dsyr performs the symmetric rank 1 operation $A := \alpha x x^T + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsyr2(char uplo, int n, double alpha, double *x, int
           incx, double *y, int incy, double *a, int lda);

void dsyr2_64(char uplo, long n, double alpha, double *x,
              long incx, double *y, long incy, double *a, long
              lda);
```

PURPOSE

dsyr2 performs the symmetric rank 2 operation $A := \alpha x y' + \alpha y x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the

elements of X. INCX \neq 0. Unchanged on exit.

Y (input)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

NAME

dsyr2k - perform one of the symmetric rank 2k operations $C := \alpha A B' + \alpha B A' + \beta C$ or $C := \alpha A' B + \alpha B' A + \beta C$

SYNOPSIS

```
SUBROUTINE DSyr2K(UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA, C,  
                  LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
INTEGER N, K, LDA, LDB, LDC  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

```
SUBROUTINE DSyr2K_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,  
                     C, LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
INTEGER*8 N, K, LDA, LDB, LDC  
DOUBLE PRECISION ALPHA, BETA  
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYR2K(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],  
                 BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
INTEGER :: N, K, LDA, LDB, LDC  
REAL(8) :: ALPHA, BETA  
REAL(8), DIMENSION(:,:) :: A, B, C
```

```
SUBROUTINE SYR2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,  
                    [LDB], BETA, C, [LDC])
```

```

CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void dsyr2k(char uplo, char transa, int n, int k, double
            alpha, double *a, int lda, double *b, int ldb,
            double beta, double *c, int ldc);
void dsyr2k_64(char uplo, char transa, long n, long k, dou-
               ble alpha, double *a, long lda, double *b, long
               ldb, double beta, double *c, long ldc);

```

PURPOSE

dsyr2k performs one of the symmetric rank 2k operations $C := \alpha A A^T + \alpha A^T A + \beta C$ or $C := \alpha A^T B + \alpha B^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \alpha A^T A + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T B + \alpha B^T A + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha * A * B + \alpha * B * A + \beta * C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

B (input)

DOUBLE PRECISION array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta.
Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

    lda, double *af, long ldaf, long *ipivot, double
    *b, long ldb, double *x, long ldx, double *ferr,
    double *berr, long *info);
```

PURPOSE

dsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. LDA >=

max(1,N).

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by DSYTRF.

LDAF (input)
 The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input)
 Details of the interchanges and the block structure of D as determined by DSYTRF.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
 On entry, the solution matrix X, as computed by DSYTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
 The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 dimension(3*N)

WORK2 (workspace)
 dimension(N)

INFO (output)

```
= 0:  successful exit  
< 0:  if INFO = -i, the i-th argument had an illegal value
```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsyrk(char uplo, char transa, int n, int k, double
           alpha, double *a, int lda, double beta, double *c,
           int ldc);
```

```
void dsyrk_64(char uplo, char transa, long n, long k, double
              alpha, double *a, long lda, double beta, double
              *c, long ldc);
```

PURPOSE

dsyrk performs one of the symmetric rank k operations $C := \alpha A A^T + \beta C$ or $C := \alpha A^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T A + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha A^T A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

lar part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dsysv(char uplo, int n, int nrhs, double *a, int lda,
            int *ipivot, double *b, int ldb, int *info);
void dsysv_64(char uplo, long n, long nrhs, double *a, long
               lda, long *ipivot, double *b, long ldb, long
               *info);
```

PURPOSE

dsysv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D

and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by DSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by DSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The length of WORK. $LWORK \geq 1$, and for best performance $LWORK \geq N*NB$, where NB is the optimal blocksize for DSYTRF.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

```

PURPOSE

dsysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A .

The form of the factorization is

$A = U * D * U^{**T}$, if $UPLO = 'U'$, or

$A = L * D * L^{**T}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is symmetric and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the

reciprocal of the condition number is less than machine precision,

INFO = N+1 is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form

of A.

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from

the factorization $A = U^*D*U^{**T}$ or $A = L^*D*L^{**T}$ as computed by DSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D*U^{**T}$ or $A = L^*D*L^{**T}$.

LDAF (input)

The leading dimension of the array AF. LDAF $\geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by DSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by DSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB $\geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX $\geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solu-

tion vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of $WORK$. $LDWORK \geq 3*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for $DSYTRF$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 <= N : $D(i,i)$ is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. = $N+1$: D is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

```
#include <sunperf.h>

void dsytd2(char uplo, int n, double *a, int lda, double *d,
            double *e, double *tau, int *info);

void dsytd2_64(char uplo, long n, double *a, long lda, double *d,
               double *e, double *tau, long *info);
```

PURPOSE

dsytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T A Q = T$.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

D (output)
The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i, i)$.

E (output)
The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i, i+1)$ if UPLO = 'U', $E(i) = A(i+1, i)$ if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(1:i-1, i+1)$, and τ in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n, i)$, and τ in TAU(i).

The contents of A on exit are illustrated by the following

examples with $n = 5$:

```

if UPLO = 'U':
    ( d e v2 v3 v4 )
)
( d e v3 v4 )
)
( d e v4 )
)
( d e )
)
( d )
)

if UPLO = 'L':
    ( d
    ( e d
    ( v1 e d
    ( v1 v2 e d
    ( v1 v2 v3 e d
    )

```

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE SYTF2_64(UPLO, [N], A, [LDA], IPIV, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsytf2(char uplo, int n, double *a, int lda, int *ipiv,
            int *info);

void dsytf2_64(char uplo, long n, double *a, long lda, long
               *ipiv, long *info);
```

PURPOSE

dsytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIV (output)

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
 < 0: if $INFO = -k$, the k-th argument had an illegal value
 > 0: if $INFO = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If $UPLO = 'U'$, then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,
 i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If $s = 1$, $D(k)$ overwrites $A(k, k)$, and v overwrites $A(1:k-$

1,k). If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

NAME

dsytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE DSYTRD(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), D(*), E(*), TAU(*), WORK(*)
```

```
SUBROUTINE DSYTRD_64(UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), D(*), E(*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRD(UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: D, E, TAU, WORK  
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE SYTRD_64(UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: D, E, TAU, WORK  
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsytrd(char uplo, int n, double *a, int lda, double *d,
            double *e, double *tau, int *info);

void dsytrd_64(char uplo, long n, double *a, long lda, double *d,
               double *e, double *tau, long *info);
```

PURPOSE

dsytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

D (output)

The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 . For optimum performance LWORK $\geq N \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(1:i-1,i+1)$, and τ in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where tau is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n,i)$, and tau in $TAU(i)$.
The contents of A on exit are illustrated by the following examples with $n = 5$:

```

if UPLO = 'U':                                if UPLO = 'L':

    (      d      e      v2      v3      v4      )                (      d
)
    (          d      e      v3      v4      )                (      e      d
)
    (              d      e      v4      )                (      v1      e      d
)
    (                  d      e      )                (      v1      v2      e      d
)
    (                      d      )                (      v1      v2      v3      e      d
)

```

where d and e denote diagonal and off-diagonal elements of T, and v_i denotes an element of the vector defining $H(i)$.

```

```
SUBROUTINE SYTRF_64(UPLO, N, A, [LDA], IPIVOT, [WORK], [LDWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LDWORK, INFO
```

```

INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void dsytrf(char uplo, int n, double *a, int lda, int
            *ipivot, int *info);

void dsytrf_64(char uplo, long n, double *a, long lda, long
               *ipivot, long *info);

```

PURPOSE

dsytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of WORK. $LDWORK \geq 1$. For best performance $LDWORK \geq N \cdot NB$, where NB is the block size returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i, i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If $UPLO = 'U'$, then $A = U \cdot D \cdot U^T$, where

$U = P(n) \cdot U(n) \cdot \dots \cdot P(k) \cdot U(k) \cdot \dots$,

i.e., U is a product of terms $P(k) \cdot U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal

block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

C INTERFACE

```
#include <sunperf.h>
```

```
void dsytri(char uplo, int n, double *a, int lda, int
           *ipivot, int *info);
```

```
void dsytri_64(char uplo, long n, double *a, long lda, long
              *ipivot, long *info);
```

PURPOSE

dsytri computes the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by DSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U*D*U^{**T}$;
 = 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by DSYTRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

               lda, long *ipivot, double *b, long ldb, long
               *info);
```

PURPOSE

dsytrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by DSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^T$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^T$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSYTRF.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by DSYTRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```

REAL(8), DIMENSION(:, :) :: A

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND,
    [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, KD, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>
void dtbcon(char norm, char uplo, char diag, int n, int kd,
    double *a, int lda, double *rcond, int *info);

void dtbcon_64(char norm, char uplo, char diag, long n, long
    kd, double *a, long lda, double *rcond, long
    *info);

```

PURPOSE

dtbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. $LDA \geq KD+1$.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension($3*N$)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

dtbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE DTBMV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, K, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTBMV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, K, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, K, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, K, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtbmv(char uplo, char transa, char diag, int n, int k,
           double *a, int lda, double *y, int incy);

void dtbmv_64(char uplo, char transa, char diag, long n,
              long k, double *a, long lda, double *y, long
              incy);
```

PURPOSE

dtbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. $K \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading ($k + 1$) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row ($k + 1$) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading ($k + 1$) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE

```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

#include <sunperf.h>
void dtbrfs(char uplo, char transa, char diag, int n, int
    kd, int nrhs, double *a, int lda, double *b, int
    ldb, double *x, int ldx, double *ferr, double
    *berr, int *info);

void dtbrfs_64(char uplo, char transa, char diag, long n,
    long kd, long nrhs, double *a, long lda, double
    *b, long ldb, double *x, long ldx, double *ferr,
    double *berr, long *info);

```

PURPOSE

dtbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by DTBTRS or some other means before entering this routine. DTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^* * X = B$ (Transpose)
 = 'C': $A^H * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. $LDA \geq KD+1$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)
The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dtbsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTBSV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, K, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTBSV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, K, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBSV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, K, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TBSV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, K, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtbsv(char uplo, char transa, char diag, int n, int k,
           double *a, int lda, double *y, int incy);

void dtbsv_64(char uplo, char transa, char diag, long n,
              long k, double *a, long lda, double *y, long
              incy);
```

PURPOSE

dtbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N \geq 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K \geq 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position

1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10     CONTINUE
20    CONTINUE

```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

[LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, KD, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:,:) :: A, B
```

```
SUBROUTINE TBTRS_64(UPLO, [TRANSA], DIAG, [N], KD, [NRHS], A, [LDA], B,  
[LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtbtrs(char uplo, char transa, char diag, int n, int
            kd, int nrhs, double *a, int lda, double *b, int
            ldb, int *info);

void dtbtrs_64(char uplo, char transa, char diag, long n,
               long kd, long nrhs, double *a, long lda, double
               *b, long ldb, long *info);
```

PURPOSE

dtbtrs solves a triangular system of the form

$$A * X = B \text{ or } A^{**T} * X = B$$

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)

Specifies the form the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of A. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j, j)$

```

        = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L',
        A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If
        DIAG = 'U', the diagonal elements of A are not
        referenced and are assumed to be 1.

LDA (input)
    The leading dimension of the array A. LDA >=
    KD+1.

B (input/output)
    On entry, the right hand side matrix B. On exit,
    if INFO = 0, the solution matrix X.

LDB (input)
    The leading dimension of the array B. LDB >=
    max(1,N).

INFO (output)
    = 0: successful exit
    < 0: if INFO = -i, the i-th argument had an ille-
    gal value
    > 0: if INFO = i, the i-th diagonal element of A
    is zero, indicating that the matrix is singular
    and the solutions X have not been computed.

    double *a, long lda, double *b, long ldb, double  
    *vl, long ldvl, double *vr, long ldvr, long mm,  
    long *m, long *info);
```

PURPOSE

dtgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{*H} * (A - wB) = 0$$

where y^{*H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B , a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products Z^*X and/or Q^*Y , where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices

$$(A0, B0) = (Q^*A^*Z^{*H}, Q^*B^*Z^{*H}),$$

then Z^*X and Q^*Y are the matrices of right or left eigenvectors of A .

A must be block upper triangular, with 1-by-1 and 2-by-2 diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
 = 'L': compute left eigenvectors only;
 = 'B': compute both right and left eigenvectors.

HOWMNY (input)

= 'A': compute all right and/or left eigenvectors;
 = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE..

N (input) The order of the matrices A and B. $N \geq 0$.

A (input) The upper quasi-triangular matrix A.

LDA (input)

The leading dimension of array A. $LDA \geq \max(1, N)$.

B (input) The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive elements.

LDB (input)

The leading dimension of array B. $LDB \geq \max(1, N)$.

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

LDVL (input)

The leading dimension of array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each

selected complex eigenvector occupies two columns.

WORK (workspace)
dimension(6*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

FURTHER DETAILS

Allocation of workspace:

----- -- -----

WORK(j) = 1-norm of j-th column of A, above the diagonal

WORK(N+j) = 1-norm of j-th column of B, above the diagonal

WORK(2*N+1:3*N) = real part of eigenvector

WORK(3*N+1:4*N) = imaginary part of eigenvector

WORK(4*N+1:5*N) = real part of back-transformed eigenvector

WORK(5*N+1:6*N) = imaginary part of back-transformed eigenvector

Rowwise vs. columnwise solution methods:

----- -- -----

Finding a generalized eigenvector consists basically of solving the singular triangular system

$(A - w B) x = 0$ (for right) or: $(A - w B)^* H y = 0$ (for left)

Consider finding the i-th right eigenvector (assume all eigenvalues are real). The equation to be solved is:

$$0 = \sum_{k=j} C(j,k) v(k) = \sum_{k=j} C(j,k) v(k) \quad \text{for } j = i, \dots, n$$

where $C = (A - w B)$ (The components $v(i+1:n)$ are 0.)

The "rowwise" method is:

(1) $v(i) := 1$

for $j = i-1, \dots, 1$:

(2) compute $s = - \sum_{k=j+1}^i C(j,k) v(k)$ and

(3) $v(j) := s / C(j,j)$

Step 2 is sometimes called the "dot product" step, since it is an inner product between the j-th row and the portion of the eigenvector that has been computed so far.

The "columnwise" method consists basically in doing the sums for all the rows in parallel. As each $v(j)$ is computed, the contribution of $v(j)$ times the j-th column of C is added to the partial sums. Since FORTRAN arrays are stored columnwise, this has the advantage that at each step, the elements of C that are accessed are adjacent to one another, whereas with the rowwise method, the elements accessed at a step are spaced LDA (and LDB) words apart.

When finding left eigenvectors, the matrix in question is the transpose of the one in storage, so the rowwise method then actually accesses columns of A and B at each step, and so is the preferred method.

               long *info);

```

PURPOSE

dtgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'$$

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)

On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

Q (input/output)
On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ \geq 1. If WANTQ = .TRUE., LDQ \geq N.

Z (input/output)
On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ \geq 1. If WANTZ = .TRUE., LDZ \geq N.

IFST (input/output)
Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 \leq IFST, ILST \leq N.

ILST (input/output)
See the description of IFST.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK \geq 4*N + 16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

=0: successful exit.
<0: if INFO = -i, the i-th argument had an illegal value.
=1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

```

PURPOSE

dtgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B . The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal

blocks. B is upper triangular.

DTGSEN also computes the generalized eigenvalues

$$w(j) = (\text{ALPHAR}(j) + i*\text{ALPHAI}(j))/\text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, DTGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, i.e. the separation(s) between the matrix pairs (A11, B11) and (A22, B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

=0: Only reorder w.r.t. SELECT. No extras.

=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate

(DIF(1:2)).

=3: Estimate of Difu and Difl. 1-norm-based estimate

(DIF(1:2)). About 5 times as expensive as IJOB =

2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, $\text{SELECT}(j)$ must be set to $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either $\text{SELECT}(j)$ or $\text{SELECT}(j+1)$ or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper quasi-triangular matrix A,

with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)

On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

ALPHAI (output)

See the description of ALPHAR.

BETA (output)

See the description of ALPHAR.

Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1; and if WANTQ = .TRUE., LDQ \geq N.

Z (input/output)

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left

eigenspaces (deflating subspaces). If WANTZ =
.FALSE., Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1; If
WANTZ = .TRUE., LDZ >= N.

M (output)

The dimension of the specified pair of left and
right eigen- spaces (deflating subspaces). 0 <= M
<= N.

PL (output)

If IJOB = 1, 4 or 5, PL, PR are lower bounds on
the reciprocal of the norm of "projections" onto
left and right eigenspaces with respect to the
selected cluster. 0 < PL, PR <= 1. If M = 0 or M
= N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR
are not referenced.

PR (output)

See the description of PL.

DIF (output)

If IJOB >= 2, DIF(1:2) store the estimates of Dif_u
and Dif_l.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper
bounds on
Dif_u and Dif_l. If IJOB = 3 or 5, DIF(1:2) are 1-
norm-based estimates of Dif_u and Dif_l. If M = 0
or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or
1, DIF is not referenced.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise,
on exit, if INFO = 0, WORK(1) returns the optimal
LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 4*N+16.
If IJOB = 1, 2 or 4, LWORK >= MAX(4*N+16, 2*M*(N-
M)). If IJOB = 3 or 5, LWORK >= MAX(4*N+16,
4*M*(N-M)).

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

IWORK (workspace/output)

If IJOB = 0, IWORK is not referenced. Otherwise,
on exit, if INFO = 0, IWORK(1) returns the optimal
LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK ≥ 1 . If IJOB = 1, 2 or 4, LIWORK $\geq N+6$. If IJOB = 3 or 5, LIWORK $\geq \text{MAX}(2*M*(N-M), N+6)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

=0: Successful exit.

<0: If INFO = -i, the i-th argument had an illegal value.

=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

DTGSEN first collects the selected eigenvalues by computing orthogonal U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in:

$$U'*(A, B)*W = \begin{pmatrix} A11 & A12 \\ 0 & A22 \end{pmatrix}, \begin{pmatrix} B11 & B12 \\ 0 & B22 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

n1 n2 n1 n2

where $N = n1+n2$ and U' means the transpose of U. The first $n1$ columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair $(C, D) = Q*(A, B)*Z'$, then the reordered generalized real Schur form of (C, D) is given by

$$(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',$$

and the first $n1$ columns of $Q*U$ and $Z*W$ span the corresponding deflating subspaces of (C, D) (Q and Z store $Q*U$ and $Z*W$, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first $n1$ columns of U and W (or

$Q*U$ and $Z*W$) may be returned in $DIF(1:2)$, corresponding to $Difu$ and $Difl$, resp.

The $Difu$ and $Difl$ are defined as:

$ifu[(A11, B11), (A22, B22)] = \text{sigma-min}(Zu)$
and

where $\text{sigma-min}(Zu)$ is the smallest singular value of the $(2*n1*n2)$ -by- $(2*n1*n2)$ matrix

$u = \begin{bmatrix} \text{kron}(In2, A11) & -\text{kron}(A22', In1) \\ \text{kron}(In2, B11) & -\text{kron}(B22', In1) \end{bmatrix}$.

Here, Inx is the identity matrix of size nx and $A22'$ is the transpose of $A22$. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

When $DIF(2)$ is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is $PS * \text{norm}((A, B)) / DIF(2)$,

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with $(A11, B11)$ may be returned in PL and PR . They are computed as follows. First we compute L and R so that $P*(A, B)*Q$ is block diagonal, where

$$\begin{aligned} &= \begin{pmatrix} I & -L \\ 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \quad \text{and} \quad Q = \begin{pmatrix} I & R \\ 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \\ &\quad \begin{matrix} n1 & n2 \end{matrix} \end{aligned}$$

and (L, R) is the solution to the generalized Sylvester equation $11*R - L*A22 = -A12$

Then $PL = (F\text{-norm}(L)**2+1)**(-1/2)$ and $PR = (F\text{-norm}(R)**2+1)**(-1/2)$. An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is $PS * \text{norm}((A, B)) / PL$.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest $F\text{-norm}(E, F)$ for which an eigenvalue of $(A11, B11)$ may move and coalesce with an eigenvalue of $(A22, B22)$ under perturbation (E, F) , (i.e. $(A + E, B + F)$), is

$$x = \min(Difu, Difl) / ((1/(PL*PL) + 1/(PR*PR))**(1/2) + 2*\max(1/PL, 1/PR)).$$

An approximate bound on x can be computed from $DIF(1:2)$, PL and PR .

If $y = (F\text{-norm}(E, F) / x) \leq 1$, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the $(1,1)$ -blocks can be bounded as

```

max-angle(L, L') <= arctan( y * PL / (1 - y * (1 - PL *
PL)**(1/2))
max-angle(R, R') <= arctan( y * PR / (1 - y * (1 - PR *
PR)**(1/2))

```

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm-based estimate DIF is not wanted (see SLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine SLATDF (IJOB = 2 will be used)). See DTGSYL for more details.

Based on contributions by

Bo Kagstrom and Peter Poromaa, Department of Computing Science,
Umea University, S-901 87 Umea, Sweden.

PURPOSE

dtgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSPV from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{array}{l}
 \begin{array}{ccccc}
 & & N-K-L & K & L \\
 A = & K & (\begin{array}{ccc} 0 & A_{12} & A_{13} \end{array}) & \text{if } M-K-L \geq 0; \\
 & L & (\begin{array}{ccc} 0 & 0 & A_{23} \end{array}) \\
 & M-K-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array} \\
 \\
 \begin{array}{ccccc}
 & & N-K-L & K & L \\
 A = & K & (\begin{array}{ccc} 0 & A_{12} & A_{13} \end{array}) & \text{if } M-K-L < 0; \\
 & M-K & (\begin{array}{ccc} 0 & 0 & A_{23} \end{array})
 \end{array}
 \end{array}$$

$$B = \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} L \\ P-L \end{matrix} & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix},$$

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:

If M-K-L >= 0,

$$D1 = \begin{matrix} & \begin{matrix} K & L \end{matrix} \\ \begin{matrix} K \\ L \\ M-K-L \end{matrix} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & \begin{matrix} K & L \end{matrix} \\ \begin{matrix} L \\ P-L \end{matrix} & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ L \end{matrix} & \begin{pmatrix} 0 & R11 & R12 \\ 0 & 0 & R22 \end{pmatrix} \end{matrix} \begin{matrix} K \\ L \end{matrix}$$

where

$$\begin{aligned} C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\ S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\ C^{**2} + S^{**2} &= I. \end{aligned}$$

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

$$D1 = \begin{matrix} & \begin{matrix} K & M-K & K+L-M \end{matrix} \\ \begin{matrix} K \\ M-K \end{matrix} & \begin{pmatrix} I & 0 & 0 \\ 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & \begin{matrix} K & M-K & K+L-M \end{matrix} \\ \begin{matrix} M-K \\ K+L-M \\ P-L \end{matrix} & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{matrix} N-K-L & K & M-K & K+L-M \end{matrix}$$

$$\begin{array}{rcccl} & M-K & (& 0 & 0 & R22 & R23 &) \\ K+L-M & (& 0 & 0 & 0 & R33 &) \end{array}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$

$C^{**2} + S^{**2} = I.$

$R = \begin{pmatrix} R11 & R12 & R13 \end{pmatrix}$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored

$\begin{pmatrix} 0 & R22 & R23 \end{pmatrix}$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the orthogonal transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1$, $V1$, or $Q1$.

DTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$U1' * A13 * Q1 = C1 * R1; V1' * B13 * Q1 = S1 * R1,$

where $U1$, $V1$ and $Q1$ are orthogonal matrix, and Z' is the transpose of Z . $C1$ and $S1$ are diagonal matrices satisfying

$C1^{**2} + S1^{**2} = I,$

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

JOBV (input)

= 'U': U must contain an orthogonal matrix $U1$ on entry, and the product $U1 * U$ is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV (input)

= 'V': V must contain an orthogonal matrix $V1$ on entry, and the product $V1 * V$ is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ (input)

= 'Q': Q must contain an orthogonal matrix $Q1$ on entry, and the product $Q1 * Q$ is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A . $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

K (input) K and L specify the subblocks in the input matrices A and B:
 $A_{23} = A(K+1:\min(K+L,M), N-L+1:N)$ and $B_{13} = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by DTGSJA. See Further details.

L (input) See the description of K.

A (input/output)
 On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,M)$.

B (input/output)
 On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,P)$.

TOLA (input)
 TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$.

TOLB (input)
 See the description of TOLA.

ALPHA (output)
 On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = \text{diag}(C)$, $BETA(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$, $BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $ALPHA(K+L+1:N) = 0$ and $BETA(K+L+1:N) = 0$.

BETA (output)

See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain a matrix U1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBU = 'I', U contains the orthogonal matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain a matrix V1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBV = 'I', V contains the orthogonal matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBQ = 'I', Q contains the orthogonal matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension(2*N)

NCYCLE (output)
The number of cycles required for convergence.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

    *vl, long ldvl, double *vr, long ldvr, double *s,
    double *dif, long mm, long *m, long *info);

```

PURPOSE

dtgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q^*A^*Z' , Q^*B^*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
 = 'E': for eigenvalues only (S);

= 'V': for eigenvectors only (DIF);
= 'B': for both eigenvalues and eigenvectors (S
and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigen-
pairs;
= 'S': compute condition numbers for selected
eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs
for which condition numbers are required. To
select condition numbers for the eigenpair
corresponding to a real eigenvalue $w(j)$, SELECT(j)
must be set to .TRUE.. To select condition numbers
corresponding to a complex conjugate pair of
eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or
SELECT(j+1) or both, must be set to .TRUE.. If
HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). $N \geq 0$.

A (input) The upper quasi-triangular matrix A in the pair
(A,B).

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) The upper triangular matrix B in the pair (A,B).

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

VL (input)
If JOB = 'E' or 'B', VL must contain left eigen-
vectors of (A, B), corresponding to the eigenpairs
specified by HOWMNT and SELECT. The eigenvectors
must be stored in consecutive columns of VL, as
returned by DTGEVC. If JOB = 'V', VL is not
referenced.

LDVL (input)
The leading dimension of the array VL. $LDVL \geq 1$.
If JOB = 'E' or 'B', $LDVL \geq N$.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigen-
vectors of (A, B), corresponding to the eigenpairs
specified by HOWMNT and SELECT. The eigenvectors

must be stored in consecutive columns of VR, as returned by DTGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq 1. If JOB = 'E' or 'B', LDVR \geq N.

S (output)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM (input)

The number of elements in the arrays S and DIF. MM \geq M.

M (output)

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

WORK (workspace)

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq N. If JOB = 'V' or 'B' LWORK \geq 2*N*(N+2)+16. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message

related to LWORK is issued by XERBLA.

```

IWORK (workspace)
      dimension(N+6) If JOB = 'E', IWORK is not referenced.

```

```
INFO (output)
    =0: Successful exit
    <0: If INFO = -i, the i-th argument had an illegal
        value
```

FURTHER DETAILS

The reciprocal of the condition number of a generalized eigenvalue $w = (a, b)$ is defined as

$$\kappa(w) = \left(|u^* A v|^2 + |u^* B v|^2 \right)^{1/2} / (\|u\| \|v\|)$$

where u and v are the left and right eigenvectors of (A, B) corresponding to w ; $|z|$ denotes the absolute value of the complex number, and $\text{norm}(u)$ denotes the 2-norm of the vector u .

The pair (a, b) corresponds to an eigenvalue $w = a/b$ ($= u'Av/u'Bv$) of the matrix pair (A, B). If both a and b equal zero, then (A B) is singular and $S(I) = -1$ is returned.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is

$$\text{hord}(w, \text{lambda}) \leq \text{EPS} * \text{norm}(A, B) / S(I)$$

where EPS is the machine precision.

The reciprocal of the condition number $DIF(i)$ of right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows:

a) If the i -th eigenvalue $w = (a, b)$ is real

Suppose U and V are orthogonal transformations such that

$$U^*(A, B)^*V = (S, T) = \begin{pmatrix} a & * \\ 0 & S_{22} \end{pmatrix} \begin{pmatrix} b & * \\ 0 & T_{22} \end{pmatrix}$$

Then the reciprocal condition number $\text{DIF}(i)$ is

$$\text{Difl}((a, b), (S22, T22)) = \text{sigma-min}(Z1),$$

where $\sigma_{\min}(Z_1)$ denotes the smallest singular value of the $2(n-1)$ -by- $2(n-1)$ matrix

Here I_{n-1} is the identity matrix of size $n-1$. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

(see DLATDF), then the parameter DIFDRI (see below) should be

See DTGSYL for more details.

Suppose U and V are orthogonal transformations such that

and (S_{11}, T_{11}) corresponds to the complex conjugate eigenvalue pair $(w, \text{conjg}(w))$. There exist unitary matrices U_1 and V_1 such that

where the generalized eigenvalues $w = s_{11}/t_{11}$ and $\text{conj}(w) = s_{22}/t_{22}$.

where, $d1 = \text{Difl}((s11, t11), (s22, t22)) = \text{sigma-min}(Z1)$,
where

This is done by computing (using real arithmetic) the

roots of the characteristical polynomial $\det(Z1' * Z1 - \lambda I)$,
 where $Z1'$ denotes the conjugate transpose of $Z1$ and
 $\det(X)$ denotes
 the determinant of X .

and $d2$ is an upper bound on $\text{Difl}((S11, T11), (S22, T22))$,
 i.e. an
 upper bound on $\sigma\text{-min}(Z2)$, where $Z2$ is $(2n-2)\text{-by-}(2n-2)$

$$Z2 = \begin{bmatrix} \text{kron}(S11', I_{n-2}) & -\text{kron}(I2, S22) \\ \text{kron}(T11', I_{n-2}) & -\text{kron}(I2, T22) \end{bmatrix}$$

Note that if the default method for computing DIF is
 wanted (see
 DLATDF), then the parameter DIFDRI (see below) should be
 changed
 from 3 to 4 (routine DLATDF(IJOB = 2 will be used)). See
 DTGSYL
 for more details.

For each eigenvalue/vector specified by SELECT, DIF stores a
 Frobenius norm-based estimate of Difl .

An approximate error bound for the i -th computed eigenvector
 $VL(i)$ or $VR(i)$ is given by

$$\text{EPS} * \text{norm}(A, B) / \text{DIF}(i).$$

See ref. [2-3] for more details and further references.

C INTERFACE

```

#include <sunperf.h>

void dtgsyl(char trans, int ijob, int m, int n, double *a,
    int lda, double *b, int ldb, double *c, int ldc,
    double *d, int ldd, double *e, int lde, double *f,
    int ldf, double *scale, double *dif, int *info);

void dtgsyl_64(char trans, long ijob, long m, long n, double
    *a, long lda, double *b, long ldb, double *c, long
    ldc, double *d, long ldd, double *e, long lde,
    double *f, long ldf, double *scale, double *dif,
    long *info);

```

PURPOSE

dtgsyl solves the generalized Sylvester equation:

$$\begin{aligned}
 A * R - L * B &= \text{scale} * C \\
 D * R - L * E &= \text{scale} * F
 \end{aligned}
 \tag{1}$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale } b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix}
 \tag{2}$$

Here I_k is the identity matrix of size k and X' is the transpose of X. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If TRANS = 'T', DTGSYL solves the transposed system $Z'y = \text{scale} * b$, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * (-F) \end{aligned} \quad (3)$$

This case (TRANS = 'T') is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If IJOB >= 1, DTGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

TRANS (input)
= 'N', solve the generalized Sylvester equation (1).
= 'T', solve the 'transposed' system (3).

IJOB (input)
Specifies what kind of functionality to be performed.
=0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (look ahead strategy IJOB = 1 is used).
=4: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (SGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper quasi triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1, M).

B (input) The upper quasi triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

C (input/output)
On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the

solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)

The leading dimension of the array C. LDC \geq max(1, M).

D (input) The upper triangular matrix D.

LDD (input)

The leading dimension of the array D. LDD \geq max(1, M).

E (input) The upper triangular matrix E.

LDE (input)

The leading dimension of the array E. LDE \geq max(1, N).

F (input/output)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)

The leading dimension of the array F. LDF \geq max(1, M).

SCALE (output)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

DIF (output)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK \geq 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(M+N+6)

INFO (output)
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or close eigenvalues.

SUBROUTINE DTPCON_64(NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,  
                     INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, INFO  
INTEGER*8 WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: A, WORK
```

```
SUBROUTINE TPCON_64(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],
```

[INFO])

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>

void dtpcon(char norm, char uplo, char diag, int n, double
            *a, double *rcond, int *info);
void dtpcon_64(char norm, char uplo, char diag, long n, double
               *a, double *rcond, long *info);
```

PURPOSE

dtpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO =

'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if
 UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for
 $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of
 A are not referenced and are assumed to be 1.

RCOND (output)

The reciprocal of the condition number of the
 matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

DOUBLE PRECISION array, dimension(3*N)

WORK2 (workspace)

INTEGER array, dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

NAME

dtpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE DTPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, INCY  
DOUBLE PRECISION A(*), Y(*)
```

```
SUBROUTINE DTPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, INCY  
DOUBLE PRECISION A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, INCY  
REAL(8), DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, INCY  
REAL(8), DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dtpmv(char uplo, char transa, char diag, int n, double
           *a, double *y, int incy);

void dtpmv_64(char uplo, char transa, char diag, long n,
              double *a, double *y, long incy);

```

PURPOSE

dtpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A.
N \geq 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

```

C INTERFACE

```

#include <sunperf.h>
void dtprfs(char uplo, char transa, char diag, int n, int
            nrhs, double *a, double *b, int ldb, double *x,
            int ldx, double *ferr, double *berr, int *info);

void dtprfs_64(char uplo, char transa, char diag, long n,
               long nrhs, double *a, double *b, long ldb, double
               *x, long ldx, double *ferr, double *berr, long
               *info);

```

PURPOSE

dtprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by DTPTRS or some other means before entering this routine. DTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

- = 'U': A is upper triangular;
- = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:

- = 'N': $A * X = B$ (No transpose)
- = 'T': $A^{**T} * X = B$ (Transpose)
- = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

- = 'N': A is non-unit triangular;
- = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B (input) DOUBLE PRECISION array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input) DOUBLE PRECISION array, dimension (LDX,NRHS)
The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
DOUBLE PRECISION array, dimension(3*N)

WORK2 (workspace)
INTEGER array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dtpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, INCY  
DOUBLE PRECISION A(*), Y(*)
```

```
SUBROUTINE DTPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, INCY  
DOUBLE PRECISION A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, INCY  
REAL(8), DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, INCY  
REAL(8), DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dtpsv(char uplo, char transa, char diag, int n, double
           *a, double *y, int incy);

void dtpsv_64(char uplo, char transa, char diag, long n,
              double *a, double *y, long incy);

```

PURPOSE

dtpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

($1 + (n-1)*abs(INCY)$). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dtptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE DTPTRI(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER N, INFO  
DOUBLE PRECISION A(*)
```

```
SUBROUTINE DTPTRI_64(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER*8 N, INFO  
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER :: N, INFO  
REAL(8), DIMENSION(:) :: A
```

```
SUBROUTINE TPTRI_64(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER(8) :: N, INFO  
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtptri(char uplo, char diag, int n, double *a, int
            *info);

void dtptri_64(char uplo, char diag, long n, double *a, long
               *info);
```

PURPOSE

dtptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = 1, J
          A(JC+I-1) = A(I,J)
A(I,J)
1      CONTINUE
      JC = JC + J
1
2 CONTINUE

```

UPLO = 'L':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = J, N
          A(JC+I-J) =
1      CONTINUE
      JC = JC + N - J +
2 CONTINUE

```

```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL(8), DIMENSION(:) :: A  
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtpttrs(char uplo, char transa, char diag, int n, int  
             nrhs, double *a, double *b, int ldb, int *info);
```

```
void dtptrs_64(char uplo, char transa, char diag, long n,
               long nrhs, double *a, double *b, long ldb, long
               *info);
```

PURPOSE

dtptrs solves a triangular system of the form

$A * X = B$ or $A^{**T} * X = B$

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) DOUBLE PRECISION array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

B (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

dtrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE DTRANS(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
INTEGER M, N  
DOUBLE PRECISION SCALE  
DOUBLE PRECISION SOURCE(*), DEST(*)
```

```
SUBROUTINE DTRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
INTEGER*8 M, N  
DOUBLE PRECISION SCALE  
DOUBLE PRECISION SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER :: M, N  
REAL(8) :: SCALE  
REAL(8), DIMENSION(:) :: SOURCE, DEST
```

```
SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER(8) :: M, N  
REAL(8) :: SCALE  
REAL(8), DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>

void dtrans(char place, double scale, double *source, int m,
            int n, double *dest);

void dtrans_64(char place, double scale, double *source,
               long m, long n, double *dest);
```

PURPOSE

dtrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)

Scale factor on the SOURCE matrix.

SOURCE (input/output)

(M, N) on input. Array of (N, M) on output if in-place transpose.

M (input)

Number of rows in the SOURCE matrix on input.

N (input)

Number of columns in the SOURCE matrix on input.

DEST (output)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

dtrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE DTRCON(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
                  INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, LDA, INFO  
INTEGER WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DTRCON_64(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
                     INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, LDA, INFO  
INTEGER*8 WORK2(*)  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK], [WORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TRCON_64(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
                   [WORK2], [INFO])
```

```

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>
void dtrcon(char norm, char uplo, char diag, int n, double
            *a, int lda, double *rcond, int *info);

void dtrcon_64(char norm, char uplo, char diag, long n, dou-
               ble *a, long lda, double *rcond, long *info);

```

PURPOSE

dtrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangu-

lar part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

C INTERFACE

```

#include <sunperf.h>

void dtrevc(char side, char howmny, int *select, int n, double *t, int ldt, double *vl, int ldvl, double *vr, int ldvr, int mm, int *m, int *info);
void dtrevc_64(char side, char howmny, long *select, long n, double *t, long ldt, double *vl, long ldvl, double *vr, long ldvr, long mm, long *m, long *info);

```

PURPOSE

dtrevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input orthogonal matrix. If T was obtained from the real-Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)

- = 'R': compute right eigenvectors only;
- = 'L': compute left eigenvectors only;
- = 'B': compute both right and left eigenvectors.

HOWMNY (input)

- = 'A': compute all right and/or left eigenvectors;
- = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL;
- = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)

The upper quasi-triangular matrix T in Schur canonical form.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL has the same quasi-lower triangular form as T'. If $T(i, i)$ is a real eigenvalue, then the i-th column VL(i) of VL is its corresponding eigenvector. If $T(i:i+1, i:i+1)$ is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then $VL(i) + \sqrt{-1} * VL(i+1)$ is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix $Q * Y$; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same

order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VR(i)+sqrt(-1)*VR(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)

dimension(3*N)

```
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i,  the i-th argument had an
          illegal value
```

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.

void dtrexc_64(char compq, long n, double *t, long ldt, dou-  
               ble *q, long ldq, long *ifst, long *ilst, long  
               *info);
```

PURPOSE

dtrexc reorders the real Schur factorization of a real matrix $A = Q^*TQ$, so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation Z^*T^*Z , and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

COMPQ (input)

= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q .

N (input) The order of the matrix T . $N \geq 0$.

T (input/output)

On entry, the upper quasi-triangular matrix T , in Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT (input)

The leading dimension of the array T . $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation

matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq max(1,N).

IFST (input/output)

Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). $1 \leq \text{IFST} \leq N$; $1 \leq \text{ILST} \leq N$.

ILST (input/output)

See the description of IFST.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG  
INTEGER(8) :: M, N, LDA, LDB
```

```
REAL(8) :: ALPHA
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtrmm(char side, char uplo, char transa, char diag, int
           m, int n, double alpha, double *a, int lda, double
           *b, int ldb);

void dtrmm_64(char side, char uplo, char transa, char diag,
              long m, long n, double alpha, double *a, long lda,
              double *b, long ldb);
```

PURPOSE

dtrmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$\text{op}(A) = A$ or $\text{op}(A) = A'$.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are

assumed to be one. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

B (input/output)

DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrmv(char uplo, char transa, char diag, int n, double  
          *a, int lda, double *y, int incy);
```

```
void dtrmv_64(char uplo, char transa, char diag, long n,  
             double *a, long lda, double *y, long incy);
```

PURPOSE

dtrmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A.
N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

void dtrrfs(char uplo, char transa, char diag, int n, int
            nrhs, double *a, int lda, double *b, int ldb, dou-
            ble *x, int ldx, double *ferr, double *berr, int
            *info);

void dtrrfs_64(char uplo, char transa, char diag, long n,
               long nrhs, double *a, long lda, double *b, long
               ldb, double *x, long ldx, double *ferr, double
               *berr, long *info);

```

PURPOSE

dtrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by DTRTRS or some other means before entering this routine. DTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

- = 'U': A is upper triangular;
- = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:

- = 'N': $A * X = B$ (No transpose)
- = 'T': $A^{**T} * X = B$ (Transpose)
- = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

- = 'N': A is non-unit triangular;
- = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The triangular matrix A. If $UPLO = 'U'$, the leading N -by- N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If $DIAG = 'U'$, the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)
The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
dimension($3*N$)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

    long *info);

```

PURPOSE

dtrsen reorders the real Schur factorization of a real matrix $A = Q^*TQ$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

= 'N': none;

= 'E': for eigenvalues only (S);

= 'V': for invariant subspace only (SEP);

= 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ (input)

= 'V': update the matrix Q of Schur vectors;

= 'N': do not update Q.

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)

On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

WR (output)

The real and imaginary parts, respectively, of the

reordered eigenvalues of T . The eigenvalues are stored in the same order as on the diagonal of T , with $WR(i) = T(i,i)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) > 0$ and $WI(i+1) = -WI(i)$. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

WI (output)

See the description of WR.

M (output)

The dimension of the specified invariant subspace.
 $0 <= M <= N$.

S (output)

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If JOB = 'N' or 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If $M = 0$ or N , $SEP = \text{norm}(T)$. If JOB = 'N' or 'E', SEP is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If JOB = 'N', $LWORK \geq \max(1,N)$; if JOB = 'E', $LWORK \geq M*(N-M)$; if JOB = 'V' or 'B', $LWORK \geq 2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

If JOB = 'N' or 'E', IWORK is not referenced.

LIWORK (input)

The dimension of the array IWORK. If JOB = 'N' or 'E', $LIWORK \geq 1$; if JOB = 'V' or 'B', $LIWORK \geq M*(N-M)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 = 1: reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and WR and WI contain the eigenvalues in the same order as in T; S and SEP (if requested) are set to zero.

FURTHER DETAILS

DTRSEN first collects the selected eigenvalues by computing an orthogonal transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

$$Z'^*T*Z = \begin{pmatrix} T11 & T12 \\ 0 & T22 \end{pmatrix} \begin{matrix} n1 \\ n2 \\ n1 & n2 \end{matrix}$$

where N = n1+n2 and Z' means the transpose of Z. The first n1 columns of Z span the specified invariant subspace of T.

If T has been obtained from the real Schur factorization of a matrix $A = Q*T*Q'$, then the reordered real Schur factorization of A is given by $A = (Q*Z)*(Z'*T*Z)*(Q*Z)'$, and the first n1 columns of Q*Z span the corresponding invariant subspace of A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

$$P = \begin{pmatrix} I & R \\ 0 & 0 \end{pmatrix} \begin{matrix} n1 \\ n2 \\ n1 & n2 \end{matrix}$$

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

$$T11*R - R*T22 = T12.$$

Let $F\text{-norm}(M)$ denote the Frobenius-norm of M and $2\text{-norm}(M)$ denote the two-norm of M . Then S is computed as the lower bound

$$(1 + F\text{-norm}(R)^{**2})^{*(-1/2)}$$

on the reciprocal of $2\text{-norm}(P)$, the true reciprocal condition number. S cannot underestimate $1 / 2\text{-norm}(P)$ by more than a factor of \sqrt{N} .

An approximate error bound for the computed average of the eigenvalues of T_{11} is

$$EPS * \text{norm}(T) / S$$

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n_1 columns of Z (or of $Q*Z$) is returned in SEP . SEP is defined as the separation of T_{11} and T_{22} :

$$\text{sep}(T_{11}, T_{22}) = \sigma\text{-min}(C)$$

where $\sigma\text{-min}(C)$ is the smallest singular value of the $n_1*n_2\text{-by-}n_1*n_2$ matrix

$$C = \text{kprod}(I(n_2), T_{11}) - \text{kprod}(\text{transpose}(T_{22}), I(n_1))$$

$I(m)$ is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate $\sigma\text{-min}(C)$ by the reciprocal of an estimate of the 1-norm of $\text{inverse}(C)$. The true reciprocal 1-norm of $\text{inverse}(C)$ cannot differ from $\sigma\text{-min}(C)$ by more than a factor of $\sqrt{n_1*n_2}$.

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

$$EPS * \text{norm}(T) / SEP$$

SUBROUTINE DTRSM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
                    LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRSM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
```

```
REAL(8) :: ALPHA
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtrsm(char side, char uplo, char transa, char diag, int
           m, int n, double alpha, double *a, int lda, double
           *b, int ldb);

void dtrsm_64(char side, char uplo, char transa, char diag,
              long m, long n, double alpha, double *a, long lda,
              double *b, long ldb);
```

PURPOSE

dtrsm solves one of the matrix equations $\text{op}(A)X = \alpha B$, or $X\text{op}(A) = \alpha B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$\text{op}(A) = A$ or $\text{op}(A) = A'$.

The matrix X is overwritten on B .

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A)X = \alpha B$.

SIDE = 'R' or 'r' $X\text{op}(A) = \alpha B$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

B (input/output)

DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

    double *t, long ldt, double *vl, long ldvl, double
    *vr, long ldvr, double *s, double *sep, long mm,
    long *m, long ldwork, long *info);

```

PURPOSE

dtrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q^*TQ with Q orthogonal).

T must be in Schur canonical form (as returned by DHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

- = 'E': for eigenvalues only (S);
- = 'V': for eigenvectors only (SEP);
- = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
 = 'A': compute condition numbers for all eigenpairs;
 = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
 If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. $N \geq 0$.

T (input) The upper quasi-triangular matrix T, in Schur canonical form.

LDT (input)
 The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input)
 If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q^*TQ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by DHSEIN or DTREVC. If JOB = 'V', VL is not referenced.

LDVL (input)
 The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

VR (input)
 If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q^*TQ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by DHSEIN or DTREVC. If JOB = 'V', VR is not referenced.

LDVR (input)
 The leading dimension of the array VR. $LDVR \geq 1$; and if JOB = 'E' or 'B', $LDVR \geq N$.

S (output)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM (input)

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)

dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)

dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue λ is defined as

$$S(\lambda) = |v' \cdot u| / (\text{norm}(u) \cdot \text{norm}(v))$$

where u and v are the right and left eigenvectors of T corresponding to λ ; v' denotes the conjugate-transpose of v , and $\text{norm}(u)$ denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If $n = 1$, $S(\lambda)$ is defined to be 1.

An approximate error bound for a computed eigenvalue $W(i)$ is given by

$$\text{EPS} * \text{norm}(T) / S(i)$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to λ is defined as follows. Suppose

$$T = \begin{pmatrix} \lambda & c \\ 0 & T_{22} \end{pmatrix}$$

Then the reciprocal condition number is

$$\text{SEP}(\lambda, T_{22}) = \text{sigma-min}(T_{22} - \lambda I)$$

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of $T_{22} - \lambda I$. If $n = 1$, $\text{SEP}(1)$ is defined to be $\text{abs}(T(1,1))$.

An approximate error bound for a computed right eigenvector $VR(i)$ is given by

$$\text{EPS} * \text{norm}(T) / \text{SEP}(i)$$

NAME

dtrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE DTRSV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

```
SUBROUTINE DTRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, LDA, INCY  
DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, LDA, INCY  
REAL(8), DIMENSION(:) :: Y  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtrsv(char uplo, char transa, char diag, int n, double
           *a, int lda, double *y, int incy);

void dtrsv_64(char uplo, char transa, char diag, long n,
              double *a, long lda, double *y, long incy);
```

PURPOSE

dtrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{ INCY }))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{ INCY } \neq 0$. Unchanged on exit.

```

F95 INTERFACE

```
SUBROUTINE TRSYL(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,  
                [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB  
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO  
REAL(8) :: SCALE  
REAL(8), DIMENSION(:,:) :: A, B, C
```

```
SUBROUTINE TRSYL_64(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,  
                   [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB
```

```

INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE
REAL(8), DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void dtrsyl(char trana, char tranb, int isgn, int m, int n,
            double *a, int lda, double *b, int ldb, double *c,
            int ldc, double *scale, int *info);

void dtrsyl_64(char trana, char tranb, long isgn, long m,
               long n, double *a, long lda, double *b, long ldb,
               double *c, long ldc, double *scale, long *info);

```

PURPOSE

dtrsyl solves the real Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**T} , and A and B are both upper quasi-triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

TRANA (input)
 Specifies the option $\text{op}(A)$:
 = 'N': $\text{op}(A) = A$ (No transpose)
 = 'T': $\text{op}(A) = A^{**T}$ (Transpose)
 = 'C': $\text{op}(A) = A^{**H}$ (Conjugate transpose = Transpose)

TRANB (input)
 Specifies the option $\text{op}(B)$:
 = 'N': $\text{op}(B) = B$ (No transpose)
 = 'T': $\text{op}(B) = B^{**T}$ (Transpose)
 = 'C': $\text{op}(B) = B^{**H}$ (Conjugate transpose = Transpose)

ISGN (input)
 Specifies the sign in the equation:
 = +1: solve $\text{op}(A)*X + X*\text{op}(B) = \text{scale}*C$
 = -1: solve $\text{op}(A)*X - X*\text{op}(B) = \text{scale}*C$

M (input) The order of the matrix A, and the number of rows in the matrices X and C. $M \geq 0$.

N (input) The order of the matrix B, and the number of columns in the matrices X and C. $N \geq 0$.

A (input) The upper quasi-triangular matrix A, in Schur canonical form.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input) The upper quasi-triangular matrix B, in Schur canonical form.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

C (input/output)
 On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC (input)
 The leading dimension of the array C. $LDC \geq \max(1, M)$

SCALE (output)
 The scale factor, scale, set ≤ 1 to avoid overflow in X.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER :: N, LDA, INFO  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER(8) :: N, LDA, INFO  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dtrti2(char uplo, char diag, int n, double *a, int lda,
            int *info);

void dtrti2_64(char uplo, char diag, long n, double *a, long
               lda, long *info);

```

PURPOSE

dtrti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
 Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
 = 'L': Lower triangular

DIAG (input)
 Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
 = 'U': Unit triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

```
INFO (output)
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an ille-
      gal value
```

               lda, long *info);

```

PURPOSE

dtrtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, A(i,i) is exactly zero. The
triangular matrix is singular and its inverse can
not be computed.

NAME

dtrtrs - solve a triangular system of the form $A * X = B$
or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE DTRTRS(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, NRHS, LDA, LDB, INFO  
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DTRTRS_64(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,  
INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, NRHS, LDA, LDB, INFO  
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRTRS(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:,:) :: A, B
```

```
SUBROUTINE TRTRS_64(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtrtrs(char uplo, char transa, char diag, int n, int
```

```

        nrhs, double *a, int lda, double *b, int ldb, int
        *info);

void dtrtrs_64(char uplo, char transa, char diag, long n,
        long nrhs, double *a, long lda, double *b, long
        ldb, long *info);

```

PURPOSE

dtrtrs solves a triangular system of the form
 $A * X = B$ or $A^{**T} * X = B$

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. LDA \geq
 max(1,N).
 B (input/output)
 On entry, the right hand side matrix B. On exit,
 if INFO = 0, the solution matrix X.

 LDB (input)
 The leading dimension of the array B. LDB \geq
 max(1,N).

 INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: if INFO = i, the i-th diagonal element of A
 is zero, indicating that the matrix is singular
 and the solutions X have not been computed.

NAME

dtzrqf - routine is deprecated and has been replaced by routine STZRZF

SYNOPSIS

```
SUBROUTINE DTZRQF(M, N, A, LDA, TAU, INFO)
```

```
INTEGER M, N, LDA, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*)
```

```
SUBROUTINE DTZRQF_64(M, N, A, LDA, TAU, INFO)
```

```
INTEGER*8 M, N, LDA, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF(M, N, A, [LDA], TAU, [INFO])
```

```
INTEGER :: M, N, LDA, INFO  
REAL(8), DIMENSION(:) :: TAU  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRQF_64(M, N, A, [LDA], TAU, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
REAL(8), DIMENSION(:) :: TAU  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void dtzrqf(int m, int n, double *a, int lda, double *tau,
            int *info);

void dtzrqf_64(long m, long n, double *a, long lda, double
               *tau, long *info);

```

PURPOSE

dtzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq M$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The k th transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A , is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the k th row of X .

The scalar τ is returned in the k th element of TAU and the vector $u(k)$ in the k th row of A , such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

NAME

dtzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

SYNOPSIS

```
SUBROUTINE DTZRZF(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER M, N, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DTZRZF_64(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LWORK, INFO  
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TZRZF([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRZF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: TAU, WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtzrzf(int m, int n, double *a, int lda, double *tau,
```

```

        int *info);

void dtzrzf_64(long m, long n, double *a, long lda, double
               *tau, long *info);

```

PURPOSE

dtzrzf reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A, is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the kth row of X.

The scalar τ is returned in the kth element of TAU and the vector $u(k)$ in the kth row of A, such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A.

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

long *bindx, long *rpntr, long *cpntr, long *bpntrb,
long *bpntre, double *b, long ldb, double beta,
double *c, long ldc);
```

DESCRIPTION

dvbrmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where alpha and beta are scalars, C and B are dense matrices,
A is a sparse M by K matrix represented in the variable block
sparse row format and op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

The number of rows in A and the number of columns in A are determined
as follows

$$M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1), \quad K = \text{CPNTR}(\text{KB}+1) - \text{CPNTR}(1).$$

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, integer KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A'))

```

3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main block diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)    On entry, scalar array VAL of length NNZ consists of the
               block entries of A where each block entry is a dense
               rectangular matrix stored column by column where NNZ
               denotes the total number of point entries in all nonzero
               block entries of a matrix A. Unchanged on exit.

INDX(input)    On entry, INDX is an integer array of length BNNZ+1 where BNNZ is
               the number of block entries of the matrix A such that the
               I-th element of INDX[] points to the location in VAL of
               the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input)    On entry, BINDX is an integer array of length BNNZ consisting
               of the block column indices of the block entries of A where
               BNNZ is the number block entries of the matrix A. Unchanged on
               exit.

RPNTR(input)    On entry, RPNTR is an integer array of length MB+1 such that
               RPNTR(I)-RPNTR(1)+1 is the row index of the first point
               row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1)
               where M is the number of rows in the matrix A.
               Thus, the number of point rows in the I-th block row is
               RPNTR(I+1)-RPNTR(I). Unchanged on exit.

CPNTR(input)    On entry, CPNTR is an integer array of length KB+1 such that
               CPNTR(J)-CPNTR(1)+1 is the column index of the first point
               column in the J-th block column. CPNTR(KB+1) is set to
               K+CPNTR(1) where K is the number of columns in the matrix A.
               Thus, the number of point columns in the J-th block column
               is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

BPNTRB(input)    On entry, BPNTRB is an integer array of length MB such that
               BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the
               first block entry of the I-th block row of A.
               Unchanged on exit.

BPNTRE(input)    On entry, BPNTRE is an integer array of length MB such that
               BPNTRE(I)-BPNTRB(1) points to location in BINDX of the
               last block entry of the I-th block row of A.
               Unchanged on exit.

B (input)       Array of DIMENSION ( LDB, N ).
               Before entry with TRANSA = 0, the leading k by n
               part of the array B must contain the matrix B, otherwise
               the leading m by n part of the array B must contain the
               matrix B. Unchanged on exit.

```

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * \text{op}(A) * B + \text{beta} * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general complex matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To

use the routine with this kind of variable block sparse row
format the following calling sequence should be used

```

SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
*                VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
*                B, LDB, BETA, C, LDC, WORK, LWORK )
```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dvbrsm (int transa, int mb, int n, int unitd, double
*dv, double alpha, int *descra, double *val, int *indx, int
*bindx, int *rpntr, int *cpntr, int *bpntrb, int *bpntre,
double *b, int ldb, double beta, double *c, int ldc);
```

```
void dvbrsm_64 (long transa, long mb, long n, long unitd,
double *dv, double alpha, long *descra, double *val, long
*indx, long *bindx, long *rpntr, long *cpntr, long *bpntrb,
long *bpntre, double *b, long ldb, double beta, double *c,
long ldc);
```

DESCRIPTION

dvbrsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a block diagonal matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the variable block sparse row format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
The number of rows in A is determined as follows
```

```
m=RPNTR(MB+1)-RPNTR(1).
```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
DV(input)	On entry, array DV contains the block entries of the block diagonal matrix D. The size of the J-th block is RPNTR(J+1)-RPNTR(J) and each block contains matrix entries stored column-major. The total length of

array DV is given by the formula:

sum over J from 1 to MB:

$((\text{RPNTR}(J+1) - \text{RPNTR}(J)) * (\text{RPNTR}(J+1) - \text{RPNTR}(J)))$

Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:

DESCRA(1) matrix structure

0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

1 : lower
2 : upper

DESCRA(3) main diagonal type

0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)

0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

0 : unknown
1 : no repeated indices

VAL(input) On entry, scalar array VAL of length NNZ consists of the block entries of A where each block entry is a dense rectangular matrix stored column by column where NNZ denotes the total number of point entries in all nonzero block entries of the matrix A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length BNNZ+1 where BNNZ is the number of block entries of the matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ is the number block entries of the matrix A. Block column indices MUST be sorted in increasing order for each block row. Unchanged on exit.

RPNTR(input) On entry, RPNTR is an integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in the matrix A. Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I). Unchanged on exit.
NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR(input) On entry, CPNTR is an integer array of length KB+1 such that

CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is the number of columns in the matrix A. Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

- BPNTRB(input) On entry, BPNTRB is an integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A. Unchanged on exit.
- BPNTRE(input) On entry, BPNTRE is an integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A. Unchanged on exit.
- B (input) Array of DIMENSION (LDB, N). Before entry with TRANSA = 0, the leading k by n part of the array B must contain the matrix B, otherwise the leading m by n part of the array B must contain the matrix B. Unchanged on exit.
- LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.
- BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.
- C(input/output) Array of DIMENSION (LDC, N). Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * A) * B + \beta * C$.
- LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.
- WORK(workspace) Scratch array of length LWORK. On exit, if LWORK = -1, WORK(1) returns the optimum size of LWORK.
- LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least $M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1)$. For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $\text{LWORK} \geq M * \text{N_CPUS}$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0`, the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)`.
3. If `DESCRA(3)=1`, the diagonal blocks in the variable block row representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2`, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.
5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation

of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
SUBROUTINE DVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
*                 VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
*                 B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

`dwiener` - perform Wiener deconvolution of two signals

SYNOPSIS

```
SUBROUTINE DWIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER N_POINTS, ISW, IERR  
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

```
SUBROUTINE DWIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER*8 N_POINTS, ISW, IERR  
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

F95 INTERFACE

```
SUBROUTINE WIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER :: N_POINTS, ISW, IERR  
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

```
SUBROUTINE WIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER(8) :: N_POINTS, ISW, IERR  
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dwiener(int n_points, double *acor, double *xcor, double *fltr, double *erop, int *isw, int *ierr);
```

```
void dwiener_64(long n_points, double *acor, double *xcor,
```

```
double  *fltr, double  *erop, long  *isw, long
*ierr);
```

PURPOSE

dwieners performs Wiener deconvolution of two signals.

ARGUMENTS

N_POINTS (input)
On entry, the number of points in the input correlations. Unchanged on exit.

ACOR (input)
On entry, autocorrelation coefficients. Unchanged on exit.

XCOR (input)
On entry, cross-correlation coefficients. Unchanged on exit.

FLTR (output)
On exit, filter coefficients.

EROP (output)
On exit, the prediction error.

ISW (input)
On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

IERR (output)
On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

NAME

dzasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZASUM(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER N, INCX
```

```
DOUBLE PRECISION FUNCTION DZASUM_64(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
REAL(8) FUNCTION ASUM_64([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dzasum(int n, doublecomplex *x, int incx);
```

```
double dzasum_64(long n, doublecomplex *x, long incx);
```

PURPOSE

`dzasum` Return the sum of the absolute values of the elements of `x` where `x` is an `n`-vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

`N` (input)

On entry, `N` specifies the number of elements in the vector. `N` must be at least one for the subroutine to have any visible effect. Unchanged on exit.

`X` (input)

(`1 + (n - 1) * abs(INCX)`). On entry, the incremented array `X` must contain the vector `x`. Unchanged on exit.

`INCX` (input)

On entry, `INCX` specifies the increment for the elements of `X`. `INCX` must not be zero or negative. Unchanged on exit.

NAME

dznrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZNRM2(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER N, INCX
```

```
DOUBLE PRECISION FUNCTION DZNRM2_64(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
REAL(8) FUNCTION NRM2_64([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dznrm2(int n, doublecomplex *x, int incx);
```

```
double dznrm2_64(long n, doublecomplex *x, long incx);
```

PURPOSE

dznrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. If INCX < 1 then DZNRM2 returns 0. Unchanged on exit.

```

F95 INTERFACE

```
SUBROUTINE EZFFTB(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER :: N  
REAL :: AZERO  
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE EZFFTB_64(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER(8) :: N  
REAL :: AZERO  
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ezfftb(int n, float *r, float azero, float *a, float
            *b, float *wsave);

void ezfftb_64(long n, float *r, float azero, float *a,
               float *b, float *wsave);

```

ARGUMENTS

N (input) Length of the sequence to be synthesized. The method is most efficient when N is the product of small primes. $N \geq 0$.

R (output)
On exit, the Fourier synthesis of the inputs.

AZERO (input)
On entry, the constant Fourier coefficient A0.
Unchanged on exit.

A (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$, initialized by EZFFTI.

ezfftf - computes the Fourier coefficients of a periodic sequence. EZFFTF is a simplified but slower version of RFFTF.

SYNOPSIS

```
SUBROUTINE EZFFTF(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER N  
REAL AZERO  
REAL R(*), A(*), B(*), WSAVE(*)
```

```
SUBROUTINE EZFFTF_64(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER*8 N  
REAL AZERO  
REAL R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTF(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER :: N  
REAL :: AZERO  
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE EZFFTF_64(N, R, AZERO, A, B, WSAVE)
```

```
INTEGER(8) :: N  
REAL :: AZERO  
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ezfftf(int n, float *r, float azero, float *a, float
            *b, float *wsave);

void ezfftf_64(long n, float *r, float azero, float *a,
               float *b, float *wsave);

```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. $N \geq 0$.

R (input) A real array of length N containing the sequence to be transformed. On exit, R is unchanged.

AZERO (output)
On exit, the sum from $i=1$ to $i=n$ of $r(i)/n$.

A (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$, initialized by EZFFTI.

NAME

`ezffti` - initializes the array `WSAVE`, which is used in both `EZFFTF` and `EZFFTB`.

SYNOPSIS

```
SUBROUTINE EZFFTI(N, WSAVE)
```

```
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE EZFFTI_64(N, WSAVE)
```

```
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTI(N, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE EZFFTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ezffti(int n, float *wsave);
```

```
void ezffti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array with a dimension of at least $(3 * N + 15)$. The same work array can be used for both EZFFTF and EZFFTB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to EZFFTF or EZFFTB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

fft - Fast Fourier transform subroutines

OVERVIEW

The signal processing software in Sun Performance Library includes a set of routines based on public domain packages FFTPACK and VFFPACK that computes the Fast Fourier Transform. These routines are now being replaced by a new interface (Perflib interface).

MAPPING

Below is a mapping of routines from the FFTPACK interface and the new Perflib interface. See individual man pages for more detail.

FFTPACK interface	Perflib interface
RFFTF (DFFTF)	SFFTC (DFFTZ)
RFFTB (DFFTB)	CFFTS (ZFFTD)
CFFTF (ZFFTF)	CFFTC (ZFFTZ)
EZFFTF (DEZFFTF)	SFFTC (DFFTZ)
EZFFTB (DEZFFTB)	CFFTS (ZFFTD)
CFFTB (ZFFTB)	CFFTC (ZFFTZ)
RFFT2F (DFFT2F)	SFFT2C (DFFT2Z)
RFFT2B (DFFT2B)	CFFT2S (ZFFT2D)
CFFT2F (ZFFT2F)	CFFT2C (ZFFT2Z)
CFFT2B (ZFFT2B)	CFFT2C (ZFFT2Z)
RFFT3F (DFFT3F)	SFFT3C (DFFT3Z)
RFFT3B (DFFT3B)	CFFT3S (ZFFT3D)
CFFT3B (ZFFT3B)	CFFT3C (ZFFT3Z)
CFFT3F (ZFFT3F)	CFFT3C (ZFFT3Z)

VCFFTF (VZFFTF)	CFFTCM (ZFFTZM)
VCFFTB (VZFFTB)	CFFTCM (ZFFTZM)
VRFFTF (VDFFTF)	SFFTCM (DFFTZM)
VRFFTB (VDFFTB)	CFFTCM (ZFFTD)
RFFTI (DFFTI)	SFFTC (DFFTZ), CFFTS (ZFFTD)
CFFTI (ZFFTI)	CFFTC (ZFFTZ)
EZFFTI (DEZFFTI)	SFFTC (DFFTZ), CFFTS (ZFFTD)
RFFT2I (DFFT2I)	SFFTC2 (DFFTZ2), CFFTS2 (ZFFTD2)
RFFT3I (DFFT3I)	SFFTC3 (DFFTZ3), CFFTS3 (ZFFTD3)
CFFT2I (ZFFT2I)	CFFTC2 (ZFFTZ2)
CFFT3I (ZFFT3I)	CFFTC3 (ZFFTZ3)
VCFFTI (VZFFTI)	CFFTCM (ZFFTZM)
VRFFTI (VDFFTI)	SFFTCM (DFFTZM), CFFTCM (ZFFTD)

NOTES

Unlike the FFTPACK interface, the Perflib interface does not provide separate routines for initialization. Computation and initialization can be selected by an argument in the calling sequence of each routine. Similar to the FFTPACK routines, the weight and factor tables need to be initialized once for a particular transform length. Once these tables are initialized, they can be used repeatedly to compute the forward and inverse transforms for different data sets until, of course, the transform length is changed. The appropriate transform routine is then called to initialize the tables for the new length.

The Perflib interface gives the user the option of computing the FFT in-place (input overwritten by transform results) or out-of-place (input unchanged) in every routine. When an out-of-place transform is requested, the input and output arrays must not overlap in memory. In-place transforms require that there be perfect overlay between the input and output arrays. That is, the arrays must begin at the same memory location. The routines assume (and therefore do not check) that these conditions are satisfied. In some cases, the dimension(s) of the input and output arrays are related to each other. Below is a summary of requirements of the array dimensions. LDX1 and LDX are leading dimensions of the input arrays and LDY1 and LDY are leading dimensions of the output arrays. LDX2 and LDY2 are the second dimensions of the input and output arrays, respectively. N1 and N2 are the first and second actual dimensions of the problem.

Routine name	in-place	out-of-place
SFFTCM, DFFTZM	LDX = 2*LDY LDY >= N1/2+1	LDX >= N1 LDY >= N1/2+1

CFFTCM, ZFFFTDM	LDX \geq N1/2+1 LDY = 2*LDX	LDX \geq N1/2+1 LDY \geq N1
CFFTCM, ZFFFTZM	LDX \geq N1 LDY = LDX	LDX \geq N1 LDY \geq N1
SFFTC2, DFFFTZ2	LDX = 2*LDY LDY \geq N1/2+1	LDX \geq N1 LDY \geq N1/2+1
CFFTS2, ZFFFTD2	LDX \geq N1/2+1 LDY = 2*LDX	LDX \geq N1/2+1 LDY \geq 2*LDX; LDY is even
CFFTC2, ZFFFTZ2	LDX \geq N1 LDY = LDX	LDX \geq N1 LDY \geq N1
CFFTS3, ZFFFTD3	LDX1 \geq N1/2+1 LDX2 \geq N2 LDY1 = 2*LDX1	LDX1 \geq N1/2+1 LDX2 \geq N2 LDY1 \geq 2*LDX1; LDY1 is even
	LDY2 = LDX2	LDY2 \geq N2
CFFTC3, ZFFFTZ3	LDX1 \geq N1 LDX2 \geq N2 LDY1 = LDX1 LDY2 = LDX2	LDX1 \geq N1 LDX2 \geq N2 LDY1 \geq N1 LDY2 \geq N2
SFFTC3, DFFFTZ3	LDX1 = 2*LDY1 LDX2 \geq N2 LDY1 \geq N1/2+1 LDY2 = LDX2	LDX1 \geq N1 LDX2 \geq N2 LDY1 \geq N1/2+1 LDY2 \geq N2

In routines that compute transforms between complex and real data type such as SFFTC2 or CFFTS3 even though the transform length is N1, only (N1/2+1) complex data points are referenced or computed. These data points make up the positive-frequency half of the spectrum of the Discrete Fourier Transform. The remaining N1-(N1/2+1) data points can be easily derived since they are complex conjugates and therefore are not stored or referenced.

NAME

icamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION ICAMAX(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER N, INCX
```

```
INTEGER*8 FUNCTION ICAMAX_64(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
int icamax(int n, complex *x, int incx);
```

```
long icamax_64(long n, complex *x, long incx);
```

PURPOSE

icamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid complex numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

NAME

idamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION IDAMAX(N, X, INCX)
```

```
INTEGER N, INCX  
DOUBLE PRECISION X(*)
```

```
INTEGER*8 FUNCTION IDAMAX_64(N, X, INCX)
```

```
INTEGER*8 N, INCX  
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])
```

```
INTEGER :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

```
INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX  
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
int idamax(int n, double *x, int incx);
```

```
long idamax_64(long n, double *x, long incx);
```

PURPOSE

idamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the sub-routine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid floating point numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

NAME

ilaenv - The name of the calling subroutine, in either upper case or lower case.

SYNOPSIS

```
INTEGER FUNCTION ILAENV(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

```
CHARACTER * 6 NAME CHARACTER * 4 OPTS  
INTEGER ISPEC, N1, N2, N3, N4
```

```
INTEGER*8 FUNCTION ILAENV_64(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

```
CHARACTER * 6 NAME CHARACTER * 4 OPTS  
INTEGER*8 ISPEC, N1, N2, N3, N4
```

F95 INTERFACE

```
INTEGER FUNCTION ILAENV(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

```
CHARACTER(LEN=6) :: NAME CHARACTER(LEN=4) :: OPTS  
INTEGER :: ISPEC, N1, N2, N3, N4
```

```
INTEGER(8) FUNCTION ILAENV_64(ISPEC, NAME, OPTS, N1, N2, N3, N4)
```

```
CHARACTER(LEN=6) :: NAME CHARACTER(LEN=4) :: OPTS  
INTEGER(8) :: ISPEC, N1, N2, N3, N4
```

C INTERFACE

```
#include <sunperf.h>
```

```
int ilaenv(int ispec, char *name, char *opts, int n1, int  
          n2, int n3, int n4);
```

```
long ilaenv_64(long ispec, char *name, char *opts, long  n1,
               long n2, long n3, long n4);
```

PURPOSE

ilaenv is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See ISPEC for a description of the parameters.

This version provides a set of parameters which should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.

This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

ARGUMENTS

ISPEC (input)

Specifies the parameter to be returned as the value of ILAENV. = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance. = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. = 3: the cross-over point (in a block routine, for N less than this value, an unblocked routine should be used) = 4: the number of shifts, used in the nonsymmetric eigenvalue routines = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k by m, where k is given by ILAENV(2,...) and m by ILAENV(5,...) = 6: the crossover point for the SVD (when reducing an m by n matrix to bidiagonal form, if $\max(m,n)/\min(m,n)$ exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.) = 7: the number of processors = 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems. = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by xGELSD and xGESDD) =10: ieee NaN arithmetic can be trusted not to trap

=11: infinity arithmetic can be trusted not to trap

NAME (input)

The name of the calling subroutine, in either upper case or lower case.

OPTS (input)

The character options to the subroutine NAME, concatenated into a single character string. For example, UPLO = 'U', TRANS = 'T', and DIAG = 'N' for a triangular routine would be specified as OPTS = 'UTN'.

N1 (input)

INTEGER

N2 (input)

INTEGER

N3 (input)

INTEGER

N4 (input)

INTEGER

N1, N2, N3, N4 are problem dimensions for the subroutine NAME; these may not all be required.

>= 0: the value of the parameter specified by ISPEC

< 0: if ILAENV = -k, the k-th argument had an illegal value.

< 0: if ILAENV = -k, the k-th argument had an illegal value.

FURTHER DETAILS

The following conventions have been used when calling ILAENV from the LAPACK routines:

1) OPTS is a concatenation of all of the character options to

subroutine NAME, in the same order that they appear in the

argument list for NAME, even if they are not used in determining

the value of the parameter specified by ISPEC.

2) The problem dimensions N1, N2, N3, N4 are specified in the order

that they appear in the argument list for NAME. N1 is used

first, N2 second, and so on, and unused problem dimensions are

passed a value of -1.

3) The parameter value returned by ILAENV is checked for validity in

the calling subroutine. For example, ILAENV is used to retrieve

the optimal blocksize for STRTRI as follows:

```
NB = ILAENV( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )  
IF( NB.LE.1 ) NB = MAX( 1, N )
```

NAME

isamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION ISAMAX(N, X, INCX)
```

```
INTEGER N, INCX  
REAL X(*)
```

```
INTEGER*8 FUNCTION ISAMAX_64(N, X, INCX)
```

```
INTEGER*8 N, INCX  
REAL X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])
```

```
INTEGER :: N, INCX  
REAL, DIMENSION(:) :: X
```

```
INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX  
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
int isamax(int n, float *x, int incx);
```

```
long isamax_64(long n, float *x, long incx);
```

PURPOSE

isamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the sub-routine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid floating point numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

NAME

izamax - return the index of the element with largest absolute value.

SYNOPSIS

```
INTEGER FUNCTION IZAMAX(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER N, INCX
```

```
INTEGER*8 FUNCTION IZAMAX_64(N, X, INCX)
```

```
DOUBLE COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
int izamax(int n, doublecomplex *x, int incx);
```

```
long izamax_64(long n, doublecomplex *x, long incx);
```

PURPOSE

izamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid double complex numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

NAME

lsame - returns .TRUE. if CA is the same letter as CB regardless of case

SYNOPSIS

```
LOGICAL FUNCTION LSAME(CA, CB)
```

```
CHARACTER * 1 CA, CB
```

```
LOGICAL*8 FUNCTION LSAME_64(CA, CB)
```

```
CHARACTER * 1 CA, CB
```

F95 INTERFACE

```
LOGICAL FUNCTION LSAME(CA, CB)
```

```
CHARACTER(LEN=1) :: CA, CB
```

```
LOGICAL(8) FUNCTION LSAME_64(CA, CB)
```

```
CHARACTER(LEN=1) :: CA, CB
```

C INTERFACE

```
#include <sunperf.h>
```

```
int lsame(char ca, char cb);
```

```
long lsame_64(char ca, char cb);
```

PURPOSE

lsame returns .TRUE. if CA is the same letter as CB regardless of case.

ARGUMENTS

CA (input)

On entry, CA is a single character to compare with CB. Unchanged on exit.

CB (input)

On entry, CB is a single character to compare with CA. Unchanged on exit.

NAME

rfft2b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by $M \cdot N$.

SYNOPSIS

```
SUBROUTINE RFFT2B(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE  
INTEGER M, N, LDA, LDB, LWORK  
REAL A(LDA,*), B(2*LDB,*), WORK(*)
```

```
SUBROUTINE RFFT2B_64(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE  
INTEGER*8 M, N, LDA, LDB, LWORK  
REAL A(LDA,*), B(2*LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER :: M, N, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE FFT2B_64(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER(8) :: M, N, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void rfft2b(char place, int m, int n, float *a, int lda,
            float *b, int ldb, float *work, int lwork);

void rfft2b_64(char place, long m, long n, float *a, long
               lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

PLACE (input)

Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

A (input/output)

Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

LDA (input)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$ and LDA must be even.

B (input/output)

Real array of dimension (2*LDB, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)

Integer. If an out-of-place transform is desired, $2*LDB$ is the leading dimension of the array B

which contains the data to be transformed and
2*LDB \geq 2*(M/2+1). Otherwise it is not referenced.

WORK (input/output)

One-dimensional real array of length at least
LWORK. On input, WORK must have been initialized
by RFFT2I.

LWORK (input)

Integer. LWORK \geq (M + 2*N + MAX(M, 2*N) + 30)

NAME

rfft2f - compute the Fourier coefficients of a periodic sequence. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by M*N.

SYNOPSIS

```
SUBROUTINE RFFT2F(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER M, N, LDA, LDB, LWORK  
REAL A(LDA,*), B(2*LDB,*), WORK(*)
```

```
SUBROUTINE RFFT2F_64(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER*8 M, N, LDA, LDB, LWORK  
REAL A(LDA,*), B(2*LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,  
                LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER :: M, N, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE FFT2F_64(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,  
                   LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER(8) :: M, N, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void rfft2f(char place, char full, int m, int n, float *a,
            int lda, float *b, int ldb, float *work, int
            lwork);

void rfft2f_64(char place, char full, long m, long n, float
               *a, long lda, float *b, long ldb, float *work,
               long lwork);
```

ARGUMENTS

PLACE (input)

Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

FULL (input)

Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause RFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

A (input/output)

On entry, a two-dimensional array A(LDA,N) that contains the data to be transformed. Upon exit, A is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, A(1:(M/2+1)*2,1:N) will contain the transformed results. If an in-place transform with full result is requested, A(1:2*M,1:N) will contain complete transformed results.

LDA (input)

Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') LDA \geq M

If PLACE = ('I' or 'i') LDA must be even. If

FULL = ('F' or 'f'), LDA \geq 2*M

FULL is not ('F' or 'f'), LDA \geq (M/2+1)*2

B (input/output)

Upon exit, a two-dimensional array B(2*LDB,N) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:(M/2+1)*2,1:N) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N) will contain the complete transformed results.

LDB (input)

2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), LDB \geq M

FULL is not ('F' or 'f'), LDB \geq M/2+1

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT2I.

LWORK (input)

Integer. LWORK \geq (M + 2*N + MAX(M, 2*N) + 30)

NAME

rfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE RFFT2I(M, N, WORK)
```

```
INTEGER M, N  
REAL WORK(*)
```

```
SUBROUTINE RFFT2I_64(M, N, WORK)
```

```
INTEGER*8 M, N  
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I(M, N, WORK)
```

```
INTEGER :: M, N  
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2I_64(M, N, WORK)
```

```
INTEGER(8) :: M, N  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft2i(int m, int n, float *work);
```

```
void rfft2i_64(long m, long n, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. $M \geq 0$.

N (input) Number of columns to be transformed. $N \geq 0$.

WORK (input/output)

On entry, an array of dimension $(M + 2*N + \text{MAX}(M, 2*N) + 30)$ or greater. RFFT2I needs to be called only once to initialize array WORK before calling RFFT2F and/or RFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

```

```
void rfft3b(char place, int m, int n, int k, float *a, int  
            lda, float *b, int ldb, float *work, int lwork);
```

```
void rfft3b_64(char place, long m, long n, long k, float *a,  
               long lda, float *b, long ldb, float *work, long  
               lwork);
```

ARGUMENTS

PLACE (input)

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

A (input/output)

On entry, the three-dimensional array A(LDA,N,K) contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N,1:K).

LDA (input)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$.

B (input/output)

Real array of dimension $B(2*LDB,N,K)$. On entry, if an out-of-place transform is requested $B(1:2*(M/2+1),1:N,1:K)$ contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)

If an out-of-place transform is desired, $2*LDB$ is the leading dimension of the array B which contains the data to be transformed and $2*LDB \geq 2*(M/2+1)$. Otherwise it is not referenced.

WORK (input/output)

One-dimensional real array of length at least $LWORK$. On input, $WORK$ must have been initialized by `RFFT3I`.

LWORK (input)

Integer. $LWORK \geq (M + 2*(N + K) + 4*K + 45)$.

NAME

rfft3f - compute the Fourier coefficients of a real periodic sequence. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by $M \cdot N \cdot K$.

SYNOPSIS

```
SUBROUTINE RFFT3F(PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK, LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER M, N, K, LDA, LDB, LWORK  
REAL A(LDA,N,*), B(2*LDB,N,*), WORK(*)
```

```
SUBROUTINE RFFT3F_64(PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,  
                     LWORK)
```

```
CHARACTER * 1 PLACE, FULL  
INTEGER*8 M, N, K, LDA, LDB, LWORK  
REAL A(LDA,N,*), B(2*LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F(PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],  
                WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER :: M, N, K, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:,:,:) :: A, B
```

```
SUBROUTINE FFT3F_64(PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],  
                   WORK, LWORK)
```

```
CHARACTER(LEN=1) :: PLACE, FULL  
INTEGER(8) :: M, N, K, LDA, LDB, LWORK  
REAL, DIMENSION(:) :: WORK
```

```
REAL, DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft3f(char place, char full, int m, int n, int k,  
            float *a, int lda, float *b, int ldb, float *work,  
            int lwork);
```

```
void rfft3f_64(char place, char full, long m, long n, long  
               k, float *a, long lda, float *b, long ldb, float  
               *work, long lwork);
```

ARGUMENTS

PLACE (input)

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

FULL (input)

Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an MxNxK real array will transform to produce an MxNxK complex array. If the caller does not select full representation then an MxNxK real array will transform to a (M/2+1)xNxK complex array that takes advantage of the symmetry properties of a transformed real sequence.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

A (input/output)

On entry, a three-dimensional array A(LDA,N,K) that contains input data to be transformed. On

exit, if an in-place transform is done and FULL is not 'F' or 'f', A(1:2*(M/2+1),1:N,1:K) will contain the partial transformed results. If FULL = 'F' or 'f', A(1:2*M,1:N,1:K) will contain the complete transformed results.

LDA (input)

Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') LDA \geq M

If PLACE = ('I' or 'i') LDA must be even. If

FULL = ('F' or 'f'), LDA \geq 2*M

FULL is not ('F' or 'f'), LDA \geq 2*(M/2+1)

B (input/output)

Upon exit, a three-dimensional array B(2*LDB,N,K) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:2*(M/2+1),1:N,1:K) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N,1:K) will contain the complete transformed results.

LDB (input)

2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), then LDB \geq M

FULL is not ('F' or 'f'), then LDB \geq M/2 + 1

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)

One-dimensional real array of length at least LWORK. WORK must have been initialized by RFFT3I.

LWORK (input)

Integer. LWORK \geq (M + 2*(N + K) + 4*K + 45).

NAME

`rfft3i` - initialize the array `WSAVE`, which is used in both `RFFT3F` and `RFFT3B`.

SYNOPSIS

```
SUBROUTINE RFFT3I(M, N, K, WORK)
```

```
INTEGER M, N, K  
REAL WORK(*)
```

```
SUBROUTINE RFFT3I_64(M, N, K, WORK)
```

```
INTEGER*8 M, N, K  
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3I(M, N, K, WORK)
```

```
INTEGER :: M, N, K  
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3I_64(M, N, K, WORK)
```

```
INTEGER(8) :: M, N, K  
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void rfft3i(int m, int n, int k, float *work);
```

```
void rfft3i_64(long m, long n, long k, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. $M \geq 0$.

N (input) Number of columns to be transformed. $N \geq 0$.

K (input) Number of planes to be transformed. $K \geq 0$.

WORK (input/output)

On entry, an array of dimension $(M + 2*(N + K) + 4*K + 45)$ or greater. RFFT3I needs to be called only once to initialize array WORK before calling RFFT3F and/or RFFT3B if M, N, K and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

- [PURPOSE](#)

NAME

`rfftopt` - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION RFFTOPT(LEN)
```

```
INTEGER LEN
```

```
INTEGER*8 FUNCTION RFFTOPT_64(LEN)
```

```
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION RFFTOPT(LEN)
```

```
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION RFFTOPT_64(LEN)
```

```
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>
```

```
int rfftopt(int len);
```

```
long rfftopt_64(long len);
```

PURPOSE

`rfftopt` computes the length of the closest fast FFT. Fast

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2^5$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

RFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. RFFTOPT will return 16 for an input of $N=16$ and return $18=2^3 \cdot 3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value returned may change as the underlying

FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2^2 \cdot 13$ rather than $51=3 \cdot 17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added

and then $N=51$ will return 51.

NAME

`sasum` - Return the sum of the absolute values of a vector `x`.

SYNOPSIS

```
REAL FUNCTION SASUM(N, X, INCX)
```

```
INTEGER N, INCX
```

```
REAL X(*)
```

```
REAL FUNCTION SASUM_64(N, X, INCX)
```

```
INTEGER*8 N, INCX
```

```
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION ASUM([N], X, [INCX])
```

```
INTEGER :: N, INCX
```

```
REAL, DIMENSION(:) :: X
```

```
REAL FUNCTION ASUM_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX
```

```
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sasum(int n, float *x, int incx);
```

```
float sasum_64(long n, float *x, long incx);
```

PURPOSE

`sasum` Return the sum of the absolute values of `x` where `x` is an `n`-vector.

ARGUMENTS

`N` (input)

On entry, `N` specifies the number of elements in the vector. `N` must be at least one for the subroutine to have any visible effect. Unchanged on exit.

`X` (input)

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array `X` must contain the vector `x`. Unchanged on exit.

`INCX` (input)

On entry, `INCX` specifies the increment for the elements of `X`. `INCX` must not be zero or negative. Unchanged on exit.

```

```
INTEGER :: N, INCX, INCY  
REAL :: ALPHA  
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL :: ALPHA  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void saxpy(int n, float alpha, float *x, int incx, float *y,
           int incy);

void saxpy_64(long n, float alpha, float *x, long incx,
              float *y, long incy);

```

PURPOSE

saxpy compute $y := \alpha * x + y$ where α is a scalar and x and y are n -vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

```

```
REAL :: A  
REAL, DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

SAXPYI Compute $y := \alpha * x + y$ where α is a scalar, x is a sparse vector, and y is a vector in full storage form

```
do i = 1, n
  y(indx(i)) = alpha * x(i) + y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

A (input)

On entry, A(LPHA) specifies the scaling value.
Unchanged on exit. A is defaulted to 1.0E0 for F95
INTERFACE.

X (input)

Vector containing the values of the compressed form.
Unchanged on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector on input which contains the vector Y in full
storage form. On exit, only the elements
corresponding to the indices in INDX have been
modified.

#include <sunperf.h>

void sbcomm (int transa, int mb, int n, int kb, float alpha,
int* descra, float *val, int *bindx, int *bjndx, int bnnz,
int lb, float *b, int ldb, float beta, float *c, int ldc);

void sbcomm_64(long transa, long mb, long n, long kb, float
alpha, long *descra, float *val, long *bindx, long *bjndx,
long bnnz, long lb, float *b, long ldb,
float beta, float *c, long ldc);
```

DESCRIPTION

cbcomm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),
A is an (mb*lb) by (kb*lb) sparse matrix represented in the block
coordinate format, alpha and beta are scalars, C and B are dense
matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, integer KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main block diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 LB*LB*BNNZ consisting of the non-zero block
 entries of A, in any order. Each block
 is stored in standard column-major form.
 Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ
 consisting of the block row indices of the non-zero
 block entries of A. Unchanged on exit.

BJNDX(input) On entry, BJNDX is an integer array of length BNNZ
 consisting of the block column indices of the non-zero
 block entries of A. Unchanged on exit.

BNNZ (input) On entry, integer BNNZ specifies the number of nonzero
 block entries in A. Unchanged on exit.

LB (input) On entry, integer LB specifies the dimension of dense
 blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading kb*lb by n
 part of the array B must contain the matrix B, otherwise
 the leading mb*lb by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading mb*lb by n
 part of the array C must contain the matrix C, otherwise
 the leading kb*lb by n part of the array C must contain the
 matrix C. On exit, the array C is overwritten by the matrix
 (alpha*op(A)* B + beta*C).

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

The all sparse blas matrix-matrix multiply routines for block entry formats are designed so that if *DESCRA*(1)> 0, the routines check the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use just one sparse matrix representation of a general block matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A .

Assume that there is the sparse matrix representation of a general real matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of *DESCRA* and the result matrix for the sparse representation of A is

<i>DESCRA</i> (1)	<i>DESCRA</i> (2)	<i>DESCRA</i> (3)	RESULT
1 or 2	1	0	$\alpha * \text{op}(L+D+L') * B + \beta * C$
1 or 2	1	1	$\alpha * \text{op}(L+I+L') * B + \beta * C$
1 or 2	2	0	$\alpha * \text{op}(U'+D+U) * B + \beta * C$
1 or 2	2	1	$\alpha * \text{op}(U'+I+U) * B + \beta * C$

3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$
4 or 6	1	0 or 1	$\alpha * \text{op}(L+D-L') * B + \beta * C$
4 or 6	2	0 or 1	$\alpha * \text{op}(U+D-U') * B + \beta * C$
5	1 or 2	0	$\alpha * \text{op}(D) * B + \beta * C$
5	1 or 2	1	$\alpha * B + \beta * C$

Remarks to the table:

1. the value of `DESCRA(3)` is simply ignored , if `DESCRA(1)= 4 or 6` but the diagonal blocks which are referenced in the sparse matrix representation are used;
2. the diagonal blocks which are referenced in the sparse matrix representation are not used, if `DESCRA(3)=1` and `DESCRA(1)` is one of 1, 2, 3 or 5;
3. if `DESCRA(3)` is not 1 and `DESCRA(1)` is one of 1,2, 4 or 6, the type of D should correspond to the choosen value of `DESCRA(1)` .

               float *beta, float *c, long ldc);
```

DESCRIPTION

sbdimm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an (mb*lb) by (kb*lb) sparse matrix represented in the block coordinate format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal 6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator

```

        1 : lower
        2 : upper
DESCRA(3) main block diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)      On entry, two-dimensional LB*LB*BLDA-by-NBDIAG array
                  consisting of the NBDIAG nonzero block diagonal in
                  any order. Each dense block is stored in standard
                  column-major form. Unchanged on exit.

BLDA(input)      On entry, BLDA*LB*LB specifies the leading block dimension
                  of VAL(). Unchanged on exit.

IBDIAG(input)    On entry, integer array of length NBDIAG consisting of the
                  corresponding diagonal offsets of the non-zero
                  block diagonals of A in VAL. Lower triangular
                  block diagonals have negative offsets, the main
                  block diagonal has offset 0, and upper triangular
                  block diagonals have positive offset. Unchanged on exit.

NBDIAG(input)    On entry, NBDIAG specifies the number of non-zero block
                  diagonals in A. Unchanged on exit.

LB (input)       On entry, LB specifies the dimension of dense blocks
                  composing A. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with TRANSA = 0, the leading kb*lb by n
                  part of the array B must contain the matrix B, otherwise
                  the leading mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with TRANSA = 0, the leading mb*lb by n
                  part of the array C must contain the matrix C, otherwise
                  the leading kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

long *ibdiag, long nbdiag, long lb, float *b, long ldb,  
float beta, float *c, long ldc);
```

DESCRIPTION

sbdism performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block diagonal format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in matrix the A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form. Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LB*LB*BLDA-by-NBDIAG array consisting of the NBDIAG non-zero block diagonal. Each dense block is stored in standard column-major form. Unchanged on exit.

BLDA(input) On entry, BLDA*LB*LB specifies the leading block dimension of VAL(). Unchanged on exit.

IBDIAG(input) On entry, IBDIAG is an integer array of length NBDIAG consisting of corresponding diagonal offsets of the non-zero block diagonals of A in VAL. Lower triangular block diagonals have negative offsets, the main block diagonal has offset 0, and upper triangular block diagonals have positive offset. Elements of IBDIAG MUST be sorted in increasing order. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block diagonal representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2` , diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine.

`WORK(1)=0` on return if the factorization for all diagonal

blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix `A` for solving triangular systems with the upper or lower block triangle of `A`. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix `A` decomposed in the form

$$A = L + D + U$$

where `L` is the strictly block lower triangle of `A`, `U` is the strictly block upper triangle of `A`, `D` is the block diagonal matrix. Let's `I` denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of `A` is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	<code>alpha*op(L+I)*B+beta*C</code>
3	1	0	<code>alpha*op(L+D)*B+beta*C</code>
3	2	1	<code>alpha*op(U+I)*B+beta*C</code>
3	2	0	<code>alpha*op(U+D)*B+beta*C</code>

```

C INTERFACE

```

#include <sunperf.h>

void sbdsdc(char uplo, char compq, int n, float *d, float
            *e, float *u, int ldu, float *vt, int ldvt, float
            *q, int *iq, int *info);
void sbdsdc_64(char uplo, char compq, long n, float *d,
               float *e, float *u, long ldu, float *vt, long
               ldvt, float *q, long *iq, long *info);

```

PURPOSE

sbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B : $B = U * S * VT$, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

```

UPLO (input)
    = 'U': B is upper bidiagonal.
    = 'L': B is lower bidiagonal.

COMPQ (input)
    Specifies whether singular vectors are to be computed as follows:

```

= 'N': Compute singular values only;
 = 'P': Compute singular values and compute singular vectors in compact form;
 = 'I': Compute singular values and singular vectors.

N (input) The order of the matrix B. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E (input/output)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U (output)

If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq 1$.
 If singular vectors are desired, then $LDU \geq \max(1, N)$.

VT (output)

If COMPQ = 'I', then: On exit, if INFO = 0, VT contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT (input)

The leading dimension of the array VT. $LDVT \geq 1$.
 If singular vectors are desired, then $LDVT \geq \max(1, N)$.

Q (input) If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2*N**2$. In particular, Q contains all the REAL data in $LDQ \geq N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ (output)

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space

instead of $2*N^2$. In particular, IQ contains all INTEGER data in LDIQ $\geq N*(3 + 3*INT(\log_2(N/(SMLSIZ+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK (workspace)

If COMPQ = 'N' then LWORK $\geq (2 * N)$. If COMPQ = 'P' then LWORK $\geq (6 * N)$. If COMPQ = 'I' then LWORK $\geq (3 * N^2 + 4 * N)$.

IWORK (workspace)

dimension($8*N$)

INFO (output)

= 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: The algorithm failed to compute an singular value. The update process of divide and conquer failed.

```

C INTERFACE

```
#include <sunperf.h>

void sbdsqr(char uplo, int n, int ncv, int nru, int ncc,
            float *d, float *e, float *vt, int ldvt, float *u,
            int ldu, float *c, int ldc, int *info);

void sbdsqr_64(char uplo, long n, long ncv, long nru, long
               ncc, float *d, float *e, float *vt, long ldvt,
               float *u, long ldu, float *c, long ldc, long
               *info);
```

PURPOSE

sbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': B is upper bidiagonal;
= 'L': B is lower bidiagonal.

N (input) The order of the matrix B. $N \geq 0$.

NCVT (input)
The number of columns of the matrix VT. $NCVT \geq 0$.

NRU (input)
The number of rows of the matrix U. $NRU \geq 0$.

NCC (input)
The number of columns of the matrix C. $NCC \geq 0$.

D (input/output)
 On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E (input/output)
 On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

VT (input/output)
 On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if NCVT = 0.

LDVT (input)
 The leading dimension of the array VT. LDVT \geq max(1,N) if NCVT > 0; LDVT \geq 1 if NCVT = 0.

U (input/output)
 On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if NRU = 0.

LDU (input)
 The leading dimension of the array U. LDU \geq max(1,NRU).

C (input/output)
 On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if NCC = 0.

LDC (input)
 The leading dimension of the array C. LDC \geq max(1,N) if NCC > 0; LDC \geq 1 if NCC = 0.

WORK (workspace)
 dimension(4*N)

INFO (output)
 = 0: successful exit
 < 0: If INFO = -i, the i-th argument had an illegal value
 > 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

(' indicates matrix transpose)

ARGUMENTS

Page 2375 of 4556

```

        2 : upper
DESCRA(3) main block diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)      On entry, VAL is a two-dimensional LB*LB*BLDA-by-MAXBNZ
                  array consisting of the non-zero blocks, stored
                  column-major within each dense block. Unchanged on exit.

BINDX(input)    On entry, BINDX is an integer two-dimensional BLDA-MAXBNZ
                  array such BINDX(i,:) consists of the block column indices
                  of the nonzero blocks in block row i, padded by the integer
                  value i if the number of nonzero blocks is less than
                  MAXBNZ. Unchanged on exit.

BLDA(input)     On entry, BLDA specifies the leading dimension of BINDX(:,:).
                  Unchanged on exit.

MAXBNZ (input)  On entry, NBDIAG specifies the max number of nonzeros
                  blocks per row. Unchanged on exit.

LB (input)      On entry, LB specifies the dimension of dense blocks
                  composing A.  Unchanged on exit.

B (input)       Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading  kb*lb by n
                  part of the array  B  must contain the matrix B,  otherwise
                  the leading  mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)     On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)    On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output) Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading  mb*lb by n
                  part of the array  C  must contain the matrix C,  otherwise
                  the leading  kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)     On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible
with NIST FORTRAN Sparse Blas but the sources are different.

Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the sbcomm manpage.

ldb, float beta, float *c, long ldc);
```

DESCRIPTION

sbelsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block ellpack format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	Integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form. Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LB*LB*BLDA-by-MAXBNZ array consisting of the non-zero blocks, stored column-major within each dense block. Unchanged on exit.

BINDX(input) On entry, BINDX is an integer two-dimensional BLDA-MAXBNZ array such BINDX(i,:) consists of the block column indices of the nonzero blocks in block row i, padded by the integer value i if the number of nonzero blocks is less than MAXBNZ. The block column indices MUST be sorted in increasing order for each block row. Unchanged on exit.

BLDA(input) On entry, BLDA specifies the leading dimension of BINDX(:,:).
Unchanged on exit.

MAXBNZ (input) On entry, MAXBNZ specifies the max number of nonzeros blocks per row. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block ellpack representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2` , diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine.

`WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix `A` for solving triangular systems with the upper or lower block triangle of `A`. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix `A` decomposed in the form

$$A = L + D + U$$

where `L` is the strictly block lower triangle of `A`, `U` is the strictly block upper triangle of `A`, `D` is the block diagonal matrix. Let's `I` denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of `A` is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

DESCRIPTION

ARGUMENTS

Page 2384 of 4556

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main block diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length LB*LB*BNNZ consisting of the non-zero block entries stored column-major within each dense block where BNNZ = BPNTRE(KB)-BPNTRB(1). Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting of the block row indices of the block entries of A where BNNZ = BPNTRE(KB)-BPNTRB(1). Unchanged on exit.

BPNTRB(input) On entry, BPNTRB is an integer array of length KB such that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the J-th block column of A. Unchanged on exit.

BPNTRE(input) On entry, BPNTRE is an integer array of length KB such that BPNTRE(J)-BPNTRB(1) points to location in BINDX of the last block entry of the J-th block column of A. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANS = 0, the leading kb*lb by n part of the array B must contain the matrix B, otherwise the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANS = 0, the leading mb*lb by n part of the array C must contain the matrix C, otherwise the leading kb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix
 $(\alpha * op(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the sbcomm manpage.

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

  int *bindx, int *bpntrb, int *bpntre, int lb, float *b,
  int ldb, float beta, float* c, int ldc);
void sbscsm_64(long transa, long mb, long n, long unitd,
  float *dv, float alpha, long *descra, float *val, long
  *bindx, long *bpntrb, long *bpntre, long lb, float *b, long
  ldb, float beta, float *c, long ldc);
```

DESCRIPTION

sbscsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block sparse column format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block columns in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form. Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length LB*LB*BNNZ
consisting of the non-zero block entries stored
column-major within each dense block where
BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting
of the block row indices of the block entries of A where
BNNZ = BPNTRE(MB)-BPNTRB(1). The block row indices MUST
be sorted in increasing order for each block column.
Unchanged on exit.

BPNTRB(input) On entry, BPNTRB is an integer array of length MB such
that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
of the first block entry of the J-th block column
of A. Unchanged on exit.

BPNTRE(input) On entry, BPNTRE is an integer array of length MB such
that BPNTRE(J)-BPNTRB(1) points to location in BINDX
of the last block entry of the J-th block column
of A. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks
composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B
must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK $\geq \text{MB} \times \text{LB} \times \text{N_CPUS}$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block sparse column representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.

4. If `DESCRA(3)=2` , the diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where *i* is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the sbcomm manpage.

NOTES/BUGS

It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
CALL SBSRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

REAL, DIMENSION(:) :: VAL, DV
REAL, DIMENSION(:, :) :: B, C

SUBROUTINE BSRSM_64(TRANSA, MB, [N], UNITD, DV, ALPHA, DESCRA, VAL, BINDX,
*                BPNTRB, BPNTRE, LB, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
INTEGER*8        TRANSA, MB, N, UNITD, LB
INTEGER*8, DIMENSION(:) :: DESCRA, BINDX, BPNTRB, BPNTRE
REAL             ALPHA, BETA
REAL, DIMENSION(:) :: VAL, DV
```

```
REAL, DIMENSION(:, :) :: B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sbsrsm(int transa, int mb, int n, int unitd,
  float *dv, float alpha, int *descra, float *val,
  int *bindx, int *bpntrb, int *bpntre, int lb, float *b,
  int ldb, float beta, float* c, int ldc);
void sbsrsm_64(long transa, long mb, long n, long unitd,
  float *dv, float alpha, long *descra, float *val, long
  *bindx, long *bpntrb, long *bpntre, long lb, float *b, long
  ldb, float beta, float *c, long ldc);
```

DESCRIPTION

sbsrsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block sparse row format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form. Unchanged on exit.

ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular 4 : Skew(Anti)-Symmetric (A=-A') 5 : Diagonal 6 : Skew-Hermitian (A= -CONJG(A')) Note: For the routine, DESCRA(1)=3 is only supported. DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper DESCRA(3) main diagonal type 0 : non-identity blocks on the main diagonal 1 : identity diagonal blocks 2 : diagonal blocks are dense matrices DESCRA(4) Array base (NOT IMPLEMENTED) 0 : C/C++ compatible 1 : Fortran compatible DESCRA(5) repeated indices? (NOT IMPLEMENTED) 0 : unknown 1 : no repeated indices
VAL(input)	On entry, VAL is a scalar array of length LB*LB*BNNZ consisting of the non-zero block entries stored column-major within each dense block where BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.
BINDX(input)	On entry, BINDX is an integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ = BPNTRE(MB)-BPNTRB(1). The block column indices MUST be sorted in increasing order for each block column. Unchanged on exit.
BPNTRB(input)	On entry, BPNTRB is an integer array of length MB such that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the J-th block row of A. Unchanged on exit.
BPNTRE(input)	On entry, BPNTRE is an integer array of length MB such that BPNTRE(J)-BPNTRB(1) points to location in BINDX of the last block entry of the J-th block row of A. Unchanged on exit.
LB (input)	On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.
B (input)	Array of DIMENSION (LDB, N). On entry, the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.
LDB (input)	On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.
BETA (input)	On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block sparse row representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.

4. If `DESCRA(3)=2` , the diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where *i* is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

<code>DESCRA(1)</code>	<code>DESCRA(2)</code>	<code>DESCRA(3)</code>	RESULT
3	1	1	<code>alpha*op(L+I)*B+beta*C</code>
3	1	0	<code>alpha*op(L+D)*B+beta*C</code>
3	2	1	<code>alpha*op(U+I)*B+beta*C</code>
3	2	0	<code>alpha*op(U+D)*B+beta*C</code>

6. It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
CALL SBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

scasum - Return the sum of the absolute values of a vector `x`.

SYNOPSIS

```
REAL FUNCTION SCASUM(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER N, INCX
```

```
REAL FUNCTION SCASUM_64(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION ASUM([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
REAL FUNCTION ASUM_64([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
float scasum(int n, complex *x, int incx);
```

```
float scasum_64(long n, complex *x, long incx);
```

PURPOSE

scasum Return the sum of the absolute values of the elements of x where x is an n -vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

($1 + (n - 1) * \text{abs}(\text{INCX})$). On entry, the incremented array X must contain the vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X . INCX must not be zero or negative. Unchanged on exit.

NAME

scnrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
REAL FUNCTION SCNRM2(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER N, INCX
```

```
REAL FUNCTION SCNRM2_64(N, X, INCX)
```

```
COMPLEX X(*)  
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION NRM2([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER :: N, INCX
```

```
REAL FUNCTION NRM2_64([N], X, [INCX])
```

```
COMPLEX, DIMENSION(:) :: X  
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>
```

```
float scnrm2(int n, complex *x, int incx);
```

```
float scnrm2_64(long n, complex *x, long incx);
```

PURPOSE

scnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. If INCX < 1 then SCNRM2 returns 0. Unchanged on exit.

#include <sunperf.h>

void scnvcor(char cnvcor, char four, int nx, float *x, int
    ifx, int incx, int ny, int npre, int m, float *y,
    int ify, int incly, int inc2y, int nz, int k,
    float *z, int ifz, int inclz, int inc2z, float
    *work, int lwork);
void scnvcor_64(char cnvcor, char four, long nx, float *x,
    long ifx, long incx, long ny, long npre, long m,
    float *y, long ify, long incly, long inc2y, long
    nz, long k, float *z, long ifz, long inclz, long
    inc2z, float *work, long lwork);
```

PURPOSE

scnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

CNVCOR (input)
 'V' or 'v' if convolution is desired, 'R' or 'r'
 if correlation is desired.

FOUR (input)
 'T' or 't' if the Fourier transform method is to
 be used, 'D' or 'd' if the computation should be
 done directly from the definition. The Fourier
 transform method is generally faster, but it may
 introduce noticeable errors into certain results,
 notably when both the filter and data vectors con-
 sist entirely of integers or vectors where ele-
 ments of either the filter vector or a given data
 vector differ significantly in magnitude from the
 1-norm of the vector.

NX (input)
 Length of the filter vector. NX >= 0. SCNVCOR
 will return immediately if NX = 0.

X (input)
 Filter vector.

IFX (input)
 Index of the first element of X. NX >= IFX >= 1.

INCX (input)

Stride between elements of the filter vector in X.
 INCX > 0.

NY (input)
 Length of the input vectors. NY >= 0. SCNVCOR
 will return immediately if NY = 0.

NPRE (input)
 The number of implicit zeros prepended to the Y
 vectors. NPRE >= 0.

M (input)
 Number of input vectors. M >= 0. SCNVCOR will
 return immediately if M = 0.

Y (input)
 Input vectors.

IFY (input)
 Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)
 Stride between elements of the input vectors in Y.
 INC1Y > 0.

INC2Y (input)
 Stride between the input vectors in Y. INC2Y > 0.

NZ (input)
 Length of the output vectors. NZ >= 0. SCNVCOR
 will return immediately if NZ = 0. See the Notes
 section below for information about how this argu-
 ment interacts with NX and NY to control circular
 versus end-off shifting.

K (input)
 Number of Z vectors. K >= 0. If K = 0 then
 SCNVCOR will return immediately. If K < M then
 only the first K input vectors will be processed.
 If K > M then M input vectors will be processed.

Z (output)
 Result vectors.

IFZ (input)
 Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
 Stride between elements of the output vectors in
 Z. INC1Z > 0.

INC2Z (input)
 Stride between the output vectors in Z. INC2Z >
 0.

WORK (input/output)

Scratch space. Before the first call to SCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to SCNVCOR or if SCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make SCNVCOR run faster.

LWORK (input)

Length of WORK. LWORK $\geq 4 \cdot \max(NX, NPRE + NY, NZ) + 15$.

NOTES

If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y \geq NY, INC1Z = 1, INC2Z \geq NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y \geq NY, INC2Y = 1, INC1Z \geq NZ, and INC2Z = 1.

    lwork);

```

PURPOSE

scnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

CNVCOR (input)
 'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
 'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

TRANSX (input)
 'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)
 'N' or 'n' if X must be preserved, 'S' or 's' if X

can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)

Number of rows in the filter matrix. $MX \geq 0$.

NX (input)

Number of columns in the filter matrix. $NX \geq 0$.

X (input) dimension(LDX,NX)

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)

Leading dimension of the array that contains the filter matrix.

MY (input)

Number of rows in the input matrix. $MY \geq 0$.

NY (input)

Number of columns in the input matrix. $NY \geq 0$.

MPRE (input)

Number of implicit zeros to prepend to each row of the input matrix. $MPRE \geq 0$.

NPRE (input)

Number of implicit zeros to prepend to each column of the input matrix. $NPRE \geq 0$.

Y (input) dimension(LDY,*)

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)

Leading dimension of the array that contains the input matrix.

MZ (input)

Number of rows in the output matrix. $MZ \geq 0$.
SCNVCOR2 will return immediately if $MZ = 0$.

NZ (input)
 Number of columns in the output matrix. NZ >= 0.
 SCNVCOR2 will return immediately if NZ = 0.

Z (output)
 dimension(LDZ,*)
 Result matrix.

LDZ (input)
 Leading dimension of the array that contains the
 result matrix. LDZ >= MAX(1,MZ).

WORKIN (input/output)
 (input/scratch) dimension(LWORK)
 On entry for the first call to SCNVCOR2,
 REAL(WORKIN(1)) must contain 0.0. After the first
 call, REAL(WORKIN(1)) must be set to 0.0 iff WOR-
 KIN has been altered since the last call to this
 subroutine or if the sizes of the arrays have
 changed.

LWORK (input)
 Length of the work vector. The upper bound of the
 workspace length requirement is 2 * (MYC + NYC) +
 15, where MYC = MAX(MAX(MX,NX), MAX(MY,NY)+NPRES)
 and NYC = MAX(MAX(MX,NX), MAX(MY,NY)+MPRES). If
 LWORK indicates a workspace that is too small, the
 routine will allocate its own workspace. If the
 FFT is not used, the value of LWORK is unimpor-
 tant.

float beta, float *c, long ldc);
```

DESCRIPTION

scoomm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the coordinate format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, integer K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal 6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$)

```

DESCRA(2) upper/lower triangular indicator
  1 : lower
  2 : upper
DESCRA(3) main diagonal type
  0 : non-unit
  1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
  0 : C/C++ compatible
  1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
  0 : unknown
  1 : no repeated indices

VAL (input)      On entry, VAL is a scalar array array of length
                  NNZ consisting of the non-zero entries of A,
                  in any order. Unchanged on exit.

INDX (input)     On entry, INDX is an integer array of length NNZ
                  consisting of the corresponding row indices of
                  the entries of A. Unchanged on exit.

JNDX (input)     On entry, JNDX is an integer array of length NNZ
                  consisting of the corresponding column indices of
                  the entries of A. Unchanged on exit.

NNZ (input)      On entry, integer NNZ specifies the number of
                  non-zero elements in A. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading  k by n
                  part of the array  B  must contain the matrix  B,  otherwise
                  the leading  m by n  part of the array  B  must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading  m by n
                  part of the array C must contain the matrix C,  otherwise
                  the leading  k by n  part of the array  C  must contain the
                  matrix C. On exit, the array  C  is overwritten by the  matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are

implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

The all sparse blas matrix-matrix multiply routines except the skyline and jagged-diagonal format routines are designed so that if *DESCRA*(1)> 0, the routines check the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A .

Assume that there is the sparse matrix representation of a general real matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of *DESCRA* and the result matrix for the sparse representation of A is

<i>DESCRA</i> (1)	<i>DESCRA</i> (2)	<i>DESCRA</i> (3)	RESULT
<hr/>			
1 or 2	1	0	$\alpha * \text{op}(L+D+L') * B + \beta * C$
1 or 2	1	1	$\alpha * \text{op}(L+I+L') * B + \beta * C$
1 or 2	2	0	$\alpha * \text{op}(U'+D+U) * B + \beta * C$
1 or 2	2	1	$\alpha * \text{op}(U'+I+U) * B + \beta * C$
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

4 or 6	1	0 or 1	$\alpha * \text{op}(L-L') * B + \beta * C$
4 or 6	2	0 or 1	$\alpha * \text{op}(U-U') * B + \beta * C$
5	1 or 2	0	$\alpha * \text{op}(D) * B + \beta * C$
5	1 or 2	1	$\alpha * B + \beta * C$

Remarks to the table:

1. the value of `DESCRA(3)` is simply ignored and the diagonal entries given in the sparse matrix representation are not used by the routine, if `DESCRA(1)= 4 or 6`;
2. the diagonal entries are not used also, if `DESCRA(3)=1` and `DESCRA(1)` is one of 1, 2, 3 or 5;
3. if `DESCRA(3)` is not 1 and `DESCRA(1)` is one of 1,2, 4 or 6, the type of D should correspond to the choosen value of `DESCRA(1)` .

NAME

scopy - Copy x to y

SYNOPSIS

```
SUBROUTINE SCOPY(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
REAL X(*), Y(*)
```

```
SUBROUTINE SCOPY_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void scopy(int n, float *x, int incx, float *y, int incy);
```

```
void scopy_64(long n, float *x, long incx, float *y, long  
            incy);
```

PURPOSE

scopy Copy x to y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

ldc);

```

DESCRIPTION

scscmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the compressed sparse column format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal 6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$)

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ = PNTRE(K)-PNTRB(1) consisting of nonzero
 entries of A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ = PNTRE(K)-PNTRB(1) consisting of the row
 indices of nonzero entries of A.
 Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length K
 such that PNTRB(J)-PNTRB(1)+1 points to location
 in VAL of the first nonzero element in column J.
 Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length K
 such that PNTRE(J)-PNTRB(1) points to location
 in VAL of the last nonzero element in column J.
 Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading k by n
 part of the array B must contain the matrix B, otherwise
 the leading m by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n
 part of the array C must contain the matrix C, otherwise
 the leading k by n part of the array C must contain the
 matrix C. On exit, the array C is overwritten by the matrix
 (alpha*op(A)* B + beta*C).

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats in the case of real sparse matrices is given in the manpage for the scoomm manpage.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,  
*                VAL, INDX, IA, IA(2), B, LDB, BETA,  
*                C, LDC, WORK, LWORK )
```

int *indx, int *pntrb, int *pntre, float *b,  
int ldb, float beta, float* c, int ldc);  
void scscsm_64(long transa, long m, long n, long unitd,  
float *dv, float alpha, long *descra, float *val, long  
*indx, long *pntrb, long *pntre, float *b, long ldb, float  
beta, float *c, long ldc);
```

DESCRIPTION

scscsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the compressed sparse column format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic column scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which

the columns of A have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-unit
1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero
entries of A. If UNITD is 4, VAL contains
the scaled matrix A*D (see section NOTES for
further details). Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
NNZ = PNTRE(M)-PNTRB(1) consisting of the row
indices of nonzero entries of A.
Row indices MUST be sorted in increasing order
for each column. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M
such that PNTRB(J)-PNTRB(1)+1 points to location
in VAL of the first nonzero element in column J.
Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M
such that PNTRE(J)-PNTRB(1) points to location
in VAL of the last nonzero element in column J.
Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B
must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).

On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M \cdot N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = - i` where `i` is the column number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the CSC representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix `A` for solving triangular systems with the upper or lower triangle of `A`. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix `A` decomposed in the form

$$A = L + D + U$$

where `L` is the strictly lower triangle of `A`, `U` is the strictly upper triangle of `A`, `D` is the diagonal matrix. Let's `I` denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of `A` is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	<code>alpha*op(L+I)*B+beta*C</code>
3	1	0	<code>alpha*op(L+D)*B+beta*C</code>
3	2	1	<code>alpha*op(U+I)*B+beta*C</code>
3	2	0	<code>alpha*op(U+D)*B+beta*C</code>

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, `IA`, containing the pointers to the beginning of each column in the arrays `VAL` and `INDX` is used instead of two arrays `PNTRB` and `PNTRE`. To use the routine with this kind of sparse column format the following calling sequence should be used

```
SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                 VAL, INDX, IA, IA(2), B, LDB, BETA,
*                 C, LDC, WORK, LWORK )
```

ldc);
```

DESCRIPTION

scsrmr performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the compressed sparse row format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: <ul style="list-style-type: none">0 : operate with matrix1 : operate with transpose matrix2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure <ul style="list-style-type: none">0 : general1 : symmetric ($A=A'$)2 : Hermitian ($A= \operatorname{CONJG}(A')$)3 : Triangular4 : Skew(Anti)-Symmetric ($A=-A'$)5 : Diagonal6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator

1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero entries
 of A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of the column
 indices of nonzero entries of A. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M such
 that PNTRB(J)-PNTRB(1)+1 points to location in VAL
 of the first nonzero element in row J.
 Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M
 such that PNTRE(J)-PNTRB(1) points to location
 in VAL of the last nonzero element in row J.
 Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading k by n
 part of the array B must contain the matrix B, otherwise
 the leading m by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.
 C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n
 part of the array C must contain the matrix C, otherwise
 the leading k by n part of the array C must contain the
 matrix C. On exit, the array C is overwritten by the matrix
 (alpha*op(A)* B + beta*C).

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

    beta, float *c, long ldc);
```

DESCRIPTION

scsrsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the compressed sparse row format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
 DESCRA (input) Descriptor argument. Five element integer array:
 DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 Note: For the routine, DESCRA(1)=3 is only supported.
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero entries
 of A. If UNITD is 4, VAL contains the scaled matrix
 D*A (see section NOTES for further details).
 Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of the column
 indices of nonzero entries of A. Column indices
 MUST be sorted in increasing order for each
 row. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M such
 that PNTRB(J)-PNTRB(1)+1 points to location in VAL
 of the first nonzero element in row J.
 Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M
 such that PNTRE(J)-PNTRB(1) points to location
 in VAL of the last nonzero element in row J.
 Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 On entry, the leading m by n part of the array B
 must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 On entry, the leading m by n part of the array C
 must contain the matrix C. On exit, the array C is
 overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK $\geq M \times N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = - i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the CSR representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSR representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But DESCRA(1) MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	alpha*op(L+I)*B+beta*C
3	1	0	alpha*op(L+D)*B+beta*C
3	2	1	alpha*op(U+I)*B+beta*C
3	2	0	alpha*op(U+D)*B+beta*C

5. It is known that there exists another representation of the compressed sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each row in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of compressed sparse row format the following calling sequence should be used

```

SUBROUTINE SCSRSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                 VAL, INDX, IA, IA(2), B, LDB, BETA, C,
*                 LDC, WORK, LWORK )

```

```

C INTERFACE

```
#include <sunperf.h>
```

```

void sdiamm (int transa, int m, int n, int k, double alpha,
int *descra, float *val, int lda, int *idiag, int ndiag,
float *b, int ldb, float beta,
float *c, int ldc);

void sdiamm_64 (long transa, long m, long n, long k, float
alpha, long *descra, float *val, long lda,
long *idiag, long ndiag, float *b, long ldb,
float beta, float *c, long ldc);

```

DESCRIPTION

sdiamm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the diagonal format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal 6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator 1 : lower 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) Two-dimensional LDA-by-NDIAG array such that VAL(:,I) consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom. Unchanged on exit.

LDA(input) On entry, NDIAG specifies the leading dimension of VAL, must be $\geq \text{MIN}(M,K)$. Unchanged on exit.

IDIAG(input) Integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset. Unchanged on exit.

NDIAG(input) On entry, NDIAG specifies the number of non-zero diagonals in A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N). Before entry with TRANSA = 0, the leading k by n part of the array B must contain the matrix B, otherwise the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N). Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * \text{op}(A) * B + \text{beta} * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different.

Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats is given in section NOTES/BUGS for the scoomm manpage.

                float beta, float *c, long ldc);
```

DESCRIPTION

sdiasm performs one of the matrix-matrix operations

$$\begin{aligned} C &\leftarrow \alpha \operatorname{op}(A) B + \beta C, & C &\leftarrow \alpha D \operatorname{op}(A) B + \beta C, \\ C &\leftarrow \alpha \operatorname{op}(A) D B + \beta C, \end{aligned}$$

where α and β are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the diagonal format and $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = \operatorname{inv}(A)$ or $\operatorname{op}(A) = \operatorname{inv}(A')$ or $\operatorname{op}(A) = \operatorname{inv}(\operatorname{conjg}(A'))$
(inv denotes matrix inverse, $'$ indicates matrix transpose).

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
 DESCRA (input) Descriptor argument. Five element integer array:
 DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 Note: For the routine, DESCRA(1)=3 is only supported.
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LDA-by-NDIAG array
 such that VAL(:,I) consists of non-zero elements on
 diagonal IDIAG(I) of A. Diagonals in the lower triangular
 part of A are padded from the top, and those in the upper
 triangular part are padded from the bottom. If UNITD is 4,
 VAL contains the scaled matrix D*A (see section NOTES for
 further details). Otherwise, unchanged on exit.

LDA(input) On entry, LDA specifies the leading dimension of VAL
 and INDX. LDA must be > MIN(M,K). Unchanged on exit.

IDIAG() On entry, IDIAG is an integer array of length NDIAG
 consisting of the corresponding diagonal offsets of
 the non-zero diagonals of A in VAL. Lower triangular
 diagonals have negative offsets, the main diagonal
 has offset 0, and upper triangular diagonals have
 positive offset. Elements of IDIAG of MUST be sorted
 in increasing order. Unchanged on exit.

NDIAG(input) On entry, NDIAG specifies the number of non-zero diagonals
 in A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 On entry, the leading m by n part of the array B
 must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 On entry, the leading m by n part of the array C
 must contain the matrix C. On exit, the array C is
 overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK $\geq M \times N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = - i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the diagonal entries are each used with the mathematical value 1. The entries of the

main diagonal in the DIA representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

NAME

sdisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

SYNOPSIS

```
SUBROUTINE SDISNA(JOB, M, N, D, SEP, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER M, N, INFO  
REAL D(*), SEP(*)
```

```
SUBROUTINE SDISNA_64(JOB, M, N, D, SEP, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER*8 M, N, INFO  
REAL D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA(JOB, M, N, D, SEP, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER :: M, N, INFO  
REAL, DIMENSION(:) :: D, SEP
```

```
SUBROUTINE DISNA_64(JOB, M, N, D, SEP, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER(8) :: M, N, INFO  
REAL, DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>

void sdisna(char job, int m, int n, float *d, float *sep,
            int *info);

void sdisna_64(char job, long m, long n, float *d, float
               *sep, long *info);
```

PURPOSE

sdisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

$$\text{SLAMCH}('E') * (\text{ANORM} / \text{SEP}(I))$$

where $\text{ANORM} = 2\text{-norm}(A) = \max(|D(j)|)$. $\text{SEP}(I)$ is not allowed to be smaller than $\text{SLAMCH}('E') * \text{ANORM}$ in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

JOB (input)

Specifies for which problem the reciprocal condition numbers should be computed:

= 'E': the eigenvectors of a symmetric/Hermitian matrix;

= 'L': the left singular vectors of a general matrix;

= 'R': the right singular vectors of a general matrix.

M (input) The number of rows of the matrix. $M \geq 0$.

N (input) If JOB = 'L' or 'R', the number of columns of the matrix, in which case $N \geq 0$. Ignored if JOB = 'E'.

D (input) dimension ($\min(M,N)$) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP (output)
dimension ($\min(M,N)$) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

sdot - compute the dot product of two vectors x and y.

SYNOPSIS

```
REAL FUNCTION SDOT(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
REAL X(*), Y(*)
```

```
REAL FUNCTION SDOT_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
REAL X(*), Y(*)
```

F95 INTERFACE

```
REAL FUNCTION DOT([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

```
REAL FUNCTION DOT_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sdot(int n, float *x, int incx, float *y, int incy);
```

```
float sdot_64(long n, float *x, long incx, float *y, long  
              incy);
```

PURPOSE

sdot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

REAL FUNCTION DOTI_64([NZ], X, INDX, Y)
```

```
REAL, DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

SDOTI Compute the indexed dot product of a real sparse vector `x` stored in compressed form with a real vector `y` in

full storage form.

```
dot = 0
do i = 1, n
  dot = dot + x(i) * y(indx(i))
enddo
```

ARGUMENTS

NZ (input)

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector in compressed form. Unchanged on exit.

INDX (input)

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)

Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

float sdsdot(int n, float sb, float *sx, int incx, float
             *sy, int incy);

float sdsdot_64(long n, float sb, float *sx, long incx,
                float *sy, long incy);
```

PURPOSE

sdsdot Computes a constant plus the double precision dot product of x and y where x and y are single precision n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

SB (input)
On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

SX (input)
(1 + (n - 1) * abs(INCX)). On entry, the incremented array SX must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of SX. Unchanged on exit.

SY (input)
(1 + (n - 1) * abs(INCY)). On entry, the incremented array SY must contain the vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of SY. Unchanged on exit.

NAME

`second` - return the user time for a process in seconds

SYNOPSIS

```
REAL FUNCTION SECOND( )
```

```
REAL FUNCTION SECOND_64( )
```

F95 INTERFACE

```
REAL FUNCTION SECOND( )
```

```
REAL FUNCTION SECOND_64( )
```

C INTERFACE

```
#include <sunperf.h>
```

```
float second( );
```

```
float second_64( );
```

PURPOSE

`second` returns the user time for a process in seconds. This version gets the time from the system function `ETIME`.

C INTERFACE

```
#include <sunperf.h>
```

```
void sellmm (int transa, int m, int n, int k, float alpha,  
int *descra, float *val, int *indx, int lda, int maxnz,  
float *b, int ldb, float beta, float *c, int ldc);
```

```
void sellmm_64 (long transa, long m, long n, long k, float  
alpha, long *descra, float *val, long *indx, long lda, long  
maxnz, float *b, long ldb, float beta, float *c, long ldc);
```

DESCRIPTION

sellmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the ellpack format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: <ul style="list-style-type: none">0 : operate with matrix1 : operate with transpose matrix2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure <ul style="list-style-type: none">0 : general1 : symmetric ($A=A'$)2 : Hermitian ($A= \operatorname{CONJG}(A')$)3 : Triangular4 : Skew(Anti)-Symmetric ($A=-A'$)5 : Diagonal6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator <ul style="list-style-type: none">1 : lower2 : upper

```

DESCRA(3) main diagonal type
    0 : non-unit
    1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
    0 : C/C++ compatible
    1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
    0 : unknown
    1 : no repeated indices

VAL(input)    On entry, VAL is a two-dimensional LDA-by-MAXNZ array
               such that VAL(I,:) consists of non-zero elements
               in row I of A, padded by zero values if the row
               contains less than MAXNZ. Unchanged on exit.

INDX(input)    On entry, INDX is an integer two-dimensional
               LDA-by-MAXNZ array such that INDX(I,:)
               consists of the column indices of the
               nonzero elements in row I, padded by the integer
               value I if the number of nonzeros is less than
               MAXNZ. Unchanged on exit.

LDA(input)     On entry, LDA specifies the leading dimension of VAL
               and INDX. Unchanged on exit.

MAXNZ(input)   On entry, MAXNZ specifies the max number of
               nonzeros elements per row. Unchanged on exit.

B (input)      Array of DIMENSION ( LDB, N ).
               Before entry with TRANSA = 0, the leading k by n
               part of the array B must contain the matrix B, otherwise
               the leading m by n part of the array B must contain the
               matrix B. Unchanged on exit.

LDB (input)    On entry, LDB specifies the first dimension of B as declared
               in the calling (sub) program. Unchanged on exit.

BETA (input)   On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output) Array of DIMENSION ( LDC, N ).
               Before entry with TRANSA = 0, the leading m by n
               part of the array C must contain the matrix C, otherwise
               the leading k by n part of the array C must contain the
               matrix C. On exit, the array C is overwritten by the matrix
               ( alpha*op( A )* B + beta*C ).

LDC (input)    On entry, LDC specifies the first dimension of C as declared
               in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

```

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are

implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats is given in section NOTES/BUGS for the scoomm manpage.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sellsm (int transa, int m, int n, int unitd, float *dv,  
float alpha, int *descra, float *val, int *indx, int lda,  
int maxnz, float *b, int ldb, float beta, float *c, int  
ldc);
```

```
void sellsm_64 (long transa, long m, long n, long unitd,  
float *dv, float alpha, long *descra, float *val, long  
*indx, long lda, long maxnz, float *b, long ldb, float beta,  
float *c, long ldc);
```

DESCRIPTION

sellsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices,
D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit,
upper or lower triangular matrix represented in the ellpack/itpack format
and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which

the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ. If UNITD is 4, VAL contains the scaled matrix $D \cdot A$ (see section NOTES for further details). Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer two-dimensional LDA-by-MAXNZ array such that INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ. The column indices MUST be sorted in increasing order for each row. Unchanged on exit.

LDA(input) On entry, LDA specifies the leading dimension of VAL and INDX. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK $\geq M \times N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = - i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the diagonal entries are

each used with the mathematical value 1. The entries of the main diagonal in the ELL representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

```

```

INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL, INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR

```

C INTERFACE

```

#include <sunperf.h>

void sfftc_ (int *iopt, int *n, float *scale, float *x, com-
             plex *y, float *trigs, int *ifac, float *work, int
             *lwork, int *ierr);

void sfftc_64_ (long *iopt, long *n, float *scale, float *x,
                complex *y, float *trigs, long *ifac, float *work,
                long *lwork, long *ierr);

```

PURPOSE

sfftc initializes the trigonometric weight and factor tables or computes the forward Fast Fourier Transform of a real sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W * X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = -1 for forward transform

$W = \exp(\text{isign} * i * j * k * 2 * \pi / N)$

In real-to-complex transform of length N, the (N/2+1) complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:

IOPT = 0 computes the trigonometric weight table and factor table

IOPT = -1 computes forward FFT

N (input)

Integer specifying length of the input sequence X.

N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled.

Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) On entry, X is a real array whose first N elements

contain the sequence to be transformed.

Y (output)

Complex array whose first $(N/2+1)$ elements contain the transform results. X and Y may be the same array starting at the same memory location, in which case the dimension of X must be at least $2*(N/2+1)$. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)

Real array of length $2*N$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0 or -1

-2 = $N < 0$

-3 = (LWORK is not 0) and (LWORK is less than N)

-4 = memory allocation for workspace failed

```

C INTERFACE

```
#include <sunperf.h>  
void sfputc2_ (int *iopt, int *n1, int *n2, float *scale,  
              float *x, int *ldx, complex *y, int *ldy, float  
              *trigs, int *ifac, float *work, int *lwork, int  
              *ierr);  
  
void sfputc2_64_ (long *iopt, long *n1, long *n2, float
```

```
*scale, float *x, long *ldx, complex *y, long
*ldy, float *trigs, long *ifac, float *work, long
*lwork, long *ierr);
```

PURPOSE

sfputc2 initializes the trigonometric weight and factor tables or computes the two-dimensional forward Fast Fourier Transform of a two-dimensional real array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

$$Y(k_1, k_2) = \text{scale} * \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_2 * W_1 * X(j_1, j_2)$$

where

k_1 ranges from 0 to N_1-1 and k_2 ranges from 0 to N_2-1

$i = \sqrt{-1}$

isign = -1 for forward transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

In real-to-complex transform of length N_1 , the $(N_1/2+1)$ complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N_1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N_2 is most efficient when it is a product of small primes $N_2 \geq 0$. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N_2) that contains input data to be transformed. X and Y can be the same array.

LDX (input)

Leading dimension of X. $LDX \geq N_1$ if X is not the same array as Y. Else, $LDX = 2 * LDY$. Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY, N_2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is

assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. LDY \geq N1/2+1 Unchanged on exit.

TRIGS (input/output)

Real array of length $2*(N1+N2)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least $\text{MAX}(N1, 2*N2)*\text{NCPUS}$, where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0 or -1

-2 = $N1 < 0$

-3 = $N2 < 0$

-4 = ($LDX < N1$) or (LDX not equal $2*LDY$ when X and Y are same array)

-5 = ($LDY < N1/2+1$)

-6 = ($LWORK$ not equal 0) and ($LWORK < \text{MAX}(N1, 2*N2)*\text{NCPUS}$)

-7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

$Y(N1/2+1:LDY,:)$ is used as scratch space. Upon returning, the original contents of $Y(N1/2+1:LDY,:)$ will be lost, whereas $Y(1:N1/2+1,1:N2)$ contains the transform results.

```

PURPOSE

sfft3 initializes the trigonometric weight and factor tables or computes the three-dimensional forward Fast Fourier Transform of a three-dimensional complex array.

$$Y(k_1, k_2, k_3) = \text{scale} * \sum_{j_3=0}^{N_3-1} \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_3 W_2 W_1 X(j_1, j_2, j_3)$$

where

k_1 ranges from 0 to N_1-1 ; k_2 ranges from 0 to N_2-1 and k_3 ranges from 0 to N_3-1

$i = \sqrt{-1}$

isign = -1 for forward transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

$W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

N3 (input)

Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. N3 >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a real array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed. X can be same array as Y.

LDX1 (input)

first dimension of X. If X is not same array as Y, LDX1 >= N1 Else, LDX1 = 2*LDY1 Unchanged on exit.

LDX2 (input)

second dimension of X. LDX2 >= N2 Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y

can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)
first dimension of Y. LDY1 \geq N1/2+1 Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 \geq N2 Unchanged on exit.

TRIGS (input/output)
Real array of length $2*(N1+N2+N3)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least $3*128$ that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least $(MAX(N,2*N2,2*N3) + 16*N3) * NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1) or (LDX not equal $2*LDY$ when X and Y are same array)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1/2+1)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
-9 = (LWORK not equal 0) and (LWORK < $(MAX(N,2*N2,2*N3) + 16*N3)*NCPUS$)
-10 = memory allocation failed

SEE ALSO

fft

CAUTIONS

This routine uses $Y((N1/2+1)+1:LDY1,:)$ as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray $Y(1:N1/2+1,1:N2,1:N3)$ contains the transform results.

void sfftcm_64_ (long *iopt, long *n1, long *n2, float
```

```
*scale, float *x, long *ldx, complex *y, long
*ldy, float *trigs, long *ifac, float *work, long
*lwork, long *ierr);
```

PURPOSE

sfctcm initializes the trigonometric weight and factor tables or computes the one-dimensional forward Fast Fourier Transform of a set of real data sequences stored in a two-dimensional array:

$$Y(k,l) = \text{scale} * \sum_{j=0}^{N1-1} W * X(j,l)$$

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1

i = sqrt(-1)

isign = -1 for forward transform

$W = \exp(\text{isign} * i * j * k * 2 * \pi / N1)$

In real-to-complex transform of length N1, the (N1/2+1) complex output data points stored are the positive-frequency half of the spectrum of the discrete Fourier transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a real array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)

Leading dimension of X. If X and Y are the same array, LDX = 2*LDY. Else LDX >= N1. Unchanged on exit.

Y (output)

Y is a complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. LDY >= N1/2 + 1. Unchanged on exit.

TRIGS (input/output)
 Real array of length $2*N1$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least 128 that contains the factors of $N1$. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
 Real array of dimension at least $N1$. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0 or -1
 -2 = $N1 < 0$
 -3 = $N2 < 0$
 -4 = (LDX < $N1$) or (LDX not equal $2*LDY$ when X and Y are same array)
 -4 = ($LDY < N1/2 + 1$)
 -6 = (LWORK not equal 0) and ($LWORK < N1$)
 -7 = memory allocation failed

#include <sunperf.h>

void sgbbbrd(char vect, int m, int n, int ncc, int kl, int
             ku, float *ab, int ldab, float *d, float *e, float
             *q, int ldq, float *pt, int ldpt, float *c, int
             ldc, int *info);
void sgbbbrd_64(char vect, long m, long n, long ncc, long kl,
                long ku, float *ab, long ldab, float *d, float *e,
                float *q, long ldq, float *pt, long ldpt, float
                *c, long ldc, long *info);

```

PURPOSE

sgbbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes Q'*C for a given matrix C.

ARGUMENTS

VECT (input)
 Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
 = 'Q': form Q only;
 = 'P': form P' only;
 = 'B': form both.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NCC (input)
 The number of columns of the matrix C. $NCC \geq 0$.

KL (input)
 The number of subdiagonals of the matrix A. $KL \geq 0$.

KU (input)
 The number of superdiagonals of the matrix A. $KU \geq 0$.

AB (input/output)
 REAL array, dimension(LDAB,N) On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by values generated during the reduction.

LDAB (input)
 The leading dimension of the array A. LDAB \geq KL+KU+1.

D (output)
 REAL array, dimension(min(M,N)) The diagonal elements of the bidiagonal matrix B.

E (output)
 REAL array, dimension(min(M,N)-1) The superdiagonal elements of the bidiagonal matrix B.

Q (output)
 REAL array, dimension(LDQ,M) If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. LDQ \geq max(1,M) if VECT = 'Q' or 'B'; LDQ \geq 1 otherwise.

PT (output)
 REAL array, dimension(LDPT,N) If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
 The leading dimension of the array PT. LDPT \geq max(1,N) if VECT = 'P' or 'B'; LDPT \geq 1 otherwise.

C (input/output)
 REAL array, dimension(LDC,NCC) On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^*C . C is not referenced if NCC = 0.

LDC (input)
 The leading dimension of the array C. LDC \geq max(1,M) if NCC > 0; LDC \geq 1 if NCC = 0.

WORK (workspace)
 REAL array, dimension(2*MAX(M,N))

INFO (output)
 = 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

SUBROUTINE GBCON_64(NORM, [N], KL, KU, A, [LDA], IPIVOT, ANORM,
                   RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, KL, KU, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>
void sgbcon(char norm, int n, int kl, int ku, float *a, int
            lda, int *ipivot, float anorm, float *rcond, int
            *info);

void sgbcon_64(char norm, long n, long kl, long ku, float
               *a, long lda, long *ipivot, float anorm, float
               *rcond, long *info);

```

PURPOSE

sgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
 The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
KU >= 0.

A (input) Details of the LU factorization of the band matrix
A, as computed by SGBTRF. U is stored as an upper
triangular band matrix with KL+KU superdiagonals
in rows 1 to KL+KU+1, and the multipliers used
during the factorization are stored in rows
KL+KU+2 to 2*KL+KU+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (input)
The pivot indices; for 1 <= i <= N, row i of the
matrix was interchanged with row IPIVOT(i).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original
matrix A. If NORM = 'I', the infinity-norm of the
original matrix A.

RCOND (output)
The reciprocal of the condition number of the
matrix A, computed as RCOND = 1/(norm(A) *
norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void sgbequ(int m, int n, int kl, int ku, float *a, int lda,
            float *r, float *c, float *rowcnd, float *colcnd,
            float *amax, int *info);

void sgbequ_64(long m, long n, long kl, long ku, float *a,
               long lda, float *r, float *c, float *rowcnd, float
               *colcnd, float *amax, long *info);

```

PURPOSE

sgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

A (input) The band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$

for $\max(1, j - k_u) \leq i \leq \min(m, j + k_l)$.

LDA (input)

The leading dimension of the array A. LDA \geq KL+KU+1.

R (output)

If INFO = 0, or INFO > M, R contains the row scale factors for A.

C (output)

If INFO = 0, C contains the column scale factors for A.

ROWCND (output)

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND \geq 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND (output)

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND \geq 0.1, it is not worth scaling by C.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
 \leq M: the i-th row of A is exactly zero
 $>$ M: the (i-M)-th column of A is exactly zero

REAL ALPHA, BETA  
REAL A(LDA,*), X(*), Y(*)
```

```
SUBROUTINE SGBMV_64(TRANSA, M, N, KL, KU, ALPHA, A, LDA, X,  
                   INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 TRANSA  
INTEGER*8 M, N, KL, KU, LDA, INCX, INCY  
REAL ALPHA, BETA  
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GBMV([TRANSA], [M], [N], KL, KU, ALPHA, A, [LDA], X,  
               [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA  
INTEGER :: M, N, KL, KU, LDA, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GBMV_64([TRANSA], [M], [N], KL, KU, ALPHA, A, [LDA],
```

```

X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, KL, KU, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void sgbmv(char transa, int m, int n, int kl, int ku, float
           alpha, float *a, int lda, float *x, int incx,
           float beta, float *y, int incy);
void sgbmv_64(char transa, long m, long n, long kl, long ku,
              float alpha, float *a, long lda, float *x, long
              incx, float beta, float *y, long incy);

```

PURPOSE

sgbmv performs one of the matrix-vector operations $y := \alpha A^*x + \beta y$ or $y := \alpha A^T x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A^*x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A^*x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the

matrix A. $N \geq 0$. Unchanged on exit.

KL (input)

On entry, KL specifies the number of sub-diagonals of the matrix A. $KL \geq 0$. Unchanged on exit.

KU (input)

On entry, KU specifies the number of super-diagonals of the matrix A. $KU \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku , the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        K = KU + 1 - J
        DO 10, I = MAX( 1, J - KU ), MIN( M, J + KL )
          A( K + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (kl + ku + 1)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANS = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

($1 + (m - 1) * \text{abs}(\text{ INCY })$) when TRANSA = 'N' or 'n' and at least ($1 + (n - 1) * \text{abs}(\text{ INCY })$) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

    long *ipivot, float *b, long ldb, float *x, long
    ldx, float *ferr, float *berr, long *info);

```

PURPOSE

sgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
 The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
 The number of superdiagonals within the band of A.
 $KU \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

LDA (input)
The leading dimension of the array A. LDA \geq KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF $\geq 2*KL+KU+1$.

IPIVOT (input)
The pivot indices from SGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1, N)$.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = $-i$, the i -th argument had an illegal value

```

```

INTEGER(8) :: N, KL, KU, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:,:) :: A, B

```

C INTERFACE

```

#include <sunperf.h>

void sgbsv(int n, int kl, int ku, int nrhs, float *a, int
           lda, int *ipivot, float *b, int ldb, int *info);

void sgbsv_64(long n, long kl, long ku, long nrhs, float *a,
              long lda, long *ipivot, float *b, long ldb, long
              *info);

```

PURPOSE

sgbsv computes the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with $KL+KU$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A .
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A .
 $KU \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)
On entry, the matrix A in band storage, in rows

KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(KL+KU+1+i-j, j) = A(i, j)$ for $\max(1, j-KU) \leq i \leq \min(N, j+KL)$. On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)

The leading dimension of the array A. $LDA \geq 2*KL+KU+1$.

IPIVOT (output)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36													
	*	*	+	+	+	+		*	*		u13	u24	u35
u46													
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56													

	a11	a22	a33	a44	a55	a66	u11	u22	u33	u44	u55
u66											
	a21	a32	a43	a54	a65	*	m21	m32	m43	m54	m65
*											
	a31	a42	a53	a64	*	*	m31	m42	m53	m64	*
*											

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

#include <sunperf.h>

void sgbsvx(char fact, char transa, int n, int kl, int ku,
    int nrhs, float *a, int lda, float *af, int ldaf,
    int *ipivot, char equed, float *r, float *c, float
    *b, int ldb, float *x, int ldx, float *rcond,
    float *ferr, float *berr, int *info);

void sgbsvx_64(char fact, char transa, long n, long kl, long
    ku, long nrhs, float *a, long lda, float *af, long
    ldaf, long *ipivot, char equed, float *r, float
    *c, float *b, long ldb, float *x, long ldx, float
    *rcond, float *ferr, float *berr, long *info);

```

PURPOSE

sgbsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

TRANS = 'N': $\text{diag}(R) * A * \text{diag}(C) * \text{inv}(\text{diag}(C)) * X = \text{diag}(R) * B$

TRANS = 'T': $(\text{diag}(R) * A * \text{diag}(C))^{**T} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

TRANS = 'C': $(\text{diag}(R) * A * \text{diag}(C))^{**H} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is

overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if TRANS='N')

or $\text{diag}(C) * B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$A = L * U,$

where L is a product of permutation and unit lower triangular

matrices with KL subdiagonals, and U is upper triangular with

KL+KU superdiagonals.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine

returns with INFO = i. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision,

INFO = N+1 is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form

of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

6. If equilibration was used, the matrix X is premultiplied by

$\text{diag}(C)$ (if TRANS = 'N') or $\text{diag}(R)$ (if TRANS = 'T' or 'C') so

that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANS (input)

Specifies the form of the system of equations. =

'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

KL (input)

The number of subdiagonals within the band of A. $KL \geq 0$.

KU (input)

The number of superdiagonals within the band of A. $KU \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the matrix A in band storage, in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(KU+1+i-j, j) = A(i, j)$ for $\max(1, j-KU) \leq i \leq \min(N, j+KL)$

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as fol-

```

      lows:  EQUED = 'R':  A := diag(R) * A
      EQUED = 'C':  A := A * diag(C)
      EQUED = 'B':  A := diag(R) * A * diag(C).

```

LDA (input)

The leading dimension of the array A. LDA >= KL+KU+1.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = L*U$ as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A.

EQUED (input or output)

Specifies the form of equilibration that was done.
 = 'N': No equilibration (always true if FACT = 'N').

= 'R': Row equilibration, i.e., A has been premultiplied by $\text{diag}(R)$. = 'C': Column equilibration, i.e., A has been postmultiplied by $\text{diag}(C)$. = 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(R) * A * \text{diag}(C)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input or output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by $\text{diag}(R)$; if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input or output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by $\text{diag}(C)$; if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by $\text{diag}(R)*B$; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by $\text{diag}(C)*B$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(C))*X$ if TRANSA = 'N' and EQUED = 'C' or 'B', or $\text{inv}(\text{diag}(R))*X$ if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to

working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$) On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A .

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = $-i$, the i -th argument had an illegal value
> 0: if INFO = i , and i is
 $\leq N$: $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned.
 $= N+1$: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest .

SUBROUTINE GBTF2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
```

```
INTEGER(8) :: M, N, KL, KU, LDAB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void sgbtf2(int m, int n, int kl, int ku, float *ab, int
            ldab, int *ipiv, int *info);

void sgbtf2_64(long m, long n, long kl, long ku, float *ab,
               long ldab, long *ipiv, long *info);
```

PURPOSE

sgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows:

$$AB(kl+ku+1+i-j, j) = A(i, j) \quad \text{for} \quad \max(1, j-ku) \leq i \leq \min(m, j+kl)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. $LDAB \geq$

$2*KL+KU+1$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = - i , the i -th argument had an illegal value
 > 0: if INFO = + i , $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36	*	*	+	+	+	+		*	*		u13	u24	u35
u46	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	
u56	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66	a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65	
*	a31	a42	a53	a64	*	*		m31	m42	m53	m64	*	
*													

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U , because of fill-in resulting from the row interchanges.

               long lda, long *ipivot, long *info);
```

PURPOSE

sgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. $M \geq 0$.

N (input) Integer
The number of columns of the matrix A. $N \geq 0$.

KL (input) Integer
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input) Integer
The number of superdiagonals within the band of A.
 $KU \geq 0$.

A (input/output) Real array of dimension (LDA, N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows:

$$A(KL+KU+1+I-J, J) = A(I, J) \quad \text{for} \quad \text{MAX}(1, J-KU) \leq I \leq \text{MIN}(M, J+KL)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input) Integer
The leading dimension of the array A. $LDA \geq 2*KL+KU+1$.

IPIVOT (output) Integer array of dimension $\min(M,N)$
The pivot indices; for $1 \leq I \leq \min(M,N)$, row I of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
= 0: successful exit
< 0: if INFO = -I, the I-th argument had an illegal value
> 0: if INFO = +I, U(I,I) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:						On exit:					
	*	*	*	+	+	+	*	*	*	u14	u25
u36	*	*	+	+	+	+	*	*		u13	u24
u46	*	a12	a23	a34	a45	a56	*	u12	u23	u34	u45
u56	a11	a22	a33	a44	a55	a66	u11	u22	u33	u44	u55
u66	a21	a32	a43	a54	a65	*	m21	m32	m43	m54	m65
*	a31	a42	a53	a64	*	*	m31	m42	m53	m64	*
*											

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

void sgbtrs_64(char transa, long n, long kl, long ku, long nrhs,
               float *a, long lda, long *ipivot, float *b,
               long ldb, long *info);

```

PURPOSE

sgbtrs solves a system of linear equations
 $A * X = B$ or $A' * X = B$ with a general band matrix A
 using the LU factorization computed by SGBTRF.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations. =
 'N': $A * X = B$ (No transpose)
 = 'T': $A' * X = B$ (Transpose)
 = 'C': $A' * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
 The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
 The number of superdiagonals within the band of A.
 $KU \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrix B. $NRHS \geq 0$.

A (input) Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDA (input)
The leading dimension of the array A. LDA \geq 2*KL+KU+1.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
CHARACTER(LEN=1) :: JOB, SIDE  
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO  
REAL, DIMENSION(:) :: SCALE
```

```
REAL, DIMENSION(:, :) :: V
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgebak(char job, char side, int n, int ilo, int ihi,  
            float *scale, int m, float *v, int ldv, int  
            *info);
```

```
void sgebak_64(char job, char side, long n, long ilo, long  
               ihi, float *scale, long m, float *v, long ldv,  
               long *info);
```

PURPOSE

sgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

JOB (input)

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGEBAL.

SIDE (input)

= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)

The integers ILO and IHI determined by SGEBAL. 1
<= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if
N=0.

IHI (input)

See the description for ILO.

SCALE (input)

Details of the permutation and scaling factors, as
returned by SGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the array V. LDV \geq max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

sgebal - balance a general real matrix A

SYNOPSIS

```
SUBROUTINE SGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER N, LDA, ILO, IHI, INFO  
REAL A(LDA,*), SCALE(*)
```

```
SUBROUTINE SGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
INTEGER*8 N, LDA, ILO, IHI, INFO  
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER :: N, LDA, ILO, IHI, INFO  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER(8) :: N, LDA, ILO, IHI, INFO  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgebal(char job, int n, float *a, int lda, int *ilo,
            int *ihi, float *scale, int *info);

void sgebal_64(char job, long n, float *a, long lda, long
               *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

sgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N,
SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute
only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the input matrix A. On exit, A is
overwritten by the balanced matrix. If JOB = 'N',
A is not referenced. See Further Details.

LDA (input)

The leading dimension of the array A. LDA >=
max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit
A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I =

IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

See the description for ILO.

SCALE (output)

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

$$P A P = \begin{pmatrix} T1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T2 \end{pmatrix}$$

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation $\text{inv}(D) * B * D$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T1 & X*D & Y \\ 0 & \text{inv}(D)*B*D & \text{inv}(D)*Z \\ 0 & 0 & T2 \end{pmatrix}.$$

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine BALANC.

[INFO])
```

```
INTEGER :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
[LWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgebrd(int m, int n, float *a, int lda, float *d, float
            *e, float *tauq, float *taup, int *info);

void sgebrd_64(long m, long n, float *a, long lda, float *d,
               float *e, float *tauq, float *taup, long *info);

```

PURPOSE

sgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation:
 $Q^{*T} * A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. $M \geq 0$.

N (input) The number of columns in the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N general matrix to be reduced.
 On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

D (output)

The diagonal elements of the bidiagonal matrix B:
 $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the bidiagonal matrix B:
 if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-$

1; if $m < n$, $E(i) = A(i+1,i)$ for $i = 1, 2, \dots, m-1$.

TAUQ (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q . See Further Details.

TAUP (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix P . See Further Details.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

LWORK (input)

The length of the array $WORK$. $LWORK \geq \max(1, M, N)$. For optimum performance $LWORK \geq (M+N)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) H(2) \dots H(n) \quad \text{and} \quad P = G(1) G(2) \dots G(n-1)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_q * v * v' \quad \text{and} \quad G(i) = I - \tau_p * u * u'$$

where τ_q and τ_p are real scalars, and v and u are real vectors; $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(i,i+2:n)$; τ_q is stored in $TAUQ(i)$ and τ_p in $TAUP(i)$.

If $m < n$,

$$Q = H(1) H(2) \dots H(m-1) \quad \text{and} \quad P = G(1) G(2) \dots G(m)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{uq} * v * v' \quad \text{and} \quad G(i) = I - \tau_{up} * u * u'$$

where τ_{uq} and τ_{up} are real scalars, and v and u are real vectors; $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(i+2:m,i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(i,i+1:n)$; τ_{uq} is stored in $TAUQ(i)$ and τ_{up} in $TAUP(i)$.

The contents of A on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

```
( d  e  u1 u1 u1 )
u1 )
( v1 d  e  u2 u2 )
u2 )
( v1 v2 d  e  u3 )
u3 )
( v1 v2 v3 d  e  )
u4 )
( v1 v2 v3 v4 d  )
u5 )
( v1 v2 v3 v4 v5 )
```

$m = 5$ and $n = 6$ ($m < n$):

```
( d  u1  u1  u1  u1
( e  d  u2  u2  u2
( v1 e  d  u3  u3
( v1 v2 e  d  u4
( v1 v2 v3 e  d
```

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

            anorm, float *rcond, int *info);  
  
void sgecon_64(char norm, long n, float *a, long lda, float  
              anorm, float *rcond, long *info);
```

PURPOSE

sgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The factors L and U from the factorization $A = P*L*U$ as computed by SGETRF.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension(4*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
INTEGER(8) :: M, N, LDA, INFO
```

```

REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void sgeequ(int m, int n, float *a, int lda, float *r, float
           *c, float *rowcnd, float *colcnd, float *amax, int
           *info);

void sgeequ_64(long m, long n, float *a, long lda, float *r,
              float *c, float *rowcnd, float *colcnd, float
              *amax, long *info);

```

PURPOSE

sgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)

If INFO = 0, C contains the column scale factors for A.

ROWCND (output)

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND (output)

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

                   lda, long *nout, float *wr, float *wi, float *z,
                   long ldz, long *info);

```

PURPOSE

sgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T(Z^*T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b^*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

```

JOBZ (input)
      = 'N': Schur vectors are not computed;

```

= 'V': Schur vectors are computed.

SORTEV (input)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)

LOGICAL FUNCTION of two REAL arguments SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j) + \sqrt{-1} * WI(j)$ is selected if $SELECT(WR(j), WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j), WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

REAL array, dimension (LDA,N) On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

NOUT (output)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

Z (output)
 If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1; if JOBZ = 'V', LDZ >= N.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) contains the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. LDWORK >= max(1,3*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK3 (workspace)
 dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is
 <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

```

PURPOSE

sgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called `s` and `sep` respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

JOBZ (input)

= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)

LOGICAL FUNCTION of two REAL arguments SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j) + \sqrt{-1} * WI(j)$ is selected if $SELECT(WR(j), WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j), WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 REAL array, dimension (LDA,N) On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,N)$.

NOUT (output)
 If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)
 WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
 See the description for WR.

Z (output)
 If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

SRCONE (output)
 If SENSE = 'E' or 'B', SRCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
 If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq max(1,3*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK \geq N+2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that N+2*NOUT*(N-NOUT) \leq N+N*N/2. For good performance, LDWORK must generally be larger.

IWORK2 (workspace/output)

Not referenced if SENSE = 'N' or 'E'. On exit, if INFO = 0, IWORK2(1) returns the optimal LDWRK2.

LDWRK2 (input)

The dimension of the array IWORK2. LDWRK2 \geq 1; if SENSE = 'V' or 'B', LDWRK2 \geq NOUT*(N-NOUT).

BWORK3 (workspace)

dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
= N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
= N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

#include <sunperf.h>

void sgeev(char jobvl, char jobvr, int n, float *a, int lda,
           float *wr, float *wi, float *vl, int ldvl, float
           *vr, int ldvr, int *info);

void sgeev_64(char jobvl, char jobvr, long n, float *a, long
              lda, float *wr, float *wi, float *vl, long ldvl,
              float *vr, long ldvr, long *info);
```

PURPOSE

sgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

WR (output)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

VL (output)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j -th eigenvalue is real, then $u(j) = VL(:,j)$, the j -th column of VL. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i*VL(:,j+1)$ and $u(j+1) = VL(:,j) - i*VL(:,j+1)$.

LDVL (input)

The leading dimension of the array VL. LDVL ≥ 1 ;
if JOBVL = 'V', LDVL $\geq N$.

VR (input)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and $v(j+1) = VR(:,j) - i*VR(:,j+1)$.

LDVR (input)

The leading dimension of the array VR. LDVR ≥ 1 ;
if JOBVR = 'V', LDVR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK $\geq \max(1, 3*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 4*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements i+1:N of WR and WI contain eigenvalues which have converged.

```

PURPOSE

sgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{**}(-1)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
 = 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by $D*A*D^{**}(-1)$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A .

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
 = 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
 = 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
 = 'E': Computed for eigenvalues only;
 = 'V': Computed for right eigenvectors only;
 = 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the N-by-N matrix A. On exit, A has been overwritten. If `JOBVL = 'V'` or `JOBVR = 'V'`, A contains the real Schur form of the balanced version of the input matrix A.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

WR (output)
 WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
 See the description for WR.

VL (output)
 If `JOBVL = 'V'`, the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If `JOBVL = 'N'`, VL is not referenced. If the j-th eigenvalue is real, then $u(j) = VL(:, j)$, the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:, j) + i*VL(:, j+1)$ and $u(j+1) = VL(:, j) - i*VL(:, j+1)$.

LDVL (input)
 The leading dimension of the array VL. $LDVL \geq 1$; if `JOBVL = 'V'`, $LDVL \geq N$.

VR (output)
 If `JOBVR = 'V'`, the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If `JOBVR = 'N'`, VR is not referenced. If the j-th eigenvalue is real, then $v(j) = VR(:, j)$, the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $v(j) = VR(:, j) + i*VR(:, j+1)$ and $v(j+1) = VR(:, j) - i*VR(:, j+1)$.

LDVR (input)
 The leading dimension of the array VR. $LDVR \geq 1$, and if `JOBVR = 'V'`, $LDVR \geq N$.

ILO (output)
 ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

IHI (output)
 See the description of ILO.

SCALE (output)
 Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
 The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)
 RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)
 RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LDWORK >= 3*N. If SENSE = 'V' or 'B', LDWORK >= N*(N+6). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)
 dimension(2*N-2) If SENSE = 'N' or 'E', not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or

condition numbers have been computed; elements
1:ILO-1 and i+1:N of WR and WI contain eigenvalues
which have converged.

```

PURPOSE

sgegs routine is deprecated and has been replaced by routine SGGES.

SGEGS computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues ($\alpha \pm i\beta$), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEQV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α, β), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of A will be "standardized" by making the corresponding elements of B have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in A and B will have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the orthogonal matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**T A (VSR), (VSL)**T B (VSR))

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A. Note: to avoid overflow, the Frobenius norm of the matrix A should be less than the overflow threshold.

LDA (input)

The leading dimension of A. LDA >= max(1,N).

B (input/output)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B. Note: to avoid overflow, the Frobenius norm of the matrix B should be less than the overflow threshold.

LDB (input)

The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user

should avoid naively computing the ratio α/β . However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)

See the description for ALPHAR.

BETA (output)

See the description for ALPHAR.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK $\geq \max(1, 4*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR The optimal LDWORK is $2*N + N*(NB+1)$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for $j=\text{INFO}+1, \dots, N$.
> N: errors that usually indicate LAPACK problems:

=N+1: error return from SGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed
iteration) =N+7: error return from SGBAK (comput-
ing VSL)
=N+8: error return from SGBAK (computing VSR)
=N+9: error return from SLASCL (various places)

              *vr, long ldvr, long *info);

```

PURPOSE

sgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n -by- n real nonsymmetric matrices A and B , the generalized eigenvalues ($\alpha + i\beta$, $\alpha - i\beta$), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A, B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A, B) is a vector r such that $(A - wB)r = 0$. A left generalized eigenvector is a vector l such that $l^H (A - wB) = 0$, where l^H is the conjugate-transpose of l .

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

```

JOBVL (input)
    = 'N': do not compute the left generalized eigen-
           vectors;
    = 'V': compute the left generalized eigenvectors.

```

JOBVR (input)
 = 'N': do not compute the right generalized
 eigenvectors;
 = 'V': compute the right generalized eigenvec-
 tors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
 On entry, the first of the pair of matrices whose
 generalized eigenvalues and (optionally) general-
 ized eigenvectors are to be computed. On exit,
 the contents will have been destroyed. (For a
 description of the contents of A on exit, see
 "Further Details", below.)

LDA (input)
 The leading dimension of A. LDA >= max(1,N).

B (input/output)
 On entry, the second of the pair of matrices whose
 generalized eigenvalues and (optionally) general-
 ized eigenvectors are to be computed. On exit,
 the contents will have been destroyed. (For a
 description of the contents of B on exit, see
 "Further Details", below.)

LDB (input)
 The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
 On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j),
 j=1,...,N, will be the generalized eigenvalues.
 If ALPHAI(j) is zero, then the j-th eigenvalue is
 real; if positive, then the j-th and (j+1)-st
 eigenvalues are a complex conjugate pair, with
 ALPHAI(j+1) negative.

 Note: the quotients ALPHAR(j)/BETA(j) and
 ALPHAI(j)/BETA(j) may easily over- or underflow,
 and BETA(j) may even be zero. Thus, the user
 should avoid naively computing the ratio
 alpha/beta. However, ALPHAR and ALPHAI will be
 always less than and usually comparable with
 norm(A) in magnitude, and BETA always less than
 and usually comparable with norm(B).

ALPHAI (output)
 See the description of ALPHAR.

BETA (output)
 See the description of ALPHAR.

VL (output)

If `JOBVL = 'V'`, the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVL = 'N'`.

`LDVL (input)`

The leading dimension of the matrix VL. `LDVL` ≥ 1 , and if `JOBVL = 'V'`, `LDVL` $\geq N$.

`VR (output)`

If `JOBVR = 'V'`, the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVR = 'N'`.

`LDVR (input)`

The leading dimension of the matrix VR. `LDVR` ≥ 1 , and if `JOBVR = 'V'`, `LDVR` $\geq N$.

`WORK (workspace)`

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

`LDWORK (input)`

The dimension of the array `WORK`. `LDWORK` $\geq \max(1, 8*N)$. For good performance, `LDWORK` must generally be larger. To compute the optimal value of `LDWORK`, call `ILAENV` to get blocksizes (for `SGEQRF`, `SORMQR`, and `SORGQR`.) Then compute: `NB` -- MAX of the blocksizes for `SGEQRF`, `SORMQR`, and `SORGQR`; The optimal `LDWORK` is: $2*N + \text{MAX}(6*N, N*(NB+1))$.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

```

INFO (output)
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:  The QZ iteration failed.  No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N.
  > N:  errors that usually indicate LAPACK problems:
  =N+1: error return from SGBAL
  =N+2: error return from SGEQRF
  =N+3: error return from SORMQR
  =N+4: error return from SORGQR
  =N+5: error return from SGGHRD
  =N+6: error return from SHGEQZ (other than failed iteration)
  =N+7: error return from STGEVC
  =N+8: error return from SGGBAK (computing VL)
  =N+9: error return from SGGBAK (computing VR)
  =N+10: error return from SLASCL (various calls)

```

FURTHER DETAILS

Balancing

This driver calls SGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL^*A^*PR and PL^*B^*R will be upper triangular except for the diagonal blocks $A(i:j,i:j)$ and $B(i:j,i:j)$, with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair $DL^*PL^*A^*PR^*DR$, $DL^*PL^*B^*PR^*DR$ have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, SGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit

----- -- - - - - -

If any eigenvectors are computed (either $JOBVL='V'$ or $JOBVR='V'$ or both), then on exit the arrays A and B will contain the real Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] See SHGEQZ, SGEQS, or read the book "Matrix Computations",

by Golub & van Loan, pub. by Johns Hopkins U. Press.

REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],  
[INFO])
```

```
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO  
REAL, DIMENSION(:) :: TAU, WORKIN  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgehrd(int n, int ilo, int ihi, float *a, int lda,
```

```

float *tau, int *info);

void sgehrd_64(long n, long ilo, long ihi, float *a, long
lda, float *tau, long *info);

```

PURPOSE

sgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq$

$N \times NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORKIN$ array, returns this value as the first entry of the $WORKIN$ array, and no error message related to $LWORKIN$ is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) H(ilo+1) \dots H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(i+2:ihi,i)$, and τ in $TAU(i)$.

The contents of A are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry,

on exit,

(a	a	a	a	a	a	a)	(a	a	h	h	h	h
a)	(a	a	a	a a)	(a	h	h	h
h a)	(a	a	a	a a)	(h	h	h	h
h h h)	(a	a	a	a a a)	(v2	h	h
h h h h)	(a	a	a	a a a)	(v2	h	h
v3 h h h h)	(a	a	a	a a a)	(
v2 v3 v4 h h h)	(a)	(
a)												

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GELQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgelqf(int m, int n, float *a, int lda, float *tau, int  
           *info);
```

```
void sgelqf_64(long m, long n, float *a, long lda, float
               *tau, long *info);
```

PURPOSE

sgelqf computes an LQ factorization of a real M-by-N matrix
A: $A = L * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(k) \dots H(2) H(1), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i,i+1:n)$, and τ in $TAU(i)$.

```

```
void sgels (char, int, int, int, float*, int, float*, int,  
            int*);
```

```
void sgels_64 (char, long, long, long, float*, long, float*,  
               long, long*);
```

PURPOSE

sgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of
an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } || B - A * X ||.$$

2. If TRANS = 'N' and m < n: find the minimum norm solution of
an underdetermined system $A * X = B$.

3. If TRANS = 'T' and m >= n: find the minimum norm solution of
an undetermined system $A^{**T} * X = B$.

4. If TRANS = 'T' and m < n: find the least squares solution of
an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } || B - A^{**T} * X ||.$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

TRANSA (input)

- = 'N': the linear system involves A;
- = 'T': the linear system involves A^{**T} .

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \geq N$, A is overwritten by details of its QR factorization as returned by SGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by SGELQF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'T'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$, where $MN = \min(M, N)$ and NB is the optimum block size.

If LDWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL :: RCOND
REAL, DIMENSION(:) :: S, WORK
REAL, DIMENSION(:, :) :: A, B

```

C INTERFACE

```

#include <sunperf.h>

void sgelsd(int m, int n, int nrhs, float *a, int lda, float
            *b, int ldb, float *s, float rcond, int *rank, int
            *info);
void sgelsd_64(long m, long n, long nrhs, float *a, long
               lda, float *b, long ldb, float *s, float rcond,
               long *rank, long *info);

```

PURPOSE

sgelsd computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } 2\text{-norm}(|b - A*x|)$$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard

digits, but we know of none.

ARGUMENTS

M (input) The number of rows of A. $M \geq 0$.

N (input) The number of columns of A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $RANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, \max(M, N))$.

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m, n))$.

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

WORK (workspace)
On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 . The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least $12*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS * (SMLSIZ+1)**2$, if M is greater than or equal to N or $12*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS + (SMLSIZ+1)**2$, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $NLVL = \text{INT}(\text{LOG}_2(\text{MIN}(M,N)/(SMLSIZ+1))) + 1$. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)

LIWORK $\geq 3 * \text{MINMN} * NLVL + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M,N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

            int *info);

void sgelss_64(long m, long n, long nrhs, float *a, long
               lda, float *b, long ldb, float *sing, float rcond,
               long *irank, long *info);
```

PURPOSE

sgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm($|b - A \cdot x|$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, the first $\min(m, n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,max(M,N)).

SING (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values SING(i) \leq RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq 1, and also: LDWORK \geq 3*min(M,N) + max(2*min(M,N), max(M,N), NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not con-

verge to zero.

               rcond, long *irank, long *info);

```

PURPOSE

sgelsx routine is deprecated and has been replaced by routine SGELSY.

SGELSX computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

JPIVOT (input/output)

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

RCOND (input)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

IRANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

```
      (max( min(M,N)+3*N, 2*min(M,N)+NRHS )),  
INFO (output)  
    = 0:  successful exit  
    < 0:  if INFO = -i, the i-th argument had an ille-  
          gal value
```

```

PURPOSE

sgelsy computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX

except three differences:

- o The call to the subroutine xGEQPF has been substituted by the
the call to the subroutine xGEQP3. This subroutine is a Blas-3
version of the QR factorization with column pivoting.
- o Matrix B (the right hand side) is updated with Blas-3.
- o The permutation of matrix B (the right hand side) is faster and
more simple.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

JPVT (input/output)

On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of AP was the k-th column of A.

RCOND (input)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

RANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq \max(MN+3*N+1, 2*MN+NRHS)$, where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq \max(MN+2*N+NB*(N+1), 2*MN+NB*NRHS)$, where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value.

NAME

sgemm - perform one of the matrix-matrix operations C :=
alpha*op(A)*op(B) + beta*C

SYNOPSIS

```
SUBROUTINE SGEMM(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,  
                BETA, C, LDC)
```

```
CHARACTER * 1 TRANSA, TRANSB  
INTEGER M, N, K, LDA, LDB, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

```
SUBROUTINE SGEMM_64(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,  
                  BETA, C, LDC)
```

```
CHARACTER * 1 TRANSA, TRANSB  
INTEGER*8 M, N, K, LDA, LDB, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE GEMM([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],  
               B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB  
INTEGER :: M, N, K, LDA, LDB, LDC  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:,:) :: A, B, C
```

```
SUBROUTINE GEMM_64([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],  
                  B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB  
INTEGER(8) :: M, N, K, LDA, LDB, LDC
```

```

REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void sgemm(char transa, char transb, int m, int n, int k,
           float alpha, float *a, int lda, float *b, int ldb,
           float beta, float *c, int ldc);

void sgemm_64(char transa, char transb, long m, long n, long k,
             float alpha, float *a, long lda, float *b, long ldb,
             float beta, float *c, long ldc);

```

PURPOSE

sgemm performs one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$ where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$,

alpha and beta are scalars, and A, B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = A'$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = B'$.

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix `op(A)` and of the matrix C. M must be at least zero. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix `op(B)` and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry, K specifies the number of columns of the matrix `op(A)` and the number of rows of the matrix `op(B)`. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, ka), where ka is k when `TRANSA = 'N' or 'n'`, and is m otherwise. Before entry with `TRANSA = 'N' or 'n'`, the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When `TRANSA = 'N' or 'n'` then `LDA >= max(1, m)`, otherwise `LDA >= max(1, k)`. Unchanged on exit.

B (input)

REAL array of DIMENSION (LDB, kb), where kb is n when `TRANSB = 'N' or 'n'`, and is k otherwise. Before entry with `TRANSB = 'N' or 'n'`, the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When `TRANSB = 'N' or 'n'` then `LDB >= max(1, k)`, otherwise `LDB >= max(1, n)`. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

REAL array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC \geq max(1, m). Unchanged on exit.

```

```
CHARACTER(LEN=1) :: TRANSA
```

```

INTEGER(8) :: M, N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void sgemv(char transa, int m, int n, float alpha, float *a,
           int lda, float *x, int incx, float beta, float *y,
           int incy);
void sgemv_64(char transa, long m, long n, float alpha,
              float *a, long lda, float *x, long incx, float
              beta, float *y, long incy);

```

PURPOSE

sgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A' x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A' x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A' x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A . $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$ when TRANS = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(\text{INCX}))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (m - 1) * \text{abs}(\text{INCY}))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

sgeqlf - compute a QL factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE SGEQLF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqlf(int m, int n, float *a, int lda, float *tau, int  
           *info);
```

```
void sgeqlf_64(long m, long n, float *a, long lda, float
               *tau, long *info);
```

PURPOSE

sgeqlf computes a QL factorization of a real M-by-N matrix A:
 $A = Q * L$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m \leq n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an ille-

gal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(k) \dots H(2) H(1)$, where $k = \min(m,n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with
 $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on
exit in $A(1:m-k+i-1, n-k+i)$, and τ in $TAU(i)$.

INTEGER*8 JPVT(*)
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
  [INFO])
```

```
INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
  [INFO])
```

```
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: TAU, WORK
```

```
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqp3(int m, int n, float *a, int lda, int *jpvt,  
            float *tau, int *info);
```

```
void sgeqp3_64(long m, long n, float *a, long lda, long  
               *jpvt, float *tau, long *info);
```

PURPOSE

sgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(M,N)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPVT (input/output)

On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the K-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq 3*N+1$.
For optimal performance LWORK $\geq 2*N+(N+1)*NB$,
where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and τ in $TAU(i)$.

INTEGER(8), DIMENSION(:) :: JPIVOT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgeqpf(int m, int n, float *a, int lda, int *jpivot,
            float *tau, int *info);

void sgeqpf_64(long m, long n, float *a, long lda, long
               *jpivot, float *tau, long *info);
```

PURPOSE

sgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

JPIVOT (input/output)

On entry, if JPIVOT(i) $\neq 0$, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n)$$

Each $H(i)$ has the form

$$H = I - \tau * v * v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$.

The matrix P is represented in `jpvt` as follows: If

$$\text{jpvt}(j) = i$$

then the j th column of P is the i th canonical unit vector.

PURPOSE

sgeqrf computes a QR factorization of a real M-by-N matrix A:
 $A = Q * R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and τ in $TAU(i)$.

NAME

sger - perform the rank 1 operation $A := \alpha x y' + A$

SYNOPSIS

```
SUBROUTINE SGER(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
INTEGER M, N, INCX, INCY, LDA  
REAL ALPHA  
REAL X(*), Y(*), A(LDA,*)
```

```
SUBROUTINE SGER_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
INTEGER*8 M, N, INCX, INCY, LDA  
REAL ALPHA  
REAL X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
INTEGER :: M, N, INCX, INCY, LDA  
REAL :: ALPHA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
INTEGER(8) :: M, N, INCX, INCY, LDA  
REAL :: ALPHA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sger(int m, int n, float alpha, float *x, int incx,
          float *y, int incy, float *a, int lda);

void sger_64(long m, long n, float alpha, float *x, long
             incx, float *y, long incy, float *a, long lda);
```

PURPOSE

sger performs the rank 1 operation $A := \alpha x y' + A$, where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)
($1 + (m - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

Y (input)
($1 + (n - 1) * \text{abs}(\text{INCY})$). Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, m). Unchanged on exit.

               float *b, long ldb, float *x, long ldx, float
               *ferr, float *berr, long *info);
```

PURPOSE

sgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original N-by-N matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)

The factors L and U from the factorization $A =$

P*L*U as computed by SGETRF.

LDAF (input)

The leading dimension of the array AF. LDAF \geq
max(1,N).

IPIVOT (input)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i
of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

X (input/output)

On entry, the solution matrix X, as computed by
SGETRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq
max(1,N).

FERR (output)

The estimated forward error bound for each solu-
tion vector X(j) (the j -th column of the solution
matrix X). If XTRUE is the true solution
corresponding to X(j), FERR(j) is an estimated
upper bound for the magnitude of the largest ele-
ment in (X(j) - XTRUE) divided by the magnitude of
the largest element in X(j). The estimate is as
reliable as the estimate for RCOND, and is almost
always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each
solution vector X(j) (i.e., the smallest relative
change in any element of A or B that makes X(j) an
exact solution).

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = - i , the i -th argument had an ille-
gal value

NAME

sgerqf - compute an RQ factorization of a real M-by-N matrix
A

SYNOPSIS

```
SUBROUTINE SGERQF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER M, N, LDA, LDWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SGERQF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LDWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GERQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgerqf(int m, int n, float *a, int lda, float *tau, int  
           *info);
```

```
void sgerqf_64(long m, long n, float *a, long lda, float
               *tau, long *info);
```

PURPOSE

sgerqf computes an RQ factorization of a real M-by-N matrix A:
 $A = R * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if $m \geq n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an ille-

gal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(1) H(2) \dots H(k)$, where $k = \min(m,n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with
 $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on
exit in $A(m-k+i,1:n-k+i-1)$, and τ in $TAU(i)$.

INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: S, WORK
REAL, DIMENSION(:, :) :: A, U, VT

```

C INTERFACE

```

#include <sunperf.h>

void sgesdd(char jobz, int m, int n, float *a, int lda,
            float *s, float *u, int ldu, float *vt, int ldvt,
            int *info);
void sgesdd_64(char jobz, long m, long n, float *a, long
               lda, float *s, float *u, long ldu, float *vt, long
               ldvt, long *info);

```

PURPOSE

sgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written

$$A = U * SIGMA * transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**T, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 Specifies options for computing all or part of the matrix U:

= 'A': all M columns of U and all N rows of $V^{*}T$ are returned in the arrays U and VT; = 'S': the first $\min(M,N)$ columns of U and the first $\min(M,N)$ rows of $V^{*}T$ are returned in the arrays U and VT; = 'O': If $M \geq N$, the first N columns of U are overwritten on the array A and all rows of $V^{*}T$ are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of $V^{*}T$ are overwritten on the array A; = 'N': no columns of U or rows of $V^{*}T$ are computed.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of $V^{*}T$ (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

S (output)

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

U (output)

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = $\min(M,N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first $\min(M,N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq 1$; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

VT (output)

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N orthogonal matrix $V^{*}T$; if JOBZ = 'S', VT contains the first $\min(M,N)$ rows of $V^{*}T$ (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. LDVT ≥ 1 ;
if JOBZ = 'A' or JOBZ = 'O' and M \geq N, LDVT \geq N;
if JOBZ = 'S', LDVT $\geq \min(M, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal
LWORK;

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 . If
LWORK = -1, then a workspace query is assumed. In
this case, the routine only calculates the optimal
size of the work array, returns this value as the
first entry of the WORK array, and no error mes-
sage related to LWORK is issued. The minimum
workspace size requirement is as follows:

If M is much larger than N such that M $\geq (N * 11/6)$:

If JOBZ = 'N', LWORK $\geq 7*N + N$

If JOBZ = 'O', LWORK $\geq 3*N*N + 4*N + 2*N*N + 3*N$

If JOBZ = 'S', LWORK $\geq 3*N*N + 4*N + N*N + 3*N$

If JOBZ = 'A', LWORK $\geq 3*N*N + 4*N + N*N + 3*N$

If M is at least N but not much larger ($N \leq M < (N * 11/6)$):

If JOBZ = 'N', LWORK $\geq 3*N + \text{MAX}(M, (7*N))$

If JOBZ = 'O', LWORK $\geq 3*N + \text{MAX}(M, N*N + (3*N*N + 4*N))$

If JOBZ = 'S', LWORK $\geq 3*N + \text{MAX}(M, (3*N*N + 4*N))$

If JOBZ = 'A', LWORK $\geq 3*N + \text{MAX}(M, (3*N*N + 4*N))$

If N is much larger than M such that N $\geq (M * 11/6)$:

If JOBZ = 'N', LWORK $\geq 7*M + M$

If JOBZ = 'O', LWORK $\geq 3*M*M + 4*M + 2*M*M + 3*M$

If JOBZ = 'S', LWORK $\geq 3*M*M + 4*M + M*M + 3*M$

If JOBZ = 'A', LWORK $\geq 3*M*M + 4*M + M*M + 3*M$

If N is at least M but not much larger ($M \leq N < (M * 11/6)$):

If JOBZ = 'N', LWORK $\geq 3*M + \text{MAX}(N, 7*M)$

If JOBZ = 'O', LWORK $\geq 3*M + \text{MAX}(N, M*M + (3*M*M + 4*M))$

If JOBZ = 'S', LWORK $\geq 3*M + \text{MAX}(N, (3*M*M + 4*M))$

If JOBZ = 'A', LWORK $\geq 3*M + \text{MAX}(N, (3*M*M + 4*M))$

IWORK (workspace)

dimension($8*\text{MIN}(M, N)$)

INFO (output)

```
= 0:  successful exit.  
< 0:  if INFO = -i, the i-th argument had an illegal value.  
> 0:  SBDSDC did not converge, updating process failed.
```

```

```
INTEGER :: N, NRHS, LDA, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GESV_64([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
```

```
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgesv(int n, int nrhs, float *a, int lda, int *ipivot,
           float *b, int ldb, int *info);

void sgesv_64(long n, long nrhs, float *a, long lda, long
              *ipivot, float *b, long ldb, long *info);

```

PURPOSE

sgesv computes the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N matrix and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)
On entry, the N -by- N coefficient matrix A . On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (output)
The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

B (input/output)
On entry, the N -by- $NRHS$ matrix of right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

C INTERFACE

```
#include <sunperf.h>

void sgesvd(char jobu, char jobvt, int m, int n, float *a,
            int lda, float *sing, float *u, int ldu, float
            *vt, int ldvt, int *info);

void sgesvd_64(char jobu, char jobvt, long m, long n, float
               *a, long lda, float *sing, float *u, long ldu,
               float *vt, long ldvt, long *info);
```

PURPOSE

sgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

$$A = U * \text{SIGMA} * \text{transpose}(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**T, not V.

ARGUMENTS

JOBV (input)

Specifies options for computing all or part of the matrix U:

- = 'A': all M columns of U are returned in array U;
- = 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U;
- = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;
- = 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)

Specifies options for computing all or part of the matrix V**T:

- = 'A': all N rows of V**T are returned in the

array VT;
 = 'S': the first min(m,n) rows of V**T (the right singular vectors) are returned in the array VT; =
 'O': the first min(m,n) rows of V**T (the right singular vectors) are overwritten on the array A;
 = 'N': no rows of V**T (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)
 On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**T (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

SING (output)
 The singular values of A, sorted so that $SING(i) \geq SING(i+1)$.

U (input) (LDU, M) if JOBU = 'A' or (LDU, min(M, N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M orthogonal matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)
 The leading dimension of the array U. $LDU \geq 1$; if JOBU = 'S' or 'A', $LDU \geq M$.

VT (input)
 If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V**T; if JOBVT = 'S', VT contains the first min(m,n) rows of V**T (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)
 The leading dimension of the array VT. $LDVT \geq 1$; if JOBVT = 'A', $LDVT \geq N$; if JOBVT = 'S', $LDVT \geq \min(M, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK; if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A, and singular vectors related by U and VT.

LDWORK (input)

The dimension of the array WORK. LDWORK >= 1. LDWORK >= MAX(3*MIN(M,N)+MAX(M,N), 5*MIN(M,N)). For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if SBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK above for details.

```

PURPOSE

sgesvx uses the LU factorization to compute the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate

the system:

TRANS = 'N': $\text{diag}(R) * A * \text{diag}(C) * \text{inv}(\text{diag}(C)) * X = \text{diag}(R) * B$

TRANS = 'T': $(\text{diag}(R) * A * \text{diag}(C)) ** T * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

TRANS = 'C': $(\text{diag}(R) * A * \text{diag}(C)) ** H * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(R)*A*\text{diag}(C)$ and B by $\text{diag}(R)*B$ (if $\text{TRANS}='N'$) or $\text{diag}(C)*B$ (if $\text{TRANS} = 'T' \text{ or } 'C'$).

2. If $\text{FACT} = 'N' \text{ or } 'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $\text{FACT} = 'E'$) as

$$A = P * L * U,$$

where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with $\text{INFO} = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, $\text{INFO} = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $\text{TRANS} = 'N'$) or $\text{diag}(R)$ (if $\text{TRANS} = 'T' \text{ or } 'C'$) so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to

AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': $A := \text{diag}(R) * A$

EQUED = 'C': $A := A * \text{diag}(C)$

EQUED = 'B': $A := \text{diag}(R) * A * \text{diag}(C)$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by SGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P*L*U$ as computed by SGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the equilibrated matrix A.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').

= 'R': Row equilibration, i.e., A has been premultiplied by diag(R).
= 'C': Column equilibration, i.e., A has been postmultiplied by diag(C).
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(R) * A * \text{diag}(C)$.
EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input or output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input or output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by $\text{diag}(R)*B$; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by $\text{diag}(C)*B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(C)) * X$ if TRANS = 'N' and EQUED = 'C' or 'B', or $\text{inv}(\text{diag}(R)) * X$ if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(4*N) On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

INTEGER, DIMENSION(:) :: IPIV  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgetf2(int m, int n, float *a, int lda, int *ipiv, int
           *info);

void sgetf2_64(long m, long n, float *a, long lda, long
              *ipiv, long *info);

```

PURPOSE

sgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur
if it is used to solve a system of equations.

               *ipivot, long *info);

```

PURPOSE

sgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

PURPOSE

sgetri computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by SGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)

On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N*\text{NB}$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

```
= 0:  successful exit  
< 0:  if INFO = -i, the i-th argument had an illegal value  
> 0:  if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.
```

               *info);
```

PURPOSE

sgetrs solves a system of linear equations

$A * X = B$ or $A' * X = B$ with a general N-by-N matrix A
using the LU factorization computed by SGETRF.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A' * X = B$ (Transpose)

= 'C': $A' * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrix B. $NRHS \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i
of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the right hand side matrix B. On exit,
the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
REAL, DIMENSION(:, :) :: V
```

```
SUBROUTINE GGBAK_64(JOB, SIDE, [N], ILO, IHI, LSCALE, RSCALE, [M], V,
                    [LDV], [INFO])
```

```

CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
REAL, DIMENSION(:,:) :: V

```

C INTERFACE

```

#include <sunperf.h>

void sggbak(char job, char side, int n, int ilo, int ihi,
            float *lscale, float *rscale, int m, float *v, int
            ldv, int *info);

void sggbak_64(char job, char side, long n, long ilo, long
               ihi, float *lscale, float *rscale, long m, float
               *v, long ldv, long *info);

```

PURPOSE

sggbak forms the right or left eigenvectors of a real generalized eigenvalue problem $Ax = \lambda Bx$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

JOB (input)
 Specifies the type of backward transformation required:
 = 'N': do nothing, return immediately;
 = 'P': do backward transformation for permutation only;
 = 'S': do backward transformation for scaling only;
 = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGGBAL.

SIDE (input)
 = 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)
 The integers ILO and IHI determined by SGGBAL. 1
 $\leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if
 $N=0$.

IHI (input)

See the description for ILO.

LSCALE (input)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGBAL.

RSCALE (input)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the matrix V. $LDV \geq \max(1, N)$.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

See R.C. Ward, Balancing the generalized eigenvalue problem, SIAM J. Sci. Stat. Comp. 2 (1981), 141-152.

SUBROUTINE GGBAL_64(JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,  
                   RSCALE, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
```

```
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sggbal(char job, int n, float *a, int lda, float *b,
            int ldb, int *ilo, int *ihi, float *lscale, float
            *rscale, int *info);

void sggbal_64(char job, long n, float *a, long lda, float
               *b, long ldb, long *ilo, long *ihi, float *lscale,
               float *rscale, long *info);
```

PURPOSE

sggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO\$-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A and B:
= 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N.
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >=

max(1,N).

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description for ILO.

LSCALE (input)
Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $D(j)$ for $J = ILO, \dots, IHI$ and $P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (input)
Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $D(j)$ for $J = ILO, \dots, IHI$ and $P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK (workspace)
dimension(6*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

    float *alphar, float *alphai, float *beta, float
    *vsl, long ldvsl, float *vsr, long ldvsr, long
    *info);

```

PURPOSE

sgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for

beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
'S': Eigenvalues are ordered (see SELCTG);

SELCTG (input)

LOGICAL FUNCTION of three REAL arguments SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j) + \text{ALPHAI}(j) \cdot i) / \text{BETA}(j)$ is selected if $\text{SELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy $\text{SELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j)) = \text{.TRUE.}$ after ordering. INFO is to be set to N+2 in this case.

N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)

On entry, the first of the pair of matrices. On

exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. $LDB \geq \max(1, N)$.

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $ALPHAR(j) + ALPHAI(j)*i$, and $BETA(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients $ALPHAR(j)/BETA(j)$ and $ALPHAI(j)/BETA(j)$ may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if JOBVSL = 'V', $LDVSL \geq N$.

VSR (input)
 If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
 The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK >= 8*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK (workspace)
 dimension(N) Not referenced if SORT = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 = 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
 =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

    n, float *a, long lda, float *b, long ldb, long
    *sdim, float *alphar, float *alphai, float *beta,
    float *vsl, long ldvsl, float *vsr, long ldvsr,
    float *rconde, float *rcondv, long *info);

```

PURPOSE

sggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$A,B = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition

number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α,β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)

LOGICAL FUNCTION of three REAL arguments SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $(\text{ALPHAR}(j) + \text{ALPHAI}(j) \cdot i) / \text{BETA}(j)$ is selected if $\text{SELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j))$ is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $\text{SELCTG}(\text{ALPHAR}(j), \text{ALPHAI}(j), \text{BETA}(j)) = .\text{TRUE.}$ after

ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)

REAL array, dimension(LDA,N) On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)

The leading dimension of A. LDA >= max(1,N).

B (input/output)

REAL array, dimension(LDB,N) On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)

The leading dimension of B. LDB >= max(1,N).

SDIM (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)

REAL array, dimension(N) On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and

ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

REAL array, dimension(N) See the description for ALPHAR.

BETA (output)

REAL array, dimension(N) See the description for ALPHAR.

VSL (input)

REAL array, dimension(LDVSL,N) If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

VSR (input)

REAL array, dimension(LDVSR,N) If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

RCONDE (output)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)

REAL array, dimension(LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq 8*(N+1)+16$. If SENSE = 'E', 'V', or 'B', LWORK $\geq \text{MAX}(8*(N+1)+16, 2*SDIM*(N-SDIM))$.

IWORK (workspace)

INTEGER array, dimension(LIWORK) Not referenced if
SENSE = 'N'.

LIWORK (input)

The dimension of the array WORK. LIWORK >= N+6.

BWORK (workspace)

LOGICAL array, dimension(N) Not referenced if SORT
= 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. >
N: =N+1: other than QZ iteration failed in SHGEQZ
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Further details =====

An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is

$EPS * \text{norm}((A, B)) / RCONDE(1).$

An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is

$EPS * \text{norm}((A, B)) / RCONDV(2).$

See LAPACK User's Guide, section 4.11 for more information.

```

PURPOSE

sggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^{**H} * A = \lambda(j) * u(j)^{**H} * B.$$

where $u(j)^{**H}$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

```

JOBVL (input)
    = 'N': do not compute the left generalized eigen-
           vectors;
    = 'V': compute the left generalized eigenvectors.

JOBVR (input)
    = 'N': do not compute the right generalized

```

```

eigenvectors;
= 'V': compute the right generalized eigenvec-
tors.

N (input) The order of the matrices A, B, VL, and VR.  N >=
0.

A (input/output)
    On entry, the matrix A in the pair (A,B).  On
    exit, A has been overwritten.

LDA (input)
    The leading dimension of A.  LDA >= max(1,N).

B (input/output)
    On entry, the matrix B in the pair (A,B).  On
    exit, B has been overwritten.

LDB (input)
    The leading dimension of B.  LDB >= max(1,N).

ALPHAR (output)
    On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j),
    j=1,...,N, will be the generalized eigenvalues.
    If ALPHAI(j) is zero, then the j-th eigenvalue is
    real; if positive, then the j-th and (j+1)-st
    eigenvalues are a complex conjugate pair, with
    ALPHAI(j+1) negative.

    Note: the quotients ALPHAR(j)/BETA(j) and
    ALPHAI(j)/BETA(j) may easily over- or underflow,
    and BETA(j) may even be zero.  Thus, the user
    should avoid naively computing the ratio
    alpha/beta.  However, ALPHAR and ALPHAI will be
    always less than and usually comparable with
    norm(A) in magnitude, and BETA always less than
    and usually comparable with norm(B).

ALPHAI (output)
    See the description for ALPHAR.

BETA (output)
    See the description for ALPHAR.

VL (input)
    If JOBVL = 'V', the left eigenvectors u(j) are
    stored one after another in the columns of VL, in
    the same order as their eigenvalues.  If the j-th
    eigenvalue is real, then u(j) = VL(:,j), the j-th
    column of VL.  If the j-th and (j+1)-th eigenvalues
    form a complex conjugate pair, then u(j) =
    VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-
    i*VL(:,j+1).  Each eigenvector will be scaled so

```

the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if `JOBVL = 'N'`.

`LDVL` (input)

The leading dimension of the matrix `VL`. `LDVL` ≥ 1 , and if `JOBVL = 'V'`, `LDVL` $\geq N$.

`VR` (input)

If `JOBVR = 'V'`, the right eigenvectors $v(j)$ are stored one after another in the columns of `VR`, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = \text{VR}(:,j)$, the j -th column of `VR`. If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = \text{VR}(:,j) + i \cdot \text{VR}(:,j+1)$ and $v(j+1) = \text{VR}(:,j) - i \cdot \text{VR}(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if `JOBVR = 'N'`.

`LDVR` (input)

The leading dimension of the matrix `VR`. `LDVR` ≥ 1 , and if `JOBVR = 'V'`, `LDVR` $\geq N$.

`WORK` (workspace)

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LWORK`.

`LWORK` (input)

The dimension of the array `WORK`. `LWORK` $\geq \max(1, 8 \cdot N)$. For good performance, `LWORK` must generally be larger.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

`INFO` (output)

`= 0`: successful exit
`< 0`: if `INFO = -i`, the i -th argument had an illegal value.
`= 1, ..., N`: The QZ iteration failed. No eigenvectors have been calculated, but `ALPHAR(j)`, `ALPHAI(j)`, and `BETA(j)` should be correct for $j = \text{INFO} + 1, \dots, N$.
`> N`: `= N + 1`: other than QZ iteration failed in `SHGEQZ`.
`= N + 2`: error return from `STGEVC`.

```

PURPOSE

sggevxx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to

improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j) .$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^*H * A = \lambda(j) * u(j)^*H * B.$$

where $u(j)^*H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

BALANC (input)

Specifies the balance option to be performed. =
 'N': do not diagonally scale or permute;
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;
 = 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;
 = 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;
 = 'E': computed for eigenvalues only;
 = 'V': computed for eigenvectors only;
 = 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
 On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA (input)
 The leading dimension of A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB (input)
 The leading dimension of B. $LDB \geq \max(1,N)$.

ALPHAR (output)
 On exit, $(\text{ALPHAR}(j) + \text{ALPHAI}(j)*i)/\text{BETA}(j)$, $j=1,\dots,N$, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients $\text{ALPHAR}(j)/\text{BETA}(j)$ and $\text{ALPHAI}(j)/\text{BETA}(j)$ may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

ALPHAI (output)
 See the description of ALPHAR.

BETA (output)
 See the description of ALPHAR.

VL (output)
 If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then $u(j) = \text{VL}(:,j)$, the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then $u(j) = \text{VL}(:,j) + i*\text{VL}(:,j+1)$ and $u(j+1) = \text{VL}(:,j) -$

$i*VL(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $\text{JOBVL} = 'N'$.

LDVL (input)

The leading dimension of the matrix VL. $\text{LDVL} \geq 1$, and if $\text{JOBVL} = 'V'$, $\text{LDVL} \geq N$.

VR (output)

If $\text{JOBVR} = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j -th eigenvalue is real, then $v(j) = \text{VR}(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -th eigenvalues form a complex conjugate pair, then $v(j) = \text{VR}(:,j) + i*\text{VR}(:,j+1)$ and $v(j+1) = \text{VR}(:,j) - i*\text{VR}(:,j+1)$. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if $\text{JOBVR} = 'N'$.

LDVR (input)

The leading dimension of the matrix VR. $\text{LDVR} \geq 1$, and if $\text{JOBVR} = 'V'$, $\text{LDVR} \geq N$.

ILO (output)

ILO and IHI are integer values such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, \text{ILO}-1$ or $i = \text{IHI}+1, \dots, N$. If $\text{BALANC} = 'N'$ or $'S'$, $\text{ILO} = 1$ and $\text{IHI} = N$.

IHI (output)

See the description of ILO.

LSCALE (output)

Details of the permutations and scaling factors applied to the left side of A and B. If $\text{PL}(j)$ is the index of the row interchanged with row j , and $\text{DL}(j)$ is the scaling factor applied to row j , then $\text{LSCALE}(j) = \text{PL}(j)$ for $j = 1, \dots, \text{ILO}-1$ and $\text{LSCALE}(j) = \text{DL}(j)$ for $j = \text{ILO}, \dots, \text{IHI}$ and $\text{LSCALE}(j) = \text{PL}(j)$ for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is N to $\text{IHI}+1$, then 1 to $\text{ILO}-1$.

RSCALE (output)

Details of the permutations and scaling factors applied to the right side of A and B. If $\text{PR}(j)$ is the index of the column interchanged with column j , and $\text{DR}(j)$ is the scaling factor applied to column j , then $\text{RSCALE}(j) = \text{PR}(j)$ for $j = 1, \dots, \text{ILO}-1$ and $\text{RSCALE}(j) = \text{DR}(j)$ for $j = \text{ILO}, \dots, \text{IHI}$ and $\text{RSCALE}(j) = \text{PR}(j)$ for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is N to $\text{IHI}+1$, then 1 to $\text{ILO}-1$.

ABNRM (output)
The one-norm of the balanced matrix A.

BBNRM (output)
The one-norm of the balanced matrix B.

RCONDE (output)
If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)
If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK $\geq \max(1, 6*N)$. If SENSE = 'E', LWORK $\geq 12*N$. If SENSE = 'V' or 'B', LWORK $\geq 2*N*N + 12*N + 16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(N+6) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)

```

= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value.
= 1,...,N:  The QZ iteration failed.  No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N.
> N:  =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

```

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{RCONDE}(I)$$

An approximate error bound for the angle between the i-th computed eigenvector $\text{VL}(i)$ or $\text{VR}(i)$ is given by

$$\text{PS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{DIF}(i).$$

For further explanation of the reciprocal condition numbers RCONDE and RCONDV , see section 4.11 of LAPACK User's Guide.

```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgglm(int n, int m, int p, float *a, int lda, float
          *b, int ldb, float *d, float *x, float *y, int
          *info);

void sgglm_64(long n, long m, long p, float *a, long lda,
             float *b, long ldb, float *d, float *x, float *y,
             long *info);

```

PURPOSE

sgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad ||y||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad ||\text{inv}(B)*(d-A*x)||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $0 \leq M \leq N$.

P (input) The number of columns of the matrix B. $P \geq N-M$.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

D (input/output)
 On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
 On exit, X and Y are the solutions of the GLM problem.

Y (output)
 See the description of X.

WORK (workspace)
 On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. $LDWORK \geq \max(1, N+M+P)$. For optimum performance, $LDWORK \geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit.
 < 0: if $INFO = -i$, the i-th argument had an illegal value.

REAL, DIMENSION(:, :) :: A, B, Q, Z

```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgghrd(char compq, char compz, int n, int ilo, int ihi,
            float *a, int lda, float *b, int ldb, float *q,
            int ldq, float *z, int ldz, int *info);

```

```

void sgghrd_64(char compq, char compz, long n, long ilo,
               long ihi, float *a, long lda, float *b, long ldb,
               float *q, long ldq, float *z, long ldz, long
               *info);

```

PURPOSE

sgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1 * Q) * H * (Z1 * Z)'$$

ARGUMENTS

COMPQ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)

= 'N': do not compute Z;
 = 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1*Z is returned.

N (input) The order of the matrices A and B. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced.
On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input/output)

On entry, the N-by-N upper triangular matrix B.
On exit, the upper triangular matrix $T = Q' B Z$.
The elements below the diagonal are set to zero.

LDB (input)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

Q (input/output)

If $\text{COMPQ}='N'$: Q is not referenced.
If $\text{COMPQ}='I'$: on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If $\text{COMPQ}='V'$: on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by $Q1*Q$.

LDQ (input)

The leading dimension of the array Q. $\text{LDQ} \geq N$ if $\text{COMPQ}='V'$ or $'I'$; $\text{LDQ} \geq 1$ otherwise.

Z (input/output)

If $\text{COMPZ}='N'$: Z is not referenced.
If $\text{COMPZ}='I'$: on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of the Givens transformations which are applied to A and B on the right. If $\text{COMPZ}='V'$: on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by $Z1*Z$.

LDZ (input)

The leading dimension of the array Z. LDZ \geq N if
COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in Matrix Computations, by Golub and Van Loan (Johns Hopkins Press.)

```

F95 INTERFACE

```
SUBROUTINE GGLSE([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],  
                 [LDWORK], [INFO])
```

```
INTEGER :: M, N, P, LDA, LDB, LDWORK, INFO  
REAL, DIMENSION(:) :: C, D, X, WORK  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],  
                   [LDWORK], [INFO])
```

```
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO  
REAL, DIMENSION(:) :: C, D, X, WORK  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sgglse(int m, int n, int p, float *a, int lda, float
            *b, int ldb, float *c, float *d, float *x, int
            *info);

void sgglse_64(long m, long n, long p, float *a, long lda,
               float *b, long ldb, float *c, float *d, float *x,
               long *info);

```

PURPOSE

sgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } ||c - A*x||_2 \quad \text{subject to } B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that

$P \leq N \leq M+P$, and

$$\text{rank}(B) = P \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

P (input) The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

C (input/output)

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)

On exit, X is the solution of the LSE problem.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK $\geq \max(1, M+N+P)$. For optimum performance LDWORK $\geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

REAL, DIMENSION(:) :: TAU, TAUB, WORK  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sggqrf(int n, int m, int p, float *a, int lda, float
           *taua, float *b, int ldb, float *taub, int *info);

void sggqrf_64(long n, long m, long p, float *a, long lda,
               float *taua, float *b, long ldb, float *taub, long
               *info);

```

PURPOSE

sggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

$$\begin{array}{l} \text{if } N \geq M, \quad R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} M \\ N-M \end{matrix}, \quad \text{or if } N < M, \quad R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} N \\ M \end{matrix} \\ \text{where } R_{11} \text{ is upper triangular, and} \end{array}$$

where R11 is upper triangular, and

$$\begin{array}{l} \text{if } N \leq P, \quad T = \begin{pmatrix} 0 & T_{12} \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } N > P, \quad T = \begin{pmatrix} T_{11} \\ & T_{21} \end{pmatrix} \begin{matrix} N \\ P \end{matrix} \\ \text{where } T_{12} \text{ or } T_{21} \text{ is upper triangular.} \end{array}$$

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $M \geq 0$.

P (input) The number of columns of the matrix B. $P \geq 0$.

A (input/output)
On entry, the N-by-M matrix A. On exit, the ele-

ments on and above the diagonal of the array contain the $\min(N,M)$ -by- M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAUA , represent the orthogonal matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1,N)$.

TAUA (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the N -by- P matrix B . On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N -by- N upper triangular matrix T ; if $N > P$, the elements on and above the $(N-P)$ -th subdiagonal contain the N -by- P upper trapezoidal matrix T ; the remaining elements, with the array TAUB , represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B . $\text{LDB} \geq \max(1,N)$.

TAUB (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)

The dimension of the array WORK . $\text{LWORK} \geq \max(1,N,M,P)$. For optimum performance $\text{LWORK} \geq \max(N,M,P) * \max(\text{NB1}, \text{NB2}, \text{NB3})$, where NB1 is the optimal blocksize for the QR factorization of an N -by- M matrix, NB2 is the optimal blocksize for the RQ factorization of an N -by- P matrix, and NB3 is the optimal blocksize for a call of SORMQR .

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA .

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(n, m).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_a v v'$$

where τ_a is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i+1:n, i)$, and τ_a in $\text{TAUA}(i)$.

To form Q explicitly, use LAPACK subroutine SORGQR.

To use Q to update another matrix, use LAPACK subroutine SORMQR.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_b v v'$$

where τ_b is a real scalar, and v is a real vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(n-k+i, 1:p-k+i-1)$, and τ_b in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine SORGRQ.

To use Z to update another matrix, use LAPACK subroutine SORMRQ.

               *info);

```

PURPOSE

sggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

$$\text{if } M \leq N, \quad R = \begin{pmatrix} 0 & R_{12} \\ & \end{pmatrix} \begin{matrix} M \\ M-N \end{matrix}, \quad \text{or if } M > N, \quad R = \begin{pmatrix} R_{11} \\ & \end{pmatrix} \begin{matrix} M \\ N \end{matrix}$$

where R12 or R21 is upper triangular, and

$$\text{if } P \geq N, \quad T = \begin{pmatrix} T_{11} \\ & \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } P < N, \quad T = \begin{pmatrix} T_{11} & T_{12} \\ & \end{pmatrix} \begin{matrix} P \\ N-P \end{matrix}$$

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*\text{inv}(B)$:

$$A*\text{inv}(B) = (R*\text{inv}(T))*Z'$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, if $M \leq$

N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU A, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAUA (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P,N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAU B, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,P)$.

TAUB (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1,N,M,P)$. For optimum performance $LWORK \geq \max(N,M,P) * \max(NB1,NB2,NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO= -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_a * v * v'$$

where τ_a is a real scalar, and v is a real vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and τ_a in $TAUA(i)$.
To form Q explicitly, use LAPACK subroutine SORGRQ.
To use Q to update another matrix, use LAPACK subroutine SORMRQ.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(p,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_b * v * v'$$

where τ_b is a real scalar, and v is a real vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i+1:p,i)$, and τ_b in $TAUB(i)$.
To form Z explicitly, use LAPACK subroutine SORGQR.
To use Z to update another matrix, use LAPACK subroutine SORMQR.

```

PURPOSE

sggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix}$$

where U, V and Q are orthogonal matrices, and Z' is the transpose of Z. Let K+L = the effective numerical rank of the matrix (A', B')', then R is a K+L-by-K+L nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D1 = \begin{matrix} & & K & L \\ & K & \begin{pmatrix} I & 0 \end{pmatrix} \\ & L & \begin{pmatrix} 0 & C \end{pmatrix} \\ M-K-L & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & & K & L \\ & L & \begin{pmatrix} 0 & S \end{pmatrix} \\ P-L & \begin{pmatrix} 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & & N-K-L & K & L \\ K & \begin{pmatrix} 0 & R11 & R12 \end{pmatrix} \\ L & \begin{pmatrix} 0 & 0 & R22 \end{pmatrix} \end{matrix}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
S = diag( BETA(K+1), ... , BETA(K+L) ),
C**2 + S**2 = I.

```

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If $M-K-L < 0$,

$$\begin{aligned}
 D1 &= \begin{matrix} & K & M-K & K+L-M \\ K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{matrix} \\
 D2 &= \begin{matrix} & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \end{matrix} \\
 \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{matrix} & N-K-L & K & M-K & K+L-M \\ K & (0 & R11 & R12 & R13) \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{matrix}
 \end{aligned}$$

where

```

C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1), ... , BETA(M) ),
C**2 + S**2 = I.

```

(R11 R12 R13) is stored in A(1:M, N-K-L+1:N), and R33 is stored
 (0 R22 R23)
 in B(M-K+1:L,N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A \cdot \text{inv}(B)$:

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V'.$$

If (A', B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' \cdot A \cdot x = \text{lambda} \cdot B' \cdot B \cdot x.$$

In some literature, the GSVD of A and B is presented in the form

$$U' \cdot A \cdot X = \begin{pmatrix} 0 & D1 \end{pmatrix}, \quad V' \cdot B \cdot X = \begin{pmatrix} 0 & D2 \end{pmatrix}$$

where U and V are orthogonal and X is nonsingular, D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$\begin{aligned}
 X &= Q \cdot \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix} \\
 &\quad \begin{pmatrix} 0 & \text{inv}(R) \end{pmatrix}.
 \end{aligned}$$

ARGUMENTS

JOBV (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in the Purpose section. $K + L =$ effective numerical rank of $(A', B')'$.

L (output)
See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if $M - K - L < 0$. See Purpose for details.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $BETA(1:K) = 0$, and if $M - K - L \geq 0$, $ALPHA(K+1:K+L) = C$,
 $BETA(K+1:K+L) = S$, or if $M - K - L < 0$,
 $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$
 $BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and
 $ALPHA(K+L+1:N) = 0$

BETA(K+L+1:N) = 0

BETA (output)

See the description of ALPHA.

U (output)

If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)

If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)

If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)

dimension (max(3*N,M,P)+N)

IWORK3 (output)

dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

    ldq, long *info);

```

PURPOSE

sggsvp computes orthogonal matrices U, V and Q such that

$$\begin{aligned}
 & \begin{matrix} & L & (& 0 & & 0 & & A23 &) \\ M-K-L & (& 0 & & 0 & & 0 &) \end{matrix} \\
 & = \begin{matrix} & N-K-L & & K & & L \\ K & (& 0 & & A12 & & A13 &) \\ M-K & (& 0 & & 0 & & A23 &) \end{matrix} \quad \text{if } M-K-L < 0; \\
 & V' * B * Q = \begin{matrix} & N-K-L & & K & & L \\ L & (& 0 & & 0 & & B13 &) \\ P-L & (& 0 & & 0 & & 0 &) \end{matrix}
 \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L ≥ 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix (A', B')'. Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSD.

ARGUMENTS

JOBV (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See the description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-

blocks described in Purpose. $K + L$ = effective numerical rank of (A', B') .

L (output)

See the description of K.

U (input) If JOBU = 'U', U contains the orthogonal matrix U.
If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq \max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

V (input) If JOBV = 'V', V contains the orthogonal matrix V.
If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. $LDV \geq \max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

Q (input) If JOBQ = 'Q', Q contains the orthogonal matrix Q.
If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

IWORK (workspace)

dimension(N)

TAU (workspace)

dimension(N)

WORK (workspace)

dimension($\max(3*N, M, P)$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine SGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

Contents

NAME

`sgssco` - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE SGSSCO ( COND, HANDLE, IER )
```

```
INTEGER          IER
REAL             COND
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

`SGSSCO` - Condition number estimate.

PARAMETERS

COND - REAL

On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, [SGSSFA](#)().

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 700 : Invalid calling sequence - need to call `SGSSFA` first.
- 710 : Condition number estimate not available (not implemented for this `HANDLE`'s matrix type).

NAME

sgssda - Deallocate working storage for the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSDA ( HANDLE, IER )
```

```
INTEGER                IER  
DOUBLE PRECISION      HANDLE(150)
```

PURPOSE

SGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

NAME

sgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE SGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )
```

```
INTEGER          NEQNS, COLSTR(*), ROWIND(*), IER
REAL             VALUES(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER
On entry, **NEQNS** specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, **COLSTR**(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, **ROWIND**(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - REAL array
On entry, **VALUES**(*) is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on

exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 300 : Invalid calling sequence - need to call SGSSOR first.
- 301 : Failure to dynamically allocate memory.
- 666 : Internal error.

INTEGER          NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                OUTUNT, MSGLVL, IER
CHARACTER*3      ORDMTHD
REAL             VALUES(*), RHS(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSFS - General sparse solver one call interface.

PARAMETERS

MTXTYP - CHARACTER*2

On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

'sp' or 'SP' - symmetric structure, positive-definite values
'ss' or 'SS' - symmetric structure, symmetric values
'su' or 'SU' - symmetric structure, unsymmetric values
'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1

On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization.
The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one.
Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, *COLSTR*(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, *ROWIND*(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - REAL array

On entry, *VALUES*(*) is an array of size COLSTR(NEQNS+1)-1, containing the non-zero numeric values of the sparse matrix to be factored.
Unchanged on exit.

NRHS - INTEGER

On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(*) - REAL array

On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER

On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver.
Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see SGSSUO)

Unchanged on exit.

OUTUNT - INTEGER
Output unit. Unchanged on exit.

MSGLVL - INTEGER
Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array of containing
information needed by the solver, and must be passed
unchanged to each sparse solver subroutine.
Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on
exit. If error encountered, it is set to a non-zero
integer. Error numbers set by this subroutine:

- 101 : Failure to dynamically allocate memory.
- 102 : Invalid matrix type.
- 103 : Invalid pivot option.
- 104 : Number of nonzeros is less than NEQNS.
- 105 : NEQNS < 1
- 106 : Invalid matrix structure.
- 201 : Failure to dynamically allocate memory.
- 301 : Failure to dynamically allocate memory.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS
- 666 : Internal error.

Contents

- [NAME](#)
- [SYNOPSIS](#)

NAME

sgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,  
                   MSGGLVL, HANDLE, IER )
```

```
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGGLVL, IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

 'sp' or 'SP' - symmetric structure, positive-definite values
 'ss' or 'SS' - symmetric structure, symmetric values
 'su' or 'SU' - symmetric structure, unsymmetric values
 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one.
Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, COLSTR(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure.
Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, ROWIND(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine.
Modified on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGLVL - INTEGER

Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.
-105 : NEQNS < 1

sgssor - General sparse solver ordering and symbolic factorization.

SYNOPSIS

```
SUBROUTINE SGSSOR ( ORDMTHD, HANDLE, IER )
```

```
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see SGSSUO)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 200 : Invalid calling sequence - need to call SGSSIN first.
- 201 : Failure to dynamically allocate memory.
- 666 : Internal error.

sgssps - Print general sparse solver statics.

SYNOPSIS

```
SUBROUTINE SGSSPS ( HANDLE, IER )
```

```
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-800 : Invalid calling sequence - need to call SGSSSL first.
-899 : Printed solver statistics not supported this release.

Contents

sgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSRP ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call SGSSOR first.

Contents

NAME

sgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )
```

```
INTEGER          NRHS, LDRHS, IER  
REAL             RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER
 On entry, NRHS specifies the number of right hand
 sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - REAL array
 On entry, RHS(LDRHS,NRHS) contains the NRHS right
 hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
 On entry, LDRHS specifies the leading dimension of
 the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
 On entry, [HANDLE](#)(*) is an array containing
 information needed by the solver, and must be passed
 unchanged to each sparse solver subroutine.
 Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call SGSSFA first.

sgssuo - User supplied permutation for ordering used in the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSUO ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

SGSSUO - User supplied permutation for ordering. Must be called after [SGSSIN\(\)](#) (sparse solver initialization) and before [SGSSOR\(\)](#) (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array

On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call SGSSIN first.

                   RCOND, [WORK], [IWORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: LOW, D, UP1, UP2, WORK

```

C INTERFACE

```

#include <sunperf.h>
void sgtcon(char norm, int n, float *low, float *diag, float
            *up1, float *up2, int *ipivot, float anorm, float
            *rcond, int *info);

void sgtcon_64(char norm, long n, float *low, float *diag,
               float *up1, float *up2, long *ipivot, float anorm,
               float *rcond, long *info);

```

PURPOSE

sgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

LOW (input)
 The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

D (input) The n diagonal elements of the upper triangular

matrix U from the LU factorization of A.

UP1 (input)

The (n-1) elements of the first superdiagonal of U.

UP2 (input)

The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension(2*N)

IWORK2 (workspace)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sgthr - Gathers specified elements from y into x.

SYNOPSIS

```
SUBROUTINE SGTHR(NZ, Y, X, INDX)
```

```
REAL Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE SGTHR_64(NZ, Y, X, INDX)
```

```
REAL Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE GTHR([NZ], Y, X, INDX)
```

```
  REAL, DIMENSION(:) :: Y, X  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE GTHR_64([NZ], Y, X, INDX)
```

```
  REAL, DIMENSION(:) :: Y, X  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

SGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only

the elements of `y` whose indices are listed in `indx` are referenced.

```
do i = 1, n
    x(i) = y(indx(i))
enddo
```

ARGUMENTS

`NZ (input)` - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

`Y (input)`

Vector in full storage form. Unchanged on exit.

`X (output)`

Vector in compressed form. Contains elements of `y` whose indices are listed in `indx` on exit.

`INDX (input)` - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in `INDX` are distinct and greater than zero. Unchanged on exit.

NAME

sgthrz - Gather and zero.

SYNOPSIS

```
SUBROUTINE SGTHRZ(NZ, Y, X, INDX)
```

```
REAL Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE SGTHRZ_64(NZ, Y, X, INDX)
```

```
REAL Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE  
SUBROUTINE GTHRZ([NZ], Y, X, INDX)
```

```
REAL, DIMENSION(:) :: Y, X  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)
```

```
REAL, DIMENSION(:) :: Y, X  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

SGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The

gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)

Vector in full storage form. Gathered elements are set to zero.

X (output)

Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

    long ldb, float *x, long ldx, float *ferr, float
    *berr, long *info);

```

PURPOSE

sgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{*T} * X = B$ (Transpose)
 = 'C': $A^{*H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number

of columns of the matrix B. NRHS ≥ 0 .

LOW (input)
The (n-1) subdiagonal elements of A.

D (input) The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1, N)$.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of

the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgtsv(int n, int nrhs, float *low, float *diag, float  
          *up, float *b, int ldb, int *info);
```

```
void sgtsv_64(long n, long nrhs, float *low, float *diag,
              float *up, float *b, long ldb, long *info);
```

PURPOSE

sgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^*X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

D (input/output)
On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) super-diagonal elements of A.

On exit, UP is overwritten by the (n-1) elements of the first super-diagonal of U.

B (input/output)
On entry, the N by NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N by NRHS
solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, U(i,i) is exactly zero, and the
solution has not been computed. The factorization
has not been completed unless i = N.

    *info);

```

PURPOSE

sgtsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
as $A = L * U$, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with

nonzeros in
only the main diagonal and first two superdiagonals.

2. If some $U(i,i)=0$, so that U is exactly singular, then the routine
returns with $INFO = i$. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A . If the
reciprocal of the condition number is less than machine
precision,
 $INFO = N+1$ is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.

3. The system of equations is solved for X using the fac-
tored form
of A .

4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A
has been supplied on entry. = 'F': LOWF, DF,
UPF1, UPF2, and IPIVOT contain the factored form
of A ; LOW, D, UP, LOWF, DF, UPF1, UPF2 and IPIVOT
will not be modified. = 'N': The matrix will be
copied to LOWF, DF, and UPF1 and factored.

TRANS (input)
Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose = Tran-
spose)

TRANS is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B . $NRHS \geq 0$.

LOW (input)
The $(n-1)$ subdiagonal elements of A .

D (input) The n diagonal elements of A.

UP (input/output)

The $(n-1)$ superdiagonal elements of A.

LOWF (input or output)

If FACT = 'F', then LOWF is an input argument and on entry contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A.

DF (input or output)

If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input or output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the $(n-1)$ elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the $(n-1)$ elements of the first superdiagonal of U.

UPF2 (input or output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the $(n-2)$ elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the $(n-2)$ elements of the second superdiagonal of U.

IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was inter-

changed with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is

$\leq N$: $U(i,i)$ is exactly zero. The factorization has not been completed unless $i = N$, but the factor U is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. $= N+1$: U is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

INTEGER*8 IPIVOT(*)  
REAL LOW(*), D(*), UP1(*), UP2(*)
```

F95 INTERFACE

```
SUBROUTINE GTTRF([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:) :: LOW, D, UP1, UP2
```

```
SUBROUTINE GTTRF_64([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:) :: LOW, D, UP1, UP2
```

C INTERFACE

```
#include <sunperf.h>

void sgtrrf(int n, float *low, float *diag, float *up1,
            float *up2, int *ipivot, int *info);

void sgtrrf_64(long n, float *low, float *diag, float *up1,
               float *up2, long *ipivot, long *info);
```

PURPOSE

sgtrrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D (input/output)

On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or $i+1$; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit
< 0: if INFO = - k , the k -th argument had an illegal value
> 0: if INFO = k , $U(k,k)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

PURPOSE

sgttrs solves one of the systems of equations
 $A * X = B$ or $A' * X = B$, with a tridiagonal matrix A using
the LU factorization computed by SGTTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A' * X = B$ (Transpose)
= 'C': $A' * X = B$ (Conjugate transpose = Trans-
pose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L
from the LU factorization of A.

D (input) The n diagonal elements of the upper triangular
matrix U from the LU factorization of A.

UP1 (input)
 The (n-1) elements of the first super-diagonal of U.

UP2 (input)
 The (n-2) elements of the second super-diagonal of U.

IPIVOT (input)
 The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or $i+1$; IPIVOT(i) = i indicates a row interchange was not required.

B (input/output)
 On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if INFO = - i , the i -th argument had an illegal value

```

PURPOSE

shgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal transformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the orthogonal transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

$$(in) A(in) Z(in)^* = Q(out) A(out) Z(out)^*$$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973), p. 241--256.

ARGUMENTS

JOB (input)
 = 'E': compute only ALPHAR, ALPHAI, and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHAR, ALPHAI, and BETA.

COMPQ (input)
 = 'N': do not modify Q.
 = 'V': multiply the array Q on the right by the transpose of the orthogonal transformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)
 = 'N': do not modify Z.
 = 'V': multiply the array Z on the right by the orthogonal transformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. $N \geq 0$.

ILO (input)
 It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)
 See the description of ILO.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

LDA (input)
 The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.) If JOB='S', then on exit A and B will have been simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements corresponding to diagonal blocks of A will be

correct, but the off-diagonal portion will be meaningless.

LDB (input)

The leading dimension of the array B. LDB \geq max(1, N).

ALPHAR (output)

ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=A(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

ALPHAI (output)

ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAI(j)=0. Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

BETA (output)

BETA(1:N) will be set to the (real) diagonal elements of B that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then BETA(j)=B(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB. (Note that BETA(1:N) will always be non-negative, and no BETAI is necessary.)

Q (input/output)

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the transpose of the orthogonal transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1. If COMPQ='V' or 'I', then LDQ \geq N.

Z (input/output)
 If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the orthogonal transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1.
 If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)
 On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK >= max(1,N).

 If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 = 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct.
 = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct.
 > 2*N: various "impossible" errors.

FURTHER DETAILS

Iteration counters:

JITER -- counts iterations.
 IITER -- counts iterations run since ILAST was last changed. This is therefore reset only when a 1-by-1 or 2-by-2 block deflates off the bottom.

               *ifailr, long *info);

```

PURPOSE

shsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y .

ARGUMENTS

SIDE (input)

- = 'R': compute right eigenvectors only;
- = 'L': compute left eigenvectors only;
- = 'B': compute both right and left eigenvectors.

EIGSRC (input)

Specifies the source of eigenvalues supplied in (WR,WI):

- = 'Q': the eigenvalues were found using SHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j -th eigenvalue can be assumed to be an eigenvalue of the block containing the j -th row/column. This property allows SHSEIN to perform inverse iteration on just one diagonal block.
- = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, SHSEIN must always per-

form inverse iteration using the whole matrix H.

INITV (input)

= 'N': no initial vectors are supplied;
= 'U': user-supplied initial vectors are stored in
the arrays VL and/or VR.

SELECT (input/output)

Specifies the eigenvectors to be computed. To
select the real eigenvector corresponding to a
real eigenvalue WR(j), SELECT(j) must be set to
.TRUE.. To select the complex eigenvector
corresponding to a complex eigenvalue
(WR(j),WI(j)), with complex conjugate
(WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1)
or both must be set to

N (input) The order of the matrix H. $N \geq 0$.

H (input) The upper Hessenberg matrix H.

LDH (input)

The leading dimension of the array H. $LDH \geq$
 $\max(1,N)$.

WR (input/output)

On entry, the real and imaginary parts of the
eigenvalues of H; a complex conjugate pair of
eigenvalues must be stored in consecutive elements
of WR and WI. On exit, WR may have been altered
since close eigenvalues are perturbed slightly in
searching for independent eigenvectors.

WI (input)

See the description of WR.

VL (input/output)

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL
must contain starting vectors for the inverse
iteration for the left eigenvectors; the starting
vector for each eigenvector must be in the same
column(s) in which the eigenvector will be stored.
On exit, if SIDE = 'L' or 'B', the left eigenvec-
tors specified by SELECT will be stored consecu-
tively in the columns of VL, in the same order as
their eigenvalues. A complex eigenvector
corresponding to a complex eigenvalue is stored in
two consecutive columns, the first holding the
real part and the second the imaginary part. If
SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. $LDVL \geq$
 $\max(1,N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ other-
wise.

VR (input/output)

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)

dimension((N+2)*N)

IFAILL (output)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, i is the number of eigenvectors

which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x|+|y|$.

```
SUBROUTINE HSEQR_64(JOB, COMPZ, N, ILO, IHI, H, [LDH], WR, WI, Z,  
                    [LDZ], [WORK], [LWORK], [INFO])
```

```

CHARACTER(LEN=1) :: JOB, COMPZ
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
REAL, DIMENSION(:) :: WR, WI, WORK
REAL, DIMENSION(:, :) :: H, Z

```

C INTERFACE

```

#include <sunperf.h>

void shseqr(char job, char compz, int n, int ilo, int ihi,
            float *h, int ldh, float *wr, float *wi, float *z,
            int ldz, int *info);
void shseqr_64(char job, char compz, long n, long ilo, long
               ihi, float *h, long ldh, float *wr, float *wi,
               float *z, long ldz, long *info);

```

PURPOSE

shseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q , so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q^*H^*Q^{**T} = (QZ)^*T^*(QZ)^{**T}$.

ARGUMENTS

JOB (input)
 = 'E': compute eigenvalues only;
 = 'S': compute eigenvalues and the Schur form T .

COMPZ (input)
 = 'N': no Schur vectors are computed;
 = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; =
 = 'V': Z must contain an orthogonal matrix Q on entry, and the product Q^*Z is returned.

N (input) The order of the matrix H . $N \geq 0$.

ILO (input)
 It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output

by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

H (input/output)

On entry, the upper Hessenberg matrix H. On exit, if $\text{JOB} = 'S'$, H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$. If $\text{JOB} = 'E'$, the contents of H are unspecified on exit.

LDH (input)

The leading dimension of the array H. $\text{LDH} \geq \max(1,N)$.

WR (output)

The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with $\text{WI}(i) > 0$ and $\text{WI}(i+1) < 0$. If $\text{JOB} = 'S'$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with $\text{WR}(i) = H(i,i)$ and, if $H(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $\text{WI}(i) = \sqrt{H(i+1,i)*H(i,i+1)}$ and $\text{WI}(i+1) = -\text{WI}(i)$.

WI (output)

See the description of WR.

Z (input) If $\text{COMPZ} = 'N'$: Z is not referenced.

If $\text{COMPZ} = 'I'$: on entry, Z need not be set, and on exit, Z contains the orthogonal matrix Z of the Schur vectors of H. If $\text{COMPZ} = 'V'$: on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the sub-matrix $Z(\text{ILO}:\text{IHI}, \text{ILO}:\text{IHI})$; on exit Z contains $Q*Z$. Normally Q is the orthogonal matrix generated by SORGHR after the call to SGEHRD which formed the Hessenberg matrix H.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq \max(1,N)$ if $\text{COMPZ} = 'I'$ or $'V'$; $\text{LDZ} \geq 1$ otherwise.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, SHSEQR failed to compute all of the eigenvalues in a total of $30 \cdot (\text{IHI} - \text{ILO} + 1)$ iterations; elements 1:i-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed.

```

```
void sinqb(int n, float *x, float *wsave);
```

```
void sinqb_64(long n, float *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine synthesis of the input.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine transform of the input.

WSAVE (input)
On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

`sinqi` - initialize the array `xWSAVE`, which is used in both `SINQF` and `SINQB`.

SYNOPSIS

```
SUBROUTINE SINQI(N, WSAVE)
```

```
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE SINQI_64(N, WSAVE)
```

```
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQI(N, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINQI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sinqi(int n, float *wsave);
```

```
void sinqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)

On entry, an array of dimension $(3 * N + 15)$ or greater. SINQI needs to be called only once to initialize WSAVE before calling SINQF and/or SINQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

sint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

SYNOPSIS

```
SUBROUTINE SINT(N, X, WSAVE)
```

```
INTEGER N  
REAL X(*), WSAVE(*)
```

```
SUBROUTINE SINT_64(N, X, WSAVE)
```

```
INTEGER*8 N  
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT(N, X, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE SINT_64(N, X, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sint(int n, float *x, float *wsave);
```

```
void sint_64(long n, float *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

X (input/output)

On entry, an array of length N containing the sequence to be transformed. On exit, the sine transform of the input.

WSAVE (input/output)

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by SINTI.

Contents

NAME

sinti - initialize the array WSAVE, which is used in subroutine SINT.

SYNOPSIS

```
SUBROUTINE SINTI(N, WSAVE)
```

```
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE SINTI_64(N, WSAVE)
```

```
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINTI(N, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE SINTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sinti(int n, float *wsave);
```

```
void sinti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input/output)

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

sjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

SYNOPSIS

```
SUBROUTINE SJADMM( TRANSA, M, N, K, ALPHA, DESCRA,  
*                VAL, INDX, PNTR, MAXNZ, IPERM,  
*                B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER          TRANSA, M, N, K, DESCRA(5), MAXNZ,  
*                LDB, LDC, LWORK  
INTEGER          INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)  
REAL             ALPHA, BETA  
REAL             VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)  
  
SUBROUTINE SJADMM_64( TRANSA, M, N, K, ALPHA, DESCRA,  
*                VAL, INDX, PNTR, MAXNZ, IPERM,  
*                B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*8        TRANSA, M, N, K, DESCRA(5), MAXNZ,  
*                LDB, LDC, LWORK  
INTEGER*8        INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)  
REAL             ALPHA, BETA  
REAL             VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

where $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ is the number of non-zero elements.

F95 INTERFACE

```
SUBROUTINE JADMM( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,  
*                PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER          TRANSA, M, K, MAXNZ  
INTEGER, DIMENSION(:) :: DESCRA, INDX, PNTR, IPERM  
REAL            ALPHA, BETA

INTEGER*8        TRANSA, M, K, MAXNZ  
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTR, IPERM  
REAL            ALPHA, BETA
```

```

REAL, DIMENSION(:) :: VAL
REAL, DIMENSION(:, :) :: B, C

```

C INTERFACE

```
#include <sunperf.h>
```

```

void sjadmm (int transa, int m, int n, int k, float alpha,
int *descra, float *val, int *indx, int *pntr, int maxnz,
int *iperm, float *b, int ldb, float beta, float *c, int
ldc)

```

```

void sjadmm_64(long transa, long m, long n, long k, float
alpha, long *descra, float *val, long *indx, long *pntr,
long maxnz, long *iperm, float *b, long ldb, float beta,
float *c, long ldc);

```

DESCRIPTION

sjadmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the jagged diagonal format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)    On entry, VAL is a scalar array of length
               NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A.
               VAL can be viewed as a column major ordering of a
               row permutation of the Ellpack representation of A,
               where the Ellpack representation is permuted so that
               the rows are non-increasing in the number of nonzero
               entries. Values added for padding in Ellpack are
               not included in the Jagged-Diagonal format.
               Unchanged on exit.

INDX(input)    On entry, INDX is an integer array of length
               NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column
               indices of the corresponding entries in VAL.
               Unchanged on exit.

PNTR(input)    On entry, PNTR is an integer array of length
               MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to
               the location in VAL of the first element
               in the row-permuted Ellpack representation of A.
               Unchanged on exit.

MAXNZ(input)   On entry, MAXNZ specifies the max number of
               nonzeros elements per row. Unchanged on exit.

IPERM(input)   On entry, IPERM is an integer array of length M
               such that I = IPERM(I'), where row I in the
               original Ellpack representation corresponds
               to row I' in the permuted representation.
               If IPERM(1) = 0, it is assumed by convention that
               IPERM(I) = I. IPERM is used to determine the order
               in which rows of C are updated. Unchanged on exit.

B (input)      Array of DIMENSION ( LDB, N ).
               Before entry with TRANSA = 0, the leading k by n
               part of the array B must contain the matrix B, otherwise
               the leading m by n part of the array B must contain the
               matrix B. Unchanged on exit.

LDB (input)    On entry, LDB specifies the first dimension of B as declared
               in the calling (sub) program. Unchanged on exit.

BETA (input)   On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION ( LDC, N ).
               Before entry with TRANSA = 0, the leading m by n
               part of the array C must contain the matrix C, otherwise

```

the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * op(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

NAME

sjadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
SUBROUTINE SJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                IPERM, WORK, LWORK )
INTEGER      TRANSP, M, K, MAXNZ, LWORK
INTEGER      INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
REAL         VAL(*)

SUBROUTINE SJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, WORK, LWORK )
INTEGER*8    TRANSP, M, K, MAXNZ, LWORK
INTEGER*8    INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
REAL         VAL(*)
```

F95 INTERFACE

```
SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*               IPERM, [WORK], [LWORK] )
INTEGER TRANSP, M, K, MAXNZ
INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
REAL, DIMENSION(:) :: VAL

SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
INTEGER*8 TRANSP, M, K, MAXNZ
INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
REAL, DIMENSION(:) :: VAL
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sjadrp (int transp, int m, int k, float *val, int
*indx, int *pntr, int maxnz, int *iperm);
```

```
void sjadrp_64 (long transp, long m, long k, float *val,
long *indx, long *pntr, long maxnz, long *iperm);
```

DESCRIPTION

sjadrp performs one of the matrix-matrix operations

```
A <- A P    or    A <- A P'
                                ( ' indicates matrix transpose)
```

where A is an M-by-K sparse matrix represented in the jagged diagonal format, the permutation matrix P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symmetrically permuted jagged diagonal matrix $P A P'$, one can explicitly permute the columns P A by calling

```
SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP(input)	TRANSP indicates how to operate with the permutation matrix: 0 : operate with matrix 1 : operate with transpose matrix Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
VAL(input/output)	On entry, VAL is a scalar array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format. On exit, VAL contains non-zero entries of the output permuted jagged diagonal matrix.
INDX(input/output)	On entry, INDX is an integer array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of the column indices of the corresponding entries in VAL. On exit, INDX is overwritten by the column indices of the output permuted jagged diagonal matrix.

PNTR(input) On entry, PNTR is an integer array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length K such that $I = IPERM(I')$. Array IPERM represents a permutation P, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P. For example, if

$$P = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

then IPERM = (3, 1, 2). Unchanged on exit.

WORK(workspace) Scratch array of length LWORK. LWORK should be at least K.

LWORK(input) On entry, LWORK specifies the length of the array WORK. If LWORK=0, the routine is to allocate workspace needed. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

float *dv, float alpha, long *descra, float *val, long  
*indx, long *pntr, long maxnz, long *iperm, float *b, long  
ldb, float beta, float *c, long ldc);
```

DESCRIPTION

sjadsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices,
D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit,
upper or lower triangular matrix represented in jagged-diagonal format
and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which

the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A.
VAL can be viewed as a column major ordering of a
row permutation of the Ellpack representation of A,
where the Ellpack representation is permuted so that
the rows are non-increasing in the number of nonzero
entries. Values added for padding in Ellpack are
not included in the Jagged-Diagonal format.
Unchanged on exit if UNITD is not equal to 4.

INDX(input) On entry, INDX is an integer array of length
NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column
indices of the corresponding entries in VAL.
Unchanged on exit.

PNTR(input) On entry, PNTR is an integer array of length
MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to
the location in VAL of the first element
in the row-permuted Ellpack representation of A.
Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of
nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length M
such that I = IPERM(I'), where row I in the
original Ellpack representation corresponds
to row I' in the permuted representation.
If IPERM(1) = 0, it is assumed by convention that
IPERM(I) = I. IPERM is used to determine the order
in which rows of C are updated. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B

must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least 2*M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, $LWORK \geq 2 \cdot M \cdot N_{CPUS}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:
<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of the sparse matrix A such that their 2-norms are one. The scaling may

improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = - i` where `i` is the row number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the JAD representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

```

```
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D
```

```
SUBROUTINE LAGTF_64([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
```

```
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
```

```
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>

void slagtf(int n, float *a, float lambda, float *b, float
            *c, float tol, float *d, int *in, int *info);

void slagtf_64(long n, float *a, float lambda, float *b,
               float *c, float tol, float *d, long *in, long
               *info);
```

PURPOSE

slagtf factorizes the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter `LAMBDA` is included in the routine so that `SLAGTF` may be used, in conjunction with `SLAGTS`, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

`N` (input) The order of the matrix T .

`A` (input/output)

On entry, `A` must contain the diagonal elements of T .

On exit, `A` is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .

`LAMBDA` (input)

On entry, the scalar λ .

`B` (input/output)

On entry, `B` must contain the $(n-1)$ super-diagonal elements of T .

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C (input/output)

On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL (input/output)

On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. TOL should normally be chosen as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5×10^{-4} . If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D (output)

On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN (output)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then $IN(k) = 1$, otherwise $IN(k) = 0$. The element $IN(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}(T - \lambda I)(j) * \text{TOL},$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then $IN(n)$ is returned as zero. If $IN(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \lambda I)$ is singular or nearly singular,

INFO (output)

= 0 : successful exit

```

```
INTEGER(8), DIMENSION(:) :: INDEX
```

```
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void slamrg(int n1, int n2, float *a, int trd1, int trd2,
            int *index);

void slamrg_64(long n1, long n2, float *a, long trd1, long
               trd2, long *index);
```

PURPOSE

slamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

N1 (input)
Length of the first sequence to be merged.

N2 (input)
Length of the second sequence to be merged.

A (input) On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

TRD1 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

TRD2 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

INDEX (output)
On exit this array will contain a permutation such that if $B(I) = A(\text{INDEX}(I))$ for $I=1, N1+N2$, then B will be sorted in ascending order.

SUBROUTINE LARZ(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
```

```
CHARACTER(LEN=1) :: SIDE  
INTEGER :: M, N, L, INCV, LDC  
REAL :: TAU  
REAL, DIMENSION(:) :: V, WORK  
REAL, DIMENSION(:,:) :: C
```

```
SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
```

```
CHARACTER(LEN=1) :: SIDE  
INTEGER(8) :: M, N, L, INCV, LDC  
REAL :: TAU  
REAL, DIMENSION(:) :: V, WORK
```

```
REAL, DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slarz(char side, int m, int n, int l, float *v, int  
          incv, float tau, float *c, int ldc);
```

```
void slarz_64(char side, long m, long n, long l, float *v,  
              long incv, float tau, float *c, long ldc);
```

PURPOSE

slarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

SIDE (input)

= 'L': form $H * C$
= 'R': form $C * H$

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) The vector v in the representation of H as returned by STZRZF. V is not used if TAU = 0.

INCV (input)

The increment between elements of v. INCV $\neq 0$.

TAU (input)

The value tau in the representation of H.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix $H * C$ if SIDE = 'L', or $C * H$ if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

REAL, DIMENSION(:,:) :: V, T, C, WORK
```

C INTERFACE

```
#include <sunperf.h>

void slarzb(char side, char trans, char direct, char storev,
            int m, int n, int k, int l, float *v, int ldv,
            float *t, int ldt, float *c, int ldc, int ldwork);

void slarzb_64(char side, char trans, char direct, char
               storev, long m, long n, long k, long l, float *v,
               long ldv, float *t, long ldt, float *c, long ldc,
               long ldwork);
```

PURPOSE

slarzb applies a real block reflector H or its transpose H^*T to a real distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)
= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not supported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) If STOREV = 'C', $NV = K$; if STOREV = 'R', $NV = L$.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', $LDV \geq L$; if STOREV = 'R', $LDV \geq K$.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. $LDT \geq K$.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
 $\text{dimension}(\text{MAX}(M, N), K)$

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', $LDWORK \geq \max(1, N)$; if SIDE = 'R', $LDWORK \geq \max(1, M)$.

INTEGER :: N, K, LDV, LDT  
REAL, DIMENSION(:) :: TAU  
REAL, DIMENSION(:, :) :: V, T
```

```
SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
```

```
CHARACTER(LEN=1) :: DIRECT, STOREV  
INTEGER(8) :: N, K, LDV, LDT  
REAL, DIMENSION(:) :: TAU
```

```
REAL, DIMENSION(:, :) :: V, T
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slarzt(char direct, char storev, int n, int k, float  
            *v, int ldv, float *tau, float *t, int ldt);
```

```
void slarzt_64(char direct, char storev, long n, long k,  
               float *v, long ldv, float *tau, float *t, long  
               ldt);
```

PURPOSE

slarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

$$H = I - V * T * V'$$

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

$$H = I - V' * T * V$$

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

= 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)

= 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
 Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):
 = 'R': rowwise

N (input) The order of the block reflector H. $N \geq 0$.

K (input) The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R'
 The matrix V. See further details.

LDV (input)
 The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i).

T (input) The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT (input)
 The leading dimension of the array T. $LDT \geq K$.

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and
 STOREV = 'R':

$$V = \begin{pmatrix} & v1 & v2 & v3 & & \\ (v1 & v2 & v3) & & & \\ & & & & & \\ & & & & & \\ & & & & & \end{pmatrix} \quad \begin{matrix} \text{-----} V \text{-----} \\ / \\ (v1 & v1 & v1 & v1 & v1 & . & . & . & 1 \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \end{matrix}$$

<pre> (v1 v2 v3) . 1) (v1 v2 v3) . . . 1 . . 1 . 1 </pre>	<pre> (v3 v3 v3 v3 v3 . </pre>
---	---------------------------------------

DIRECT = 'B' and STOREV = 'C': STOREV = 'R':	DIRECT = 'B' and
---	------------------

<pre> 1 . 1 . . 1 v2 v2 v2) . . . v3 v3 v3) . . . (v1 v2 v3) V = (v1 v2 v3) (v1 v2 v3) </pre>	$\frac{\text{-----}V\text{-----}}{/}$ <pre> (1 v1 v1 v1 v1 v1) (. 1 . . . v2 v2 (. . 1 . . v3 v3 </pre>

```

```
CHARACTER(LEN=1) :: ID  
INTEGER :: N, INFO  
REAL, DIMENSION(:) :: D
```

```
SUBROUTINE LASRT_64(ID, [N], D, [INFO])
```

```
CHARACTER(LEN=1) :: ID  
INTEGER(8) :: N, INFO  
REAL, DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void slasrt(char id, int n, float *d, int *info);

void slasrt_64(char id, long n, float *d, long *info);
```

PURPOSE

slasrt the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of size ≤ 20 . Dimension of STACK limits N to about 2^{32} .

ARGUMENTS

ID (input)
= 'I': sort D in increasing order;
= 'D': sort D in decreasing order.

N (input) The length of the array D.

D (input/output)
On entry, the array to be sorted. On exit, D has been sorted into increasing order ($D(1) \leq \dots \leq D(N)$) or into decreasing order ($D(1) \geq \dots \geq D(N)$), depending on ID.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void slatzm(char side, int m, int n, float *v, int incv,  
            float tau, float *c1, float *c2, int ldc);
```

```
void slatzm_64(char side, long m, long n, float *v, long  
               incv, float tau, float *c1, float *c2, long ldc);
```

PURPOSE

slatzm routine is deprecated and has been replaced by routine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a matrix.

Let $P = I - \tau u u'$, $u = \begin{pmatrix} 1 \\ v \end{pmatrix}$,

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals $'L'$, let

$$C = \begin{bmatrix} C1 \\ C2 \end{bmatrix} \begin{matrix} 1 \\ m-1 \end{matrix}$$

n

Then C is overwritten by $P * C$.

If $SIDE$ equals $'R'$, let

$$C = \begin{bmatrix} C1 & C2 \end{bmatrix} \begin{matrix} m \\ 1 \end{matrix}$$

$n-1$

Then C is overwritten by $C * P$.

ARGUMENTS

$SIDE$ (input)

= $'L'$: form $P * C$
= $'R'$: form $C * P$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

V (input) $(1 + (M-1)*abs(INCV))$ if $SIDE = 'L'$ $(1 + (N-1)*abs(INCV))$ if $SIDE = 'R'$ The vector v in the representation of P . V is not used if $TAU = 0$.

$INCV$ (input)

The increment between elements of v . $INCV \neq 0$

TAU (input)

The value tau in the representation of P.

C1 (input/output)

(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)

The leading dimension of the arrays C1 and C2. LDC >= (1,M).

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

snrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
REAL FUNCTION SNRM2(N, X, INCX)
```

```
INTEGER N, INCX
```

```
REAL X(*)
```

```
REAL FUNCTION SNRM2_64(N, X, INCX)
```

```
INTEGER*8 N, INCX
```

```
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION NRM2([N], X, [INCX])
```

```
INTEGER :: N, INCX
```

```
REAL, DIMENSION(:) :: X
```

```
REAL FUNCTION NRM2_64([N], X, [INCX])
```

```
INTEGER(8) :: N, INCX
```

```
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
float snrm2(int n, float *x, int incx);
```

```
float snrm2_64(long n, float *x, long incx);
```

PURPOSE

snrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. If INCX < 1 then SNRM2 returns 0. Unchanged on exit.

REAL, DIMENSION(:) :: AP, TAU, WORK  
REAL, DIMENSION(:, :) :: Q
```

C INTERFACE

```
#include <sunperf.h>

void sopgtr(char uplo, int n, float *ap, float *tau, float
            *q, int ldq, int *info);

void sopgtr_64(char uplo, long n, float *ap, float *tau,
               float *q, long ldq, long *info);
```

PURPOSE

sopgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

N (input) The order of the matrix Q . $N \geq 0$.

AP (input)
The vectors which define the elementary reflectors, as returned by SSPTRD.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSPTRD.

Q (output)
The N -by- N orthogonal matrix Q .

LDQ (input)
The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

WORK (workspace)
dimension($N-1$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER :: M, N, LDC, INFO  
REAL, DIMENSION(:) :: AP, TAU, WORK  
REAL, DIMENSION(:, :) :: C
```

```
SUBROUTINE OPMTR_64(SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],  
[WORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS  
INTEGER(8) :: M, N, LDC, INFO  
REAL, DIMENSION(:) :: AP, TAU, WORK
```

```
REAL, DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sopmtr(char side, char uplo, char trans, int m, int n,  
            float *ap, float *tau, float *c, int ldc, int  
            *info);
```

```
void sopmtr_64(char side, char uplo, char trans, long m,  
               long n, float *ap, float *tau, float *c, long ldc,  
               long *info);
```

PURPOSE

sopmtr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by SSPTRD
using packed storage:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

UPLO (input)

= 'U': Upper triangular packed storage used in
previous call to SSPTRD; = 'L': Lower triangular
packed storage used in previous call to SSPTRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

AP (input)

($M*(M+1)/2$) if SIDE = 'L' ($N*(N+1)/2$) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

TAU (input)

or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q*C$ or $Q**T*C$ or $C*Q**T$ or $C*Q$.

LDC (input)

The leading dimension of the array C. LDC $\geq \max(1,M)$.

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

        *tau, int *info);

void sorg2l_64(long m, long n, long k, float *a, long lda,
              float *tau, long *info);

```

PURPOSE

sorg2l L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA (input)

The first dimension of the array A. LDA >= max(1,M).

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK (workspace)

dimension(N)

INFO (output)

INTEGER*8 M, N, K, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGBR(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],  
                [INFO])
```

```
CHARACTER(LEN=1) :: VECT  
INTEGER :: M, N, K, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],  
                   [INFO])
```

```
CHARACTER(LEN=1) :: VECT  
INTEGER(8) :: M, N, K, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK
```

```
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgbr(char vect, int m, int n, int k, float *a, int  
            lda, float *tau, int *info);
```

```
void sorgbr_64(char vect, long m, long n, long k, float *a,  
               long lda, float *tau, long *info);
```

PURPOSE

sorgbr generates one of the real orthogonal matrices Q or P^{**T} determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and SORGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and SORGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{**T} is of order N :

if $k < n$, $P^{**T} = G(k) \dots G(2) G(1)$ and SORGBR returns the first m rows of P^{**T} , where $n \geq m \geq k$;

if $k \geq n$, $P^{**T} = G(n-1) \dots G(2) G(1)$ and SORGBR returns P^{**T} as an N -by- N matrix.

ARGUMENTS

VECT (input)

Specifies whether the matrix Q or the matrix P^{**T} is required, as defined in the transformation applied by SGEBRD:

= 'Q': generate Q ;

= 'P': generate P^{**T} .

M (input) The number of rows of the matrix Q or P^{**T} to be returned. $M \geq 0$.

N (input) The number of columns of the matrix Q or P^{**T} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M, K)$; if $VECT = 'P'$, $N \geq M \geq \min(N, K)$.

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by SGEBRD. $K \geq 0$.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M-by-N matrix Q or P**T.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)
(min(M,K)) if VECT = 'Q' (min(N,K)) if VECT = 'P'
TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**T, as returned by SGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq \max(1, \min(M, N))$. For optimum performance $LWORK \geq \min(M, N) * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD

SYNOPSIS

```
SUBROUTINE SORGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER N, ILO, IHI, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],  
[INFO])
```

```
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorghr(int n, int ilo, int ihi, float *a, int lda,  
float *tau, int *info);
```

```
void sorghr_64(long n, long ilo, long ihi, float *a, long
               lda, float *tau, long *info);
```

PURPOSE

sorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

N (input) The order of the matrix Q . $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N -by- N orthogonal matrix Q .

LDA (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

TAU (input)

$\text{TAU}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEHRD.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)

The dimension of the array WORK . $\text{LWORK} \geq \text{IHI} - \text{ILO}$. For optimum performance $\text{LWORK} \geq (\text{IHI} - \text{ILO}) * \text{NB}$, where NB is the optimal blocksize.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sorgl2 - generate an m by n real matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE SORGL2(M, N, K, A, LDA, TAU, WORK, INFO)
```

```
INTEGER M, N, K, LDA, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGL2_64(M, N, K, A, LDA, TAU, WORK, INFO)
```

```
INTEGER*8 M, N, K, LDA, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGL2([M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
```

```
INTEGER :: M, N, K, LDA, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGL2_64([M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
```

```
INTEGER(8) :: M, N, K, LDA, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgl2(int m, int n, int k, float *a, int lda, float
```

```

        *tau, int *info);

void sorgl2_64(long m, long n, long k, float *a, long lda,
              float *tau, long *info);

```

PURPOSE

sorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA (input)

The first dimension of the array A. LDA >= max(1,M).

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

WORK (workspace)

dimension(M)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument has an illegal value

```
void sorglq(int m, int n, int k, float *a, int lda, float  
*tau, int *info);
```

```
void sorglq_64(long m, long n, long k, float *a, long lda,
              float *tau, long *info);
```

PURPOSE

sorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q . $M \geq 0$.

N (input) The number of columns of the matrix Q . $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

A (input/output)

On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A . On exit, the M -by- N matrix Q .

LDA (input)

The first dimension of the array A . $LDA \geq \max(1, M)$.

TAU (input)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGELQF.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The dimension of the array $WORK$. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message

related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument has an illegal value

void sorgql(int m, int n, int k, float *a, int lda, float  
*tau, int *info);
```

```
void sorgql_64(long m, long n, long k, float *a, long lda,
               float *tau, long *info);
```

PURPOSE

sorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $M \geq N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)
 $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQLF.

WORK (workspace)
On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N \cdot NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

NAME

sorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

SYNOPSIS

```
SUBROUTINE SORGTR(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE SORGTR_64(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGTR(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sorgtr(char uplo, int n, float *a, int lda, float *tau,
            int *info);

void sorgtr_64(char uplo, long n, float *a, long lda, float
               *tau, long *info);

```

PURPOSE

sorgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by SSYTRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A contains elementary reflectors from SSYTRD; = 'L': Lower triangle of A contains elementary reflectors from SSYTRD.

N (input) The order of the matrix Q . $N \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N -by- N orthogonal matrix Q .

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSYTRD.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, N-1)$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               float *c, long ldc, long *info);
```

PURPOSE

sormbr VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'	TRANS = 'N':
Q * C	C * Q	TRANS = 'T':	Q**T * C
Q**T			C * Q**T

If VECT = 'P', SORMBR overwrites the general real M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'
TRANS = 'N':	P * C	C * P
TRANS = 'T':	P**T * C	C * P**T

Here Q and P**T are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P**T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P**T that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix:
 if $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;
 if $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If VECT = 'P', A is assumed to have been a K-by-NQ matrix:
 if $k < nq$, $P = G(1) G(2) \dots G(k)$;
 if $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

ARGUMENTS

VECT (input)
 = 'Q': apply Q or Q**T;
 = 'P': apply P or P**T.

SIDE (input)
 = 'L': apply Q, Q**T, P or P**T from the Left;
 = 'R': apply Q, Q**T, P or P**T from the Right.

TRANS (input)
 = 'N': No transpose, apply Q or P;
 = 'T': Transpose, apply Q**T or P**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the original matrix reduced by SGEHRD. If VECT = 'P', the number of rows in the original matrix reduced by SGEHRD. K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q' (LDA,nq) if
 VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by SGEHRD.

LDA (input)
 The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq,K)).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by SGEHRD in the array argument TAUQ or TAUH.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q or P*C or P**T*C or C*P or C*P**T.

LDC (input)
 The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R',

where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```
REAL, DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sormhr(char side, char trans, int m, int n, int ilo,  
            int ihi, float *a, int lda, float *tau, float *c,  
            int ldc, int *info);
```

```
void sormhr_64(char side, char trans, long m, long n, long  
               ilo, long ihi, float *a, long lda, float *tau,  
               float *c, long ldc, long *info);
```

PURPOSE

sormhr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of IHI-ILO elementary reflectors, as returned by
SGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the
previous call of SGEHRD. Q is equal to the unit
matrix except in the submatrix
 $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. If SIDE = 'L', then $1 \leq$
 $\text{ILO} \leq \text{IHI} \leq M$, if $M > 0$, and $\text{ILO} = 1$ and $\text{IHI} =$
0, if $M = 0$; if SIDE = 'R', then $1 \leq \text{ILO} \leq \text{IHI}$
 $\leq N$, if $N > 0$, and $\text{ILO} = 1$ and $\text{IHI} = 0$, if $N = 0$.

IHI (input)
See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,M) if SIDE = 'L'; LDA \geq max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or CQ^{**T} or CQ .

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               k, float *a, long lda, float *tau, float *c, long
               ldc, long *info);
```

PURPOSE

sormlq overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGELQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector H(i), for $i = 1, 2, \dots, k$, as
returned by SGELQF in the first k rows of its
array argument A. A is modified by the routine
but restored on exit.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by $Q \cdot C$ or $Q^T \cdot C$ or $C \cdot Q^T$ or $C \cdot Q$.

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

            int *info);

void sormql_64(char side, char trans, long m, long n, long
               k, float *a, long lda, float *tau, float *c, long
               ldc, long *info);
```

PURPOSE

sormql overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{**T} * C$ $C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by SGEQLF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{**T} from the Left;
= 'R': apply Q or Q^{**T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{**T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
 The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
 The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

               k, float *a, long lda, float *tau, float *c, long
               ldc, long *info);
```

PURPOSE

sormqr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{**T} * C$ $C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGEQRF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{**T} from the Left;
= 'R': apply Q or Q^{**T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{**T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQRF in the first k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
 The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQRF.

C (input/output)
 On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*T^*C or C^*Q^*T or C^*Q .

LDC (input)
 The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGERQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{**T} from the Left;
= 'R': apply Q or Q^{**T} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{**T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector H(i), for $i = 1, 2, \dots, k$, as
returned by SGERQF in the last k rows of its array
argument A. A is modified by the routine but
restored on exit.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by $Q \cdot C$ or $Q^* \cdot T \cdot C$ or $C \cdot Q^* \cdot T$ or $C \cdot Q$.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               k, long l, float *a, long lda, float *tau, float
               *c, long ldc, long *info);
```

PURPOSE

sormrz overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{**T} * C$ $C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by STZRZF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', M >= K >= 0;
if SIDE = 'R', N >= K >= 0.

L (input) The number of columns of the matrix A containing
the meaningful part of the Householder reflectors.
If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L
>= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The

i-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by STZRZF.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

               long ldc, long *info);
```

PURPOSE

sormtr overwrites the general real M-by-N matrix C with
TRANS = 'T': $Q^{*T} * C$ $C * Q^{*T}$

where Q is a real orthogonal matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by
SSYTRD:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*T} from the Left;
= 'R': apply Q or Q^{*T} from the Right.

UPLO (input)

= 'U': Upper triangle of A contains elementary
reflectors from SSYTRD; = 'L': Lower triangle of A
contains elementary reflectors from SSYTRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q^{*T} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The

vectors which define the elementary reflectors, as returned by SSYTRD.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$ if $SIDE = 'L'$; $LDA \geq \max(1, N)$ if $SIDE = 'R'$.

TAU (input)

$(M-1)$ if $SIDE = 'L'$ $(N-1)$ if $SIDE = 'R'$ TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or CQ^{**T} or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if $SIDE = 'L'$, and $LWORK \geq M \cdot NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

SUBROUTINE PBCON_64(UPLO, [N], KD, A, [LDA], ANORM, RCOND, [WORK],
    [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
C INTERFACE
#include <sunperf.h>

void spbcon(char uplo, int n, int kd, float *a, int lda,
    float anorm, float *rcond, int *info);

void spbcon_64(char uplo, long n, long kd, float *a, long
    lda, float anorm, float *rcond, long *info);

```

PURPOSE

spbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

A (input) The triangular factor U or L from the Cholesky

factorization $A = U^*T^*U$ or $A = L^*L^*T$ of the band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

LDA (input)

The leading dimension of the array A. $LDA \geq KD+1$.

ANORM (input)

The 1-norm (or infinity-norm) of the symmetric band matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

                     INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, LDA, INFO  
REAL SCOND, AMAX  
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,  
                [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE PBEQU_64(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
```

```
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>  
  
void spbequ(char uplo, int n, int kd, float *a, int lda,  
            float *scale, float *scond, float *amax, int  
            *info);  
void spbequ_64(char uplo, long n, long kd, float *a, long  
               lda, float *scale, float *scond, float *amax, long  
               *info);
```

PURPOSE

spbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular of A is stored;
= 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KD \geq 0$.

A (input) The upper or lower triangle of the symmetric band
matrix A, stored in the first KD+1 rows of the
array. The j-th column of A is stored in the j-th
column of the array A as follows: if UPLO = 'U',

```

A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if
UPLO = 'L', A(1+i-j,j) = A(i,j) for
j<=i<=min(n,j+kd).

```

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

SCALE (output)

If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, the i-th diagonal element is nonpositive.

    *a, long lda, float *af, long ldaf, float *b, long
    ldb, float *x, long ldx, float *ferr, float *berr,
    long *info);

```

PURPOSE

spbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
The leading dimension of the array A. LDA \geq KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ of the band matrix A as computed by SPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF \geq KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an

exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)

```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, LDAB, INFO  
REAL AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBSTF(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDAB, INFO  
REAL, DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDAB, INFO  
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void spbstf(char uplo, int n, int kd, float *ab, int ldab,
            int *info);

void spbstf_64(char uplo, long n, long kd, float *ab, long
               ldab, long *info);
```

PURPOSE

spbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.

The factorization has the form $A = S^*T^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & (M \ L) \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^*T^*S$. See Further Details.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13           )
      (      s22  s23  s24      )
      (          s33  s34      )
      (              s44      )
      (          s53  s54  s55  )
      (              s64  s65  s66 )
      (                  s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

on entry:

on exit:

```

*      *  a13  a24  a35  a46  a57  *      *  s13  s24  s53
s64  s75
*  a12  a23  a34  a45  a56  a67  *  s12  s23  s34  s54
s65  s76  a11  a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If UPLO = 'L', the array AB holds:

on entry:

on exit:

```

a11  a22  a33  a44  a55  a66  a77  s11  s22  s33  s44  s55
s66  s77  a21  a32  a43  a54  a65  a76  *  s12  s23  s34
s54  s65  s76  *  a31  a42  a53  a64  a64  *      *  s13
s24  s53  s64  s75  *      *
```

Array elements marked * are not used by the routine.

```

F95 INTERFACE

```
SUBROUTINE PBSV(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE PBSV_64(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void spbsv(char uplo, int n, int kd, int nrhs, float *a, int
           lda, float *b, int ldb, int *info);

void spbsv_64(char uplo, long n, long kd, long nrhs, float
              *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

spbsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite band matrix and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if $UPLO = 'U'$, or

$A = L * L^{**T}$, if $UPLO = 'L'$,

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KD \geq 0$.

$NRHS$ (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(KD+1+i-j,j) = A(i,j)$ for $\max(1,j-$

KD)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j)
for j<=i<=min(N,j+KD). See below for further
details.

On exit, if INFO = 0, the triangular factor U or L
from the Cholesky factorization $A = U^*T^*U$ or $A =$
 L^*L^*T of the band matrix A, in the same storage
format as A.

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B.
On exit, if INFO = 0, the N-by-NRHS solution
matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, the leading minor of order i of
A is not positive definite, so the factorization
could not be completed, and the solution has not
been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following
example, when N = 6, KD = 2, and UPLO = 'U':

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65

On exit:

```
*  
  a31  a42  a53  a64  *    *    131  142  153  164    *  
*
```

Array elements marked * are not used by the routine.

    char equed, float *s, float *b, long ldb, float
    *x, long ldx, float *rcond, float *ferr, float
    *berr, long *info);

```

PURPOSE

spbsvx uses the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite band matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$
Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} * U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{**T}, \quad \text{if UPLO} = 'L',$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix.

3. If the leading i-by-i principal minor is not positive definite,

then the routine returns with INFO = i. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A. If the reciprocal of the condition number is less than machine

precision, INFO = N+1 is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by

$\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is

factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
 = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

NRHS (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(KD+1+i-j, j) = A(i, j)$ for $\max(1, j-KD) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+KD)$. See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq KD+1$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**T*U$ or $A = L*L**T$ of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from

the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq KD+1.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').

= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S))*X$.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in par-

particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. $= N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A :

a11 a12 a13

```

      a22  a23  a24
      a33  a34  a35
      a44  a45  a46
      a55  a56
(aij=conjg(aji))      a66

```

Band storage of the upper triangle of A:

```

      *      *      a13  a24  a35  a46
      *      a12  a23  a34  a45  a56
a11  a22  a33  a44  a55  a66

```

Similarly, if UPLO = 'L' the format of A is as follows:

```

a11  a22  a33  a44  a55  a66
a21  a32  a43  a54  a65  *
a31  a42  a53  a64  *      *

```

Array elements marked * are not used by the routine.

INTEGER*8 N, KD, LDAB, INFO  
REAL AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTf2(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDAB, INFO  
REAL, DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBTf2_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDAB, INFO  
REAL, DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void spbtf2(char uplo, int n, int kd, float *ab, int ldab,
            int *info);

void spbtf2_64(char uplo, long n, long kd, float *ab, long
               ldab, long *info);
```

PURPOSE

spbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization $A = U^*U$ or $A = L^*L'$ of the band matrix A , in the same storage format as A .

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if $UPLO = 'L'$ the format of A is as follows:

On entry:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65
*												
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*
*												

On exit:

Array elements marked * are not used by the routine.

NAME

spbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE SPBTRF(UPLO, N, KD, A, LDA, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, KD, LDA, INFO  
REAL A(LDA,*)
```

```
SUBROUTINE SPBTRF_64(UPLO, N, KD, A, LDA, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, LDA, INFO  
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE PBTRF(UPLO, [N], KD, A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE PBTRF_64(UPLO, [N], KD, A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void spbtrf(char uplo, int n, int kd, float *a, int lda, int
            *info);

void spbtrf_64(char uplo, long n, long kd, float *a, long
               lda, long *info);
```

PURPOSE

spbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$A = U^*U$, if UPLO = 'U', or

$A = L L^*$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^*U$ or $A = L L^*$ of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

On entry:

On exit:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:

On exit:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65
*												
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*
*												

Array elements marked * are not used by the routine.

NAME

spbtrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPBTRF

SYNOPSIS

```
SUBROUTINE SPBTRS(UPLO, N, KD, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, KD, NRHS, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SPBTRS_64(UPLO, N, KD, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, KD, NRHS, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTRS(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, KD, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE PBTRS_64(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void spbtrs(char uplo, int n, int kd, int nrhs, float *a,
            int lda, float *b, int ldb, int *info);

void spbtrs_64(char uplo, long n, long kd, long nrhs, float
               *a, long lda, float *b, long ldb, long *info);
```

PURPOSE

spbtrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^*T \cdot U$ or $A = L \cdot L^*T$ computed by SPBTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky
 factorization $A = U^*T \cdot U$ or $A = L \cdot L^*T$ of the band
 matrix A, stored in the first $KD+1$ rows of the
 array. The j-th column of U or L is stored in the
 j-th column of the array A as follows: if UPLO
 = 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$
 for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $KD+1$.

B (input/output)
 On entry, the right hand side matrix B. On exit,
 the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

    anorm, float *rcond, int *info);

void spocon_64(char uplo, long n, float *a, long lda, float
    anorm, float *rcond, long *info);
```

PURPOSE

spocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ computed by SPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$, as computed by SPOTRF.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

ANORM (input)
 The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
 The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$,
where AINVNM is an estimate of the 1-norm of
inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

NAME

spoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE SPOEQU(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
INTEGER N, LDA, INFO  
REAL SCOND, AMAX  
REAL A(LDA,*), SCALE(*)
```

```
SUBROUTINE SPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
INTEGER*8 N, LDA, INFO  
REAL SCOND, AMAX  
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
INTEGER :: N, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
INTEGER(8) :: N, LDA, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: SCALE  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void spoequ(int n, float *a, int lda, float *scale, float
            *scond, float *amax, int *info);

void spoequ_64(long n, float *a, long lda, float *scale,
               float *scond, float *amax, long *info);
```

PURPOSE

spoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input) The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, the i-th diagonal element is nonpositive.

#include <sunperf.h>
void sporfs(char uplo, int n, int nrhs, float *a, int lda,
            float *af, int ldaf, float *b, int ldb, float *x,
            int ldx, float *ferr, float *berr, int *info);

void sporfs_64(char uplo, long n, long nrhs, float *a, long
               lda, float *af, long ldaf, float *b, long ldb,
               float *x, long ldx, float *ferr, float *berr, long
               *info);

```

PURPOSE

sporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$, as computed by SPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF $\geq \max(1,N)$.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (input/output)
On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1,N)$.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sposv(char uplo, int n, int nrhs, float *a, int lda,
           float *b, int ldb, int *info);

void sposv_64(char uplo, long n, long nrhs, float *a, long
              lda, float *b, long ldb, long *info);

```

PURPOSE

sposv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

LDA (input)
 The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

```

C INTERFACE

```

#include <sunperf.h>

void sposvx(char fact, char uplo, int n, int nrhs, float *a,
    int lda, float *af, int ldaf, char equed, float
    *s, float *b, int ldb, float *x, int ldx, float
    *rcond, float *ferr, float *berr, int *info);

void sposvx_64(char fact, char uplo, long n, long nrhs,
    float *a, long lda, float *af, long ldaf, char
    equed, float *s, float *b, long ldb, float *x,
    long ldx, float *rcond, float *ferr, float *berr,
    long *info);

```

PURPOSE

sposvx uses the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A

is
overwritten by $\text{diag}(S) * A * \text{diag}(S)$ and B by $\text{diag}(S) * B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} * U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{**T}, \quad \text{if UPLO} = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix

A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has

been equilibrated with scaling factors given by S.
A and AF will not be modified. = 'N': The matrix
A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if
necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A, except if FACT =
'F' and EQUED = 'Y', then A must contain the
equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. If UPLO =
'U', the leading N-by-N upper triangular part of A
contains the upper triangular part of the matrix
A, and the strictly lower triangular part of A is
not referenced. If UPLO = 'L', the leading N-by-N
lower triangular part of A contains the lower tri-
angular part of the matrix A, and the strictly
upper triangular part of A is not referenced. A
is not modified if FACT = 'F' or 'N', or if FACT =
'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is
overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq$
 $\max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on
entry contains the triangular factor U or L from
the Cholesky factorization $A = U**T*U$ or $A =$
 $L*L**T$, in the same storage format as A. If EQUED
.ne. 'N', then AF is the factored form of the
equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$.

If FACT = 'N', then AF is an output argument and
on exit returns the triangular factor U or L from
the Cholesky factorization $A = U**T*U$ or $A =$
 $L*L**T$ of the original matrix A.

If FACT = 'E', then AF is an output argument and
on exit returns the triangular factor U or L from

the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF $\geq \max(1, N)$.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A ; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B . LDB $\geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = $N+1$, the N -by- $NRHS$ solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)

The leading dimension of the array X . LDX $\geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0 .

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($3*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 <= N : the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned.
 = $N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

INTEGER :: N, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spotf2(char uplo, int n, float *a, int lda, int *info);

void spotf2_64(char uplo, long n, float *a, long lda, long
               *info);
```

PURPOSE

spotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

#include <sunperf.h>
```

```
void spotrf(char uplo, int n, float *a, int lda, int *info);

void spotrf_64(char uplo, long n, float *a, long lda, long
               *info);
```

PURPOSE

spotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L^{**T}L$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

void spotri_64(char uplo, long n, float *a, long lda, long
               *info);
```

PURPOSE

spotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$, as computed by SPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

void spotrs_64(char uplo, long n, long nrhs, float *a, long
               lda, float *b, long ldb, long *info);
```

PURPOSE

spotrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$ computed by SPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$, as computed by SPOTRF.

LDA (input)
 The leading dimension of the array A . $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)
 The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value

```

```
SUBROUTINE PPCON_64(UPLO, [N], A, ANORM, RCOND, [WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INFO
```

```

INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK

```

C INTERFACE

```

#include <sunperf.h>

void sppcon(char uplo, int n, float *a, float anorm, float
            *rcond, int *info);
void sppcon_64(char uplo, long n, float *a, float anorm,
               float *rcond, long *info);

```

PURPOSE

sppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$ computed by SPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

ANORM (input)
 The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

REAL array, WORK (workspace)

```
dimension(3*N)

WORK2 (workspace)
    INTEGER array, dimension(N)
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an illegal value
```

SUBROUTINE PPEQU(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
REAL :: SCOND, AMAX  
REAL, DIMENSION(:) :: A, SCALE
```

```
SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: A, SCALE

```

C INTERFACE

```

#include <sunperf.h>

void sppequ(char uplo, int n, float *a, float *scale, float
            *scond, float *amax, int *info);

void sppequ_64(char uplo, long n, float *a, float *scale,
               float *scond, float *amax, long *info);

```

PURPOSE

sppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

SCALE (output) REAL array, dimension (N)
 If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
 If INFO = 0, SCALE contains the ratio of the smal-

lest $\text{SCALE}(i)$ to the largest $\text{SCALE}(i)$. If $\text{SCOND} \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by SCALE .

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i -th argument had an illegal value
> 0: if $\text{INFO} = i$, the i -th diagonal element is nonpositive.

C INTERFACE

```
#include <sunperf.h>
void spprfs(char uplo, int n, int nrhs, float *a, float *af,
    float *b, int ldb, float *x, int ldx, float *ferr,
    float *berr, int *info);

void spprfs_64(char uplo, long n, long nrhs, float *a, float
    *af, float *b, long ldb, float *x, long ldx, float
    *ferr, float *berr, long *info);
```

PURPOSE

spprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input) REAL array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U**T*U$ or $A = L*L**T$, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) REAL array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output) REAL array, dimension (LDX,NRHS)
On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output) REAL array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) REAL array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
REAL array, dimension(3*N)

WORK2 (workspace)
INTEGER array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
SUBROUTINE PPSV_64(UPLO, [N], [NRHS], A, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: A  
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>

void sppsv(char uplo, int n, int nrhs, float *a, float *b,
            int ldb, int *info);

void sppsv_64(char uplo, long n, long nrhs, float *a, float
               *b, long ldb, long *info);
```

PURPOSE

sppsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output) REAL array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T$, in the same storage format as A.

B (input/output) REAL array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B.
On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

    *b, long ldb, float *x, long ldx, float *rcond,
    float *ferr, float *berr, long *info);

```

PURPOSE

sppsvx uses the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ to compute the solution to a real system of linear equations

$A * X = B$, where A is an N -by- N symmetric positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A , but if equilibration is used, A is

overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{**T} U, \text{ if UPLO = 'U', or}$$

$$A = L * L^{**T}, \text{ if UPLO = 'L',}$$
 where U is an upper triangular matrix and L is a lower triangular matrix.
3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output) REAL array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

AF (input or output) REAL array, dimension $(N*(N+1)/2)$

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$, in the same storage format as A. If EQUED = 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U'*U$ or $A = L*L'$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').

= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output) REAL array, dimension (N)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output) REAL array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (output) REAL array, dimension (LDX,NRHS)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1,N)$.

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output) REAL array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) REAL array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

```

        change in any element of A or B that makes X(j) an
        exact solution).
WORK (workspace)
        REAL array, dimension (3*N)

WORK2 (workspace)
        INTEGER array, dimension(N)

INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an illegal value
    > 0:  if INFO = i, and i is
    <= N:  the leading minor of order i of A is not
    positive definite, so the factorization could not
    be completed, and the solution has not been computed.
    RCOND = 0 is returned.
    = N+1: U is non-singular, but RCOND is less than machine precision,
    meaning that the matrix is singular to working precision.
    Nevertheless, the solution and error bounds are computed because
    there are a number of situations where the computed solution
    can be more accurate than the value of RCOND would suggest.

```

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A:

```

a11 a12 a13 a14
  a22 a23 a24
    a33 a34    (aij = conjg(aji))
      a44

```

Packed storage of the upper triangle of A:

```

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]

```

```
#include <sunperf.h>

void spptrf(char uplo, int n, float *a, int *info);

void spptrf_64(char uplo, long n, float *a, long *info);
```

PURPOSE

spptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

$A = U^{**T} * U$, if UPLO = 'U', or

$A = L * L^{**T}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) REAL array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, in the same storage format as A.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = aji)
            a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

C INTERFACE

```
#include <sunperf.h>

void spptri(char uplo, int n, float *a, int *info);

void spptri_64(char uplo, long n, float *a, long *info);
```

PURPOSE

spptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*TU$ or $A = L^*L$ computed by SPSTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor is stored in A;
 = 'L': Lower triangular factor is stored in A.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) REAL array, dimension $(N(N+1)/2)$
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*TU$ or $A = L^*L$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

void spptrs(char uplo, int n, int nrhs, float *a, float *b,  
            int ldb, int *info);
```

```
void spptrs_64(char uplo, long n, long nrhs, float *a, float  
               *b, long ldb, long *info);
```

PURPOSE

spptrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$ computed by SPPTRF.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) REAL array, dimension $(N \cdot (N+1)/2)$

The triangular factor U or L from the Cholesky factorization $A = U^* \cdot T \cdot U$ or $A = L \cdot L^* \cdot T$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1) \cdot j/2) = U(i, j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1) \cdot (2n-j)/2) = L(i, j)$ for $j \leq i \leq n$.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

```
INFO (output)
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an ille-
        gal value
```

void sptcon(int n, float *d, float *e, float anorm, float
            *rcond, int *info);

void sptcon_64(long n, float *d, float *e, float anorm,
               float *rcond, long *info);
```

PURPOSE

sptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L*D*L^T$ or $A = U^T*D*U$ computed by SPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by SPTTRF.

E (input) The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, INFO
```

```
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void spteqr(char compz, int n, float *d, float *e, float *z,
            int ldz, int *info);

void spteqr_64(char compz, long n, float *d, float *e, float
               *z, long ldz, long *info);
```

PURPOSE

spteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
 dimension(4*N)

INFO (output)
 = 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

            float *ferr, float *berr, int *info);

void sptrfs_64(long n, long nrhs, float *d, float *e, float
               *df, float *ef, float *b, long ldb, float *x, long
               ldx, float *ferr, float *berr, long *info);

```

PURPOSE

sptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix A.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF (input)
The n diagonal elements of the diagonal matrix D from the factorization computed by SPTTRF.

EF (input)
The (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization computed by SPTTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

void sptsv(int n, int nrhs, float *d, float *e, float *b,
           int ldb, int *info);

void sptsv_64(long n, long nrhs, float *d, float *e, float
              *b, long ldb, long *info);

```

PURPOSE

sptsv computes the solution to a real system of linear equations $A \cdot X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

A is factored as $A = L \cdot D \cdot L^{**T}$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix D from the factorization $A = L \cdot D \cdot L^{**T}$.

E (input/output)
On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L \cdot D \cdot L^{**T}$ factorization of A . (E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^{**T} \cdot D \cdot U$ factorization of A .)

B (input/output)
On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq$

`max(1,N).`

INFO (output)

`= 0:` successful exit
`< 0:` if INFO = -i, the i-th argument had an illegal value
`> 0:` if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

```

#include <sunperf.h>
void sptsvx(char fact, int n, int nrhs, float *d, float *e,
            float *df, float *ef, float *b, int ldb, float *x,
            int ldx, float *rcond, float *ferr, float *berr,
            int *info);

void sptsvx_64(char fact, long n, long nrhs, float *d, float
               *e, float *df, float *ef, float *b, long ldb,
               float *x, long ldx, float *rcond, float *ferr,
               float *berr, long *info);

```

PURPOSE

sptsvx uses the factorization $A = L^*D*L^{**T}$ to compute the solution to a real system of linear equations $A*X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the matrix A is factored as $A = L^*D*L^{**T}$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^{**T}*D*U$.
2. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix
 - A. If the reciprocal of the condition number is less

than machine
precision, INFO = N+1 is returned as a warning, but the
routine
still goes on to solve for X and compute error bounds as
described below.

3. The system of equations is solved for X using the fac-
tored form
of A.

4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, DF
and EF contain the factored form of A. D, E, DF,
and EF will not be modified. = 'N': The matrix A
will be copied to DF and EF and factored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix
A.

E (input) The (n-1) subdiagonal elements of the tridiagonal
matrix A.

DF (input or output)

If FACT = 'F', then DF is an input argument and on
entry contains the n diagonal elements of the
diagonal matrix D from the $L^*D^*L^*T$ factorization
of A. If FACT = 'N', then DF is an output argu-
ment and on exit contains the n diagonal elements
of the diagonal matrix D from the $L^*D^*L^*T$ factor-
ization of A.

EF (input or output)

If FACT = 'F', then EF is an input argument and on
entry contains the (n-1) subdiagonal elements of

the unit bidiagonal factor L from the L^*D*L^{**T} factorization of A . If $FACT = 'N'$, then EF is an output argument and on exit contains the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the L^*D*L^{**T} factorization of A .

B (input) The N -by- $NRHS$ right hand side matrix B .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

X (output)
If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X .

LDX (input)
The leading dimension of the array X . $LDX \geq \max(1, N)$.

$RCOND$ (output)
The reciprocal condition number of the matrix A . If $RCOND$ is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

$FERR$ (output)
The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

$BERR$ (output)
The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

$WORK$ (workspace)
 $\text{dimension}(2*N)$

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 <= N : the leading minor of order i of A is not positive definite, so the factorization could not

be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is non-singular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```
void spttrf(int n, float *d, float *e, int *info);
```

```
void spttrf_64(long n, float *d, float *e, long *info);
```

PURPOSE

spttrf computes the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L^*D^*L' factorization of A.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*D^*L' factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*D^*U factorization of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if $k < N$, the factorization could not be completed, while if $k = N$, the factorization was completed, but $D(N) = 0$.

```

```
SUBROUTINE SPTTRS_64(N, NRHS, D, E, B, LDB, INFO)
```

```
INTEGER*8 N, NRHS, LDB, INFO  
REAL D(*), E(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PTTRS([N], [NRHS], D, E, B, [LDB], [INFO])
```

```
INTEGER :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: D, E  
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE PTTRS_64([N], [NRHS], D, E, B, [LDB], [INFO])
```

```
INTEGER(8) :: N, NRHS, LDB, INFO  
REAL, DIMENSION(:) :: D, E  
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void spttrs(int n, int nrhs, float *d, float *e, float *b,
```

```

        int ldb, int *info);

void spttrs_64(long n, long nrhs, float *d, float *e, float
        *b, long ldb, long *info);

```

PURPOSE

spttrs solves a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D , L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E , and X and B are N by $NRHS$ matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A . $N \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the $L*D*L'$ factorization of A .

E (input) The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L*D*L'$ factorization of A . E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U'*D*U$.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -k$, the k -th argument had an illegal value

```

```

        int ldb);

void sptts2_64(long n, long nrhs, float *d, float *e, float
        *b, long ldb);

```

PURPOSE

sptts2 solves a tridiagonal system of the form
 $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D , L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E , and X and B are N by $NRHS$ matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A . $N \geq 0$.

$NRHS$ (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the $L*D*L'$ factorization of A .

E (input) The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L*D*L'$ factorization of A . E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U'*D*U$.

B (input/output)
 On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X .

LDB (input)
 The leading dimension of the array B . $LDB \geq \max(1, N)$.

NAME

srot - Apply a Given's rotation constructed by SROTG.

SYNOPSIS

```
SUBROUTINE SROT(N, X, INCX, Y, INCY, C, S)
```

```
INTEGER N, INCX, INCY  
REAL C, S  
REAL X(*), Y(*)
```

```
SUBROUTINE SROT_64(N, X, INCX, Y, INCY, C, S)
```

```
INTEGER*8 N, INCX, INCY  
REAL C, S  
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
INTEGER :: N, INCX, INCY  
REAL :: C, S  
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL :: C, S  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void srot(int n, float *x, int incx, float *y, int incy,
          float c, float s);

void srot_64(long n, float *x, long incx, float *y, long
             incy, float c, float s);

```

PURPOSE

srot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

N (input)
 On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
 (1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x.

INCX (input)
 On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)
 (1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
 On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

C (input) On entry, the C rotation value constructed by SROTG. Unchanged on exit.

S (input) On entry, the S rotation value constructed by SROTG. Unchanged on exit.

NAME

srotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE SROTG(A, B, C, S)
```

```
REAL A, B, C, S
```

```
SUBROUTINE SROTG_64(A, B, C, S)
```

```
REAL A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)
```

```
REAL :: A, B, C, S
```

```
SUBROUTINE ROTG_64(A, B, C, S)
```

```
REAL :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srotg(float *a, float *b, float *c, float *s);
```

```
void srotg_64(float *a, float *b, float *c, float *s);
```

PURPOSE

srotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input/output)

On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or $1/C$ depending on which of the input values of A and B is larger.

C (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)

See the description of C.

- [ARGUMENTS](#)

NAME

sroti - Apply an indexed Givens rotation.

SYNOPSIS

```
SUBROUTINE SROTI(NZ, X, INDX, Y, C, S)

INTEGER NZ
INTEGER INDX(*)
REAL C, S
REAL X(*), Y(*)

SUBROUTINE SROTI_64(NZ, X, INDX, Y, C, S)

INTEGER*8 NZ
INTEGER*8 INDX(*)
REAL C, S
REAL X(*), Y(*)

F95 INTERFACE
SUBROUTINE ROTI([NZ], X, INDX, Y, C, S)

INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
REAL :: C, S
REAL, DIMENSION(:) :: X, Y

SUBROUTINE ROTI_64([NZ], X, INDX, Y, C, S)

INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
REAL :: C, S
REAL, DIMENSION(:) :: X, Y
```

PURPOSE

SROTI - Applies a Givens rotation to a sparse vector x stored in compressed form and another vector y in full storage form

```
do i = 1, n
  temp = -s * x(i) + c * y(indx(i))
  x(i) = c * x(i) + s * y(indx(i))
  y(indx(i)) = temp
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector containing the values of the compressed form.

INDX (input) - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input/output)

Vector on input which contains the vector Y in full storage form. On exit, only the elements corresponding to the indices in INDX have been modified.

C (input)

Scalar defining the Givens rotation

S (input)

Scalar defining the Givens rotation

SUBROUTINE ROTM([N], X, [INCX], Y, [INCY], PARAM)
```

```
INTEGER :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y, PARAM
```

```
SUBROUTINE ROTM_64([N], X, [INCX], Y, [INCY], PARAM)
```

```
INTEGER(8) :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y, PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srotm(int n, float *x, int incx, float *y, int incy,  
          float *param);
```

```
void srotm_64(long n, float *x, long incx, float *y, long
              incy, float *param);
```

PURPOSE

srotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, X is overwritten by the updated vector x.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

PARAM (input)

On entry, the rotation values constructed by SROTMG. Unchanged on exit.

```

```
REAL :: D1, D2, B1, B2  
REAL, DIMENSION(:) :: PARAM
```

```
SUBROUTINE ROTMG_64(D1, D2, B1, B2, PARAM)
```

```
REAL :: D1, D2, B1, B2  
REAL, DIMENSION(:) :: PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srotmg(float d1, float d2, float b1, float b2, float  
            *param);
```

```
void srotmg_64(float d1, float d2, float b1, float b2, float
               *param);
```

PURPOSE

srotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

D1 (input/output)

On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

D2 (input/output)

On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

B1 (input/output)

On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

B2 (input)

On entry, the second element of the vector to which the H matrix is applied. Unchanged on exit.

PARAM (output)

On exit, PARAM(1) describes the form of the rotation matrix H, and PARAM(2..5) contain the H matrix.

If PARAM(1) = -2 then H = I and no elements of PARAM are modified.

If PARAM(1) = -1 then PARAM(2) = h11, PARAM(3) = h21, PARAM(4) = h12, and PARAM(5) = h22.

If PARAM(1) = 0 then h11 = h22 = 1, PARAM(3) = h21, and PARAM(4) = h12.

If PARAM(1) = 1 then h12 = 1, h21 = -1, PARAM(2) = h11, and PARAM(5) = h22.

NAME

ssbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

```
SUBROUTINE SSBEV(JOBZ, UPLO, N, KD, A, LDA, W, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, KD, LDA, LDZ, INFO  
REAL A(LDA,*), W(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SSBEV_64(JOBZ, UPLO, N, KD, A, LDA, W, Z, LDZ, WORK,  
INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, KD, LDA, LDZ, INFO  
REAL A(LDA,*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBEV(JOBZ, UPLO, [N], KD, A, [LDA], W, Z, [LDZ], [WORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, KD, LDA, LDZ, INFO  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: A, Z
```

```
SUBROUTINE SBEV_64(JOBZ, UPLO, [N], KD, A, [LDA], W, Z, [LDZ],  
[WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, KD, LDA, LDZ, INFO  
REAL, DIMENSION(:) :: W, WORK
```

```
REAL, DIMENSION(:,:) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbev(char jobz, char uplo, int n, int kd, float *a,  
           int lda, float *w, float *z, int ldz, int *info);
```

```
void ssbev_64(char jobz, char uplo, long n, long kd, float  
              *a, long lda, float *w, float *z, long ldz, long  
              *info);
```

PURPOSE

ssbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd) <= i <= j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j <= i <= min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and

first subdiagonal of T are returned in the first two rows of A.

LDA (input)

The leading dimension of the array A. $LDA \geq KD + 1$.

W (output)

If $INFO = 0$, the eigenvalues in ascending order.

Z (input) If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace)

$\text{dimension}(\text{MAX}(1, 3*N-2))$

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an illegal value

> 0: if $INFO = i$, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

```
SUBROUTINE SSBEVD_64(JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK,  
                    LWORK, IWORK, LIWORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, KD, LDAB, LDZ, LWORK, LIWORK, INFO  
INTEGER*8 IWORK(*)  
REAL AB(LDAB,*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBEVD(JOBZ, UPLO, [N], KD, AB, [LDAB], W, Z, [LDZ], [WORK],  
                [LWORK], [IWORK], [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: AB, Z
```

```
SUBROUTINE SBEVD_64(JOBZ, UPLO, [N], KD, AB, [LDAB], W, Z, [LDZ],  
                   [WORK], [LWORK], [IWORK], [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO
```

```

INTEGER(8) :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: AB, Z

```

C INTERFACE

```

#include <sunperf.h>

void ssbevd(char jobz, char uplo, int n, int kd, float *ab,
            int ldab, float *w, float *z, int ldz, int *info);
void ssbevd_64(char jobz, char uplo, long n, long kd, float
               *ab, long ldab, float *w, float *z, long ldz, long
               *info);

```

PURPOSE

ssbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. KD >= 0.

AB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix A, stored in the first KD+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array AB as follows: if

```

      UPLO = 'U', AB(kd+1+i-j,j) = A(i,j)  for  max(1,j-
      kd)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
      for j<=i<=min(n,j+kd).

```

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)

The leading dimension of the array AB. LDAB >= KD + 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (output)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 2, LWORK must be at least 2*N. If JOBZ = 'V' and N > 2, LWORK must be at least (1 + 5*N + 2*N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array LIWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 2, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

    long *nfound, float *w, float *z, long ldz, long
    *ifail, long *info);

```

PURPOSE

ssbevz computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found;
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the sym-
metric band matrix A, stored in the first KD+1
rows of the array. The j-th column of A is stored
in the j-th column of the array A as follows: if
UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-$
 $kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$
for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated dur-
ing the reduction to tridiagonal form. If UPLO =
'U', the first superdiagonal and the diagonal of
the tridiagonal matrix T are returned in rows KD
and KD+1 of A, and if UPLO = 'L', the diagonal and
first subdiagonal of T are returned in the first
two rows of A.

LDA (input)
The leading dimension of the array A. LDA >= KD +
1.

Q (output)
If JOBZ = 'V', the N-by-N orthogonal matrix used
in the reduction to tridiagonal form. If JOBZ =
'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ =
'V', then LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the
interval to be searched for eigenvalues. VL < VU.
Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of
the smallest and largest eigenvalues to be
returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1
and IU = 0 if $N = 0$. Not referenced if RANGE =
'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)

The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension(7*N)

IWORK2 (workspace)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

               float *x, long ldx, long *info);

```

PURPOSE

ssbgst reduces a real symmetric-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A.

B must have been previously factorized as $S**T*S$ by SPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**T*A*X$, where $X = S**(-1)*Q$ and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

ARGUMENTS

VECT (input)
 = 'N': do not form the transformation matrix X;
 = 'V': form X.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq KB \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix X^*TAX , stored in the same format as A .

LDAB (input)

The leading dimension of the array AB . $LDAB \geq KA+1$.

BB (input)

The banded factor S from the split Cholesky factorization of B , as returned by `SPBSTF`, stored in the first $KB+1$ rows of the array.

LDBB (input)

The leading dimension of the array BB . $LDBB \geq KB+1$.

X (output)

If $VECT = 'V'$, the n -by- n matrix X . If $VECT = 'N'$, the array X is not referenced.

LDX (input)

The leading dimension of the array X . $LDX \geq \max(1,N)$ if $VECT = 'V'$; $LDX \geq 1$ otherwise.

WORK (workspace)

$\text{dimension}(2*N)$

INFO (output)

$= 0$: successful exit
 < 0 : if $INFO = -i$, the i -th argument had an illegal value.

```

PURPOSE

ssbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda) *B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KB \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the sym-
 metric band matrix A, stored in the first ka+1
 rows of the array. The j-th column of A is stored

in the j-th column of the array AB as follows: if
 UPLO = 'U', $AB(ka+1+i-j, j) = A(i, j)$ for $\max(1, j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$
 for $j \leq i \leq \min(n, j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KA+1.

BB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j, j) = B(i, j)$ for $\max(1, j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j, j) = B(i, j)$ for $j \leq i \leq \min(n, j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)

The leading dimension of the array BB. LDBB \geq KB+1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that $Z^*T^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq N.

WORK (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, and i is:
 <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then SPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and

no eigenvalues or eigenvectors were computed.

               float *w, float *z, long ldz, long *info);

```

PURPOSE

ssbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the sym-
metric band matrix A, stored in the first ka+1
rows of the array. The j-th column of A is stored
in the j-th column of the array AB as follows: if
UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-
ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j)
for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >=
KA+1.

BB (input/output)
On entry, the upper or lower triangle of the sym-
metric band matrix B, stored in the first kb+1
rows of the array. The j-th column of B is stored
in the j-th column of the array BB as follows: if
UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-
kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j)
for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky fac-
torization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >=
KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the
matrix Z of eigenvectors, with the i-th column of
Z holding the eigenvector associated with W(i).
The eigenvectors are normalized so $Z^*T^*B^*Z = I$.
If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1,
and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 3*N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 5*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if LIWORK > 0 , IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
 $\leq N$: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;
 $> N$: if INFO = $N + i$, for $1 \leq i \leq N$, then SPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

    long il, long iu, float abstol, long *m, float *w,
    float *z, long ldz, long *ifail, long *info);

```

PURPOSE

ssbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

JOBZ (input)
    = 'N': Compute eigenvalues only;
    = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
    = 'A': all eigenvalues will be found.
    = 'V': all eigenvalues in the half-open interval

```

(VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)

The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KA \geq 0$.

KB (input)

The number of superdiagonals of the matrix B if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KB \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if
UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$
for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KA+1$.

BB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if
UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$
for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

LDBB (input)

The leading dimension of the array BB. $LDBB \geq KB+1$.

Q (output)

If JOBZ = 'V', the n -by- n matrix used in the reduction of $A*x = (\lambda)B*x$ to standard form, i.e. $C*x = (\lambda)x$, and consequently C to triangular form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with INFO > 0, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)
The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU - IL + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so $Z^T B Z = I$.

If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1,
and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

dimension(7*N)

IWORK (workspace/output)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0 : successful exit
< 0 : if INFO = -i, the i-th argument had an illegal value
<= N: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in IFAIL. > N
: SPBSTF returned an error code; i.e., if INFO = N + i, for 1 \leq i \leq N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

INTEGER :: N, K, LDA, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SBMV_64(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX],
```

```
BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, K, LDA, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssbmv(char uplo, int n, int k, float alpha, float *a,  
           int lda, float *x, int incx, float beta, float *y,  
           int incy);  
void ssbmv_64(char uplo, long n, long k, float alpha, float  
              *a, long lda, float *x, long incx, float beta,  
              float *y, long incy);
```

PURPOSE

ssbmv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

K (input)

On entry, K specifies the number of super-diagonals of the matrix A . $K \geq 0$. Unchanged on

exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading ($k + 1$) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row ($k + 1$) of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading ($k + 1$) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

X (input)
(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

                     INFO)
```

```
CHARACTER * 1 VECT, UPLO  
INTEGER*8 N, KD, LDAB, LDQ, INFO  
REAL AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBTRD(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
                [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER :: N, KD, LDAB, LDQ, INFO  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: AB, Q
```

```
SUBROUTINE SBTRD_64(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
                   [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO
```

```

INTEGER(8) :: N, KD, LDAB, LDQ, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: AB, Q

```

C INTERFACE

```
#include <sunperf.h>
```

```

void ssbtrd(char vect, char uplo, int n, int kd, float *ab,
            int ldab, float *d, float *e, float *q, int ldq,
            int *info);

```

```

void ssbtrd_64(char vect, char uplo, long n, long kd, float
               *ab, long ldab, float *d, float *e, float *q, long
               ldq, long *info);

```

PURPOSE

ssbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

VECT (input)

```

= 'N': do not form Q;
= 'V': form Q;
= 'U': update a matrix X, by forming X*Q.

```

UPLO (input)

```

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the

elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

D (output)

The diagonal elements of the tridiagonal matrix T.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i, i+1)$ if UPLO = 'U'; $E(i) = T(i+1, i)$ if UPLO = 'L'.

Q (input/output)

On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product $X*Q$; if VECT = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1, and LDQ \geq N if VECT = 'V' or 'U'.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE SSCAL(N, ALPHA, Y, INCY)
```

```
INTEGER N, INCY  
REAL ALPHA  
REAL Y(*)
```

```
SUBROUTINE SSCAL_64(N, ALPHA, Y, INCY)
```

```
INTEGER*8 N, INCY  
REAL ALPHA  
REAL Y(*)
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
INTEGER :: N, INCY  
REAL :: ALPHA  
REAL, DIMENSION(:) :: Y
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
INTEGER(8) :: N, INCY  
REAL :: ALPHA  
REAL, DIMENSION(:) :: Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sscal(int n, float alpha, float *y, int incy);

void sscal_64(long n, float alpha, float *y, long incy);
```

PURPOSE

sscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

Y (input/output)

($1 + (n - 1) * \text{INCY}$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y. This routine returns immediately if INCY is less than or equal to zero. Unchanged on exit.

NAME

`ssctr` - Scatters elements from `x` into `y`.

SYNOPSIS

```
SUBROUTINE SSCTR(NZ, X, INDX, Y)
```

```
REAL X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE SSCTR_64(NZ, X, INDX, Y)
```

```
REAL X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE SCTR([NZ], X, INDX, Y)
```

```
  REAL, DIMENSION(:) :: X, Y  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE SCTR_64([NZ], X, INDX, Y)
```

```
  REAL, DIMENSION(:) :: X, Y  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

`SSCTR` - Scatters the components of a sparse vector `x` stored in compressed form into specified components of a vector `y`

in full storage form.

```
do i = 1, n
  y(indx(i)) = x(i)
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector containing the values to be scattered from
compressed form into full storage form. Unchanged
on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector whose elements specified by indx have been
set to the corresponding entries of x. Only the
elements corresponding to the indices in indx have
been modified.

DESCRIPTION

sskymm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the skyline format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, integer K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general (NOT SUPPORTED) 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

        5 : Diagonal
        6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
        1 : lower
        2 : upper
DESCRA(3) main diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array consisting of the
                  nonzeros of A in skyline profile form.
                  Row-oriented if DESCRA(2) = 1 (lower triangular),
                  column oriented if DESCRA(2) = 2 (upper triangular).
                  Unchanged on exit.

PNTR (input)     On entry, INDX is an integer array of length
                  M+1 (lower triangular) or K+1 (upper triangular)
                  such that PNTR(I)-PNTR(1)+1 points to the
                  location in VAL of the first element of the skyline
                  profile in row (column) I. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading k by n
                  part of the array B must contain the matrix B,  otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading m by n
                  part of the array C must contain the matrix C,  otherwise
                  the leading k by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

```

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

The SKY data structure is not supported for a general matrix structure (*DESCRA*(1)=0).

Also not supported:

1. lower triangular matrix A of size m by n where $m > n$
2. upper triangular matrix A of size m by n where $m < n$

C INTERFACE

```
#include <sunperf.h>
```

```

void sskysm (int transa, int m, int n, int unitd, float *dv,
float alpha, int *descra, float *val, int *pntr, float *b,
int ldb, float beta, float *c, int ldc);
void sskysm_64 (long transa, long m, long n, long unitd,
float *dv, float alpha, long *descra, float *val, long
*pntr, float *b, long ldb, float beta, float *c, long ldc);

```

DESCRIPTION

sskysm performs one of the matrix-matrix operations

```

C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,

```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the skyline format and op(A) is one of

```

op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).

```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row or column scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which

the rows (columns) have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array.

DESCRA(1) matrix structure

- 0 : general (NOT SUPPORTED)
- 1 : symmetric ($A=A'$)
- 2 : Hermitian ($A= \text{CONJG}(A')$)
- 3 : Triangular
- 4 : Skew(Anti)-Symmetric ($A=-A'$)
- 5 : Diagonal
- 6 : Skew-Hermitian ($A= -\text{CONJG}(A')$)

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL(input) On entry, VAL contains the nonzeros of A in skyline profile form. Row-oriented if DESCRA(2) = 1 (lower triangular), column oriented if DESCRA(2) = 2 (upper triangular). Unchanged on exit if UNITD is not 4. Otherwise, VAL contains entries of $D*A$ or $A*D$ (see section NOTES for further details).

PNTR (input) On entry, INDX is an integer array of length M+1 such that PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element of the skyline profile in row (column) I. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK
>=M*N_CPUS where N_CPUS is the maximum number of
processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the
routine only calculates the optimum size of the WORK array,
returns this value as the first entry of the WORK array,
and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is
fully compatible with NIST FORTRAN Sparse Blas but the sources are different.
Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas.
Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS)
Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included
in this routine. Such tests must be performed before calling
this routine.

2. If UNITD =4, the routine scales the rows of A if
`DESCRA(2)=1` (lower triangular), and the columns of A if
`DESCRA(2)=2` (upper triangular) such that their 2-norms are
one. The scaling may improve the accuracy of the computed
solution. Corresponding entries of VAL are changed only in
this particular case. On exit, DV matrix stored as a vector
contains the diagonal matrix by which the rows (columns)
have been scaled. UNITD=2 if `DESCRA(2)=1` and UNITD=3 if
`DESCRA(2)=2` should be used for the next calls to the routine
with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed
successfully, otherwise `WORK(1) = -i` where i is the row
(column) number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are
each used with the mathematical value 1. The entries of the
main diagonal in the skyline representation of a sparse
matrix don't need to be referenced in this usage but they
need to be 1.0 if they are referenced. However if UNITD=4,
the unit diagonal elements with the mathematical value 1
MUST be referenced in the skyline representation.

INTEGER IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL A(*), WORK(*)
```

```
SUBROUTINE SSPCON_64(UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, IWORK2,  
                    INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
REAL ANORM, RCOND  
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPCON(UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [IWORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: A, WORK
```

```
SUBROUTINE SPCON_64(UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],
    [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
void sspcon(char uplo, int n, float *a, int *ipivot, float
    anorm, float *rcond, int *info);

void sspcon_64(char uplo, long n, float *a, long *ipivot,
    float anorm, float *rcond, long *info);
```

PURPOSE

sspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U \cdot D \cdot U^T$;
 = 'L': Lower triangular, form is $A = L \cdot D \cdot L^T$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) Real array, dimension $(N \cdot (N+1)/2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)

Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

ANORM (input)

The 1-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A , computed as $RCOND = 1/(ANORM * AINVNM)$, where $AINVNM$ is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)

Real array, dimension(2*N)

IWORK2 (workspace)

Integer array, dimension (2*N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

sspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```
SUBROUTINE SSPEV(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, LDZ, INFO  
REAL AP(*), W(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SSPEV_64(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDZ, INFO  
REAL AP(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEV(JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDZ, INFO  
REAL, DIMENSION(:) :: AP, W, WORK  
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE SPEV_64(JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDZ, INFO  
REAL, DIMENSION(:) :: AP, W, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sspev(char jobz, char uplo, int n, float *ap, float *w,
           float *z, int ldz, int *info);

void sspev_64(char jobz, char uplo, long n, float *ap, float
              *w, float *z, long ldz, long *info);
```

PURPOSE

sspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)
 Real array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)
 Real array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors.

tors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

Real array, dimension(3*N)

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

C INTERFACE

```

#include <sunperf.h>

void sspevd(char jobz, char uplo, int n, float *ap, float
            *w, float *z, int ldz, int *info);
void sspevd_64(char jobz, char uplo, long n, float *ap,
               float *w, float *z, long ldz, long *info);

```

PURPOSE

sspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows:
 if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated

during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)

Real array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (input) Real array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Real array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

    float *ap, float vl, float vu, long il, long iu,
    float abtol, long *nfound, float *w, float *z,
    long ldz, long *ifail, long *info);

```

PURPOSE

sspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found;
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A,

packed columnwise in a linear array. The j -th column of A is stored in the array AP as follows:
 if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If $UPLO = 'U'$, the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A , and if $UPLO = 'L'$, the diagonal and first subdiagonal of T overwrite the corresponding elements of A .

VL (input)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

VU (input)

See the description of VL.

IL (input)

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If $ABTOL$ is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when $ABTOL$ is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO>0$, indicating that some eigenvectors did not converge, try setting $ABTOL$ to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,"

by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

Real array, dimension (N) If $\text{INFO} = 0$, the selected eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, $\max(1, M)$) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

Real array, dimension(8*N)

IWORK2 (workspace)

Integer array, dimension (5*N)

IFAIL (output)

Integer array, dimension (N) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```

```
SUBROUTINE SPGST_64(ITYPE, UPLO, [N], AP, BP, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: ITYPE, N, INFO  
REAL, DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```

void sspgst(int itype, char uplo, int n, float *ap, float
            *bp, int *info);

void sspgst_64(long itype, char uplo, long n, float *ap,
               float *bp, long *info);

```

PURPOSE

sspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$.
 If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**T}$ or $L^{**T}*A*L$.

B must have been previously factorized as $U^{**T}*U$ or $L*L^{**T}$ by SPPTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$;
 = 2 or 3: compute $U*A*U^{**T}$ or $L^{**T}*A*L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**T}*U$; = 'L': Lower triangle of A is stored and B is factored as $L*L^{**T}$.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows:
 if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)

Real array, dimension $(N*(N+1)/2)$ The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPSTRF.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

          *info);
```

```
void sspgv_64(long itype, char jobz, char uplo, long n,  
              float *ap, float *bp, float *w, float *z, long  
              ldz, long *info);
```

PURPOSE

sspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*B*x=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)*B*x$
- = 2: $A*B*x = (\lambda)*x$
- = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

- = 'U': Upper triangles of A and B are stored;
- = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows:
if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

W (output)

Real array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**T*B*Z = I$; if ITYPE = 3, $Z**T*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace)

Real array, dimension(3*N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: SPPTRF or SSPEV returned an error code:
 <= N: if INFO = i, SSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

               ldz, long *info);
```

PURPOSE

sspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)*B*x$
- = 2: $A*B*x = (\lambda)*x$
- = 3: $B*A*x = (\lambda)*x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows:
 if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows:
 if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*U$ or $B = L^*L$, in the same storage format as B.

W (output)
 Real array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)
 Real array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows:
 if ITYPE = 1 or 2, $Z^*BZ = I$; if ITYPE = 3, $Z^*inv(B)Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace/output)
 Real array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If $N \leq 1$,

LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPPTRF or SSPEVD returned an error code:
<= N: if INFO = i, SSPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

#include <sunperf.h>

void sspgvx(int itype, char jobz, char range, char uplo, int
           n, float *ap, float *bp, float vl, float vu, int
           il, int iu, float abstol, int *m, float *w, float
           *z, int ldz, int *ifail, int *info);

void sspgvx_64(long itype, char jobz, char range, char uplo,
               long n, float *ap, float *bp, float vl, float vu,
               long il, long iu, float abstol, long *m, float *w,
               float *z, long ldz, long *ifail, long *info);

```

PURPOSE

sspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval

(VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangle of A and B are stored;
= 'L': Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B). $N \geq 0$.

AP (input/output)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$, in the same storage format as B.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b]

of width less than or equal to

$ABSTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

Real array, dimension (N) On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, max(1,M)) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^* T^* B^* Z = I$; if $ITYPE = 3$, $Z^* T^* \text{inv}(B)^* Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)

Real array, dimension(8*N)

IWORK (workspace)

INTEGER array, dimension(5*N)

IFAIL (output)

INTEGER array, dimension (N) If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPPTRF or SSPEVX returned an error code:
 <= N: if INFO = i, SSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL.
 > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

sspmv - perform the matrix-vector operation $y := \alpha A x + \beta y$

SYNOPSIS

```
SUBROUTINE SSPMV(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER N, INCX, INCY  
REAL ALPHA, BETA  
REAL A(*), X(*), Y(*)
```

```
SUBROUTINE SSPMV_64(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, INCX, INCY  
REAL ALPHA, BETA  
REAL A(*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SPMV(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: A, X, Y
```

```
SUBROUTINE SPMV_64(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX, INCY  
REAL :: ALPHA, BETA
```

```
REAL, DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspmv(char uplo, int n, float alpha, float *a, float  
          *x, int incx, float beta, float *y, int incy);
```

```
void sspmv_64(char uplo, long n, float alpha, float *a,  
              float *x, long incx, float beta, float *y, long  
              incy);
```

PURPOSE

sspmv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

A (input)

(($n * (n + 1) / 2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$

contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. Before entry with $UPLO = 'L'$ or $'l'$, the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

$INCX$ (input)

On entry, $INCX$ specifies the increment for the elements of X . $INCX \neq 0$. Unchanged on exit.

$BETA$ (input)

On entry, $BETA$ specifies the scalar β . When $BETA$ is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . On exit, Y is overwritten by the updated vector y .

$INCY$ (input)

On entry, $INCY$ specifies the increment for the elements of Y . $INCY \neq 0$. Unchanged on exit.

REAL X(*), A(*)
```

F95 INTERFACE

```
SUBROUTINE SPR(UPLO, N, ALPHA, X, [INCX], A)
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INCX  
REAL :: ALPHA  
REAL, DIMENSION(:) :: X, A
```

```
SUBROUTINE SPR_64(UPLO, N, ALPHA, X, [INCX], A)
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX  
REAL :: ALPHA
```

```
REAL, DIMENSION(:) :: X, A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspr(char uplo, int n, float alpha, float *x, int incx,  
          float *a);
```

```
void sspr_64(char uplo, long n, float alpha, float *x, long  
             incx, float *a);
```

PURPOSE

sspr performs the symmetric rank 1 operation $A := \alpha x x^T + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

          incx, float *y, int incy, float *ap);
```

```
void sspr2_64(char uplo, long n, float alpha, float *x, long  
             incx, float *y, long incy, float *ap);
```

PURPOSE

sspr2 performs the symmetric rank 2 operation $A := \alpha x x^T + \alpha y y^T + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

X (input)

Real array, dimension $(1 + (n - 1) \cdot \text{abs}(\text{INCX}))$
Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

Y (input)

Real array, dimension $(1 + (n - 1) * \text{abs}(\text{INCY}))$
Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

AP (input/output)

Real array, dimension $((n * (n + 1)) / 2)$ Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix.

C INTERFACE

```

#include <sunperf.h>
void ssprfs(char uplo, int n, int nrhs, float *ap, float
            *af, int *ipivot, float *b, int ldb, float *x, int
            ldx, float *ferr, float *berr, int *info);

void ssprfs_64(char uplo, long n, long nrhs, float *ap,
               float *af, long *ipivot, float *b, long ldb, float
               *x, long ldx, float *ferr, float *berr, float
               *work, long *iwork, long *info);

```

PURPOSE

ssprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) Real array, dimension $(N*(N+1)/2)$ The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

AF (input)
 Real array, dimension $(N*(N+1)/2)$ The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

B (input) Real array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
 Real array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
 Real array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 Real array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 Real array, dimension(3*N)

WORK2 (workspace)
 Integer array, dimension(N)

INFO (output) Integer
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NRHS, LDB, INFO
```

```

INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP
REAL, DIMENSION(:, :) :: B

```

C INTERFACE

```

#include <sunperf.h>

void sspsv(char uplo, int n, int nrhs, float *ap, int
           *ipivot, float *b, int ldb, int *info);

void sspsv_64(char uplo, long n, long nrhs, float *ap, long
             *ipivot, float *b, long ldb, long *info);

```

PURPOSE

sspsv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

AP (input/output)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for

$1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A .

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D , as determined by SSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

Real array, dimension (LDB,NRHS) On entry, the N-by-NRHS right hand side matrix B . On exit, if $INFO = 0$, the N-by-NRHS solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
```

```
      a33 a34      (aij = aji)
      a44
```

Packed storage of the upper triangle of A:

```
AP = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

void sspsvx(char fact, char uplo, int n, int nrhs, float
    *ap, float *af, int *ipivot, float *b, int ldb,
    float *x, int ldx, float *rcond, float *ferr,
    float *berr, int *info);

void sspsvx_64(char fact, char uplo, long n, long nrhs,
    float *ap, float *af, long *ipivot, float *b, long
    ldb, float *x, long ldx, float *rcond, float
    *ferr, float *berr, long *info);

```

PURPOSE

SSPSVX uses the diagonal pivoting factorization $A = U^*D U^{**T}$ or $A = L^*D L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$$A = U * D * U^{**T}, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * D * L^{**T}, \text{ if } UPLO = 'L',$$
 where U (or L) is a product of permutation and unit upper (lower) triangular matrices and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine

precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.

3. The system of equations is solved for X using the factored form
of A.
4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, AF
and IPIVOT contain the factored form of A. AP, AF
and IPIVOT will not be modified. = 'N': The
matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

AP (input)
Real array, dimension $(N*(N+1)/2)$ The upper or
lower triangle of the symmetric matrix A, packed
columnwise in a linear array. The j-th column of
A is stored in the array AP as follows: if UPLO =
'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if
UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for
 $j \leq i \leq n$. See below for further details.

AF (input or output)
Real array, dimension $(N*(N+1)/2)$ If FACT = 'F',
then AF is an input argument and on entry contains
the block diagonal matrix D and the multipliers
used to obtain the factor U or L from the factori-
zation $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by
SSPTRF, stored as a packed triangular matrix in
the same storage format as A.

If FACT = 'N', then AF is an output argument and

on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

B (input) Real array, dimension (LDB,NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

Real array, dimension (LDX,NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

Real array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by

the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

Real array, dimension (NRHS) The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

Real array, dimension(3*N)

WORK2 (workspace)

Integer array, dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: $D(i,i)$ is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. = N+1: D is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = aji)
            a44
```

Packed storage of the upper triangle of A :

AP = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

REAL, DIMENSION(:) :: AP, D, E, TAU
```

C INTERFACE

```
#include <sunperf.h>

void ssptdr(char uplo, int n, float *ap, float *d, float *e,
            float *tau, int *info);

void ssptdr_64(char uplo, long n, float *ap, float *d, float
               *e, float *tau, long *info);
```

PURPOSE

ssptdr reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input)

Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D (output)

Real array, dimension (N) The diagonal elements of the tridiagonal matrix T: $D(i) = A(i,i)$.

E (output)

Real array, dimension (N-1) The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)

Real array, dimension (N-1) The scalar factors of the elementary reflectors (see Further Details).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in AP, overwriting $A(1:i-1,i+1)$, and tau is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in AP, overwriting $A(i+2:n,i)$, and tau is stored in TAU(i).

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:) :: AP
```

```
SUBROUTINE SPTRF_64(UPLO, [N], AP, IPIVOT, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP

```

C INTERFACE

```

#include <sunperf.h>

void ssptrf(char uplo, int n, float *ap, int *ipivot, int
            *info);

void ssptrf_64(char uplo, long n, float *ap, long *ipivot,
               long *info);

```

PURPOSE

ssptrf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Real array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows:
 if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,
i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L * D * L'$, where

$$L = P(1) * L(1) * \dots * P(k) * L(k) * \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \\ & & & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \\ k-1 \quad s \quad n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

            *info);

void ssptri_64(char uplo, long n, float *a, long *ipivot,
               long *info);
```

PURPOSE

ssptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U^*D^*U^{**T}$;
= 'L': Lower triangular, form is $A = L^*D^*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
Real array, dimension $(N*(N+1)/2)$ On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array AP as follows: if UPLO = 'U', $\text{AP}(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $\text{AP}(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

WORK (workspace)

Real array, dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

NAME

ssptrs - solve a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE SSPTRS(UPLO, N, NRHS, AP, IPIVOT, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER N, NRHS, LDB, INFO  
INTEGER IPIVOT(*)  
REAL AP(*), B(LDB,*)
```

```
SUBROUTINE SSPTRS_64(UPLO, N, NRHS, AP, IPIVOT, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 N, NRHS, LDB, INFO  
INTEGER*8 IPIVOT(*)  
REAL AP(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SPTRS(UPLO, [N], [NRHS], AP, IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, NRHS, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL, DIMENSION(:) :: AP  
REAL, DIMENSION(:, :) :: B
```

```
SUBROUTINE SPTRS_64(UPLO, [N], [NRHS], AP, IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP
REAL, DIMENSION(:, :) :: B

```

C INTERFACE

```

#include <sunperf.h>

void sspttrs(char uplo, int n, int nrhs, float *ap, int
             *ipivot, float *b, int ldb, int *info);

void sspttrs_64(char uplo, long n, long nrhs, float *ap, long
                *ipivot, float *b, long ldb, long *info);

```

PURPOSE

sspttrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by SSPTRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
 = 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

AP (input)
 Real array, dimension $(N \cdot (N+1) / 2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

B (input/output)
 Real array, dimension $(LDB, NRHS)$ On entry, the right hand side matrix B . On exit, the solution

matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```

#include <sunperf.h>

void sstebz(char range, char order, int n, float vl, float
            vu, int il, int iu, float abstol, float *d, float
            *e, int *m, int *nsplit, float *w, int *iblock,
            int *isplit, int *info);

void sstebz_64(char range, char order, long n, float vl,
               float vu, long il, long iu, float abstol, float
               *d, float *e, long *m, long *nsplit, float *w,
               long *iblock, long *isplit, long *info);

```

PURPOSE

sstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than $\text{overflow}^{1/2}$ * $\text{underflow}^{1/4}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

RANGE (input)

- = 'A': ("All") all eigenvalues will be found.
- = 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found.
- = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER (input)

- = 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT)

and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N (input) The order of the tridiagonal matrix T. $N \geq 0$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then $ULP*|T|$ will be used, where $|T|$ means the 1-norm of T.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) off-diagonal elements of the tridiagonal matrix T.

M (output)

The actual number of eigenvalues found. $0 \leq M \leq N$. (See also the description of INFO=2,3.)

NSPLIT (output)

The number of diagonal blocks in the matrix T. $1 \leq NSPLIT \leq N$.

W (output)

On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK (output)

At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (SSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT (output)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK (workspace)

dimension(4*N)

IWORK (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: some or all of the eigenvalues failed to converge or were not computed:
=1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found.
Effect: M < IU+1-IL
Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick out eigenvalues IL:IU. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:,:) :: Z
```

```
SUBROUTINE STEDC_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
                   [LIWORK], [INFO])
```

```

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: Z

```

C INTERFACE

```

#include <sunperf.h>

void sstedc(char compz, int n, float *d, float *e, float *z,
            int ldz, int *info);
void sstedc_64(char compz, long n, float *d, float *e, float
               *z, long ldz, long *info);

```

PURPOSE

sstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)

- = 'N': Compute eigenvalues only.
- = 'I': Compute eigenvectors of tridiagonal matrix also.
- = 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.
N >= 0.

D (input/output)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If COMPZ = 'N' or $N \leq 1$ then LWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LWORK must be at least $(1 + 3*N + 2*N*\lg N + 3*N**2)$, where $\lg(N)$ = smallest integer k such that $2**k \geq N$. If COMPZ = 'I' and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$ then LIWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LIWORK must be at least $(6 + 6*N + 5*N*\lg N)$. If COMPZ = 'I' and $N > 1$ then LIWORK must be at least $(3 + 5*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

               ldz, long *isuppz, long *info);

```

PURPOSE

sstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
 (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
 (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.
 The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently SSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine SSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. SSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : SSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 See the description of VL.

IL (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
 See the description of IL.

ABSTOL (input)
 The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. $LWORK \geq \max(1, 18*N)$
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. $LIWORK \geq \max(1, 10*N)$
If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if
INFO = 2, internal error in SLARRV.

#include <sunperf.h>

void sstein(int n, float *d, float *e, int m, float *w, int
            *iblock, int *isplit, float *z, int ldz, int
            *ifail, int *info);

void sstein_64(long n, float *d, float *e, long m, float *w,
               long *iblock, long *isplit, float *z, long ldz,
               long *ifail, long *info);
```

PURPOSE

sstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBCZ with ORDER = 'B' is expected here.)

IBLOCK (input)
The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix

from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)

ISPLIT (input)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)

Z (output)

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ (input)

The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)

dimension(5*N)

IWORK (workspace)

dimension(N)

IFAIL (output)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

NAME

ssteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE SSTEQR(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
INTEGER N, LDZ, INFO  
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE SSTEQR_64(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
INTEGER*8 N, LDZ, INFO  
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEQR_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, INFO  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void ssteqr(char compz, int n, float *d, float *e, float *z,
            int ldz, int *info);

void ssteqr_64(char compz, long n, float *d, float *e, float
               *z, long ldz, long *info);
```

PURPOSE

ssteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I',

Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if eigenvectors are desired, then LDZ \geq max(1,N).

WORK (workspace)

dimension(max(1,2*N-2)) If COMPZ = 'N', then WORK is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: the algorithm has failed to find all the eigenvalues in a total of 30*N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

           int ldz, int *info);

void sstev_64(char jobz, long n, float *d, float *e, float
              *z, long ldz, long *info);
```

PURPOSE

sstev computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E; E(N) need not be set, but is used by the routine. On exit, the contents of E are destroyed.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with D(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

WORK (workspace)
If JOBZ = 'N', WORK is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEVD(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
                [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, WORK  
REAL, DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEVD_64(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
                   [LIWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ
```

```

INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:, :) :: Z

```

C INTERFACE

```

#include <sunperf.h>

void sstevd(char jobz, int n, float *d, float *e, float *z,
            int ldz, int *info);
void sstevd_64(char jobz, long n, float *d, float *e, float
               *z, long ldz, long *info);

```

PURPOSE

sstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix A . On exit, if $INFO = 0$, the eigenvalues in ascending order.

E (input/output)
 On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A , stored in elements 1 to $N-1$ of E ; $E(N)$ need not be set, but is used by the routine. On exit, the contents of E are destroyed.

Z (input) If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A , with the i -th column of Z holding the eigenvector associ-

ated with $D(i)$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension (LWORK) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array $WORK$. If $JOBZ = 'N'$ or $N \leq 1$ then LWORK must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal LIWORK.

LIWORK (input)

The dimension of the array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$ then LIWORK must be at least 1. If $JOBZ = 'V'$ and $N > 1$ then LIWORK must be at least $3+5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, the algorithm failed to converge; i off-diagonal elements of E did not converge to zero.

               ldz, long *isuppz, long *info);

```

PURPOSE

sstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSTEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T ,

(a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$

is a relatively robust representation,

(b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high

relative accuracy by the dqds algorithm,

(c) If there is a cluster of close eigenvalues, "choose" σ_i

close to the cluster, and go to step (a),

(d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$,

compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by

Note 1 : SSTEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSTEVR calls SSTEGBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E; E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$\text{ABSTOL} + \text{EPS} * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = \text{IU} - \text{IL} + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z , i.e., the indices indicating the nonzero elements in Z . The i -th eigenvector is nonzero only in elements $ISUPPZ(2*i-1)$ through $ISUPPZ(2*i)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal (and minimal) $LWORK$.

LWORK (input)

The dimension of the array WORK. $LWORK \geq 20*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal (and minimal) $LIWORK$.

LIWORK (input)

The dimension of the array IWORK. $LIWORK \geq 10*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: Internal error

CHARACTER(LEN=1) :: JOBZ, RANGE
INTEGER(8) :: N, IL, IU, NFOUND, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IWORK2, IFAIL
REAL :: VL, VU, ABTOL
REAL, DIMENSION(:) :: D, E, W, WORK
REAL, DIMENSION(:, :) :: Z

```

C INTERFACE

```

#include <sunperf.h>
void sstevx(char jobz, char range, int n, float *d, float
            *e, float vl, float vu, int il, int iu, float
            abtol, int *nfound, float *w, float *z, int ldz,
            int *ifail, int *info);

void sstevx_64(char jobz, char range, long n, float *d,
               float *e, float vl, float vu, long il, long iu,
               float abtol, long *nfound, float *w, float *z,
               long ldz, long *ifail, long *info);

```

PURPOSE

sstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a

constant factor chosen to avoid over/underflow in computing the eigenvalues.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E; E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge ($\text{INFO} > 0$), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL . If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

dimension($5 \cdot N$)

IWORK2 (workspace)

IFAIL (output)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if $\text{INFO} = -i$, the i-th argument had an illegal value
> 0: if $\text{INFO} = i$, then i eigenvectors failed to converge. Their indices are stored in array IFAIL .

```

```
INTEGER(8) :: N, NRHS, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV  
REAL, DIMENSION(:) :: L, D, SUBL  
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>

void sstsv(int n, int nrhs, float *l, float *d, float *subl,
           float *b, int ldb, int *ipiv, int *info);

void sstsv_64(long n, long nrhs, float *l, float *d, float
              *subl, float *b, long ldb, long *ipiv, long
              *info);
```

PURPOSE

sstsv computes the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides in B.

L (input/output)
REAL array, dimension (N-1)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
REAL array, dimension (N-2)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)

INTEGER

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

#include <sunperf.h>

void ssttrf(int n, float *l, float *d, float *subl, int
            *ipiv, int *info);

void ssttrf_64(long n, float *l, float *d, float *subl, long
               *ipiv, long *info);
```

PURPOSE

ssttrf computes the L^*D^*L' factorization of a real symmetric tridiagonal matrix A using the Bunch-Kaufman diagonal pivoting method.

ARGUMENTS

N (input) INTEGER
 The order of the matrix A. $N \geq 0$.

L (input/output)
 REAL array, dimension (N-1)
 On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
 REAL array, dimension (N)
 On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the $L^*D^*L^{**H}$ factorization of A.

SUBL (output)
 REAL array, dimension (N-2)
 On exit, part of the factorization of A.

IPIV (output)
 INTEGER array, dimension (N)
 On exit, the pivot indices of the factorization.

INFO (output)
 INTEGER
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block

diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

#include <sunperf.h>

void ssttrs(int n, int nrhs, float *l, float *d, float
            *subl, float *b, int ldb, int *ipiv, int *info);

void ssttrs_64(long n, long nrhs, float *l, float *d, float
               *subl, float *b, long ldb, long *ipiv, long
               *info);
```

PURPOSE

ssttrs computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

NRHS (input) INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

L (input) REAL array, dimension (N-1)
On entry, the subdiagonal elements of L.

D (input) REAL array, dimension (N)
On entry, the diagonal elements of D.

SUBL (input) REAL array, dimension (N-2)
On entry, the second subdiagonal elements of L.

B (input/output) REAL array, dimension (LDB, NRHS)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input) INTEGER
The leading dimension of the array B. $LDB \geq \max(1, N)$

IPIV (output) INTEGER array, dimension (N)
Details of the interchanges and block pivot. If

IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1
an interchange done; If IPIV(K) < 0, 2 by 2
pivot, no interchange required.

INFO (output)

INTEGER
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an ille-
gal value

NAME

sswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE SSWAP(N, X, INCX, Y, INCY)
```

```
INTEGER N, INCX, INCY  
REAL X(*), Y(*)
```

```
SUBROUTINE SSWAP_64(N, X, INCX, Y, INCY)
```

```
INTEGER*8 N, INCX, INCY  
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SWAP([N], X, [INCX], Y, [INCY])
```

```
INTEGER :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

```
SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])
```

```
INTEGER(8) :: N, INCX, INCY  
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sswap(int n, float *x, int incx, float *y, int incy);
```

```
void sswap_64(long n, float *x, long incx, float *y, long  
              incy);
```

PURPOSE

sswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

    [IWORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
void ssycon(char uplo, int n, float *a, int lda, int
    *ipivot, float anorm, float *rcond, int *info);

void ssycon_64(char uplo, long n, float *a, long lda, long
    *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

ssycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by SSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U*D*U^{**T}$;
 = 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by SSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

ssyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

SYNOPSIS

```
SUBROUTINE SSYEV(JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, LDA, LDWORK, INFO  
REAL A(LDA,*), W(*), WORK(*)
```

```
SUBROUTINE SSYEV_64(JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)
```

```
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, LDA, LDWORK, INFO  
REAL A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEV(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYEV_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDA, LDWORK, INFO  
REAL, DIMENSION(:) :: W, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssyev(char jobz, char uplo, int n, float *a, int lda,
           float *w, int *info);

void ssyev_64(char jobz, char uplo, long n, float *a, long
              lda, float *w, long *info);
```

PURPOSE

ssyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

W (output)
 If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK \geq max(1,3*N-1). For optimal efficiency, LDWORK \geq (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

                    [IWORK], [LIWORK], [INFO])
```

```

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void ssyevd(char jobz, char uplo, int n, float *a, int lda,
            float *w, int *info);
void ssyevd_64(char jobz, char uplo, long n, float *a, long
               lda, float *w, long *info);

```

PURPOSE

ssyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, SSYEVD needs N^2 more workspace than SSYEVX.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if

INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

    *z, long ldz, long *isuppz, long *info);
```

PURPOSE

ssyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSYEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSYEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSYEVR calls SSTEGBZ and SSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of

M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq \max(1, 26*N)$. For optimal efficiency, LWORK $\geq (NB+6)*N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK $\geq \max(1, 10*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: Internal error

    float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
- = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy,"

by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output)

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. $\text{LDWORK} \geq \max(1, 8*N)$. For optimal efficiency, $\text{LDWORK} \geq (\text{NB} + 3)*N$, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)

IFAIL (output)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value
> 0:  if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.
```

REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SYGS2(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: ITYPE, N, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE SYGS2_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ssygs2(int itype, char uplo, int n, float *a, int lda,
            float *b, int ldb, int *info);

void ssygs2_64(long itype, char uplo, long n, float *a, long
               lda, float *b, long ldb, long *info);

```

PURPOSE

ssygs2 reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $Ax = \lambda Bx$, and A is overwritten by $\text{inv}(U')A\text{inv}(U)$ or $\text{inv}(L)A\text{inv}(L')$. If ITYPE = 2 or 3, the problem is $ABx = \lambda x$ or $B^*Ax = \lambda x$, and A is overwritten by U^*AU' or L'^*AL .

B must have been previously factorized as U^*U or L^*L' by SPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U')A\text{inv}(U)$ or $\text{inv}(L)A\text{inv}(L')$;
 = 2 or 3: compute U^*AU' or L'^*AL .

UPLO (input)
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular
 = 'L': Lower triangular

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
