 On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

ssygst - reduce a real symmetric-definite generalized eigenproblem to standard form

SYNOPSIS

```
SUBROUTINE SSYGST(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER ITYPE, N, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE SSYGST_64(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO  
INTEGER*8 ITYPE, N, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SYGST(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: ITYPE, N, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

```
SUBROUTINE SYGST_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO  
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ssygst(int itype, char uplo, int n, float *a, int lda,
            float *b, int ldb, int *info);

void ssygst_64(long itype, char uplo, long n, float *a, long
               lda, float *b, long ldb, long *info);

```

PURPOSE

ssygst reduces a real symmetric-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $Ax = \lambda Bx$, and A is overwritten by $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$.
 If ITYPE = 2 or 3, the problem is $A * B * x = \lambda x$ or $B * A * x = \lambda x$, and A is overwritten by $U * A * U^{**T}$ or $L^{**T} * A * L$.

B must have been previously factorized as $U^{**T} * U$ or $L * L^{**T}$ by SPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**T}) * A * \text{inv}(U)$ or $\text{inv}(L) * A * \text{inv}(L^{**T})$;
 = 2 or 3: compute $U * A * U^{**T}$ or $L^{**T} * A * L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**T} * U$; = 'L': Lower triangle of A is stored and B is factored as $L * L^{**T}$.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,

stored in the same format as A.

LDA (input)

The leading dimension of the array A. LDA \geq
max(1,N).

B (input) The triangular factor from the Cholesky factoriza-
tion of B, as returned by SPOTRF.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

```
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void ssygv(int itype, char jobz, char uplo, int n, float *a,
           int lda, float *b, int ldb, float *w, int *info);

void ssygv_64(long itype, char jobz, char uplo, long n,
              float *a, long lda, float *b, long ldb, float *w,
              long *info);
```

PURPOSE

ssygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also positive definite.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:
 = 1: $A*x = (\lambda)*B*x$
 = 2: $A*B*x = (\lambda)*x$
 = 3: $B*A*x = (\lambda)*x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or

2, $Z^{**T}B*Z = I$; if $ITYPE = 3$, $Z^{**T}inv(B)*Z = I$.
 If $JOBZ = 'N'$, then on exit the upper triangle (if $UPLO='U'$) or the lower triangle (if $UPLO='L'$) of A , including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1,N)$.

B (input/output)

On entry, the symmetric positive definite matrix B . If $UPLO = 'U'$, the leading N -by- N upper triangular part of B contains the upper triangular part of the matrix B . If $UPLO = 'L'$, the leading N -by- N lower triangular part of B contains the lower triangular part of the matrix B .

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^{**T}U$ or $B = L*L^{**T}$.

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

W (output)

If $INFO = 0$, the eigenvalues in ascending order.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of the array $WORK$. $LDWORK \geq \max(1,3*N-1)$. For optimal efficiency, $LDWORK \geq (NB+2)*N$, where NB is the blocksize for $SSYTRD$ returned by $ILAENV$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

INFO (output)

= 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value
 > 0: $SPOTRF$ or $SSYEV$ returned an error code:
 <= N : if $INFO = i$, $SSYEV$ failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N : if $INFO = N + i$, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no

eigenvalues or eigenvectors were computed.

               long *info);
```

PURPOSE

ssygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)
Specifies the problem type to be solved:
= 1: $A*x = (\lambda)*B*x$
= 2: $A*B*x = (\lambda)*x$
= 3: $B*A*x = (\lambda)*x$

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^T B Z = I$; if ITYPE = 3, $Z^T \text{inv}(B) Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^T U$ or $B = L L^T$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq 2*N+1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 1 + 6*N + 2*N^2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEVD returned an error code:
<= N: if INFO = i, SSYEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

    abstol, long *m, float *w, float *z, long ldz,
    long *ifail, long *info);

```

PURPOSE

ssygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $Ax = (\lambda)Bx$, $ABx = (\lambda)x$, or $B^*Ax = (\lambda)x$. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

ITYPE (input)
    Specifies the problem type to be solved:
    = 1:  $Ax = (\lambda)Bx$ 
    = 2:  $ABx = (\lambda)x$ 
    = 3:  $B^*Ax = (\lambda)x$ 

JOBZ (input)
    = 'N': Compute eigenvalues only;

```

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A and B are stored;
 = 'L': Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B). $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

 On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

 On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

VL (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * DLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'N', then Z is not referenced. If JOBZ

= 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^* T * B * Z = I$; if $ITYPE = 3$, $Z^* T * \text{inv}(B) * Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
 The leading dimension of the array Z. LDZ ≥ 1 ,
 and if JOBZ = 'V', LDZ $\geq \max(1, N)$.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal
 LWORK.

LWORK (input)
 The length of the array WORK. LWORK \geq
 $\max(1, 8*N)$. For optimal efficiency, LWORK \geq
 $(NB+3)*N$, where NB is the blocksize for SSYTRD
 returned by ILAENV.

If LWORK = -1, then a workspace query is assumed;
 the routine only calculates the optimal size of
 the WORK array, returns this value as the first
 entry of the WORK array, and no error message
 related to LWORK is issued by XERBLA.

IWORK (workspace)
 dimension(5*N)

IFAIL (output)
 If JOBZ = 'V', then if INFO = 0, the first M ele-
 ments of IFAIL are zero. If INFO > 0, then IFAIL
 contains the indices of the eigenvectors that
 failed to converge. If JOBZ = 'N', then IFAIL is
 not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: SPOTRF or SSYEVX returned an error code:
 <= N: if INFO = i, SSYEVX failed to converge; i
 eigenvectors failed to converge. Their indices
 are stored in array IFAIL. > N: if INFO = N +
 i, for 1 <= i <= N, then the leading minor of
 order i of B is not positive definite. The fac-
 torization of B could not be completed and no
 eigenvalues or eigenvectors were computed.

FURTHER DETAILS

Based on contributions by
 Mark Fahey, Department of Mathematics, Univ. of Kentucky,

NAME

ssymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE SSYMM(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,  
                LDC)
```

```
CHARACTER * 1 SIDE, UPLO  
INTEGER M, N, LDA, LDB, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

```
SUBROUTINE SSYMM_64(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,  
                  LDC)
```

```
CHARACTER * 1 SIDE, UPLO  
INTEGER*8 M, N, LDA, LDB, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],  
               BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO  
INTEGER :: M, N, LDA, LDB, LDC  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:,:) :: A, B, C
```

```
SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],  
                  BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
```

```

INTEGER(8) :: M, N, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void ssymm(char side, char uplo, int m, int n, float alpha,
           float *a, int lda, float *b, int ldb, float beta,
           float *c, int ldc);

void ssymm_64(char side, char uplo, long m, long n, float
              alpha, float *a, long lda, float *b, long ldb,
              float beta, float *c, long ldc);

```

PURPOSE

ssymm performs one of the matrix-matrix operations $C := \alpha A^*B + \beta C$ or $C := \alpha B^*A + \beta C$ where α and β are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha A^*B + \beta C$,

SIDE = 'R' or 'r' $C := \alpha B^*A + \beta C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, `M` specifies the number of rows of the matrix `C`. `M` ≥ 0 . Unchanged on exit.

`N` (input)

On entry, `N` specifies the number of columns of the matrix `C`. `N` ≥ 0 . Unchanged on exit.

`ALPHA` (input)

On entry, `ALPHA` specifies the scalar `alpha`. Unchanged on exit.

`A` (input)

REAL array of DIMENSION (`LDA`, `ka`), where `ka` is `m` when `SIDE` = 'L' or 'l' and is `n` otherwise.

Before entry with `SIDE` = 'L' or 'l', the `m` by `m` part of the array `A` must contain the symmetric matrix, such that when `UPLO` = 'U' or 'u', the leading `m` by `m` upper triangular part of the array `A` must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of `A` is not referenced, and when `UPLO` = 'L' or 'l', the leading `m` by `m` lower triangular part of the array `A` must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of `A` is not referenced.

Before entry with `SIDE` = 'R' or 'r', the `n` by `n` part of the array `A` must contain the symmetric matrix, such that when `UPLO` = 'U' or 'u', the leading `n` by `n` upper triangular part of the array `A` must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of `A` is not referenced, and when `UPLO` = 'L' or 'l', the leading `n` by `n` lower triangular part of the array `A` must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of `A` is not referenced.

Unchanged on exit.

`LDA` (input)

On entry, `LDA` specifies the first dimension of `A` as declared in the calling (sub) program. When `SIDE` = 'L' or 'l' then `LDA` $\geq \max(1, m)$, otherwise `LDA` $\geq \max(1, n)$. Unchanged on exit.

`B` (input)

REAL array of DIMENSION (`LDB`, `n`). Before entry, the leading `m` by `n` part of the array `B` must contain the matrix `B`. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB \geq max(1, m). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

REAL array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC \geq max(1, m). Unchanged on exit.

REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SYMV(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: X, Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYMV_64(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INCX, INCY  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:) :: X, Y
```

```
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssymv(char uplo, int n, float alpha, float *a, int lda,  
           float *x, int incx, float beta, float *y, int  
           incy);
```

```
void ssymv_64(char uplo, long n, float alpha, float *a, long  
              lda, float *x, long incx, float beta, float *y,  
              long incy);
```

PURPOSE

ssymv performs the matrix-vector operation $y := \alpha A x + \beta y$, where α and β are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly

upper triangular part of A is not referenced.
Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYR_64(UPLO, [N], ALPHA, X, [INCX], A, [LDA])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INCX, LDA
```

```

REAL :: ALPHA
REAL, DIMENSION(:) :: X
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void ssyr(char uplo, int n, float alpha, float *x, int incx,
          float *a, int lda);

void ssyr_64(char uplo, long n, float alpha, float *x, long
             incx, float *a, long lda);

```

PURPOSE

ssyr performs the symmetric rank 1 operation $A := \alpha x x^T + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

```
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssyr2(char uplo, int n, float alpha, float *x, int
           incx, float *y, int incy, float *a, int lda);

void ssyr2_64(char uplo, long n, float alpha, float *x, long
              incx, float *y, long incy, float *a, long lda);
```

PURPOSE

ssyr2 performs the symmetric rank 2 operation $A := \alpha x y' + \alpha y x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

Y (input)
 (1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
 On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

A (input/output)
 Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)
 On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

```
SUBROUTINE SSYR2K_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,  
                     C, LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
INTEGER*8 N, K, LDA, LDB, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYR2K(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],  
                BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
INTEGER :: N, K, LDA, LDB, LDC  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:, :) :: A, B, C
```

```
SUBROUTINE SYR2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,  
                   [LDB], BETA, C, [LDC])
```

```

CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void ssyr2k(char uplo, char transa, int n, int k, float
            alpha, float *a, int lda, float *b, int ldb, float
            beta, float *c, int ldc);
void ssyr2k_64(char uplo, char transa, long n, long k, float
               alpha, float *a, long lda, float *b, long ldb,
               float beta, float *c, long ldc);

```

PURPOSE

ssyr2k performs one of the symmetric rank 2k operations $C := \alpha A A^T + \alpha A^T A + \beta C$ or $C := \alpha A^T B + \alpha B^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \alpha A^T A + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T B + \alpha B^T A + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha * A * B + \alpha * B * A + \beta * C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, ka),
where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

B (input)

REAL array of DIMENSION (LDB, kb),
where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta.
Unchanged on exit.

C (input/output)

REAL array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

```

PURPOSE

ssyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. LDA >=

max(1,N).

AF (input)
 The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^T$ or $A = L*D*L^T$ as computed by SSYTRF.

LDAF (input)
 The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input)
 Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
 On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

LDX (input)
 The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
 The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
 dimension(3*N)

WORK2 (workspace)
 dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

ssyrk - perform one of the symmetric rank k operations C
:= alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

SYNOPSIS

```
SUBROUTINE SSYRK(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
INTEGER N, K, LDA, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), C(LDC,*)
```

```
SUBROUTINE SSYRK_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
INTEGER*8 N, K, LDA, LDC  
REAL ALPHA, BETA  
REAL A(LDA,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYRK(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,  
                  [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
INTEGER :: N, K, LDA, LDC  
REAL :: ALPHA, BETA  
REAL, DIMENSION(:, :) :: A, C
```

```
SUBROUTINE SYRK_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,  
                  C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
INTEGER(8) :: N, K, LDA, LDC
```

```
REAL :: ALPHA, BETA
REAL, DIMENSION(:, :) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssyrk(char uplo, char transa, int n, int k, float
           alpha, float *a, int lda, float beta, float *c,
           int ldc);
```

```
void ssyrk_64(char uplo, char transa, long n, long k, float
              alpha, float *a, long lda, float beta, float *c,
              long ldc);
```

PURPOSE

ssyrk performs one of the symmetric rank k operations $C := \alpha A A^T + \beta C$ or $C := \alpha A^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T A + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha A A^T + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

REAL array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangu-

lar part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void ssysv(char uplo, int n, int nrhs, float *a, int lda,
           int *ipivot, float *b, int ldb, int *info);
void ssysv_64(char uplo, long n, long nrhs, float *a, long
              lda, long *ipivot, float *b, long ldb, long
              *info);
```

PURPOSE

ssysv computes the solution to a real system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*T}$, if UPLO = 'U', or

$A = L * D * L^{*T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D

and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by SSYTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The length of WORK. $LWORK \geq 1$, and for best performance $LWORK \geq N*NB$, where NB is the optimal blocksize for SSYTRF.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

    float *rcond, float *ferr, float *berr, long
    *info);

```

PURPOSE

ssysvx uses the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A .

The form of the factorization is

$A = U * D * U^{**T}$, if $UPLO = 'U'$, or

$A = L * D * L^{**T}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is symmetric and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine

returns with $INFO = i$. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A . If the

reciprocal of the condition number is less than machine precision,

INFO = N+1 is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form

of A.

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from

the factorization $A = U^*D*U^{**T}$ or $A = L^*D*L^{**T}$ as computed by SSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D*U^{**T}$ or $A = L^*D*L^{**T}$.

LDAF (input)

The leading dimension of the array AF. LDAF $\geq \max(1, N)$.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB $\geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX $\geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solu-

tion vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of $WORK$. $LDWORK \geq 3*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for $SSYTRF$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
<= N : $D(i,i)$ is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned. = $N+1$: D is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

REAL A(LDA,*), D(*), E(*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE SYTD2(UPLO, N, A, [LDA], D, E, TAU, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INFO  
REAL, DIMENSION(:) :: D, E, TAU  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYTD2_64(UPLO, N, A, [LDA], D, E, TAU, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INFO  
REAL, DIMENSION(:) :: D, E, TAU  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytd2(char uplo, int n, float *a, int lda, float *d,
            float *e, float *tau, int *info);

void ssytd2_64(char uplo, long n, float *a, long lda, float
               *d, float *e, float *tau, long *info);
```

PURPOSE

ssytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^T A Q = T$.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

D (output)
The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i, i)$.

E (output)
The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i, i+1)$ if UPLO = 'U', $E(i) = A(i+1, i)$ if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(1:i-1, i+1)$, and τ in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n, i)$, and τ in TAU(i).

The contents of A on exit are illustrated by the following

examples with $n = 5$:

```

if UPLO = 'U':
    ( d e v2 v3 v4 )
    )
    ( d e v3 v4 )
    )
    ( d e v4 )
    )
    ( d e )
    )
    ( d )
    )

if UPLO = 'L':
    ( d
    )
    ( e d
    )
    ( v1 e d
    )
    ( v1 v2 e d
    )
    ( v1 v2 v3 e d
    )

```

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

INTEGER*8 N, LDA, INFO  
INTEGER*8 IPIV(*)  
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYTF2(UPLO, [N], A, [LDA], IPIV, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIV  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE SYTF2_64(UPLO, [N], A, [LDA], IPIV, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytf2(char uplo, int n, float *a, int lda, int *ipiv,
            int *info);

void ssytf2_64(char uplo, long n, float *a, long lda, long
               *ipiv, long *info);
```

PURPOSE

ssytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIV (output)

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
 < 0: if $INFO = -k$, the k-th argument had an illegal value
 > 0: if $INFO = k$, $D(k, k)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If $UPLO = 'U'$, then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,

i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If $s = 1$, $D(k)$ overwrites $A(k, k)$, and v overwrites $A(1:k-$

1,k). If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAU, WORK  
REAL, DIMENSION(:,:) :: A
```

```
SUBROUTINE SYTRD_64(UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: D, E, TAU, WORK  
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytrd(char uplo, int n, float *a, int lda, float *d,
            float *e, float *tau, int *info);

void ssytrd_64(char uplo, long n, float *a, long lda, float
               *d, float *e, float *tau, long *info);
```

PURPOSE

ssytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

D (output)

The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 . For optimum performance LWORK $\geq N \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each H(i) has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(1:i-1,i+1)$, and τ in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each H(i) has the form

$$H(i) = I - \tau \cdot v \cdot v'$$

where tau is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n,i)$, and tau in $TAU(i)$. The contents of A on exit are illustrated by the following examples with $n = 5$:

```

if UPLO = 'U':                                if UPLO = 'L':

    (      d      e      v2      v3      v4      )                (      d
)
    (          d      e      v3      v4      )                (      e      d
)
    (              d      e      v4      )                (      v1      e      d
)
    (                  d      e      )                (      v1      v2      e      d
)
    (                      d      )                (      v1      v2      v3      e      d
)

```

where d and e denote diagonal and off-diagonal elements of T, and v_i denotes an element of the vector defining $H(i)$.

[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, LDA, LDWORK, INFO
```

```

INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void ssytrf(char uplo, int n, float *a, int lda, int
            *ipivot, int *info);

void ssytrf_64(char uplo, long n, float *a, long lda, long
               *ipivot, long *info);

```

PURPOSE

ssytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of WORK. $LDWORK \geq 1$. For best performance $LDWORK \geq N \cdot NB$, where NB is the block size returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i, i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If $UPLO = 'U'$, then $A = U^* D^* U$, where

$U = P(n) \cdot U(n) \cdot \dots \cdot P(k) \cdot U(k) \cdot \dots$,

i.e., U is a product of terms $P(k) \cdot U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal

block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$. If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

```
SUBROUTINE SYTRI_64(UPLO, N, A, [LDA], IPIVOT, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>

void ssytri(char uplo, int n, float *a, int lda, int
            *ipivot, int *info);

void ssytri_64(char uplo, long n, float *a, long lda, long
               *ipivot, long *info);

```

PURPOSE

ssytri computes the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by SSYTRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U*D*U^{**T}$;
 = 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

 On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by SSYTRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

void ssytrs_64(char uplo, long n, long nrhs, float *a, long
               lda, long *ipivot, float *b, long ldb, long
               *info);
```

PURPOSE

ssytrs solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A using the factorization $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$ computed by SSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^T$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^T$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

                     WORK2, INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, KD, LDA, INFO  
INTEGER*8 WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND, [WORK],  
                 [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, KD, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK
```

```

REAL, DIMENSION(:,:) :: A

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND,
                  [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, KD, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

```

C INTERFACE

```

#include <sunperf.h>
void stbcon(char norm, char uplo, char diag, int n, int kd,
            float *a, int lda, float *rcond, int *info);

void stbcon_64(char norm, char uplo, char diag, long n, long
               kd, float *a, long lda, float *rcond, long *info);

```

PURPOSE

stbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. $LDA \geq KD+1$.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension($3*N$)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

stbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE STBMV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, K, LDA, INCY  
REAL A(LDA,*), Y(*)
```

```
SUBROUTINE STBMV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, K, LDA, INCY  
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, K, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, K, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stbmvm(char uplo, char transa, char diag, int n, int k,
            float *a, int lda, float *y, int incy);

void stbmvm_64(char uplo, char transa, char diag, long n,
               long k, float *a, long lda, float *y, long incy);
```

PURPOSE

stbmvm performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit

triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N \geq 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K \geq 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE

```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

#include <sunperf.h>
```

```

void stbrfs(char uplo, char transa, char diag, int n, int
            kd, int nrhs, float *a, int lda, float *b, int
            ldb, float *x, int ldx, float *ferr, float *berr,
            int *info);

```

```

void stbrfs_64(char uplo, char transa, char diag, long n,
               long kd, long nrhs, float *a, long lda, float *b,
               long ldb, float *x, long ldx, float *ferr, float
               *berr, long *info);

```

PURPOSE

stbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. STBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

```

= 'U': A is upper triangular;
= 'L': A is lower triangular.

```

TRANSA (input)

```

Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose = Transpose)

```

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals or subdiagonals of
 the triangular band matrix A. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A,
 stored in the first $kd+1$ rows of the array. The
 j-th column of A is stored in the j-th column of
 the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-$
 $j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO =$
 $'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.
 If $DIAG = 'U'$, the diagonal elements of A are not
 referenced and are assumed to be 1.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $KD+1$.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq$
 $\max(1,N)$.

X (input) The solution matrix X.

LDX (input)
 The leading dimension of the array X. $LDX \geq$
 $\max(1,N)$.

FERR (output)
 The estimated forward error bound for each solu-
 tion vector $X(j)$ (the j-th column of the solution
 matrix X). If $XTRUE$ is the true solution
 corresponding to $X(j)$, $FERR(j)$ is an estimated
 upper bound for the magnitude of the largest ele-
 ment in $(X(j) - XTRUE)$ divided by the magnitude of
 the largest element in $X(j)$. The estimate is as
 reliable as the estimate for $RCOND$, and is almost
 always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each

solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, K, LDA, INCY  
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TBSV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, K, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TBSV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, K, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stbsv(char uplo, char transa, char diag, int n, int k,
           float *a, int lda, float *y, int incy);

void stbsv_64(char uplo, char transa, char diag, long n,
              long k, float *a, long lda, float *y, long incy);
```

PURPOSE

stbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N \geq 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K \geq 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k

triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10     CONTINUE
20    CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void stbtrs(char uplo, char transa, char diag, int n, int
            kd, int nrhs, float *a, int lda, float *b, int
            ldb, int *info);

void stbtrs_64(char uplo, char transa, char diag, long n,
               long kd, long nrhs, float *a, long lda, float *b,
               long ldb, long *info);
```

PURPOSE

stbtrs solves a triangular system of the form

$$A * X = B \text{ or } A^{**T} * X = B$$

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j)$

```

        = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L',
        A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If
        DIAG = 'U', the diagonal elements of A are not
        referenced and are assumed to be 1.

LDA (input)
    The leading dimension of the array A. LDA >=
    KD+1.

B (input/output)
    On entry, the right hand side matrix B. On exit,
    if INFO = 0, the solution matrix X.

LDB (input)
    The leading dimension of the array B. LDB >=
    max(1,N).

INFO (output)
    = 0: successful exit
    < 0: if INFO = -i, the i-th argument had an ille-
    gal value
    > 0: if INFO = i, the i-th diagonal element of A
    is zero, indicating that the matrix is singular
    and the solutions X have not been computed.

    long ldvl, float *vr, long ldvr, long mm, long *m,
    long *info);
```

PURPOSE

stgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{*H} * (A - wB) = 0$$

where y^{*H} denotes the conjugate transpose of y.

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices

$$(A0, B0) = (Q*A*Z^{*H}, Q*B*Z^{*H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A.

A must be block upper triangular, with 1-by-1 and 2-by-2

diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)

- = 'R': compute right eigenvectors only;
- = 'L': compute left eigenvectors only;
- = 'B': compute both right and left eigenvectors.

HOWMNY (input)

- = 'A': compute all right and/or left eigenvectors;
- = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE..

N (input) The order of the matrices A and B. $N \geq 0$.

A (input) The upper quasi-triangular matrix A.

LDA (input)

The leading dimension of array A. $LDA \geq \max(1, N)$.

B (input) The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive elements.

LDB (input)

The leading dimension of array B. $LDB \geq \max(1, N)$.

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the

orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

LDVL (input)

The leading dimension of array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)

```

dimension(6*N)

INFO (output)
    = 0:  successful exit.
    < 0:  if INFO = -i, the i-th argument had an illegal value.
    > 0:  the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

```

FURTHER DETAILS

Allocation of workspace:

```

    WORK( j ) = 1-norm of j-th column of A, above the diagonal
    WORK( N+j ) = 1-norm of j-th column of B, above the diagonal
    WORK( 2*N+1:3*N ) = real part of eigenvector
    WORK( 3*N+1:4*N ) = imaginary part of eigenvector
    WORK( 4*N+1:5*N ) = real part of back-transformed eigenvector
    WORK( 5*N+1:6*N ) = imaginary part of back-transformed eigenvector

```

Rowwise vs. columnwise solution methods:

Finding a generalized eigenvector consists basically of solving the singular triangular system

$(A - w B) x = 0$ (for right) or: $(A - w B)^* H y = 0$ (for left)

Consider finding the i-th right eigenvector (assume all eigenvalues are real). The equation to be solved is:

$$0 = \sum_{k=j} C(j,k) v(k) = \sum_{k=j} C(j,k) v(k) \quad \text{for } j = i, \dots, 1$$

where $C = (A - w B)$ (The components $v(i+1:n)$ are 0.)

The "rowwise" method is:

```

(1) v(i) := 1
for j = i-1, .. 1:
    (2) compute  $s = - \sum_{k=j+1}^i C(j,k) v(k)$  and

```

```

    (3) v(j) := s / C(j,j)

```

Step 2 is sometimes called the "dot product" step, since it

is an inner product between the j -th row and the portion of the eigenvector that has been computed so far.

The "columnwise" method consists basically in doing the sums for all the rows in parallel. As each $v(j)$ is computed, the contribution of $v(j)$ times the j -th column of C is added to the partial sums. Since FORTRAN arrays are stored columnwise, this has the advantage that at each step, the elements of C that are accessed are adjacent to one another, whereas with the rowwise method, the elements accessed at a step are spaced LDA (and LDB) words apart.

When finding left eigenvectors, the matrix in question is the transpose of the one in storage, so the rowwise method then actually accesses columns of A and B at each step, and so is the preferred method.

C INTERFACE

```

#include <sunperf.h>

void stgexc(int wantq, int wantz, int n, float *a, int lda,
            float *b, int ldb, float *q, int ldq, float *z,
            int ldz, int *ifst, int *ilst, int *info);

void stgexc_64(long wantq, long wantz, long n, float *a,
               long lda, float *b, long ldb, float *q, long ldq,
               float *z, long ldz, long *ifst, long *ilst, long
               *info);

```

PURPOSE

stgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'$$

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)

On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

Q (input/output)
On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ \geq 1. If WANTQ = .TRUE., LDQ \geq N.

Z (input/output)
On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ \geq 1. If WANTZ = .TRUE., LDZ \geq N.

IFST (input/output)
Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 \leq IFST, ILST \leq N.

ILST (input/output)
See the description of IFST.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK \geq 4*N + 16.
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

=0: successful exit.
<0: if INFO = -i, the i-th argument had an illegal value.
=1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

```

PURPOSE

stgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B . The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal

blocks. B is upper triangular.

STGSEN also computes the generalized eigenvalues

$$w(j) = (\text{ALPHAR}(j) + i*\text{ALPHAI}(j))/\text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, STGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, i.e. the separation(s) between the matrix pairs (A11, B11) and (A22, B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

=0: Only reorder w.r.t. SELECT. No extras.

=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate

(DIF(1:2)).

=3: Estimate of Difu and Difl. 1-norm-based estimate

(DIF(1:2)). About 5 times as expensive as IJOB =

2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, $\text{SELECT}(j)$ must be set to $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either $\text{SELECT}(j)$ or $\text{SELECT}(j+1)$ or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper quasi-triangular matrix A,

with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)

On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

ALPHAI (output)

See the description of ALPHAR.

BETA (output)

See the description of ALPHAR.

Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq 1; and if WANTQ = .TRUE., LDQ \geq N.

Z (input/output)

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left

eigenspaces (deflating subspaces). If WANTZ =
.FALSE., Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1; If
WANTZ = .TRUE., LDZ \geq N.

M (output)

The dimension of the specified pair of left and
right eigen- spaces (deflating subspaces). $0 \leq M$
 $\leq N$.

PL (output)

If IJOB = 1, 4 or 5, PL, PR are lower bounds on
the reciprocal of the norm of "projections" onto
left and right eigenspaces with respect to the
selected cluster. $0 < PL, PR \leq 1$. If M = 0 or M
= N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR
are not referenced.

PR (output)

See the description of PL.

DIF (output)

If IJOB \geq 2, DIF(1:2) store the estimates of Dif_u
and Dif_l.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper
bounds on
Dif_u and Dif_l. If IJOB = 3 or 5, DIF(1:2) are 1-
norm-based estimates of Dif_u and Dif_l. If M = 0
or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or
1, DIF is not referenced.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise,
on exit, if INFO = 0, WORK(1) returns the optimal
LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq 4*N+16$.
If IJOB = 1, 2 or 4, LWORK $\geq \text{MAX}(4*N+16, 2*M*(N-$
M)). If IJOB = 3 or 5, LWORK $\geq \text{MAX}(4*N+16,$
 $4*M*(N-M))$.

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

IWORK (workspace/output)

If IJOB = 0, IWORK is not referenced. Otherwise,
on exit, if INFO = 0, IWORK(1) returns the optimal
LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK ≥ 1 . If IJOB = 1, 2 or 4, LIWORK $\geq N+6$. If IJOB = 3 or 5, LIWORK $\geq \text{MAX}(2*M*(N-M), N+6)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

=0: Successful exit.

<0: If INFO = -i, the i-th argument had an illegal value.

=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

STGSEN first collects the selected eigenvalues by computing orthogonal U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in:

$$U'*(A, B)*W = \begin{pmatrix} A11 & A12 \\ 0 & A22 \end{pmatrix}, \begin{pmatrix} B11 & B12 \\ 0 & B22 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

n1 n2 n1 n2

where $N = n1+n2$ and U' means the transpose of U. The first $n1$ columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair $(C, D) = Q*(A, B)*Z'$, then the reordered generalized real Schur form of (C, D) is given by

$$(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',$$

and the first $n1$ columns of $Q*U$ and $Z*W$ span the corresponding deflating subspaces of (C, D) (Q and Z store $Q*U$ and $Z*W$, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first $n1$ columns of U and W (or

Q^*U and Z^*W) may be returned in $DIF(1:2)$, corresponding to $Difu$ and $Difl$, resp.

The $Difu$ and $Difl$ are defined as:

$ifu[(A11, B11), (A22, B22)] = \text{sigma-min}(Zu)$
and

where $\text{sigma-min}(Zu)$ is the smallest singular value of the $(2*n1*n2)$ -by- $(2*n1*n2)$ matrix

$u = \begin{bmatrix} \text{kron}(In2, A11) & -\text{kron}(A22', In1) \\ \text{kron}(In2, B11) & -\text{kron}(B22', In1) \end{bmatrix}$.

Here, Inx is the identity matrix of size nx and $A22'$ is the transpose of $A22$. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

When $DIF(2)$ is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is $PS * \text{norm}((A, B)) / DIF(2)$,

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with $(A11, B11)$ may be returned in PL and PR . They are computed as follows. First we compute L and R so that $P^*(A, B)*Q$ is block diagonal, where

$$\begin{aligned} &= \begin{pmatrix} I & -L \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \quad Q = \begin{pmatrix} I & R \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \\ &\quad \begin{pmatrix} 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \quad \text{and} \quad \begin{pmatrix} 0 & I \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix} \end{aligned}$$

and (L, R) is the solution to the generalized Sylvester equation $11*R - L*A22 = -A12$

Then $PL = (F\text{-norm}(L)**2+1)**(-1/2)$ and $PR = (F\text{-norm}(R)**2+1)**(-1/2)$. An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is $PS * \text{norm}((A, B)) / PL$.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest $F\text{-norm}(E, F)$ for which an eigenvalue of $(A11, B11)$ may move and coalesce with an eigenvalue of $(A22, B22)$ under perturbation (E, F) , (i.e. $(A + E, B + F)$), is

$$x = \min(Difu, Difl) / ((1/(PL*PL) + 1/(PR*PR))**(1/2) + 2*\max(1/PL, 1/PR)).$$

An approximate bound on x can be computed from $DIF(1:2)$, PL and PR .

If $y = (F\text{-norm}(E, F) / x) \leq 1$, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the $(1,1)$ -blocks can be bounded as

```

max-angle(L, L') <= arctan( y * PL / (1 - y * (1 - PL *
PL)**(1/2))
max-angle(R, R') <= arctan( y * PR / (1 - y * (1 - PR *
PR)**(1/2))

```

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm-based estimate DIF is not wanted (see SLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine SLATDF (IJOB = 2 will be used)). See STGSYL for more details.

Based on contributions by

Bo Kagstrom and Peter Poromaa, Department of Computing Science,
Umea University, S-901 87 Umea, Sweden.

```

PURPOSE

stgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSPV from a general M-by-N matrix A and P-by-N matrix B:

$$A = \begin{array}{ccc} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ L \\ M-K-L \end{matrix} & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix} \end{array} \text{ if } M-K-L \geq 0;$$

$$A = \begin{array}{ccc} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ M-K \end{matrix} & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \end{pmatrix} \end{array} \text{ if } M-K-L < 0;$$

$$B = \begin{array}{c} \begin{array}{ccc} & N-K-L & K & L \\ L & (\begin{array}{ccc} 0 & 0 & B13 \end{array}) \\ P-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array}) \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U'*A*Q = D1*(\begin{array}{cc} 0 & R \end{array}), \quad V'*B*Q = D2*(\begin{array}{cc} 0 & R \end{array}),$$

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:

If M-K-L >= 0,

$$D1 = \begin{array}{c} \begin{array}{ccc} & K & L \\ K & (\begin{array}{cc} I & 0 \end{array}) \\ L & (\begin{array}{cc} 0 & C \end{array}) \\ M-K-L & (\begin{array}{cc} 0 & 0 \end{array}) \end{array}$$

$$D2 = \begin{array}{c} \begin{array}{ccc} & K & L \\ L & (\begin{array}{cc} 0 & S \end{array}) \\ P-L & (\begin{array}{cc} 0 & 0 \end{array}) \end{array}$$

$$\begin{array}{c} \begin{array}{ccc} & N-K-L & K & L \\ (\begin{array}{cc} 0 & R \end{array}) = K & (\begin{array}{ccc} 0 & R11 & R12 \end{array}) K \\ L & (\begin{array}{ccc} 0 & 0 & R22 \end{array}) L \end{array}$$

where

$$\begin{aligned} C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\ S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\ C^{**2} + S^{**2} &= I. \end{aligned}$$

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

$$D1 = \begin{array}{c} \begin{array}{cccc} & K & M-K & K+L-M \\ K & (\begin{array}{ccc} I & 0 & 0 \end{array}) \\ M-K & (\begin{array}{ccc} 0 & C & 0 \end{array}) \end{array}$$

$$D2 = \begin{array}{c} \begin{array}{cccc} & K & M-K & K+L-M \\ M-K & (\begin{array}{ccc} 0 & S & 0 \end{array}) \\ K+L-M & (\begin{array}{ccc} 0 & 0 & I \end{array}) \\ P-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array}) \end{array}$$

$$\begin{array}{c} \begin{array}{cccc} & N-K-L & K & M-K & K+L-M \\ M-K & (\begin{array}{cccc} 0 & 0 & R22 & R23 \end{array}) \end{array}$$

$$K+L-M \begin{pmatrix} 0 & 0 & 0 & R33 \end{pmatrix}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M))$,

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M))$,

$C^{**2} + S^{**2} = I$.

$R = \begin{pmatrix} R11 & R12 & R13 \end{pmatrix}$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored

$\begin{pmatrix} 0 & R22 & R23 \end{pmatrix}$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the orthogonal transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1$, $V1$, or $Q1$.

STGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$U1' * A13 * Q1 = C1 * R1$; $V1' * B13 * Q1 = S1 * R1$,

where $U1$, $V1$ and $Q1$ are orthogonal matrix, and Z' is the transpose of Z . $C1$ and $S1$ are diagonal matrices satisfying

$C1^{**2} + S1^{**2} = I$,

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

JOBV (input)

= 'U': U must contain an orthogonal matrix $U1$ on entry, and the product $U1 * U$ is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV (input)

= 'V': V must contain an orthogonal matrix $V1$ on entry, and the product $V1 * V$ is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ (input)

= 'Q': Q must contain an orthogonal matrix $Q1$ on entry, and the product $Q1 * Q$ is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A . $M \geq 0$.

P (input) The number of rows of the matrix B . $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

K (input) K and L specify the subblocks in the input matrices A and B:
 $A_{23} = A(K+1:\min(K+L,M), N-L+1:N)$ and $B_{13} = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by STGSJA. See Further details.

L (input) See the description of K.

A (input/output)
 On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
 On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)
 TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$.

TOLB (input)
 See the description of TOLA.

ALPHA (output)
 On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $\text{ALPHA}(1:K) = 1$, $\text{BETA}(1:K) = 0$, and if $M-K-L \geq 0$, $\text{ALPHA}(K+1:K+L) = \text{diag}(C)$, $\text{BETA}(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $\text{ALPHA}(K+1:M) = C$, $\text{ALPHA}(M+1:K+L) = 0$, $\text{BETA}(K+1:M) = S$, $\text{BETA}(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $\text{ALPHA}(K+L+1:N) = 0$ and $\text{BETA}(K+L+1:N) = 0$.

BETA (output)
 See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain a matrix

U1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBU = 'I', U contains the orthogonal matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain a matrix V1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBV = 'I', V contains the orthogonal matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the orthogonal matrix returned by SGGSPV). On exit, if JOBQ = 'I', Q contains the orthogonal matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)

dimension(2*N)

NCYCLE (output)

The number of cycles required for convergence.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

    *dif, long mm, long *m, long *info);

```

PURPOSE

stgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q^*A^*Z' , Q^*B^*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
 = 'E': for eigenvalues only (S);

= 'V': for eigenvectors only (DIF);
= 'B': for both eigenvalues and eigenvectors (S
and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigen-
pairs;
= 'S': compute condition numbers for selected
eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs
for which condition numbers are required. To
select condition numbers for the eigenpair
corresponding to a real eigenvalue $w(j)$, SELECT(j)
must be set to .TRUE.. To select condition numbers
corresponding to a complex conjugate pair of
eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or
SELECT(j+1) or both, must be set to .TRUE.. If
HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). $N \geq 0$.

A (input) The upper quasi-triangular matrix A in the pair
(A,B).

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) The upper triangular matrix B in the pair (A,B).

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

VL (input)
If JOB = 'E' or 'B', VL must contain left eigen-
vectors of (A, B), corresponding to the eigenpairs
specified by HOWMNT and SELECT. The eigenvectors
must be stored in consecutive columns of VL, as
returned by STGEVC. If JOB = 'V', VL is not
referenced.

LDVL (input)
The leading dimension of the array VL. $LDVL \geq 1$.
If JOB = 'E' or 'B', $LDVL \geq N$.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigen-
vectors of (A, B), corresponding to the eigenpairs
specified by HOWMNT and SELECT. The eigenvectors

must be stored in consecutive columns of VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq 1. If JOB = 'E' or 'B', LDVR \geq N.

S (output)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM (input)

The number of elements in the arrays S and DIF. MM \geq M.

M (output)

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

WORK (workspace)

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq N. If JOB = 'V' or 'B' LWORK \geq $2*N*(N+2)+16$. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message

related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(N+6) If JOB = 'E', IWORK is not referenced.

INFO (output)
=0: Successful exit
<0: If INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of a generalized eigenvalue $w = (a, b)$ is defined as

$$(w) = (|u'Av|^2 + |u'Bv|^2)^{1/2} / (\text{norm}(u) * \text{norm}(v))$$

where u and v are the left and right eigenvectors of (A, B) corresponding to w ; $|z|$ denotes the absolute value of the complex number, and $\text{norm}(u)$ denotes the 2-norm of the vector u .

The pair (a, b) corresponds to an eigenvalue $w = a/b (= u'Av/u'Bv)$ of the matrix pair (A, B) . If both a and b equal zero, then (A, B) is singular and $S(I) = -1$ is returned.

An approximate error bound on the chordal distance between the i -th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(A, B) / S(I)$$

where EPS is the machine precision.

The reciprocal of the condition number $\text{DIF}(i)$ of right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows:

a) If the i -th eigenvalue $w = (a, b)$ is real

Suppose U and V are orthogonal transformations such that

$$U^*(A, B)V = (S, T) = \begin{pmatrix} a & & \\ & \ddots & \\ & & b \end{pmatrix} \begin{pmatrix} & & \\ & \ddots & \\ & & \end{pmatrix}$$

$$\begin{matrix} 1 & & & \\ & (0 & S_{22}) & \\ & & \ddots & \\ & & & (0 & T_{22}) \\ n-1 & & & & \end{matrix}$$

$$\begin{matrix} & & & & 1 & n-1 & & 1 & n-1 \end{matrix}$$

Then the reciprocal condition number $\text{DIF}(i)$ is

$$\text{Difl}((a, b), (S_{22}, T_{22})) = \text{sigma-min}(Z_1),$$

where $\text{sigma-min}(Z_1)$ denotes the smallest singular value of the $2(n-1)$ -by- $2(n-1)$ matrix

$$Z1 = \begin{bmatrix} \text{kron}(a, In-1) & -\text{kron}(1, S22) \\ \text{kron}(b, In-1) & -\text{kron}(1, T22) \end{bmatrix}.$$

Here $In-1$ is the identity matrix of size $n-1$. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

Note that if the default method for computing $DIF(i)$ is wanted (see SLATDF), then the parameter DIFDRI (see below) should be changed from 3 to 4 (routine SLATDF(IJOB = 2 will be used)). See STGSYL for more details.

b) If the i -th and $(i+1)$ -th eigenvalues are complex conjugate pair,

Suppose U and V are orthogonal transformations such that

$$U'*(A, B)*V = (S, T) = \begin{pmatrix} S11 & * \\ 0 & S22 \end{pmatrix}, \begin{pmatrix} T11 & * \\ 0 & T22 \end{pmatrix}$$

$2 \quad n-2 \quad 2 \quad n-2$

and $(S11, T11)$ corresponds to the complex conjugate eigenvalue pair $(w, \text{conjg}(w))$. There exist unitary matrices $U1$ and $V1$ such that

$$U1'*S11*V1 = \begin{pmatrix} s11 & s12 \\ 0 & s22 \end{pmatrix} \quad \text{and} \quad U1'*T11*V1 = \begin{pmatrix} t11 & t12 \\ 0 & t22 \end{pmatrix}$$

where the generalized eigenvalues $w = s11/t11$ and $\text{conjg}(w) = s22/t22$.

Then the reciprocal condition number $DIF(i)$ is bounded by

$$\min(d1, \max(1, |\text{real}(s11)/\text{real}(s22)|)*d2)$$

where, $d1 = \text{Difl}((s11, t11), (s22, t22)) = \text{sigma-min}(Z1)$, where $Z1$ is the complex 2-by-2 matrix

$$Z1 = \begin{bmatrix} s11 & -s22 \\ t11 & -t22 \end{bmatrix},$$

This is done by computing (using real arithmetic) the

roots of the characteristic polynomial $\det(Z1' * Z1 - \lambda I)$,
 where $Z1'$ denotes the conjugate transpose of $Z1$ and
 $\det(X)$ denotes
 the determinant of X .

and $d2$ is an upper bound on $\text{Difl}((S11, T11), (S22, T22))$,
 i.e. an
 upper bound on $\sigma\text{-min}(Z2)$, where $Z2$ is $(2n-2)\text{-by-}(2n-2)$

$$Z2 = \begin{bmatrix} \text{kron}(S11', I_{n-2}) & -\text{kron}(I2, S22) \\ \text{kron}(T11', I_{n-2}) & -\text{kron}(I2, T22) \end{bmatrix}$$

Note that if the default method for computing DIF is
 wanted (see
 SLATDF), then the parameter DIFDRI (see below) should be
 changed
 from 3 to 4 (routine SLATDF(IJOB = 2 will be used)). See
 STGSYL
 for more details.

For each eigenvalue/vector specified by SELECT, DIF stores a
 Frobenius norm-based estimate of Difl .

An approximate error bound for the i -th computed eigenvector
 $VL(i)$ or $VR(i)$ is given by

$$\text{EPS} * \text{norm}(A, B) / \text{DIF}(i).$$

See ref. [2-3] for more details and further references.

```

PURPOSE

stgsyl solves the generalized Sylvester equation:

$$\begin{aligned}
 A * R - L * B &= \text{scale} * C \\
 D * R - L * E &= \text{scale} * F
 \end{aligned}
 \tag{1}$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale } b$, where Z is defined as

$$\begin{aligned}
 Z = [& \text{kron}(I_n, A) \quad -\text{kron}(B', I_m)] \\
 & [\text{kron}(I_n, D) \quad -\text{kron}(E', I_m)].
 \end{aligned}
 \tag{2}$$

Here I_k is the identity matrix of size k and X' is the transpose of X. $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If TRANS = 'T', STGSYL solves the transposed system $Z'y = \text{scale} * b$, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * (-F) \end{aligned} \quad (3)$$

This case (TRANS = 'T') is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If IJOB >= 1, STGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

TRANS (input)
 = 'N', solve the generalized Sylvester equation (1).
 = 'T', solve the 'transposed' system (3).

IJOB (input)
 Specifies what kind of functionality to be performed.
 =0: solve (1) only.
 =1: The functionality of 0 and 3.
 =2: The functionality of 0 and 4.
 =3: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (look ahead strategy IJOB = 1 is used).
 =4: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (SGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper quasi triangular matrix A.

LDA (input)
 The leading dimension of the array A. LDA >= max(1, M).

B (input) The upper quasi triangular matrix B.

LDB (input)
 The leading dimension of the array B. LDB >= max(1, N).

C (input/output)
 On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the

solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)

The leading dimension of the array C. LDC \geq max(1, M).

D (input) The upper triangular matrix D.

LDD (input)

The leading dimension of the array D. LDD \geq max(1, M).

E (input) The upper triangular matrix E.

LDE (input)

The leading dimension of the array E. LDE \geq max(1, N).

F (input/output)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)

The leading dimension of the array F. LDF \geq max(1, M).

DIF (output)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

SCALE (output)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK \geq 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(M+N+6)

INFO (output)
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or close eigenvalues.

REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: A, WORK
```

```
SUBROUTINE TPCON_64(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],
```

[INFO])

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>

void stpcon(char norm, char uplo, char diag, int n, float
            *a, float *rcond, int *info);
void stpcon_64(char norm, char uplo, char diag, long n,
               float *a, float *rcond, long *info);
```

PURPOSE

stpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO =

'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if
 UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for
 $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of
 A are not referenced and are assumed to be 1.

RCOND (output)

The reciprocal of the condition number of the
 matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

REAL array, dimension(3*N)

WORK2 (workspace)

INTEGER array, dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

NAME

stpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

SYNOPSIS

```
SUBROUTINE STPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, INCY  
REAL A(*), Y(*)
```

```
SUBROUTINE STPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, INCY  
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, INCY  
REAL, DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, INCY  
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void stpmv(char uplo, char transa, char diag, int  n, float
           *a, float *y, int incy);

void stpmv_64(char uplo, char transa, char diag, long n,
              float *a, float *y, long incy);

```

PURPOSE

stpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A.
N \geq 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

```

```

INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: A, FERR, BERR, WORK
REAL, DIMENSION(:, :) :: B, X

```

C INTERFACE

```

#include <sunperf.h>

void stprfs(char uplo, char transa, char diag, int n, int
            nrhs, float *a, float *b, int ldb, float *x, int
            ldx, float *ferr, float *berr, int *info);
void stprfs_64(char uplo, char transa, char diag, long n,
               long nrhs, float *a, float *b, long ldb, float *x,
               long ldx, float *ferr, float *berr, long *info);

```

PURPOSE

stprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. STPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$
The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B (input) REAL array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (input) REAL array, dimension (LDX,NRHS)
The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1,N)$.

FERR (output) REAL array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) REAL array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
REAL array, dimension(3*N)

WORK2 (workspace)
INTEGER array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

stpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$

SYNOPSIS

```
SUBROUTINE STPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, INCY  
REAL A(*), Y(*)
```

```
SUBROUTINE STPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, INCY  
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, INCY  
REAL, DIMENSION(:) :: A, Y
```

```
SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, INCY  
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```

void stpsv(char uplo, char transa, char diag, int  n, float
           *a, float *y, int incy);

void stpsv_64(char uplo, char transa, char diag, long n,
              float *a, float *y, long incy);

```

PURPOSE

stpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

($1 + (n-1)*abs(INCY)$). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

stptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE STPTRI(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER N, INFO  
REAL A(*)
```

```
SUBROUTINE STPTRI_64(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER*8 N, INFO  
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER :: N, INFO  
REAL, DIMENSION(:) :: A
```

```
SUBROUTINE TPTRI_64(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER(8) :: N, INFO  
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stptri(char uplo, char diag, int n, float *a, int
            *info);

void stptri_64(char uplo, char diag, long n, float *a, long
               *info);
```

PURPOSE

stptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) REAL array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = 1, J
          A(JC+I-1) = A(I,J)
A(I,J)
      1    CONTINUE
        JC = JC + J
1
      2 CONTINUE

```

UPLO = 'L':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = J, N
          A(JC+I-J) =
1    CONTINUE
        JC = JC + N - J +
2 CONTINUE

```

REAL, DIMENSION(:) :: A  
REAL, DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stptrs(char uplo, char transa, char diag, int n, int  
            nrhs, float *a, float *b, int ldb, int *info);
```

```
void stptrs_64(char uplo, char transa, char diag, long n,
               long nrhs, float *a, float *b, long ldb, long
               *info);
```

PURPOSE

stptrs solves a triangular system of the form

$A * X = B$ or $A^{**T} * X = B$

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) REAL array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

B (input/output) REAL array,

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

strans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE STRANS(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
INTEGER M, N  
REAL SCALE  
REAL SOURCE(*), DEST(*)
```

```
SUBROUTINE STRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
INTEGER*8 M, N  
REAL SCALE  
REAL SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER :: M, N  
REAL :: SCALE  
REAL, DIMENSION(:) :: SOURCE, DEST
```

```
SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
INTEGER(8) :: M, N  
REAL :: SCALE  
REAL, DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>

void strans(char place, float scale, float *source, int m,
            int n, float *dest);

void strans_64(char place, float scale, float *source, long
               m, long n, float *dest);
```

PURPOSE

strans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)

Scale factor on the SOURCE matrix.

SOURCE (input/output)

(M, N) on input. Array of (N, M) on output if in-place transpose.

M (input)

Number of rows in the SOURCE matrix on input.

N (input)

Number of columns in the SOURCE matrix on input.

DEST (output)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

strcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE STRCON(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
                  INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER N, LDA, INFO  
INTEGER WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

```
SUBROUTINE STRCON_64(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
                    INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
INTEGER*8 N, LDA, INFO  
INTEGER*8 WORK2(*)  
REAL RCOND  
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK], [WORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRCON_64(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
                   [WORK2], [INFO])
```

```

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: A

```

C INTERFACE

```

#include <sunperf.h>
void strcon(char norm, char uplo, char diag, int n, float
            *a, int lda, float *rcond, int *info);

void strcon_64(char norm, char uplo, char diag, long n,
               float *a, long lda, float *rcond, long *info);

```

PURPOSE

strcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$RCOND = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangu-

lar part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:, :) :: T, VL, VR

```

C INTERFACE

```

#include <sunperf.h>

void strevc(char side, char howmny, int *select, int n,
            float *t, int ldt, float *vl, int ldvl, float *vr,
            int ldvr, int mm, int *m, int *info);
void strevc_64(char side, char howmny, long *select, long n,
               float *t, long ldt, float *vl, long ldvl, float
               *vr, long ldvr, long mm, long *m, long *info);

```

PURPOSE

strevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T .

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y .

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T , or the products $Q*X$ and/or $Q*Y$, where Q is an input orthogonal

matrix. If T was obtained from the real-Schur factorization of an original matrix $A = Q*T*Q'$, then $Q*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A .

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)

- = 'R': compute right eigenvectors only;
- = 'L': compute left eigenvectors only;
- = 'B': compute both right and left eigenvectors.

HOWMNY (input)

- = 'A': compute all right and/or left eigenvectors;
- = 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL;
- = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex conjugate pair $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)

The upper quasi-triangular matrix T in Schur canonical form.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL has the same quasi-lower triangular form as T'. If $T(i, i)$ is a real eigenvalue, then the i-th column VL(i) of VL is its corresponding eigenvector. If $T(i:i+1, i:i+1)$ is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then $VL(i) + \sqrt{-1} * VL(i+1)$ is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix $Q * Y$; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same

order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VR(i)+sqrt(-1)*VR(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)

dimension(3*N)

```
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i,  the i-th argument had an
          illegal value
```

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.

                     INFO)
```

```
CHARACTER * 1 COMPQ  
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO  
REAL T(LDT,*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],  
                [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO  
REAL, DIMENSION(:) :: WORK  
REAL, DIMENSION(:, :) :: T, Q
```

```
SUBROUTINE TREXC_64(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],  
                   [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO  
REAL, DIMENSION(:) :: WORK
```

```
REAL, DIMENSION(:,:) :: T, Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strexc(char compq, int n, float *t, int ldt, float *q,  
            int ldq, int *ifst, int *ilst, int *info);
```

```
void strexc_64(char compq, long n, float *t, long ldt, float  
               *q, long ldq, long *ifst, long *ilst, long *info);
```

PURPOSE

strexc reorders the real Schur factorization of a real matrix $A = Q^*TQ$, so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation $Z^*T^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

COMPQ (input)

= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q .

N (input) The order of the matrix T . $N \geq 0$.

T (input/output)

On entry, the upper quasi-triangular matrix T , in Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT (input)

The leading dimension of the array T . $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T . If COMPQ = 'N', Q is

not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ \geq max(1,N).

IFST (input/output)

Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). $1 \leq \text{IFST} \leq N$; $1 \leq \text{ILST} \leq N$.

ILST (input/output)

See the description of IFST.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

strmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$

SYNOPSIS

```
SUBROUTINE STRMM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,  
                LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG  
INTEGER M, N, LDA, LDB  
REAL ALPHA  
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE STRMM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,  
                  LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG  
INTEGER*8 M, N, LDA, LDB  
REAL ALPHA  
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRMM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],  
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG  
INTEGER :: M, N, LDA, LDB  
REAL :: ALPHA  
REAL, DIMENSION(:,:) :: A, B
```

```
SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,  
                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG  
INTEGER(8) :: M, N, LDA, LDB
```

```
REAL :: ALPHA
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void strmm(char side, char uplo, char transa, char diag, int
           m, int n, float alpha, float *a, int lda, float
           *b, int ldb);

void strmm_64(char side, char uplo, char transa, char diag,
              long m, long n, float alpha, float *a, long lda,
              float *b, long ldb);
```

PURPOSE

strmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$\text{op}(A) = A$ or $\text{op}(A) = A'$.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are

assumed to be one. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

B (input/output)

REAL array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void strmv(char uplo, char transa, char diag, int n, float
           *a, int lda, float *y, int incy);

void strmv_64(char uplo, char transa, char diag, long n,
              float *a, long lda, float *y, long incy);
```

PURPOSE

strmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := A'*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A.
N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

#include <sunperf.h>

void strrfs(char uplo, char transa, char diag, int n, int
    nrhs, float *a, int lda, float *b, int ldb, float
    *x, int ldx, float *ferr, float *berr, int *info);
void strrfs_64(char uplo, char transa, char diag, long n,
    long nrhs, float *a, long lda, float *b, long ldb,
    float *x, long ldx, float *ferr, float *berr, long
    *info);

```

PURPOSE

strrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. STRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

    *wi, int *m, float *s, float *sep, int *info);

void strsen_64(char job, char compq, long *select, long n,
    float *t, long ldt, float *q, long ldq, float *wr,
    float *wi, long *m, float *s, float *sep, long
    *info);

```

PURPOSE

strsen reorders the real Schur factorization of a real matrix $A = Q^*TQ$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):
 = 'N': none;
 = 'E': for eigenvalues only (S);
 = 'V': for invariant subspace only (SEP);
 = 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ (input)
 = 'V': update the matrix Q of Schur vectors;
 = 'N': do not update Q.

SELECT (input)
 SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, SELECT(j) must be set to $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)
 On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

LDT (input)
 The leading dimension of the array T. $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

WR (output)
 The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are

stored in the same order as on the diagonal of T , with $WR(i) = T(i,i)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) > 0$ and $WI(i+1) = -WI(i)$. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

WI (output)

See the description of WR.

M (output)

The dimension of the specified invariant subspace.
 $0 < M \leq N$.

S (output)

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If JOB = 'N' or 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If $M = 0$ or N , $SEP = \text{norm}(T)$. If JOB = 'N' or 'E', SEP is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If JOB = 'N', $LWORK \geq \max(1,N)$; if JOB = 'E', $LWORK \geq M*(N-M)$; if JOB = 'V' or 'B', $LWORK \geq 2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

If JOB = 'N' or 'E', IWORK is not referenced.

LIWORK (input)

The dimension of the array IWORK. If JOB = 'N' or 'E', $LIWORK \geq 1$; if JOB = 'V' or 'B', $LIWORK \geq M*(N-M)$.

If LIWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 = 1: reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and WR and WI contain the eigenvalues in the same order as in T; S and SEP (if requested) are set to zero.

FURTHER DETAILS

STRSEN first collects the selected eigenvalues by computing an orthogonal transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

$$Z'^*T*Z = \begin{pmatrix} T11 & T12 \\ 0 & T22 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

where $N = n1+n2$ and Z' means the transpose of Z. The first $n1$ columns of Z span the specified invariant subspace of T.

If T has been obtained from the real Schur factorization of a matrix $A = Q*T*Q'$, then the reordered real Schur factorization of A is given by $A = (Q*Z)*(Z'*T*Z)*(Q*Z)'$, and the first $n1$ columns of $Q*Z$ span the corresponding invariant subspace of A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

$$P = \begin{pmatrix} I & R \\ 0 & 0 \end{pmatrix} \begin{matrix} n1 \\ n2 \end{matrix}$$

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

$$T11*R - R*T22 = T12.$$

Let $F\text{-norm}(M)$ denote the Frobenius-norm of M and $2\text{-norm}(M)$ denote the two-norm of M. Then S is computed as the lower

bound

$$(1 + F\text{-norm}(R)^{**2})^{*(-1/2)}$$

on the reciprocal of 2-norm(P), the true reciprocal condition number. S cannot underestimate $1 / 2\text{-norm}(P)$ by more than a factor of \sqrt{N} .

An approximate error bound for the computed average of the eigenvalues of T11 is

$$\text{EPS} * \text{norm}(T) / S$$

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n1 columns of Z (or of $Q*Z$) is returned in SEP. SEP is defined as the separation of T11 and T22:

$$\text{sep}(T11, T22) = \text{sigma-min}(C)$$

where $\text{sigma-min}(C)$ is the smallest singular value of the $n1*n2$ -by- $n1*n2$ matrix

$$C = \text{kprod}(I(n2), T11) - \text{kprod}(\text{transpose}(T22), I(n1))$$

$I(m)$ is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate $\text{sigma-min}(C)$ by the reciprocal of an estimate of the 1-norm of $\text{inverse}(C)$. The true reciprocal 1-norm of $\text{inverse}(C)$ cannot differ from $\text{sigma-min}(C)$ by more than a factor of $\sqrt{n1*n2}$.

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

$$\text{EPS} * \text{norm}(T) / \text{SEP}$$

INTEGER*8 M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRSM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B
```

```
SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
                  [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
```

```
REAL :: ALPHA
REAL, DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void strsm(char side, char uplo, char transa, char diag, int
           m, int n, float alpha, float *a, int lda, float
           *b, int ldb);

void strsm_64(char side, char uplo, char transa, char diag,
              long m, long n, float alpha, float *a, long lda,
              float *b, long ldb);
```

PURPOSE

strsm solves one of the matrix equations $\text{op}(A)X = \alpha B$, or $X\text{op}(A) = \alpha B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$\text{op}(A) = A$ or $\text{op}(A) = A'$.

The matrix X is overwritten on B .

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A)X = \alpha B$.

SIDE = 'R' or 'r' $X\text{op}(A) = \alpha B$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANS (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, k),
where k is m when SIDE = 'L' or 'l' and is n
when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, n)$. Unchanged on exit.

B (input/output)

REAL array of DIMENSION (LDB, n).
Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

```

```

void strсна(char job, char howmny, int *select, int n, float
    *t, int ldt, float *vl, int ldvl, float *vr, int
    ldvr, float *s, float *sep, int mm, int *m, int
    ldwork, int *info);

```

```

void strсна_64(char job, char howmny, long *select, long n,
    float *t, long ldt, float *vl, long ldvl, float
    *vr, long ldvr, float *s, float *sep, long mm,
    long *m, long ldwork, long *info);

```

PURPOSE

strсна estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q^*TQ with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

- = 'E': for eigenvalues only (S);
- = 'V': for eigenvectors only (SEP);
- = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
 = 'A': compute condition numbers for all eigenpairs;
 = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
 If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue $w(j)$, SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. $N \geq 0$.

T (input) The upper quasi-triangular matrix T, in Schur canonical form.

LDT (input)
 The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input)
 If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q^*TQ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

LDVL (input)
 The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

VR (input)
 If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q^*TQ with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

LDVR (input)
 The leading dimension of the array VR. $LDVR \geq 1$; and if JOB = 'E' or 'B', $LDVR \geq N$.

S (output)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM (input)

The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)

dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)

The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)

dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue λ is defined as

$$S(\lambda) = |v'^*u| / (\text{norm}(u)*\text{norm}(v))$$

where u and v are the right and left eigenvectors of T corresponding to λ ; v' denotes the conjugate-transpose of v , and $\text{norm}(u)$ denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If $n = 1$, $S(\lambda)$ is defined to be 1.

An approximate error bound for a computed eigenvalue $W(i)$ is given by

$$\text{EPS} * \text{norm}(T) / S(i)$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to λ is defined as follows. Suppose

$$T = \begin{pmatrix} \lambda & c \\ 0 & T_{22} \end{pmatrix}$$

Then the reciprocal condition number is

$$\text{SEP}(\lambda, T_{22}) = \text{sigma-min}(T_{22} - \lambda I)$$

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of $T_{22} - \lambda I$. If $n = 1$, $\text{SEP}(1)$ is defined to be $\text{abs}(T(1,1))$.

An approximate error bound for a computed right eigenvector $VR(i)$ is given by

$$\text{EPS} * \text{norm}(T) / \text{SEP}(i)$$

REAL A(LDA,*), Y(*)
```

```
SUBROUTINE STRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, LDA, INCY  
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, LDA, INCY  
REAL, DIMENSION(:) :: Y  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>

void strsv(char uplo, char transa, char diag, int n, float
           *a, int lda, float *y, int incy);

void strsv_64(char uplo, char transa, char diag, long n,
              float *a, long lda, float *y, long incy);
```

PURPOSE

strsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $A'*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE TRSYL(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,  
                [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB  
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO  
REAL :: SCALE  
REAL, DIMENSION(:, :) :: A, B, C
```

```
SUBROUTINE TRSYL_64(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,  
                   [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB
```

```

INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
REAL, DIMENSION(:, :) :: A, B, C

```

C INTERFACE

```

#include <sunperf.h>

void strsyl(char trana, char tranb, int isgn, int m, int n,
            float *a, int lda, float *b, int ldb, float *c,
            int ldc, float *scale, int *info);

void strsyl_64(char trana, char tranb, long isgn, long m,
               long n, float *a, long lda, float *b, long ldb,
               float *c, long ldc, float *scale, long *info);

```

PURPOSE

strsyl solves the real Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**T} , and A and B are both upper quasi-triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

TRANA (input)

Specifies the option $\text{op}(A)$:

- = 'N': $\text{op}(A) = A$ (No transpose)
- = 'T': $\text{op}(A) = A^{**T}$ (Transpose)
- = 'C': $\text{op}(A) = A^{**H}$ (Conjugate transpose = Transpose)

TRANB (input)

Specifies the option $\text{op}(B)$:

- = 'N': $\text{op}(B) = B$ (No transpose)
- = 'T': $\text{op}(B) = B^{**T}$ (Transpose)
- = 'C': $\text{op}(B) = B^{**H}$ (Conjugate transpose = Transpose)

ISGN (input)
 Specifies the sign in the equation:
 = +1: solve $\text{op}(A)*X + X*\text{op}(B) = \text{scale}*C$
 = -1: solve $\text{op}(A)*X - X*\text{op}(B) = \text{scale}*C$

M (input) The order of the matrix A, and the number of rows in the matrices X and C. $M \geq 0$.

N (input) The order of the matrix B, and the number of columns in the matrices X and C. $N \geq 0$.

A (input) The upper quasi-triangular matrix A, in Schur canonical form.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input) The upper quasi-triangular matrix B, in Schur canonical form.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

C (input/output)
 On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC (input)
 The leading dimension of the array C. $LDC \geq \max(1, M)$

SCALE (output)
 The scale factor, scale, set ≤ 1 to avoid overflow in X.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 = 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

NAME

strti2 - compute the inverse of a real upper or lower triangular matrix

SYNOPSIS

```
SUBROUTINE STRTI2(UPLO, DIAG, N, A, LDA, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER N, LDA, INFO  
REAL A(LDA,*)
```

```
SUBROUTINE STRTI2_64(UPLO, DIAG, N, A, LDA, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
INTEGER*8 N, LDA, INFO  
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE TRTI2(UPLO, DIAG, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER :: N, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
INTEGER(8) :: N, LDA, INFO  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void strti2(char uplo, char diag, int n, float *a, int lda,
            int *info);

void strti2_64(char uplo, char diag, long n, float *a, long
               lda, long *info);

```

PURPOSE

strti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)

Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
= 'L': Lower triangular

DIAG (input)

Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
= 'U': Unit triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

```
INFO (output)
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an ille-
      gal value
```

```

C INTERFACE

```
#include <sunperf.h>
```

```

void strtri(char uplo, char diag, int n, float *a, int lda,
            int *info);

void strtri_64(char uplo, char diag, long n, float *a, long
               lda, long *info);

```

PURPOSE

strtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, A(i,i) is exactly zero. The
triangular matrix is singular and its inverse can
not be computed.

NAME

strtrs - solve a triangular system of the form $A * X = B$
or $A^{**T} * X = B$,

SYNOPSIS

```
SUBROUTINE STRTRS(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER N, NRHS, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

```
SUBROUTINE STRTRS_64(UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,  
INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
INTEGER*8 N, NRHS, LDA, LDB, INFO  
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRTRS(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER :: N, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:,:) :: A, B
```

```
SUBROUTINE TRTRS_64(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strtrs(char uplo, char transa, char diag, int n, int
```

```

        nrhs, float *a, int lda, float *b, int ldb, int
        *info);

void strtrs_64(char uplo, char transa, char diag, long n,
               long nrhs, float *a, long lda, float *b, long ldb,
               long *info);

```

PURPOSE

strtrs solves a triangular system of the form
 $A * X = B$ or $A^{**T} * X = B$

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. LDA \geq
 max(1,N).
 B (input/output)
 On entry, the right hand side matrix B. On exit,
 if INFO = 0, the solution matrix X.

 LDB (input)
 The leading dimension of the array B. LDB \geq
 max(1,N).

 INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: if INFO = i, the i-th diagonal element of A
 is zero, indicating that the matrix is singular
 and the solutions X have not been computed.

NAME

stzrqf - routine is deprecated and has been replaced by routine STZRZF

SYNOPSIS

```
SUBROUTINE STZRQF(M, N, A, LDA, TAU, INFO)
```

```
INTEGER M, N, LDA, INFO  
REAL A(LDA,*), TAU(*)
```

```
SUBROUTINE STZRQF_64(M, N, A, LDA, TAU, INFO)
```

```
INTEGER*8 M, N, LDA, INFO  
REAL A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF(M, N, A, [LDA], TAU, [INFO])
```

```
INTEGER :: M, N, LDA, INFO  
REAL, DIMENSION(:) :: TAU  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRQF_64(M, N, A, [LDA], TAU, [INFO])
```

```
INTEGER(8) :: M, N, LDA, INFO  
REAL, DIMENSION(:) :: TAU  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```

void stzrqf(int m, int n, float *a, int lda, float *tau, int
            *info);

void stzrqf_64(long m, long n, float *a, long lda, float
               *tau, long *info);

```

PURPOSE

stzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq M$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The k th transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A , is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the k th row of X .

The scalar τ is returned in the k th element of TAU and the vector $u(k)$ in the k th row of A , such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

NAME

stzrzf - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

SYNOPSIS

```
SUBROUTINE STZRZF(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER M, N, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE STZRZF_64(M, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
INTEGER*8 M, N, LDA, LWORK, INFO  
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TZRZF([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

```
SUBROUTINE TZRZF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL, DIMENSION(:) :: TAU, WORK  
REAL, DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stzrzf(int m, int n, float *a, int lda, float *tau, int
```

```

        *info);

void stzrzf_64(long m, long n, float  *a, long lda, float
        *tau, long *info);

```

PURPOSE

stzrzf reduces the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$
where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A, is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the kth row of X.

The scalar τ is returned in the kth element of TAU and the vector $u(k)$ in the kth row of A, such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A.

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

long *bpntre, float *b, long ldb, float beta, float *c,
long ldc);
```

DESCRIPTION

svbrmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where alpha and beta are scalars, C and B are dense matrices,
A is a sparse M by K matrix represented in the variable block
sparse row format and op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

The number of rows in A and the number of columns in A are determined
as follows

$$M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1), \quad K = \text{CPNTR}(\text{KB}+1) - \text{CPNTR}(1).$$

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, integer KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A'))

```

3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main block diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, scalar array VAL of length NNZ consists of the
                  block entries of A where each block entry is a dense
                  rectangular matrix stored column by column where NNZ
                  denotes the total number of point entries in all nonzero
                  block entries of a matrix A. Unchanged on exit.

INDX(input)      On entry, INDX is an integer array of length BNNZ+1 where BNNZ is
                  the number of block entries of the matrix A such that the
                  I-th element of INDX[] points to the location in VAL of
                  the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input)     On entry, BINDX is an integer array of length BNNZ consisting
                  of the block column indices of the block entries of A where
                  BNNZ is the number block entries of the matrix A. Unchanged on
                  exit.

RPNTR(input)     On entry, RPNTR is an integer array of length MB+1 such that
                  RPNTR(I)-RPNTR(1)+1 is the row index of the first point
                  row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1)
                  where M is the number of rows in the matrix A.
                  Thus, the number of point rows in the I-th block row is
                  RPNTR(I+1)-RPNTR(I). Unchanged on exit.

CPNTR(input)     On entry, CPNTR is an integer array of length KB+1 such that
                  CPNTR(J)-CPNTR(1)+1 is the column index of the first point
                  column in the J-th block column. CPNTR(KB+1) is set to
                  K+CPNTR(1) where K is the number of columns in the matrix A.
                  Thus, the number of point columns in the J-th block column
                  is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

BPNTRB(input)    On entry, BPNTRB is an integer array of length MB such that
                  BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the
                  first block entry of the I-th block row of A.
                  Unchanged on exit.

BPNTRE(input)    On entry, BPNTRE is an integer array of length MB such that
                  BPNTRE(I)-BPNTRB(1) points to location in BINDX of the
                  last block entry of the I-th block row of A.
                  Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with TRANSA = 0, the leading k by n
                  part of the array B must contain the matrix B, otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

```

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANS = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * A) * B + \beta * C$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the sbcomm manpage.

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To

use the routine with this kind of variable block sparse row
format the following calling sequence should be used

```
SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
*                B, LDB, BETA, C, LDC, WORK, LWORK )
```

C INTERFACE

```
#include <sunperf.h>
```

```

void svbrsm (int transa, int mb, int n, int unitd, float
*dv, float alpha, int *descra, float *val, int *indx, int
*bindx, int *rpntr, int *cpntr, int *bpntrb, int *bpntre,
float *b, int ldb, float beta, float *c, int ldc);

```

```

void svbrsm_64 (long transa, long mb, long n, long unitd,
float *dv, float alpha, long *descra, float *val, long
*indx, long *bindx, long *rpntr, long *cpntr, long *bpntrb,
long *bpntre, float *b, long ldb, float beta, float *c,
long ldc);

```

DESCRIPTION

svbrsm performs one of the matrix-matrix operations

```

C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,

```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a block diagonal matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the variable block sparse row format and op(A) is one of

```

op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
The number of rows in A is determined as follows

```

```
m=RPNTR(MB+1)-RPNTR(1).
```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
DV(input)	On entry, array DV contains the block entries of the block diagonal matrix D. The size of the J-th block is RPNTR(J+1)-RPNTR(J) and each block contains matrix entries stored column-major. The total length of

array DV is given by the formula:

$$\text{sum over } J \text{ from } 1 \text{ to } MB: ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))$$

Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, scalar array VAL of length NNZ consists of the block entries of A where each block entry is a dense rectangular matrix stored column by column where NNZ denotes the total number of point entries in all nonzero block entries of the matrix A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length BNNZ+1 where BNNZ is the number of block entries of the matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ is the number block entries of the matrix A. Block column indices MUST be sorted in increasing order for each block row. Unchanged on exit.

RPNTR(input) On entry, RPNTR is an integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in the matrix A. Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I). Unchanged on exit.
 NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR(input) On entry, CPNTR is integer array of length KB+1 such that

CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is the number of columns in the matrix A. Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

- BPNTRB(input) On entry, BPNTRB is an integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A. Unchanged on exit.
- BPNTRE(input) On entry, BPNTRE is an integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A. Unchanged on exit.
- B (input) Array of DIMENSION (LDB, N). Before entry with TRANSA = 0, the leading k by n part of the array B must contain the matrix B, otherwise the leading m by n part of the array B must contain the matrix B. Unchanged on exit.
- LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.
- BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.
- C(input/output) Array of DIMENSION (LDC, N). Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * A) * B + \beta * C$.
- LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.
- WORK(workspace) Scratch array of length LWORK. On exit, if LWORK = -1, WORK(1) returns the optimum size of LWORK.
- LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least $M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1)$. For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $\text{LWORK} \geq M * \text{N_CPUS}$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)= 0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)`.
3. If `DESCRA(3)=1` , the diagonal blocks in the variable block row representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2` , diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where i is the block number for which the LU factorization could not be computed.
5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation

of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of the variable block sparse row format the following calling sequence should be used

```
SUBROUTINE SVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
*                VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
*                B, LDB, BETA, C, LDC, WORK, LWORK )
```

```

F95 INTERFACE

```
SUBROUTINE WIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER :: N_POINTS, ISW, IERR  
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

```
SUBROUTINE WIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)
```

```
INTEGER(8) :: N_POINTS, ISW, IERR  
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void swiener(int n_points, float *acor, float *xcor, float  
            *fltr, float *erop, int *isw, int *ierr);
```

```
void swiener_64(long n_points, float *acor, float *xcor,
```

```
float *fltr, float *erop, long *isw, long *ierr);
```

PURPOSE

swiener performs Wiener deconvolution of two signals.

ARGUMENTS

N_POINTS (input)

On entry, the number of points in the input correlations. Unchanged on exit.

ACOR (input)

On entry, autocorrelation coefficients. Unchanged on exit.

XCOR (input)

On entry, cross-correlation coefficients. Unchanged on exit.

FLTR (output)

On exit, filter coefficients.

EROP (output)

On exit, the prediction error.

ISW (input)

On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

IERR (output)

On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

 - [C INTERFACE](#)
- [PURPOSE](#)

NAME

`use_threads` - Sets the number of threads to use for subsequent parallel regions

SYNOPSIS

```
SUBROUTINE USE_THREADS(NTHREADS)
```

```
INTEGER NTHREADS
```

```
SUBROUTINE USE_THREADS_64(NTHREADS)
```

```
INTEGER*8 NTHREADS
```

F95 INTERFACE

```
SUBROUTINE USE_THREADS(NTHREADS)
```

```
INTEGER :: NTHREADS
```

```
SUBROUTINE USE_THREADS_64(NTHREADS)
```

```
INTEGER(8) :: NTHREADS
```

C INTERFACE

```
#include <sunperf.h>
```

```
void use_threads(int nthreads);
```

```
void use_threads_64(long nthreads);
```

PURPOSE

`USE_THREADS(NTHREADS)` sets the number of threads to

MAX(1,NTHREADS) to use for subsequent parallel regions by calling library routine OMP_SET_NUM_THREADS which is part of the OpenMP Fortran Application Program Interface. From the OpenMP Fortran Application Program Interface which can be found at the official OpenMP website, <http://www.openmp.org/>,

OMP_SET_NUM_THREADS(scalar_integer_expression), where scalar_integer_expression = MAX(1,NTHREADS), is described as follows: "The effect of this function depends on whether dynamic adjustment of the number of threads is enabled. If dynamic adjustment is disabled, the value of the scalar_integer_expression is used as the number of threads for all subsequent parallel regions prior to the next call to this function; otherwise, the value is used as the maximum number of threads that will be used. This function has effect only when called from serial portions of the program. If it is called from a portion of the program where the OMP_IN_PARALLEL function returns .TRUE., the behavior of this function is unspecified."

Contents

- [NAME](#)
- [SYNOPSIS](#)
 - [F95 INTERFACE](#)
 - [C INTERFACE](#)
- [PURPOSE](#)

NAME

`using_threads` - In a parallel environment, if called from a serial region of the master thread it returns the number of threads available for execution (determined by function `OMP_GET_NUM_THREADS`). Else, if it is called from a thread in the team executing the parallel region it returns a 1.

`USING_THREADS` subroutine

SYNOPSIS

```
INTEGER FUNCTION USING_THREADS()
```

```
INTEGER*8 FUNCTION USING_THREADS_64()
```

F95 INTERFACE

```
INTEGER FUNCTION USING_THREADS()
```

```
INTEGER(8) FUNCTION USING_THREADS_64()
```

C INTERFACE

```
#include <sunperf.h>
```

```
int using_threads();
```

```
long using_threads_64();
```

PURPOSE

In a parallel environment, if called from a serial region of the master thread `USING_THREADS` returns the number of threads available for execution. This number is determined

by function call OMP_GET_NUM_THREADS (See the specifications for the OpenMP Fortran Application Program Interface at <http://www.openmp.org> for more details on OMP_GET_NUM_THREADS). Else, if it is called from a thread in the team executing the parallel region, it returns a 1. A user routine can call using_threads to determine if it is already in a parallel region. If this is the case, a 1 is returned and the routine can choose the serial path instead of going parallel, thus avoiding nested parallelism.

NAME

vcfftb - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCFFTB(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER M, N, MDIMX
```

```
SUBROUTINE VCFFTB_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX, DIMENSION(:) :: WSAVE  
COMPLEX, DIMENSION(:, :) :: X, XT  
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTB_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX, DIMENSION(:) :: WSAVE  
COMPLEX, DIMENSION(:, :) :: X, XT  
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vcffftb(int m, int n, complex *x, complex *xt, int
             mdimx, char rowcol, complex *wsave);

void vcffftb_64(long m, long n, complex *x, complex *xt, long
                mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

M (input) If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. M >= 0.

N (input) If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. N >= 0.

X (input) On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

XT (input)
A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (get_env, available_threads, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)

On entry, an array of dimension (L2+15) or greater, where $L2 = 2 \times M$ if ROWCOL = ('R' or 'r'). Otherwise, $L2 = 2 \times N$. WSAVE is initialized by VCFFTI.

NAME

vcfftf - compute the Fourier coefficients of a periodic sequence. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCFFTF(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER M, N, MDIMX
```

```
SUBROUTINE VCFFTF_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTF([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX, DIMENSION(:) :: WSAVE  
COMPLEX, DIMENSION(:, :) :: X, XT  
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTF_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX, DIMENSION(:) :: WSAVE  
COMPLEX, DIMENSION(:, :) :: X, XT  
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vcfftft(int m, int n, complex *x, complex *xt, int
             mdimx, char rowcol, complex *wsave);

void vcfftft_64(long m, long n, complex *x, complex *xt, long
               mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

M (input) If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. M >= 0.

N (input) If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. N >= 0.

X (input) On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

XT (input)
A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (get_env, available_threads, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

MDIMX (input)
Leading dimension of the arrays X. MDIMX >= M.

ROWCOL (input)
Indicates whether data sequences in X are stored row-wise ('R' or 'r') or column-wise ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (L2+15) or

greater, where $L2 = 2 \cdot M$ if ROWCOL = ('R' or 'r').
Otherwise, $L2 = 2 \cdot N$. WSAVE is initialized by
VCFFTI.

NAME

`vcffti` - initialize the array `WSAVE`, which is used in both `VCFFTF` and `VCFFTB`.

SYNOPSIS

```
SUBROUTINE VCFFTI(N, WSAVE)
```

```
COMPLEX WSAVE(*)  
INTEGER N
```

```
SUBROUTINE VCFFTI_64(N, WSAVE)
```

```
COMPLEX WSAVE(*)  
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: WSAVE  
INTEGER :: N
```

```
SUBROUTINE VFFTI_64(N, WSAVE)
```

```
COMPLEX, DIMENSION(:) :: WSAVE  
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcffti(int n, complex *wsave);
```

```
void vcffti_64(long n, complex *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array of dimension $(2*N + 15)$ or greater. VCFFTI needs to be called only once to initialize WSAVE before calling VCFFTF and/or VCFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

`vcosqb` - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The `VCOSQ` operations are normalized, so a call of `VCOSQF` followed by a call of `VCOSQB` will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCOSQB(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER M, N, MDIMX  
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VCOSQB_64(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER*8 M, N, MDIMX  
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER :: M, N, MDIMX  
REAL, DIMENSION(:) :: WSAVE  
REAL, DIMENSION(:,:) :: X, XT
```

```
SUBROUTINE COSQB_64([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER(8) :: M, N, MDIMX  
REAL, DIMENSION(:) :: WSAVE  
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```

void vcosqb(int m, int n, float *x, float *xt, int mdimx,
            float *wsave);

void vcosqb_64(long m, long n, float *x, float *xt, long
               mdimx, float *wsave);

```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, the rows contain the sequences to be transformed. On exit, the quarter-wave cosine synthesis of the input.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater initialized by VCOSQI.

```

```

void vdfftb(int m, int n, double *x, double *xt, int mdimx,
            double *wsave);

void vdfftb_64(long m, long n, double *x, double *xt, long
               mdimx, double *wsave);

```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (N+15) or greater initialized by VRFFTI.

NAME

vdfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFT followed by a call of VRFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDFFT(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER M, N, MDIMX
```

```
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDFFT_64(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER*8 M, N, MDIMX
```

```
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER :: M, N, MDIMX
```

```
REAL(8), DIMENSION(:) :: WSAVE
```

```
REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE FFTF_64([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER(8) :: M, N, MDIMX
```

```
REAL(8), DIMENSION(:) :: WSAVE
```

```
REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```

void vdfftf(int m, int n, double *x, double *xt, int  mdimx,
            double *wsave);

void vdfftf_64(long m, long n, double *x, double  *xt,  long
               mdimx, double *wsave);

```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two- dimensional array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (N+15) or greater initialized by VRFFTI.

NAME

vdffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

SYNOPSIS

```
SUBROUTINE VDFFTI(N, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE VDFFTI_64(N, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE VFFTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdffti(int n, double *wsave);
```

```
void vdffti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array of dimension $(N + 15)$ or greater. VRFFTI needs to be called only once to initialize WSAVE before calling VRFFTF and/or VRFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

`vdsmiq` - initialize the array `WSAVE`, which is used in both `VSINQF` and `VSINQB`.

SYNOPSIS

```
SUBROUTINE VDSINQI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDSINQI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINQI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VSINQI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdsinqi(int n, double *wsave);

void vdsinqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)

On entry, an array with a dimension of at least $(2 * N + 15)$. The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

vdsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by 2 * (N+1). The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINT(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER M, N, MDIMX  
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VDSINT_64(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER*8 M, N, MDIMX  
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER :: M, N, MDIMX  
REAL(8), DIMENSION(:) :: WSAVE  
REAL(8), DIMENSION(:, :) :: X, XT
```

```
SUBROUTINE SINT_64([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER(8) :: M, N, MDIMX  
REAL(8), DIMENSION(:) :: WSAVE  
REAL(8), DIMENSION(:, :) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>

void vdsint(int m, int n, double *x, double *xt, int mdimx,
            double *wsave);

void vdsint_64(long m, long n, double *x, double *xt, long
               mdimx, double *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N+1 is a product of small primes. N >= 0.

X (input/output)
On entry, a real two-dimensional array with dimensions of (MDIMX x (N+1)) whose rows contain the sequences to be transformed. On exit, the sine transform of the input.

XT (input/output)
A real two-dimensional work array with dimensions of (MDIMX x (N+1)).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by VSINTI.

NAME

`vdsinti` - initialize the array `WSAVE`, which is used in sub-routine `VSINT`.

SYNOPSIS

```
SUBROUTINE VDSINTI(N, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE VDSINTI_64(N, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI(N, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE VSINTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsinti(int n, double *wsave);
```

```
void vdsinti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. VSINTI is called once to initialize WSAVE before calling VSINT and need not be called again between calls to VSINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsinqi(int n, float *wsave);
```

```
void vsinqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)

On entry, an array with a dimension of at least $(2 * N + 15)$. The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

vsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by 2 * (N+1). The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

SYNOPSIS

```
SUBROUTINE VSINT(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER M, N, MDIMX  
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

```
SUBROUTINE VSINT_64(M, N, X, XT, MDIMX, WSAVE)
```

```
INTEGER*8 M, N, MDIMX  
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER :: M, N, MDIMX  
REAL, DIMENSION(:) :: WSAVE  
REAL, DIMENSION(:,:) :: X, XT
```

```
SUBROUTINE SINT_64([M], [N], X, XT, [MDIMX], WSAVE)
```

```
INTEGER(8) :: M, N, MDIMX  
REAL, DIMENSION(:) :: WSAVE  
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>

void vsint(int m, int n, float *x, float *xt, int mdimx,
           float *wsave);

void vsint_64(long m, long n, float *x, float *xt, long
              mdimx, float *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N+1 is a product of small primes. N >= 0.

X (input/output)
On entry, a real two-dimensional array with dimensions of (MDIMX x (N+1)) whose rows contain the sequences to be transformed. On exit, the sine transform of the input.

XT (input/output)
A real two-dimensional work array with dimensions of (MDIMX x (N+1)).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by VSINTI.

NAME

vsinti - initialize the array WSAVE, which is used in sub-routine VSINT.

SYNOPSIS

```
SUBROUTINE VSINTI(N, WSAVE)
```

```
INTEGER N  
REAL WSAVE(*)
```

```
SUBROUTINE VSINTI_64(N, WSAVE)
```

```
INTEGER*8 N  
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI(N, WSAVE)
```

```
INTEGER :: N  
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE VSINTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsinti(int n, float *wsave);
```

```
void vsinti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. VSINTI is called once to initialize WSAVE before calling VSINT and need not be called again between calls to VSINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

vzfftb - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFT followed by a call of VZFTTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VZFTTB(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER M, N, MDIMX
```

```
SUBROUTINE VZFTTB_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)
```

```
CHARACTER * 1 ROWCOL  
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)  
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX(8), DIMENSION(:) :: WSAVE  
COMPLEX(8), DIMENSION(:, :) :: X, XT  
INTEGER :: M, N, MDIMX
```

```
SUBROUTINE FFTB_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)
```

```
CHARACTER(LEN=1) :: ROWCOL  
COMPLEX(8), DIMENSION(:) :: WSAVE  
COMPLEX(8), DIMENSION(:, :) :: X, XT  
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vzfftb(int m, int n, doublecomplex *x, doublecomplex
            *xt, int mdimx, char rowcol, doublecomplex
            *wsave);

void vzfftb_64(long m, long n, doublecomplex *x, doublecom-
               plex *xt, long mdimx, char rowcol, doublecomplex
               *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, the rows contain the sequences to be transformed.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (K+15) or greater, where K = M if ROWCOL = ('R' or 'r'). Otherwise, K = N. WSAVE is initialized by VZFFTI.

COMPLEX(8), DIMENSION(:, :) :: X, XT  
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vzfft_f(int m, int n, doublecomplex *x, doublecomplex
             *xt, int mdimx, char rowcol, doublecomplex
             *wsave);

void vzfft_f_64(long m, long n, doublecomplex *x, doublecom-
                plex *xt, long mdimx, char rowcol, doublecomplex
                *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (K+15) or greater, where K = M if ROWCOL = ('R' or 'r'). Otherwise, K = N. WSAVE is initialized by VZFFT_I.

NAME

vzffti - initialize the array WSAVE, which is used in both VZFFTF and VZFFTB.

SYNOPSIS

```
SUBROUTINE VZFFTI(N, WSAVE)
```

```
DOUBLE COMPLEX WSAVE(*)  
INTEGER N
```

```
SUBROUTINE VZFFTI_64(N, WSAVE)
```

```
DOUBLE COMPLEX WSAVE(*)  
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)
```

```
COMPLEX(8), DIMENSION(:) :: WSAVE  
INTEGER :: N
```

```
SUBROUTINE VFFTI_64(N, WSAVE)
```

```
COMPLEX(8), DIMENSION(:) :: WSAVE  
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vzffti(int n, doublecomplex *wsave);
```

```
void vzffti_64(long n, doublecomplex *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input)

On entry, an array of dimension $(N + 15)$ or greater. VZFFTI needs to be called only once to initialize WSAVE before calling VZFFTF and/or VZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

zaxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE ZAXPY(N, ALPHA, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZAXPY_64(N, ALPHA, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zaxpy(int n, doublecomplex *alpha, doublecomplex *x,
          int incx, doublecomplex *y, int incy);

void zaxpy_64(long n, doublecomplex *alpha, doublecomplex
             *x, long incx, doublecomplex *y, long incy);

```

PURPOSE

zaxpy compute $y := \alpha * x + y$ where α is a scalar and x and y are n -vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

NAME

zaxpyi - Compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE ZAXPYI(NZ, A, X, INDX, Y)
```

```
DOUBLE COMPLEX A  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE ZAXPYI_64(NZ, A, X, INDX, Y)
```

```
DOUBLE COMPLEX A  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)
```

```
COMPLEX(8) :: A  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)
```

```
COMPLEX(8) :: A  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

ZAXPYI Compute $y := \alpha * x + y$ where α is a scalar, x is a sparse vector, and y is a vector in full storage form

```
do i = 1, n
  y(indx(i)) = alpha * x(i) + y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

A (input)

On entry, A(LPHA) specifies the scaling value.
Unchanged on exit. A is defaulted to (1.0D0,0.0D0)
for F95 INTERFACE.

X (input)

Vector containing the values of the compressed form.
Unchanged on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector on input which contains the vector Y in full
storage form. On exit, only the elements
corresponding to the indices in INDX have been
modified.

```

C INTERFACE

```
#include <sunperf.h>

void zbcomm(int transa, int mb, int n, int kb, doublecomplex
*alpha, int *descra, doublecomplex *val, int *bindx, int
*bjndx, int bnnz, int lb,
doublecomplex *b, int ldb, doublecomplex *beta,
doublecomplex *c, int ldc);
void zbcomm_64(long transa, long mb, long n, long kb,
complex *alpha, long *descra, doublecomplex *val, long
*bindx, long *bjndx, long bnnz, long lb, doublecomplex *b,
long ldb,
doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

cbcomm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an (mb*lb) by (kb*lb) sparse matrix represented in the block coordinate format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in matrix C. Unchanged on exit.
KB(input)	On entry, KB specifies the number of block columns in matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal

```

        6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
        1 : lower
        2 : upper
DESCRA(3) main block diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)    On entry, scalar array of length LB*LB*BNNZ consisting of
               the non-zero block entries of A, in any order.
               Each block is stored in standard column-major form.
               Unchanged on exit.

BINDX(input)  On entry, integer array of length BNNZ consisting of the
               block row indices of the non-zero block entries of A.
               Unchanged on exit.

BJNDX(input)  On entry, integer array of length BNNZ consisting of the
               block column indices of the non-zero block entries of A.
               Unchanged on exit.

BNNZ (input)  On entry, BNNZ specifies the number of nonzero block
               entries in A. Unchanged on exit.

LB (input)    On entry, LB specifies the dimension of dense blocks
               composing A. Unchanged on exit.

B (input)     Array of DIMENSION ( LDB, N ).
               Before entry with TRANSA = 0, the leading kb*lb by n
               part of the array B must contain the matrix B, otherwise
               the leading mb*lb by n part of the array B must contain the
               matrix B. Unchanged on exit.

LDB (input)   On entry, LDB specifies the first dimension of B as declared
               in the calling (sub) program. Unchanged on exit.

BETA (input)  On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output) Array of DIMENSION ( LDC, N ).
               Before entry with TRANSA = 0, the leading mb*lb by n
               part of the array C must contain the matrix C, otherwise
               the leading kb*lb by n part of the array C must contain the
               matrix C. On exit, the array C is overwritten by the matrix
               ( alpha*op( A )* B + beta*C ).

LDC (input)   On entry, LDC specifies the first dimension of C as declared
               in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general complex matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

```

C INTERFACE

```
#include <sunperf.h>

void zbdimm (int transa, int mb, int n, int kb,
doublecomplex *alpha,
int *descra, doublecomplex *val, int blda, int *ibdiag, int
nbdiag, int lb, doublecomplex *b, int ldb, doublecomplex
*beta, doublecomplex *c, int ldc);
void zbdimm_64(long transa, long mb, long n, long kb,
doublecomplex *alpha, long *descra, doublecomplex *val,
long blda,
long *ibdiag, long nbdiag, long lb, doublecomplex *b, long
ldb,
doublecomplex *beta, doublecomplex *c, long ldc)
```

DESCRIPTION

zbdimm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an (mb*lb) by (kb*lb) sparse matrix represented in the block coordinate format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main block diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
                  consisting of the NBDIAG nonzero block diagonal in
                  any order. Each dense block is stored in standard
                  column-major form. Unchanged on exit.

BLDA(input)      On entry, BLDA*LB*LB specifies the leading block dimension
                  of VAL(). Unchanged on exit.

IBDIAG(input)    On entry, integer array of length NBDIAG consisting of the
                  corresponding diagonal offsets of the non-zero
                  block diagonals of A in VAL. Lower triangular
                  block diagonals have negative offsets, the main
                  block diagonal has offset 0, and upper triangular
                  block diagonals have positive offset. Unchanged on exit.

NBDIAG(input)    On entry, NBDIAG specifies the number of non-zero block
                  diagonals in A. Unchanged on exit.

LB (input)       On entry, LB specifies the dimension of dense blocks
                  composing A. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0, the leading kb*lb by n
                  part of the array B must contain the matrix B, otherwise
                  the leading mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0, the leading mb*lb by n
                  part of the array C must contain the matrix C, otherwise
                  the leading kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A ) * B + beta * C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general complex matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

doublecomplex *val, long blda, long *ibdiag, long nbdiag,
long lb, doublecomplex *b, long ldb, doublecomplex *beta,
doublecomplex *c, long ldc)
```

DESCRIPTION

zbdism performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block diagonal format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose)
```

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix A. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D. The size of each square block is LB-by-LB and each block is stored in standard column-major form.

Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LB*LB*BLDA-by-NBDIAG array consisting of the NBDIAG non-zero block diagonal. Each dense block is stored in standard column-major form. Unchanged on exit.

BLDA(input) On entry, BLDA*LB*LB specifies the leading block dimension of VAL(). Unchanged on exit.

IBDIAG(input) On entry, IBDIAG is an integer array of length NBDIAG consisting of corresponding diagonal offsets of the non-zero block diagonals of A in VAL. Lower triangular block diagonals have negative offsets, the main block diagonal has offset 0, and upper triangular block diagonals have positive offset. Elements of IBDIAG MUST be sorted in increasing order. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block diagonal representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2` , diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine.

`WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix `A` for solving triangular systems with the upper or lower block triangle of `A`. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix `A` decomposed in the form

$$A = L + D + U$$

where `L` is the strictly block lower triangle of `A`, `U` is the strictly block upper triangle of `A`, `D` is the block diagonal matrix. Let's `I` denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of `A` is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	<code>alpha*op(L+I)*B+beta*C</code>
3	1	0	<code>alpha*op(L+D)*B+beta*C</code>
3	2	1	<code>alpha*op(U+I)*B+beta*C</code>
3	2	0	<code>alpha*op(U+D)*B+beta*C</code>

               *c, long ldc, long *info);

```

PURPOSE

zbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
 = 'U': B is upper bidiagonal;
 = 'L': B is lower bidiagonal.

N (input) The order of the matrix B. N >= 0.

NCVT (input)
 The number of columns of the matrix VT. NCVT >= 0.

NRU (input)
 The number of rows of the matrix U. NRU >= 0.

NCC (input)
The number of columns of the matrix C. $NCC \geq 0$.

D (input/output)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if $INFO=0$, the singular values of B in decreasing order.

E (input/output)
On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit ($INFO = 0$), E is destroyed. If the algorithm does not converge ($INFO > 0$), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. $E(N)$ is used for workspace.

VT (input/output)
On entry, an N -by- $NCVT$ matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

LDVT (input)
The leading dimension of the array VT. $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

U (input/output)
On entry, an NRU -by- N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

LDU (input)
The leading dimension of the array U. $LDU \geq \max(1, NRU)$.

C (input/output)
On entry, an N -by- NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

WORK (workspace)
dimension $(4*N)$

INFO (output)
= 0: successful exit
< 0: If $INFO = -i$, the i -th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is

orthogonally similar to the input matrix B ; if
INFO = i , i elements of E have not converged to
zero.

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A' \quad \text{or} \quad \text{op}(A) = \text{conjg}(A').$$

(' indicates matrix transpose)

ARGUMENTS

MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
-----------	---

N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
----------	---

KB(input)	On entry, KB specifies the number of block columns in the matrix A. Unchanged on exit.
-----------	--

Page 3481 of 4556

```

        2 : upper
DESCRA(3) main block diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)      On entry, VAL is a two-dimensional LB*LB*BLDA-by-MAXBNZ
                  array consisting of the non-zero blocks, stored
                  column-major within each dense block. Unchanged on exit.

BINDX(input)    On entry, BINDX is an integer two-dimensional BLDA-MAXBNZ
                  array such BINDX(i,:) consists of the block column indices
                  of the nonzero blocks in block row i, padded by the integer
                  value i if the number of nonzero blocks is less than
                  MAXBNZ. Unchanged on exit.

BLDA(input)     On entry, BLDA specifies the leading dimension of BINDX(:,:).
                  Unchanged on exit.

MAXBNZ (input)  On entry, MAXBNZ specifies the max number of nonzeros
                  blocks per row. Unchanged on exit.

LB (input)      On entry, LB specifies the dimension of dense blocks
                  composing A.  Unchanged on exit.

B (input)       Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading  kb*lb by n
                  part of the array  B  must contain the matrix B,  otherwise
                  the leading  mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)     On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)    On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output) Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading  mb*lb by n
                  part of the array  C  must contain the matrix C,  otherwise
                  the leading  kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)     On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
```

```
void zbelism(int transa, int mb, int n, int unitd,  
doublecomplex *dv, doublecomplex *alpha, int *descra,  
doublecomplex *val,  
int *bindx, int blda, int maxbnz, int lb, doublecomplex *b,  
int ldb, doublecomplex *beta, doublecomplex *c, int ldc);
```

```
void zbelism_64(long transa, long mb, long n, long unitd,  
doublecomplex *dv, doublecomplex *alpha, long *descra,  
doublecomplex *val, long *bindx, long blda, long maxbnz,  
long lb, doublecomplex *b, long ldb, doublecomplex *beta,  
doublecomplex *c, long ldc);
```

DESCRIPTION

zbelism performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block ellpack format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	Integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting of the elements of the diagonal blocks of the matrix D.

The size of each square block is LB-by-LB and each block is stored in standard column-major form.
 Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
 Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
 DESCRA(1) matrix structure
 0 : general
 1 : symmetric (A=A')
 2 : Hermitian (A= CONJG(A'))
 3 : Triangular
 4 : Skew(Anti)-Symmetric (A=-A')
 5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-identity blocks on the main diagonal
 1 : identity diagonal blocks
 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LB*LB*BLDA-by-MAXBNZ array consisting of the non-zero blocks, stored column-major within each dense block. Unchanged on exit.

BINDX(input) On entry, BINDX is an integer two-dimensional BLDA-MAXBNZ array such BINDX(i,:) consists of the block column indices of the nonzero blocks in block row i, padded by the integer value i if the number of nonzero blocks is less than MAXBNZ. The block column indices MUST be sorted in increasing order for each block row. Unchanged on exit.

BLDA(input) On entry, BLDA specifies the leading dimension of BINDX(:,:).
 Unchanged on exit.

MAXBNZ (input) On entry, MAXBNZ specifies the max number of nonzeros blocks per row. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 On entry, the leading mb*lb by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).

On entry, the leading $mb \times lb$ by n part of the array C must contain the matrix C . On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK = -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least $MB \times LB$.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq MB \times LB \times N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0`, the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)`.
3. If `DESCRA(3)=1`, the diagonal blocks in the block ellpack representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3)=2`, diagonal blocks are considered as dense

matrices and the LU factorization with partial pivoting is used by the routine.

`WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix `A` for solving triangular systems with the upper or lower block triangle of `A`. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix `A` decomposed in the form

$$A = L + D + U$$

where `L` is the strictly block lower triangle of `A`, `U` is the strictly block upper triangle of `A`, `D` is the block diagonal matrix. Let's `I` denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of `A` is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

*b, long ldb, doublecomplex *beta, doublecomplex *c, long
ldc);
```

zbscmm performs one of the matrix-matrix operations

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A' \quad \text{or} \quad \text{op}(A) = \text{conjg}(A').$$

(' indicates matrix transpose)

```

TRANSA(input)      TRANSA specifies the form of op( A ) to be used in
                    the matrix multiplication as follows:
                    0 : operate with matrix
                    1 : operate with transpose matrix
                    2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.
                    Unchanged on exit.

MB(input)          On entry, MB specifies the number of block rows
                    in the matrix A. Unchanged on exit.

N(input)           On entry, N specifies the number of columns
                    in the matrix C. Unchanged on exit.

KB(input)          On entry, KB specifies the number of block columns in
                    the matrix A. Unchanged on exit.

ALPHA(input)       On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)     Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
                    0 : general
                    1 : symmetric (A=A')
                    2 : Hermitian (A= CONJG(A'))
                    3 : Triangular

```

```

      4 : Skew(Anti)-Symmetric (A=-A')
      5 : Diagonal
      6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
      1 : lower
      2 : upper
DESCRA(3) main block diagonal type
      0 : non-unit
      1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
      0 : C/C++ compatible
      1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
      0 : unknown
      1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array of length LB*LB*BNNZ
                  consisting of the non-zero block entries stored
                  column-major within each dense block where
                  BNNZ = BPNTRE(KB)-BPNTRB(1). Unchanged on exit.

BINDX(input)    On entry, BINDX is an integer array of length BNNZ consisting
                  of the block row indices of the block entries of A where
                  BNNZ = BPNTRE(KB)-BPNTRB(1). Unchanged on exit.

BPNTRB(input)   On entry, BPNTRB is an integer array of length KB such
                  that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                  of the first block entry of the J-th block column
                  of A. Unchanged on exit.

BPNTRE(input)   On entry, BPNTRE is an integer array of length KB such
                  that BPNTRE(J)-BPNTRB(1) points to location in BINDX
                  of the last block entry of the J-th block column
                  of A. Unchanged on exit.

LB (input)      On entry, LB specifies the dimension of dense blocks
                  composing A. Unchanged on exit.

B (input)       Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading  kb*lb by n
                  part of the array  B  must contain the matrix  B,  otherwise
                  the leading  mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)     On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)    On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading  mb*lb by n
                  part of the array  C  must contain the matrix C,  otherwise
                  the leading  kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)     On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general complex matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL ZBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

doublecomplex *val, long *bindx, long *bpntrb, long *bpntre,  
long lb, doublecomplex *b, long ldb, doublecomplex *beta,  
doublecomplex *c, long ldc);
```

DESCRIPTION

zbscsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block sparse column format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block columns in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting

of the elements of the diagonal blocks of the matrix D.
The size of each square block is LB-by-LB and each
block is stored in standard column-major form.
Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length LB*LB*BNNZ
consisting of the non-zero block entries stored
column-major within each dense block where
BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting
of the block row indices of the block entries of A where
BNNZ = BPNTRE(MB)-BPNTRB(1). The block row indices MUST
be sorted in increasing order for each block column.
Unchanged on exit.

BPNTRB(input) On entry, BPNTRB is an integer array of length MB such
that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
of the first block entry of the J-th block column
of A. Unchanged on exit.

BPNTRE(input) On entry, BPNTRE is an integer array of length MB such
that BPNTRE(J)-BPNTRB(1) points to location in BINDX
of the last block entry of the J-th block column
of A. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks
composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B
must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared

in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 On entry, the leading mb*lb by n part of the array C
 must contain the matrix C. On exit, the array C is
 overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
 On exit, if LWORK= -1, WORK(1) returns the optimum size
 of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK
 should be at least MB*LB.

For good performance, LWORK should generally be larger.
 For optimum performance on multiple processors, LWORK
 $\geq \text{MB} * \text{LB} * \text{N_CPUS}$ where N_CPUS is the maximum number of
 processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the
 routine only calculates the optimum size of the WORK array,
 returns this value as the first entry of the WORK array,
 and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is
 fully compatible with NIST FORTRAN Sparse Blas but the sources are different.
 Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas.
 Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS)
 Standard", University of Tennessee, Knoxville, Tennessee, 1996:
<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included
 in this routine. Such tests must be performed before calling
 this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of
 each diagonal block is used by the routine depending on
`DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block sparse

column representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.

4. If `DESCRA(3)=2` , the diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where *i* is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
CALL ZBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

*bindx, long *bpntrb, long *bpntre, long lb, doublecomplex
*b, long ldb, doublecomplex *beta, doublecomplex *c, long
ldc);
```

zbsrmm performs one of the matrix-matrix operations

where alpha and beta are scalars, C and B are dense matrices, A is an (mb*lb) by (kb*lb) sparse matrix represented in the block sparse row format and op(A) is one of

ARGUMENTS

ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A') 2 : Hermitian (A= CONJG(A')) 3 : Triangular

```

4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main block diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array of length LB*LB*BNNZ
                  consisting of the non-zero block entries stored
                  column-major within each dense block where
                  BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.

BINDX(input)     On entry, BINDX is an integer array of length BNNZ consisting
                  of the block column indices of the block entries of A where
                  BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.

BPNTRB(input)    On entry, BPNTRB is an integer array of length MB such
                  that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                  of the first block entry of the J-th block row
                  of A. Unchanged on exit.

BPNTRE(input)    On entry, BPNTRE is an integer array of length MB such
                  that BPNTRE(J)-BPNTRB(1) points to location in BINDX
                  of the last block entry of the J-th block row
                  of A. Unchanged on exit.

LB (input)       On entry, LB specifies the dimension of dense blocks
                  composing A. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with TRANSA = 0, the leading kb*lb by n
                  part of the array B must contain the matrix B, otherwise
                  the leading mb*lb by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with TRANSA = 0, the leading mb*lb by n
                  part of the array C must contain the matrix C, otherwise
                  the leading kb*lb by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general complex matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

NOTES/BUGS

It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
CALL ZBSRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*           VAL, BINDX, IA, IA(2), LB,  
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

doublecomplex *c, long ldc);
```

DESCRIPTION

zbsrsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are mb*lb by n dense matrices, D is a block diagonal matrix, A is a sparse mb*lb by mb*lb unit, or non-unit, upper or lower triangular matrix represented in the block sparse row format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) Unchanged on exit.
DV(input)	On entry, DV is an array of length MB*LB*LB consisting

of the elements of the diagonal blocks of the matrix D.
The size of each square block is LB-by-LB and each
block is stored in standard column-major form.
Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-identity blocks on the main diagonal
1 : identity diagonal blocks
2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length LB*LB*BNNZ
consisting of the non-zero block entries stored
column-major within each dense block where
BNNZ = BPNTRE(MB)-BPNTRB(1). Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting
of the block column indices of the block entries of A where
BNNZ = BPNTRE(MB)-BPNTRB(1). The block column indices MUST
be sorted in increasing order for each block column.
Unchanged on exit.

BPNTRB(input) On entry, BPNTRB is an integer array of length MB such
that BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
of the first block entry of the J-th block row
of A. Unchanged on exit.

BPNTRE(input) On entry, BPNTRE is an integer array of length MB such
that BPNTRE(J)-BPNTRB(1) points to location in BINDX
of the last block entry of the J-th block row
of A. Unchanged on exit.

LB (input) On entry, LB specifies the dimension of dense blocks
composing A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading mb*lb by n part of the array B
must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared

in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading mb*lb by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK \geq MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:
<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)=0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)` .
3. If `DESCRA(3)=1` , the diagonal blocks in the block sparse

row representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.

4. If `DESCRA(3)=2` , the diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.

5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	<code>alpha*op(L+I)*B+beta*C</code>
3	1	0	<code>alpha*op(L+D)*B+beta*C</code>
3	2	1	<code>alpha*op(U+I)*B+beta*C</code>
3	2	0	<code>alpha*op(U+D)*B+beta*C</code>

6. It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, `IA`, containing the pointers to the beginning of each block row in the arrays `VAL` and `BINDX` is used instead of two arrays `BPNTRB` and `BPNTRE`. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
CALL ZBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, IA, IA(2), LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
```

    long inc2y, long nz, long k, doublecomplex *z,
    long ifz, long inclz, long inc2z, doublecomplex
    *work, long lwork);
```

PURPOSE

zcnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

CNVCOR (input)

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the real and imaginary parts of the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)

Length of the filter vector. NX >= 0. ZCNVCOR will return immediately if NX = 0.

X (input) dimension(*)

Filter vector.

IFX (input)

Index of the first element of X. NX >= IFX >= 1.

INCX (input)
 Stride between elements of the filter vector in X.
 INCX > 0.

NY (input)
 Length of the input vectors. NY >= 0. ZCNVCOR
 will return immediately if NY = 0.

NPRES (input)
 The number of implicit zeros prepended to the Y
 vectors. NPRES >= 0.

M (input)
 Number of input vectors. M >= 0. ZCNVCOR will
 return immediately if M = 0.

Y (input) dimension(*)
 Input vectors.

IFY (input)
 Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)
 Stride between elements of the input vectors in Y.
 INC1Y > 0.

INC2Y (input)
 Stride between the input vectors in Y. INC2Y > 0.

NZ (input)
 Length of the output vectors. NZ >= 0. ZCNVCOR
 will return immediately if NZ = 0. See the Notes
 section below for information about how this argu-
 ment interacts with NX and NY to control circular
 versus end-off shifting.

K (input)
 Number of Z vectors. K >= 0. If K = 0 then
 ZCNVCOR will return immediately. If K < M then
 only the first K input vectors will be processed.
 If K > M then M input vectors will be processed.

Z (output)
 dimension(*)
 Result vectors.

IFZ (input)
 Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
 Stride between elements of the output vectors in
 Z. INC1Z > 0.

INC2Z (input)
 Stride between the output vectors in Z. INC2Z >

0.

WORK (input/output)

(input/scratch) dimension(LWORK)

Scratch space. Before the first call to ZCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to ZCNVCOR or if ZCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make ZCNVCOR run faster.

LWORK (input)

Length of WORK. $LWORK \geq 2 * MAX(NX, NY, NZ) + 8$.

    doublecomplex *workin, long lwork);

```

PURPOSE

zcnvcor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

CNVCOR (input)
 'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
 'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

TRANSX (input)
 'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)
 'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X

are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)

Number of rows in the filter matrix. MX \geq 0.

NX (input)

Number of columns in the filter matrix. NX \geq 0.

X (input) dimension(LDX,NX)

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)

Leading dimension of the array that contains the filter matrix.

MY (input)

Number of rows in the input matrix. MY \geq 0.

NY (input)

Number of columns in the input matrix. NY \geq 0.

MPRE (input)

Number of implicit zeros to prepend to each row of the input matrix. MPRE \geq 0.

NPRE (input)

Number of implicit zeros to prepend to each column of the input matrix. NPRE \geq 0.

Y (input) dimension(LDY,*)

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)

Leading dimension of the array that contains the input matrix.

MZ (input)

Number of rows in the output matrix. MZ \geq 0. ZCNVCOR2 will return immediately if MZ = 0.

NZ (input)

Number of columns in the output matrix. $NZ \geq 0$.
ZCNVCOR2 will return immediately if $NZ = 0$.

Z (output)

dimension(LDZ,*)
Result matrix.

LDZ (input)

Leading dimension of the array that contains the
result matrix. $LDZ \geq \text{MAX}(1, MZ)$.

WORKIN (input/output)

(input/scratch) dimension(LWORK)
On entry for the first call to ZCNVCOR2, WORKIN(1)
must contain CMPLX(0.0,0.0). After the first
call, WORKIN(1) must be set to CMPLX(0.0,0.0) iff
WORKIN has been altered since the last call to
this subroutine or if the sizes of the arrays have
changed.

LWORK (input)

Length of the work vector. If the FFT is to be
used then for best performance LWORK should be at
least 30 words longer than the amount of memory
needed to hold the trig tables. If the FFT is not
used, the value of LWORK is unimportant.

doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zcoomm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the coordinate format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, integer K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

        5 : Diagonal
        6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
        1 : lower
        2 : upper
DESCRA(3) main diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL (input)      On entry, VAL is a scalar array array of length
                  NNZ consisting of the non-zero entries of A,
                  in any order. Unchanged on exit.

INDX (input)     On entry, INDX is an integer array of length NNZ
                  consisting of the corresponding row indices of
                  the entries of A. Unchanged on exit.

JNDX (input)     On entry, JNDX is an integer array of length NNZ
                  consisting of the corresponding column indices of
                  the entries of A. Unchanged on exit.

NNZ (input)      On entry, integer NNZ specifies the number of
                  non-zero elements in A. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading k by n
                  part of the array B must contain the matrix B,  otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading m by n
                  part of the array C must contain the matrix C,  otherwise
                  the leading k by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with
NIST FORTRAN Sparse Blas but the sources are different.

Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas.
Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS)
Standard", University of Tennessee, Knoxville, Tennessee,
1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to
use just one sparse matrix representation of a general
matrix A for computing matrix-matrix multiply for another
sparse matrix composed by triangles and/or the main
diagonal of A. The full description of the feature for point
entry formats in the case of complex matrices is given in
section NOTES/BUGS for the ccoomm manpage.

NAME

zcopy - Copy x to y

SYNOPSIS

```
SUBROUTINE ZCOPY(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZCOPY_64(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zcopy(int n, doublecomplex *x, int incx, doublecomplex  
          *y, int incy);
```

```
void zcopy_64(long n, doublecomplex *x, long incx, doub-
```

```
lecomplex *y, long incy);
```

PURPOSE

zcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (output)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

INTEGER*8 TRANSA, M, K  
INTEGER*8, DIMENSION(:) :: DESCRA, INDX, PNTRB, PNTRE  
DOUBLE COMPLEX ALPHA, BETA
```

```
DOUBLE COMPLEX, DIMENSION(:) :: VAL
DOUBLE COMPLEX, DIMENSION(:, :) :: B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zcscmm(int transa, int m, int n, int k, doublecomplex
*alpha, int *descra, doublecomplex *val, int *indx, int
*pntrb, int *pntre, doublecomplex *b, int ldb,
doublecomplex *beta, doublecomplex* c, int ldc);
```

```
void zcscmm_64(long transa, long m, long n, long k,
doublecomplex *alpha, long *descra, doublecomplex *val, long
*indx, long *pntrb, long *pntre, doublecomplex *b, long ldb,
doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zcscmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the compressed sparse column format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

```

5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array of length
NNZ = PNTRE(K)-PNTRB(1) consisting of nonzero
entries of A. Unchanged on exit.

INDX(input)      On entry, INDX is an integer array of length
NNZ = PNTRE(K)-PNTRB(1) consisting of the row
indices of nonzero entries of A.
Unchanged on exit.

PNTRB(input)      On entry, PNTRB is an integer array of length K
such that PNTRB(J)-PNTRB(1)+1 points to location
in VAL of the first nonzero element in column J.
Unchanged on exit.

PNTRE(input)      On entry, PNTRE is an integer array of length K
such that PNTRE(J)-PNTRB(1) points to location
in VAL of the last nonzero element in column J.
Unchanged on exit.

B (input)         Array of DIMENSION ( LDB, N ).
Before entry with  TRANSA = 0,  the leading  k by n
part of the array  B  must contain the matrix  B,  otherwise
the leading  m by n  part of the array  B  must contain the
matrix B. Unchanged on exit.

LDB (input)        On entry, LDB specifies the first dimension of B as declared
in the calling (sub) program. Unchanged on exit.

BETA (input)        On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output)      Array of DIMENSION ( LDC, N ).
Before entry with  TRANSA = 0,  the leading  m by n
part of the array  C  must contain the matrix C,  otherwise
the leading  k by n  part of the array C must contain the
matrix C. On exit, the array  C  is overwritten by the  matrix
( alpha*op( A )* B  + beta*C ).

LDC (input)         On entry, LDC specifies the first dimension of C as declared
in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats in the case of complex matrices is given in section NOTES/BUGS for the ccoomm manpage.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
SUBROUTINE ZCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,  
*                VAL, INDX, IA, IA(2), B, LDB, BETA,  
*                C, LDC, WORK, LWORK )
```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zcscsm(int transa, int m, int n, int unitd,  
doublecomplex *dv, doublecomplex *alpha, int *descra,  
doublecomplex *val,  
int *indx, int *pntrb, int *pntre, doublecomplex *b,  
int ldb, doublecomplex *beta, doublecomplex* c, int ldc);
```

```
void zcscsm_64(long transa, long m, long n, long unitd,  
doublecomplex *dv, doublecomplex *alpha, long *descra,  
doublecomplex *val, long *indx, long *pntrb, long *pntre,  
doublecomplex *b, long ldb, doublecomplex *beta,  
doublecomplex *c, long ldc);
```

DESCRIPTION

zcscsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the compressed sparse column format and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic column scaling (see section NOTES for further details) Unchanged on exit.

DV(input) On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the columns of A have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper

DESCRA(3) main diagonal type
0 : non-unit
1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero entries of A. If UNITD is 4, VAL contains the scaled matrix A*D (see section NOTES for further details). Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer array of length NNZ = PNTRE(M)-PNTRB(1) consisting of the row indices of nonzero entries of A. Row indices MUST be sorted in increasing order for each column. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in column J. Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in column J. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 On entry, the leading m by n part of the array C
 must contain the matrix C. On exit, the array C is
 overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
 On exit, if LWORK= -1, WORK(1) returns the optimum size
 of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK
 should be at least M.

 For good performance, LWORK should generally be larger.
 For optimum performance on multiple processors, LWORK
 $\geq M \times N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of
 processors available to the program.

 If LWORK=0, the routine is to allocate workspace needed.

 If LWORK = -1, then a workspace query is assumed; the
 routine only calculates the optimum size of the WORK array,
 returns this value as the first entry of the WORK array,
 and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible
 with NIST FORTRAN Sparse Blas but the sources are different.
 Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN
 Sparse Blas. Besides several new features and routines are
 implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS)
 Standard", University of Tennessee, Knoxville, Tennessee,
 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included
 in this routine. Such tests must be performed before calling
 this routine.
2. If UNITD =4, the routine scales the columns of A such
 that their 2-norms are one. The scaling may improve the
 accuracy of the computed solution. Corresponding entries of
 VAL are changed only in the particular case. On return DV
 matrix stored as a vector contains the diagonal matrix by

which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = - i` where `i` is the column number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the CSC representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
SUBROUTINE ZCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
```

```
*      VAL, INDX, IA, IA(2), B, LDB, BETA,  
*      C, LDC, WORK, LWORK )
```

doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zcsrmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the compressed sparse row format, alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: <ul style="list-style-type: none">0 : operate with matrix1 : operate with transpose matrix2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure <ul style="list-style-type: none">0 : general1 : symmetric ($A=A'$)2 : Hermitian ($A= \operatorname{CONJG}(A')$)3 : Triangular4 : Skew(Anti)-Symmetric ($A=-A'$)5 : Diagonal6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$)

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero entries
 of A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ = PNTRE(M)-PNTRB(1) consisting of the column
 indices of nonzero entries of A. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M such
 that PNTRB(J)-PNTRB(1)+1 points to location in VAL
 of the first nonzero element in row J.
 Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M
 such that PNTRE(J)-PNTRB(1) points to location
 in VAL of the last nonzero element in row J.
 Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading k by n
 part of the array B must contain the matrix B, otherwise
 the leading m by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n
 part of the array C must contain the matrix C, otherwise
 the leading k by n part of the array C must contain the
 matrix C. On exit, the array C is overwritten by the matrix
 (alpha*op(A)* B + beta*C).

LDC (input) On entry, LDC specifies the first dimension of C as declared
 in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible

with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats in the case of complex matrices is given in section NOTES/BUGS for the ccoomm manpage.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each row in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of compressed sparse row format the following calling sequence should be used

```
SUBROUTINE ZCSRMM( TRANSA, M, N, K, ALPHA, DESCRA,  
*                VAL, INDX, IA, IA(2), B, LDB, BETA,  
*                C, LDC, WORK, LWORK )
```

C INTERFACE

```
#include <sunperf.h>

void zcsrsm(int transa, int m, int n, int unitd,
doublecomplex *dv, doublecomplex *alpha, int *descra,
doublecomplex *val,
int *indx, int *pntrb, int *pntre, doublecomplex *b,
int ldb, doublecomplex *beta, doublecomplex* c, int ldc);

void zcsrsm_64(long transa, long m, long n, long unitd,
doublecomplex *dv, doublecomplex *alpha, long *descra,
doublecomplex *val, long *indx, long *pntrb, long *pntre,
doublecomplex *b, long ldb, doublecomplex *beta,
doublecomplex *c, long ldc);
```

DESCRIPTION

zcsrsm performs one of the matrix-matrix operations

$$\begin{aligned} C &\leftarrow \alpha \operatorname{op}(A) B + \beta C, & C &\leftarrow \alpha D \operatorname{op}(A) B + \beta C, \\ C &\leftarrow \alpha \operatorname{op}(A) D B + \beta C, \end{aligned}$$

where α and β are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the compressed sparse row format and $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = \operatorname{inv}(A)$ or $\operatorname{op}(A) = \operatorname{inv}(A')$ or $\operatorname{op}(A) = \operatorname{inv}(\operatorname{conjg}(A'))$
(inv denotes matrix inverse, $'$ indicates matrix transpose).

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D.

If UNITD is 4, DV contains diagonal matrix by which the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
NNZ = PNTRE(M)-PNTRB(1) consisting of nonzero entries of A. If UNITD is 4, VAL contains the scaled matrix D*A (see section NOTES for further details). Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
NNZ = PNTRE(M)-PNTRB(1) consisting of the column indices of nonzero entries of A. Column indices MUST be sorted in increasing order for each row. Unchanged on exit.

PNTRB(input) On entry, PNTRB is an integer array of length M such that PNTRB(J)-PNTRB(1)+1 points to location in VAL of the first nonzero element in row J. Unchanged on exit.

PNTRE(input) On entry, PNTRE is an integer array of length M such that PNTRE(J)-PNTRB(1) points to location in VAL of the last nonzero element in row J. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C

must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK $\geq M \times N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = - i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the CSR representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSR representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But DESCRA(1) MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	alpha*op(L+I)*B+beta*C
3	1	0	alpha*op(L+D)*B+beta*C
3	2	1	alpha*op(U+I)*B+beta*C
3	2	0	alpha*op(U+D)*B+beta*C

5. It is known that there exists another representation of the compressed sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each row in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of compressed sparse row format the following calling sequence should be used

```

SUBROUTINE ZCSRSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                 VAL, INDX, IA, IA(2), B, LDB, BETA, C,
*                 LDC, WORK, LWORK )

```

lda,
long *idiag, long ndiag, doublecomplex *b, long ldb,
doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zdiamm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),
A is an M-by-K sparse matrix represented in the diagonal format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$) 5 : Diagonal 6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator

```

        1 : lower
        2 : upper
DESCRA(3) main diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)    Two-dimensional LDA-by-NDIAG array such that VAL(:,I)
               consists of non-zero elements on diagonal IDIAG(I)
               of A. Diagonals in the lower triangular part of A
               are padded from the top, and those in the upper
               triangular part are padded from the bottom.
               Unchanged on exit.

LDA(input)    On entry, NDIAG specifies the leading dimension of VAL,
               must be >= MIN(M,K). Unchanged on exit.

IDIAG(input)  Integer array of length NDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               diagonals of A in VAL. Lower triangular diagonals
               have negative offsets, the main diagonal has offset 0,
               and upper triangular diagonals have positive offset.
               Unchanged on exit.

NDIAG(input)  On entry, NDIAG specifies the number of non-zero diagonals
               in A. Unchanged on exit.

B (input)    Array of DIMENSION ( LDB, N ).
               Before entry with TRANSA = 0, the leading k by n
               part of the array B must contain the matrix B, otherwise
               the leading m by n part of the array B must contain the
               matrix B. Unchanged on exit.

LDB (input)  On entry, LDB specifies the first dimension of B as declared
               in the calling (sub) program. Unchanged on exit.

BETA (input)  On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output) Array of DIMENSION ( LDC, N ).
               Before entry with TRANSA = 0, the leading m by n
               part of the array C must contain the matrix C, otherwise
               the leading k by n part of the array C must contain the
               matrix C. On exit, the array C is overwritten by the matrix
               ( alpha*op( A )* B + beta*C ).

LDC (input)  On entry, LDC specifies the first dimension of C as declared
               in the calling (sub) program. Unchanged on exit.

DESCRIPTION

zdiasm performs one of the matrix-matrix operations

$$\begin{aligned} C &\leftarrow \alpha \operatorname{op}(A) B + \beta C, & C &\leftarrow \alpha D \operatorname{op}(A) B + \beta C, \\ C &\leftarrow \alpha \operatorname{op}(A) D B + \beta C, \end{aligned}$$

where α and β are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the diagonal format and $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = \operatorname{inv}(A)$ or $\operatorname{op}(A) = \operatorname{inv}(A')$ or $\operatorname{op}(A) = \operatorname{inv}(\operatorname{conjg}(A'))$
(inv denotes matrix inverse, $'$ indicates matrix transpose).

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.
DV(input)	On entry, DV is an array of length M consisting of the

diagonal entries of the diagonal scaling matrix D.
If UNITD is 4, DV contains diagonal matrix by which
the rows have been scaled (see section NOTES for further
details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LDA-by-NDIAG array
such that VAL(:,I) consists of non-zero elements on
diagonal IDIAG(I) of A. Diagonals in the lower triangular
part of A are padded from the top, and those in the upper
triangular part are padded from the bottom. If UNITD is 4,
VAL contains the scaled matrix D*A (see section NOTES for
further details). Otherwise, unchanged on exit.

LDA(input) On entry, LDA specifies the leading dimension of VAL
and INDX. LDA must be > MIN(M,K). Unchanged on exit.

IDIAG() On entry, IDIAG is an integer array of length NDIAG
consisting of the corresponding diagonal offsets of
the non-zero diagonals of A in VAL. Lower triangular
diagonals have negative offsets, the main diagonal
has offset 0, and upper triangular diagonals have
positive offset. Elements of IDIAG of MUST be sorted
in increasing order. Unchanged on exit.

NDIAG(input) On entry, NDIAG specifies the number of non-zero diagonals
in A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B
must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).

On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M \times N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = - i` where i is the row

number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the DIA representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

NAME

zdotc - compute the dot product of two vectors conjg(x) and y.

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTC(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
DOUBLE COMPLEX FUNCTION ZDOTC_64(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX(8) FUNCTION DOTC([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
COMPLEX(8) FUNCTION DOTC_64([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
doublecomplex zdotc(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
doublecomplex zdotc_64(long n, doublecomplex *x, long incx,  
    doublecomplex *y, long incy);
```

PURPOSE

zdotc compute the dot product of conjg(x) and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input)

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

NAME

`zdotci` - Compute the complex conjugated indexed dot product.

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTCI(NZ, X, INDX, Y)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
DOUBLE COMPLEX FUNCTION ZDOTCI_64(NZ, X, INDX, Y)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
DOUBLE COMPLEX FUNCTION DOTCI([NZ], X, INDX, Y)
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
DOUBLE COMPLEX FUNCTION DOTCI_64([NZ], X, INDX, Y)
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

`ZDOTCI` Compute the complex conjugated indexed dot product of a complex sparse vector `x` stored in compressed form with a

complex vector *y* in full storage form.

```
dot = 0
do i = 1, n
  dot = dot + conjg(x(i)) * y(indx(i))
enddo
```

ARGUMENTS

NZ (input)

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector in compressed form. Unchanged on exit.

INDX (input)

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)

Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

NAME

zdotu - compute the dot product of two vectors x and y.

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTU(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
DOUBLE COMPLEX FUNCTION ZDOTU_64(N, X, INCX, Y, INCY)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX(8) FUNCTION DOT([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
COMPLEX(8) FUNCTION DOT_64([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
doublecomplex zdotu(int n, doublecomplex *x, int incx, doublecomplex *y, int incy);
```

```
doublecomplex zdotu_64(long n, doublecomplex *x, long incx,
```

```
doublecomplex *y, long incy);
```

PURPOSE

zdotu compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)

of DIMENSION at least (1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input)

of DIMENSION at least (1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

```

```
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

ZDOTUI Compute the complex unconjugated indexed dot product

of a complex sparse vector x stored in compressed form with a complex vector y in full storage form.

```
dot = 0
do i = 1, n
  dot = dot + x(i) * y(indx(i))
enddo
```

ARGUMENTS

NZ (input)

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector in compressed form. Unchanged on exit.

INDX (input)

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)

Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

NAME

zdrot - Apply a plane rotation.

SYNOPSIS

```
SUBROUTINE ZDROT(N, X, INCX, Y, INCY, C, S)
```

```
DOUBLE PRECISION C, S  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZDROT_64(N, X, INCX, Y, INCY, C, S)
```

```
DOUBLE PRECISION C, S  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
REAL(8) :: C, S  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
REAL(8) :: C, S  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zdrot(int n, doublecomplex *x, int incx, doublecomplex
           *y, int incy, double c, double s);

void zdrot_64(long n, doublecomplex *x, long incx, double-
              lecomplex *y, long incy, double c, double s);

```

PURPOSE

zdrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

Before entry, the incremented array CX must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of CX. INCX must not be zero. Unchanged on exit.

Y (input/output)

On entry, the incremented array CY must contain the vector y. On exit, CY is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of CY. INCY must not be zero. Unchanged on exit.

C (input)

On entry, the cosine. Unchanged on exit.

S (input)

On entry, the sin. Unchanged on exit.

NAME

zdsca1 - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE ZDSCAL(N, ALPHA, Y, INCY)
```

```
DOUBLE COMPLEX Y(*)
INTEGER N, INCY
DOUBLE PRECISION ALPHA
```

```
SUBROUTINE ZDSCAL_64(N, ALPHA, Y, INCY)
```

```
DOUBLE COMPLEX Y(*)
INTEGER*8 N, INCY
DOUBLE PRECISION ALPHA
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL(8) :: ALPHA
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL(8) :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zdscal(int n, double alpha, doublecomplex *y, int
            incy);

void zdscal_64(long n, double alpha, doublecomplex *y, long
               incy);

```

PURPOSE

zdscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

N (input)
 On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
 On entry, ALPHA specifies the scalar α . Unchanged on exit.

Y (input/output)
 (1 + (n - 1) * INCY). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)
 On entry, INCY specifies the increment for the elements of Y. This routine returns immediately if INCY is less than or equal to zero. Unchanged on exit.

int maxnz, doublecomplex *b, int ldb, doublecomplex *beta,
doublecomplex *c, int ldc);
void zellmm_64 (long transa, long m, long n, long k,
doublecomplex *alpha, long *descra, doublecomplex *val, long
*indx, long lda, long maxnz, doublecomplex *b, long ldb,
doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zellmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the ellpack format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: <ul style="list-style-type: none">0 : operate with matrix1 : operate with transpose matrix2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure <ul style="list-style-type: none">0 : general1 : symmetric ($A=A'$)2 : Hermitian ($A= \operatorname{CONJG}(A')$)3 : Triangular4 : Skew(Anti)-Symmetric ($A=-A'$)5 : Diagonal6 : Skew-Hermitian ($A= -\operatorname{CONJG}(A')$) DESCRA(2) upper/lower triangular indicator <ul style="list-style-type: none">1 : lower

```

        2 : upper
DESCRA(3) main diagonal type
        0 : non-unit
        1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
        0 : C/C++ compatible
        1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
        0 : unknown
        1 : no repeated indices

VAL(input)      On entry, VAL is a two-dimensional LDA-by-MAXNZ array
                  such that VAL(I,:) consists of non-zero elements
                  in row I of A, padded by zero values if the row
                  contains less than MAXNZ. Unchanged on exit.

INDX(input)      On entry, INDX is an integer two-dimensional
                  LDA-by-MAXNZ array such that INDX(I,:)
                  consists of the column indices of the
                  nonzero elements in row I, padded by the integer
                  value I if the number of nonzeros is less than
                  MAXNZ. Unchanged on exit.

LDA(input)       On entry, LDA specifies the leading dimension of VAL
                  and INDX. Unchanged on exit.

MAXNZ(input)     On entry, MAXNZ specifies the max number of
                  nonzeros elements per row. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with TRANSA = 0, the leading k by n
                  part of the array B must contain the matrix B, otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with TRANSA = 0, the leading m by n
                  part of the array C must contain the matrix C, otherwise
                  the leading k by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

Libsunperf SPARSE BLAS is fully parallel and compatible
 with NIST FORTRAN Sparse Blas but the sources are different.
 Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN

Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by triangles and/or the main diagonal of A. The full description of the feature for point entry formats in the case of complex matrices is given in section NOTES/BUGS for the ccoomm manpage.

NAME

zellsm - Ellpack format triangular solve

SYNOPSIS

```
SUBROUTINE ZELLSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,  
*                VAL, INDX, LDA, MAXNZ,  
*                B, LDB, BETA, C, LDC, WORK, LWORK)  
INTEGER          TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,  
*                LDB, LDC, LWORK  
INTEGER          INDX(LDA,MAXNZ)  
DOUBLE COMPLEX  ALPHA, BETA  
DOUBLE COMPLEX  DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)  
  
SUBROUTINE ZELLSM_64( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,  
*                    VAL, INDX, LDA, MAXNZ,  
*                    B, LDB, BETA, C, LDC, WORK, LWORK)  
INTEGER*8        TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,  
*                    LDB, LDC, LWORK  
INTEGER*8        INDX(LDA,MAXNZ)  
DOUBLE COMPLEX  ALPHA, BETA  
DOUBLE COMPLEX  DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
SUBROUTINE ELLSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,  
*                INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER          TRANSA, M, MAXNZ  
INTEGER, DIMENSION(:) :: DESCRA  
INTEGER, DIMENSION(:, :) :: INDX  
DOUBLE COMPLEX    ALPHA, BETA  
DOUBLE COMPLEX, DIMENSION(:) :: DV  
DOUBLE COMPLEX, DIMENSION(:, :) :: VAL, B, C  
  
SUBROUTINE ELLSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,  
*                   INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])  
INTEGER*8        TRANSA, M, MAXNZ  
INTEGER*8, DIMENSION(:) :: DESCRA  
INTEGER*8, DIMENSION(:, :) :: INDX  
DOUBLE COMPLEX    ALPHA, BETA  
DOUBLE COMPLEX, DIMENSION(:) :: DV
```

```
DOUBLE COMPLEX, DIMENSION(:, :) :: VAL, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zellsm (int transa, int m, int n, int unitd,  
doublecomplex *dv, doublecomplex *alpha, int *descra,  
doublecomplex *val, int *indx, int lda, int maxnz,  
doublecomplex *b, int ldb, doublecomplex *beta,  
doublecomplex *c, int ldc);
```

```
void zellsm_64 (long transa, long m, long n, long unitd,  
doublecomplex *dv, doublecomplex *alpha, long *descra,  
doublecomplex *val, long *indx, long lda, long maxnz,  
doublecomplex *b, long ldb, doublecomplex *beta,  
doublecomplex *c, long ldc);
```

DESCRIPTION

zellsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices,
D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit,
upper or lower triangular matrix represented in the ellpack/itpack format
and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.

DV(input) On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a two-dimensional LDA-by-MAXNZ array such that VAL(I,:) consists of non-zero elements in row I of A, padded by zero values if the row contains less than MAXNZ. If UNITD is 4, VAL contains the scaled matrix D*A (see section NOTES for further details). Otherwise, unchanged on exit.

INDX(input) On entry, INDX is an integer two-dimensional LDA-by-MAXNZ array such that INDX(I,:) consists of the column indices of the nonzero elements in row I, padded by the integer value I if the number of nonzeros is less than MAXNZ. The column indices MUST be sorted in increasing order for each row. Unchanged on exit.

LDA(input) On entry, LDA specifies the leading dimension of VAL and INDX. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).

On entry, the leading m by n part of the array C must contain the matrix C . On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M .

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M \cdot N_{CPUS}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

$WORK(1)=0$ on return if the scaling has been completed successfully, otherwise $WORK(1) = -i$ where i is the row

number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the ELL representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if `UNITD=4`, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

NAME

zfft2b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M \cdot N$.

SYNOPSIS

```
SUBROUTINE ZFFT2B(M, N, A, LDA, WORK, LWORK)
```

```
DOUBLE COMPLEX A(LDA,*)  
INTEGER M, N, LDA, LWORK  
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT2B_64(M, N, A, LDA, WORK, LWORK)
```

```
DOUBLE COMPLEX A(LDA,*)  
INTEGER*8 M, N, LDA, LWORK  
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B([M], [N], A, [LDA], WORK, LWORK)
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LWORK  
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2B_64([M], [N], A, [LDA], WORK, LWORK)
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LWORK  
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void zfft2b(int m, int n, doublecomplex *a, int lda, double
            *work, int lwork);

void zfft2b_64(long m, long n, doublecomplex *a, long lda,
               double *work, long lwork);
```

ARGUMENTS

M (input) Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

N (input) Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

A (input/output)
On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

LDA (input)
Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

WORK (input)
On entry, an array with dimension of at least LWORK. WORK must have been initialized by ZFFT2I.

LWORK (input)
The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

NAME

zfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE ZFFT2I(M, N, WORK)
```

```
INTEGER M, N  
DOUBLE PRECISION WORK(*)
```

```
SUBROUTINE ZFFT2I_64(M, N, WORK)
```

```
INTEGER*8 M, N  
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFT2I(M, N, WORK)
```

```
INTEGER :: M, N  
REAL(8), DIMENSION(:) :: WORK
```

```
SUBROUTINE ZFFT2I_64(M, N, WORK)
```

```
INTEGER(8) :: M, N  
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfft2i(int m, int n, double *work);
```

```
void zfft2i_64(long m, long n, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. $M \geq 0$.

N (input) Number of columns to be transformed. $N \geq 0$.

WORK (input/output)

On entry, an array of dimension $(4 * (M + N) + 30)$ or greater. ZFFT2I needs to be called only once to initialize array WORK before calling ZFFT2F and/or ZFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

C INTERFACE

```

#include <sunperf.h>

void zfftd_ (int *iopt, int *n, double *scale, doublecomplex
            *x, double *y, double *trigs, int *ifac, double
            *work, int *lwork, int *ierr);

void zfftd_64_ (long *iopt, long *n, double *scale, doublecomplex
               *x, double *y, double *trigs, long
               *ifac, double *work, long *lwork, long *ierr);

```

PURPOSE

zfftd initializes the trigonometric weight and factor tables or computes the inverse Fast Fourier Transform of a double complex sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W^j X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

$W = \exp(\text{isign} * i * j * k * 2 * \pi / N)$

In complex-to-real transform of length N, the (N/2+1) complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored. Furthermore, due to symmetries the imaginary of the component of X(0) and X(N/2) (if N is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = 1 computes inverse FFT

N (input)

Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a double complex array whose first (N/2+1) elements are the input sequence to be transformed.

Y (output) Double precision array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output) Double precision array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output) Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1. Unchanged on exit.

WORK (workspace) Double precision array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input) Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output) On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than N)
-4 = memory allocation for workspace failed

```

PURPOSE

zfftd2 initializes the trigonometric weight and factor tables or computes the two-dimensional inverse Fast Fourier Transform of a two-dimensional double complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the rows of the input array. One-dimensional FFTs are then computed along the columns of the intermediate results.

$$Y(k_1, k_2) = \text{scale} * \sum_{j_1=0}^{N_1-1} \sum_{j_2=0}^{N_2-1} W_2 * W_1 * X(j_1, j_2)$$

where

k_1 ranges from 0 to N_1-1 and k_2 ranges from 0 to N_2-1

$i = \sqrt{-1}$

isign = 1 for inverse transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

In complex-to-real transform of length N_1 , the $(N_1/2+1)$ complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = 1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N_1 is most efficient when it is a product of small primes. $N_1 \geq 0$. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N_2 is most efficient when it is a product of small primes. $N_2 \geq 0$. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N_2) that contains input data to be transformed.

LDX (input)

Leading dimension of X. $LDX \geq (N_1/2 + 1)$
 Unchanged on exit.

Y (output)

Y is a double precision array of dimensions (LDY, N_2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are

overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same array, $LDY = 2 * LDX$ Else $LDY \geq 2 * LDX$ and LDY must be even. Unchanged on exit.

TRIGS (input/output)

Double precision array of length $2 * (N1 + N2)$ that contains the trigonometric weights. The weights are computed when the routine is called with $IOPT = 0$ and they are used in subsequent calls when $IOPT = 1$. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least $2 * 128$ that contains the factors of N1 and N2. The factors are computed when the routine is called with $IOPT = 0$ and they are used in subsequent calls when $IOPT = 1$. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least $\text{MAX}(N1, 2 * N2)$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0, 1
- 2 = $N1 < 0$
- 3 = $N2 < 0$
- 4 = $(LDX < N1/2 + 1)$
- 5 = LDY not equal $2 * LDX$ when X and Y are same array
- 6 = $(LDY < 2 * LDX$ or LDY odd) when X and Y are same array
- 7 = (LWORK not equal 0) and $(LWORK < \text{MAX}(N1, 2 * N2))$
- 8 = memory allocation failed

PURPOSE

zfftd3 initializes the trigonometric weight and factor tables or computes the three-dimensional inverse Fast Fourier Transform of a three-dimensional double complex array.

$$Y(k_1, k_2, k_3) = \text{scale} * \sum_{j_3=0}^{N_3-1} \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_3 W_2 W_1 X(j_1, j_2, j_3)$$

where

k_1 ranges from 0 to N_1-1 ; k_2 ranges from 0 to N_2-1 and k_3 ranges from 0 to N_3-1

$i = \sqrt{-1}$

isign = 1 for inverse transform

$W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$

$W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$

$W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

N3 (input)

Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. N3 >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input)

X is a double complex array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed.

LDX1 (input)

first dimension of X. LDX1 >= N1/2+1 Unchanged on exit.

LDX2 (input)

second dimension of X. LDX2 >= N2 Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY1,

LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. If X and Y are the same array, LDY1 = 2*LDX1 Else LDY1 >= 2*LDX1 and LDY1 is even Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)

Double precision array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least (MAX(N,2*N2,2*N3) + 16*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

- 0 = normal return
- 1 = IOPT is not 0 or 1
- 2 = N1 < 0
- 3 = N2 < 0
- 4 = N3 < 0
- 5 = (LDX1 < N1/2+1)
- 6 = (LDX2 < N2)
- 7 = LDY1 not equal 2*LDX1 when X and Y are same array
- 8 = (LDY1 < 2*LDX1) or (LDY1 is odd) when X and Y are not same array
- 9 = (LDY2 < N2) or (LDY2 not equal LDX2) when X and Y are same array
- 10 = (LWORK not equal 0) and ((LWORK < MAX(N,2*N2,2*N3) + 16*N3)*NCPUS)
- 11 = memory allocation failed

```

PURPOSE

zfftdm initializes the trigonometric weight and factor tables or computes the one-dimensional inverse Fast Fourier Transform of a set of double complex data sequences stored in a two-dimensional array:

$$Y(k,l) = \text{scale} * \sum_{j=0}^{N1-1} W * X(j,l)$$

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1

i = sqrt(-1)

isign = 1 for inverse transform

$W = \exp(\text{isign} * i * j * k * 2 * \pi / N1)$

In complex-to-real transform of length N1, the (N1/2+1) complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored. Furthermore, due to symmetries the imaginary of the component of X(0,0:N2-1) and X(N1/2,0:N2-1) (if N1 is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = 1 computes inverse FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns in X(0:N1/2, 0:N2-1).

LDX (input)

Leading dimension of X. LDX >= (N1/2+1) Unchanged on exit.

Y (output)

Y is a double precision array of dimensions (LDY, N2) that contains the transform results of the input sequences in Y(0:N1-1,0:N2-1). X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
 Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
 double precision array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
 double precision array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0 or 1
 -2 = N1 < 0
 -3 = N2 < 0
 -4 = (LDX < N1/2+1)
 -5 = (LDY < N1) or (LDY not equal 2*LDX when X and Y are same array)
 -6 = (LWORK not equal 0) and (LWORK < N1)
 -7 = memory allocation failed

NAME

zfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE ZFFTF(N, X, WSAVE)
```

```
DOUBLE COMPLEX X(*)  
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE ZFFTF_64(N, X, WSAVE)
```

```
DOUBLE COMPLEX X(*)  
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([N], X, WSAVE)
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE FFTF_64([N], X, WSAVE)
```

```
COMPLEX(8), DIMENSION(:) :: X  
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zfftf(int n, doublecomplex *x, double *wsave);

void zfftf_64(long n, doublecomplex *x, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array of length N containing the sequence to be transformed.

WSAVE (input)
On entry, WSAVE must be an array of dimension (4 * N + 15) or greater and must have been initialized by ZFFTI.

NAME

zfffti - initialize the array WSAVE, which is used in both ZFFTF and ZFFTB.

SYNOPSIS

```
SUBROUTINE ZFFTI(N, WSAVE)
```

```
INTEGER N  
DOUBLE PRECISION WSAVE(*)
```

```
SUBROUTINE ZFFTI_64(N, WSAVE)
```

```
INTEGER*8 N  
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFTI(N, WSAVE)
```

```
INTEGER :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

```
SUBROUTINE ZFFTI_64(N, WSAVE)
```

```
INTEGER(8) :: N  
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zfffti(int n, double *wsave);
```

```
void zfffti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. $N \geq 0$.

WSAVE (input/output)

On entry, an array of dimension $(4 * N + 15)$ or greater. ZFFTI needs to be called only once to initialize array WORK before calling ZFFTF and/or ZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

`zfftopt` - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION ZFFTOPT(LEN)
```

```
INTEGER LEN
```

```
INTEGER*8 FUNCTION ZFFTOPT_64(LEN)
```

```
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION ZFFTOPT(LEN)
```

```
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION ZFFTOPT_64(LEN)
```

```
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>
```

```
int zfftopt(int len);
```

```
long zfftopt_64(long len);
```

PURPOSE

`zfftopt` computes the length of the closest fast FFT. Fast

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2^5$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

ZFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. ZFFTOPT will return 16 for an input of $N=16$ and return $18=2^3 \cdot 3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value returned may change as the underlying

FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2^2 \cdot 13$ rather than $51=3 \cdot 17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added

and then $N=51$ will return 51.

COMPLEX(8), INTENT(OUT), DIMENSION(:) :: Y  
REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS
```

```

INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL(8), INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR

```

C INTERFACE

```

#include <sunperf.h>

void zfftz_ (int *iopt, int *n, double *scale, doublecomplex
            *x, doublecomplex *y, double *trigs, int *ifac,
            double *work, int *lwork, int *ierr);

void zfftz_64_ (long *iopt, long *n, double *scale, doublecomplex
               *x, doublecomplex *y, double *trigs,
               long *ifac, double *work, long *lwork, long
               *ierr);

```

PURPOSE

zfftz initializes the trigonometric weight and factor tables or computes the Fast Fourier transform (forward or inverse) of a double complex sequence as follows:

$$Y(k) = \text{scale} * \sum_{j=0}^{N-1} W * X(j)$$

where

k ranges from 0 to N-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

$W = \exp(\text{isign} * i * j * k * 2 * \pi / N)$

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT
 IOPT = +1 computes inverse FFT

N (input)

Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a double complex array of dimension at least N that contains the sequence to be transformed.

Y (output)

Double complex array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)

Double precision array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least 2*N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0, 1 or -1

-2 = $N < 0$

-3 = (LWORK is not 0) and (LWORK is less than 2*N)

-4 = memory allocation for workspace failed

```

C INTERFACE

```
#include <sunperf.h>  
void zfftz2_ (int *iopt, int *n1, int *n2, double *scale,  
doublecomplex *x, int *ldx, doublecomplex *y, int  
*ldy, double *trigs, int *ifac, double *work, int  
*lwork, int *ierr);
```

```
void zfftz2_64_ (long *iopt, long *n1, long *n2, double
    *scale, doublecomplex *x, long *ldx, doublecomplex
    *y, long *ldy, double *trigs, long *ifac, double
    *work, long *lwork, long *ierr);
```

PURPOSE

zfftz2 initializes the trigonometric weight and factor tables or computes the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional double complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

$$Y(k1,k2) = \text{scale} * \sum_{j2=0}^{N2-1} \sum_{j1=0}^{N1-1} W2*W1*X(j1,j2)$$

where

k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

W1 = exp(isign*i*j1*k1*2*pi/N1)

W2 = exp(isign*i*j2*k2*2*pi/N2)

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT
 IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)

Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same

array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
 Double precision array of length $2*(N1+N2)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
 Integer array of dimension at least $2*128$ that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
 Double precision array of dimension at least $2*MAX(N1,N2)*NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
 Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
 On exit, integer IERR has one of the following values:
 0 = normal return
 -1 = IOPT is not 0, 1 or -1
 -2 = $N1 < 0$
 -3 = $N2 < 0$
 -4 = $(LDX < N1)$
 -5 = $(LDY < N1)$ or (LDY not equal LDX when X and Y are same array)
 -6 = (LWORK not equal 0) and $(LWORK < 2*MAX(N1,N2)*NCPUS)$
 -7 = memory allocation failed

PURPOSE

zfftz3 initializes the trigonometric weight and factor tables or computes the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional double complex array.

$$Y(k_1, k_2, k_3) = \text{scale} * \sum_{j_3=0}^{N_3-1} \sum_{j_2=0}^{N_2-1} \sum_{j_1=0}^{N_1-1} W_3 W_2 W_1 X(j_1, j_2, j_3)$$

where
 k_1 ranges from 0 to N_1-1 ; k_2 ranges from 0 to N_2-1 and k_3 ranges from 0 to N_3-1
 $i = \sqrt{-1}$
 $\text{isign} = 1$ for inverse transform or -1 for forward transform
 $W_1 = \exp(\text{isign} * i * j_1 * k_1 * 2 * \pi / N_1)$
 $W_2 = \exp(\text{isign} * i * j_2 * k_2 * 2 * \pi / N_2)$
 $W_3 = \exp(\text{isign} * i * j_3 * k_3 * 2 * \pi / N_3)$

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

N3 (input)
Integer specifying length of the transform in the third dimension. N3 is most efficient when it is a product of small primes. N3 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX1, LDX2, N3) that contains input data to be transformed.

LDX1 (input)
first dimension of X. LDX1 >= N1 Unchanged on exit.

LDX2 (input)
second dimension of X. LDX2 >= N2 Unchanged on

exit.

Y (output)
Y is a double complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)
first dimension of Y. If X and Y are the same array, LDY1 = LDX1 Else LDY1 >= N1 Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
Double precision array of length $2*(N1+N2+N3)$ that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least $3*128$ that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least $(2*MAX(N,N2,N3) + 32*N3) * NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1) or (LDY1 not equal LDX1 when X and Y are same array)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
-9 = (LWORK not equal 0) and (LWORK < $(2*MAX(N,N2,N3) + 16*N3) * NCPUS$)
-10 = memory allocation failed

INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>  
void zfftzm_ (int *iopt, int *m, int *n, double *scale,  
doublecomplex *x, int *ldx, doublecomplex *y, int  
*ldy, double *trigs, int *ifac, double *work, int  
*lwork, int *ierr);
```

```
void zfftzm_64_ (long *iopt, long *m, long *n, double
```

```

*scale, doublecomplex *x, long *ldx, doublecomplex
*y, long *ldy, double *trigs, long *ifac, double
*work, long *lwork, long *ierr);

```

PURPOSE

zfftzm initializes the trigonometric weight and factor tables or computes the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional double complex array:

```

      N1-1
Y(k,l) = SUM W*X(j,l)
      j=0

```

where

k ranges from 0 to N1-1 and l ranges from 0 to N2-1

i = sqrt(-1)

isign = 1 for inverse transform or -1 for forward transform

W = exp(isign*i*j*k*2*pi/N1)

ARGUMENTS

IOPT (input)

Integer specifying the operation to be performed:
 IOPT = 0 computes the trigonometric weight table and factor table
 IOPT = -1 computes forward FFT
 IOPT = +1 computes inverse FFT

N1 (input)

Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)

Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)

Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)

Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)

Y is a double complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)

Double precision array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0

and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least $2*N1*NCPUS$ where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0, 1 or -1

-2 = $N1 < 0$

-3 = $N2 < 0$

-4 = ($LDX < N1$)

-5 = ($LDY < N1$) or (LDY not equal LDX when X and Y are same array)

-6 = (LWORK not equal 0) and ($LWORK < 2*N1*NCPUS$)

-7 = memory allocation failed

void zgbbrd_64(char vect, long m, long n, long ncc, long kl,
               long ku, doublecomplex *ab, long ldab, double *d,
               double *e, doublecomplex *q, long ldq, doublecom-
               plex *pt, long ldpt, doublecomplex *c, long ldc,
               long *info);
```

PURPOSE

zgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

VECT (input)

Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
 = 'Q': form Q only;
 = 'P': form P' only;
 = 'B': form both.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NCC (input)

The number of columns of the matrix C. $NCC \geq 0$.

KL (input)

The number of subdiagonals of the matrix A. $KL \geq$

0.

KU (input)

The number of superdiagonals of the matrix A. KU
>= 0.

AB (input/output)

On entry, the m-by-n band matrix A, stored in rows
1 to KL+KU+1. The j-th column of A is stored in
the j-th column of the array AB as follows:
 $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by
values generated during the reduction.

LDAB (input)

The leading dimension of the array A. LDAB >=
KL+KU+1.

D (output)

The diagonal elements of the bidiagonal matrix B.

E (output)

The superdiagonal elements of the bidiagonal
matrix B.

Q (output)

If VECT = 'Q' or 'B', the m-by-m unitary matrix Q.
If VECT = 'N' or 'P', the array Q is not refer-
enced.

LDQ (input)

The leading dimension of the array Q. LDQ >=
max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)

If VECT = 'P' or 'B', the n-by-n unitary matrix
P'. If VECT = 'N' or 'Q', the array PT is not
referenced.

LDPT (input)

The leading dimension of the array PT. LDPT >=
max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 other-
wise.

C (input/output)

On entry, an m-by-ncc matrix C. On exit, C is
overwritten by Q^*C . C is not referenced if NCC =
0.

LDC (input)

The leading dimension of the array C. LDC >=
max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK (workspace)

```
dimension(MAX(M,N))

RWORK (workspace)
dimension(MAX(M,N))

INFO (output)
= 0:  successful exit.
< 0:  if INFO = -i, the i-th argument had an illegal value.
```

INTEGER*8 IPIVOT(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON(NORM, [N], KL, KU, A, [LDA], IPIVOT, ANORM,  
                RCOND, [WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: NORM  
COMPLEX(8), DIMENSION(:) :: WORK
```

```

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER :: N, KL, KU, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE GBCON_64(NORM, [N], KL, KU, A, [LDA], IPIVOT, ANORM,
    RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, KL, KU, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

```

C INTERFACE

```

#include <sunperf.h>

void zgbcon(char norm, int n, int kl, int ku, doublecomplex
    *a, int lda, int *ipivot, double anorm, double
    *rcond, int *info);

void zgbcon_64(char norm, long n, long kl, long ku, doub-
    lecomplex *a, long lda, long *ipivot, double
    anorm, double *rcond, long *info);

```

PURPOSE

zgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by ZGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A)))$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

= '1' or 'O': 1-norm;

= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
KL >= 0.

KU (input)
The number of superdiagonals within the band of A.
KU >= 0.

A (input) Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU([M], [N], KL, KU, A, [LDA], R, C,  
                 ROWCND, COLCND, AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, KL, KU, LDA, INFO  
REAL(8) :: ROWCND, COLCND, AMAX  
REAL(8), DIMENSION(:) :: R, C
```

```
SUBROUTINE GBEQU_64([M], [N], KL, KU, A, [LDA], R, C,
```

```
ROWCND, COLCND, AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, KL, KU, LDA, INFO  
REAL(8) :: ROWCND, COLCND, AMAX  
REAL(8), DIMENSION(:) :: R, C
```

C INTERFACE

```
#include <sunperf.h>  
  
void zgbequ(int m, int n, int kl, int ku, doublecomplex *a,  
            int lda, double *r, double *c, double *rowcnd,  
            double *colcnd, double *amax, int *info);  
void zgbequ_64(long m, long n, long kl, long ku, doublecom-  
               plex *a, long lda, double *r, double *c, double  
               *rowcnd, double *colcnd, double *amax, long  
               *info);
```

PURPOSE

zgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

A (input) The band matrix A, stored in rows 1 to $KL+KU+1$.

The j -th column of A is stored in the j -th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

LDA (input)

The leading dimension of the array A . $LDA \geq KL+KU+1$.

R (output)

If $INFO = 0$, or $INFO > M$, R contains the row scale factors for A .

C (output)

If $INFO = 0$, C contains the column scale factors for A .

ROWCND (output)

If $INFO = 0$ or $INFO > M$, $ROWCND$ contains the ratio of the smallest $R(i)$ to the largest $R(i)$. If $ROWCND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by R .

COLCND (output)

If $INFO = 0$, $COLCND$ contains the ratio of the smallest $C(i)$ to the largest $C(i)$. If $COLCND \geq 0.1$, it is not worth scaling by C .

AMAX (output)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 <= M : the i -th row of A is exactly zero
 > M : the $(i-M)$ -th column of A is exactly zero

                   INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER*8 M, N, KL, KU, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GBMV([TRANSA], [M], [N], KL, KU, ALPHA, A, [LDA], X,  
               [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, KL, KU, LDA, INCX, INCY
```

```
SUBROUTINE GBMV_64([TRANSA], [M], [N], KL, KU, ALPHA, A, [LDA],
    X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, KL, KU, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgblmv(char transa, int m, int n, int kl, int ku, doublecomplex *alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex *beta, doublecomplex *y, int incy);
```

```
void zgblmv_64(char transa, long m, long n, long kl, long ku, doublecomplex *alpha, doublecomplex *a, long lda, doublecomplex *x, long incx, doublecomplex *beta, doublecomplex *y, long incy);
```

PURPOSE

zgblmv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^* x + \beta y$, or $y := \alpha \text{conjg}(A^*) x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^* x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A^*) x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

KL (input)

On entry, KL specifies the number of sub-diagonals of the matrix A. KL must satisfy $0 \leq KL$. Unchanged on exit.

KU (input)

On entry, KU specifies the number of super-diagonals of the matrix A. KU must satisfy $0 \leq KU$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku , the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        K = KU + 1 - J
        DO 10, I = MAX( 1, J - KU ), MIN( M, J + KL
          )
          A( K + I, J ) = matrix( I, J )
10      CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least $(kl + ku + 1)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$ when TRANS = 'N' or

'n' and at least $(1 + (m - 1) * \text{abs}(\text{INCX}))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (m - 1) * \text{abs}(\text{INCY}))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{INCY}))$ otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

    long ldb, doublecomplex *x, long ldx, double
    *ferr, double *berr, long *info);

```

PURPOSE

zgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
 The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)
The pivot indices from ZGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

X (input/output)
On entry, the solution matrix X, as computed by ZGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1, N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as

reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void zgbsv(int n, int kl, int ku, int nrhs, doublecomplex
          *a, int lda, int *ipivot, doublecomplex *b, int
          ldb, int *info);

void zgbsv_64(long n, long kl, long ku, long nrhs, doub-
             lecomplex *a, long lda, long *ipivot, doublecom-
             plex *b, long ldb, long *info);

```

PURPOSE

zgbsv computes the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with $KL+KU$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A .
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A .
 $KU \geq 0$.

$NRHS$ (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)

On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows:
 $A(KL+KU+1+i-j, j) = A(i, j)$ for $\max(1, j-KU) \leq i \leq \min(N, j+KL)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)

The leading dimension of the array A. $LDA \geq 2*KL+KU+1$.

IPIVOT (output)

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25	
u36													
	*	*	+	+	+	+		*	*		u13	u24	u35
u46													
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45	

```

u56
  a11  a22  a33  a44  a55  a66      u11  u22  u33  u44  u55
u66
  a21  a32  a43  a54  a65  *      m21  m32  m43  m54  m65
*
  a31  a42  a53  a64  *    *      m31  m42  m53  m64    *
*

```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

```

PURPOSE

zgbsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate

the system:

TRANS = 'N': $\text{diag}(R) * A * \text{diag}(C) * \text{inv}(\text{diag}(C)) * X = \text{diag}(R) * B$

TRANS = 'T': $(\text{diag}(R) * A * \text{diag}(C))^{**T} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

TRANS = 'C': $(\text{diag}(R) * A * \text{diag}(C))^{**H} * \text{inv}(\text{diag}(R)) * X = \text{diag}(C) * B$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is

overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if TRANS='N')

or $\text{diag}(C) * B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the

matrix A (after equilibration if FACT = 'E') as

$A = L * U$,

where L is a product of permutation and unit lower triangular

matrices with KL subdiagonals, and U is upper triangular with

KL+KU superdiagonals.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine

returns with INFO = i. Otherwise, the factored form of A is used

to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision,

INFO = N+1 is returned as a warning, but the routine still goes on

to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form

of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A^{*T} * X = B$ (Transpose)
= 'C': $A^{*H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

KL (input)

The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)

The number of superdiagonals within the band of A.
 $KU \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the matrix A in band storage, in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(KU+1+i-j, j) = A(i, j)$ for $\max(1, j-KU) \leq i \leq \min(N, j+KL)$

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows:
EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)

The leading dimension of the array A. LDA >= KL+KU+1.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by ZGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the

factorization $A = L*U$ of the equilibrated matrix A.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by $\text{diag}(R)$.
= 'C': Column equilibration, i.e., A has been postmultiplied by $\text{diag}(C)$.
= 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag}(R) * A * \text{diag}(C)$.
EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input or output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by $\text{diag}(R)$; if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input or output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by $\text{diag}(C)$; if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by $\text{diag}(R)*B$; if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by $\text{diag}(C)*B$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(C))*X$ if TRANS = 'N' and EQUED = 'C' or 'B', or $\text{inv}(\text{diag}(R))*X$ if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N) On exit, $WORK2(1)$ contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If $WORK2(1)$ is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < INFO \leq N$, then $WORK2(1)$ contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could

not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

void zgbtf2(int m, int n, int kl, int ku, doublecomplex *ab,
            int ldab, int *ipiv, int *info);

void zgbtf2_64(long m, long n, long kl, long ku, doublecom-
               plex *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

zgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows:

$$AB(kl+ku+1+i-j, j) = A(i, j) \quad \text{for} \quad \max(1, j-ku) \leq i \leq \min(m, j+kl)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. $LDAB \geq$

2*KL+KU+1.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = - i , the i -th argument had an illegal value
 > 0: if INFO = + i , U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:

On exit:

	*	*	*	+	+	+		*	*	*	u14	u25						
u36		*	*	+	+	+	+	*	*		u13	u24	u35					
u46			*	a12	a23	a34	a45	a56	*		u12	u23	u34	u45				
u56				a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55			
u66					a21	a32	a43	a54	a65	*		m21	m32	m43	m54	m65		
*						*					m21	m32	m43	m54	m65			
*							a31	a42	a53	a64	*	*		m31	m42	m53	m64	*
*																		*

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U, because of fill-in resulting from the row interchanges.

```

C INTERFACE

```
#include <sunperf.h>

void zgbtrf(int m, int n, int kl, int ku, doublecomplex *a,
            int lda, int *ipivot, int *info);

void zgbtrf_64(long m, long n, long kl, long ku, doublecom-
               plex *a, long lda, long *ipivot, long *info);
```

PURPOSE

zgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. $M \geq 0$.

N (input) Integer
The number of columns of the matrix A. $N \geq 0$.

KL (input) Integer
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input) Integer
The number of superdiagonals within the band of A.
 $KU \geq 0$.

A (input/output) Double complex array of dimension (LDA,N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows:

$$A(KL+KU+1+I-J, J) = A(I, J) \quad \text{for} \quad \text{MAX}(1, J-KU) \leq I \leq \text{MIN}(M, J+KL)$$

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input) Integer
The leading dimension of the array A. $LDA \geq 2*KL+KU+1$.

IPIVOT (output) Integer array of dimension MIN(M,N)
The pivot indices; for $1 \leq I \leq \min(M,N)$, row I of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
= 0: successful exit
< 0: if INFO = -I, the I-th argument had an illegal value
> 0: if INFO = +I, U(I,I) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $M = N = 6$, $KL = 2$, $KU = 1$:

On entry:						On exit:					
	*	*	*	+	+	+	*	*	*	u14	u25
u36	*	*	+	+	+	+	*	*		u13	u24
u46	*	a12	a23	a34	a45	a56	*	u12	u23	u34	u45
u56	a11	a22	a33	a44	a55	a66	u11	u22	u33	u44	u55
u66	a21	a32	a43	a54	a65	*	m21	m32	m43	m54	m65
*	a31	a42	a53	a64	*	*	m31	m42	m53	m64	*
*											

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGBTRS_64(TRANSA, N, KL, KU, NRHS, A, LDA, IPIVOT,  
                    B, LDB, INFO)
```

```
CHARACTER * 1 TRANSA  
DOUBLE COMPLEX A(LDA,*), B(LDB,*)  
INTEGER*8 N, KL, KU, NRHS, LDA, LDB, INFO  
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GBTRS([TRANSA], [N], KL, KU, [NRHS], A, [LDA],  
                IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8), DIMENSION(:,*) :: A, B  
INTEGER :: N, KL, KU, NRHS, LDA, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GBTRS_64([TRANSA], [N], KL, KU, [NRHS], A, [LDA],
```

```
IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA  
COMPLEX(8), DIMENSION(:, :) :: A, B  
INTEGER(8) :: N, KL, KU, NRHS, LDA, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>  
  
void zgbtrs(char transa, int n, int kl, int ku, int nrhs,  
            doublecomplex *a, int lda, int *ipivot, doublecom-  
            plex *b, int ldb, int *info);  
void zgbtrs_64(char transa, long n, long kl, long ku, long  
               nrhs, doublecomplex *a, long lda, long *ipivot,  
               doublecomplex *b, long ldb, long *info);
```

PURPOSE

zgbtrs solves a system of linear equations
 $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a gen-
eral band matrix A using the LU factorization computed by
ZGBTRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

KL (input)
The number of subdiagonals within the band of A.
 $KL \geq 0$.

KU (input)
The number of superdiagonals within the band of A.
 $KU \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. $NRHS \geq 0$.

A (input) Details of the LU factorization of the band matrix A, as computed by ZGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDA (input)
The leading dimension of the array A. LDA \geq 2*KL+KU+1.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE

```

C INTERFACE

```
#include <sunperf.h>
```

```

void zgebak(char job, char side, int n, int ilo, int ihi,
            double *scale, int m, doublecomplex *v, int ldv,
            int *info);

```

```

void zgebak_64(char job, char side, long n, long ilo, long
               ihi, double *scale, long m, doublecomplex *v, long
               ldv, long *info);

```

PURPOSE

zgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by ZGEBAL.

ARGUMENTS

JOB (input)

Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to ZGEBAL.

SIDE (input)

= 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)

The integer ILO determined by ZGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)

The integer IHI determined by ZGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE (input)

Details of the permutation and scaling factors, as returned by ZGEBAL.

M (input) The number of columns of the matrix V. $M \geq 0$.

V (input/output)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)

The leading dimension of the array V. $LDV \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value.

NAME

zgebal - balance a general complex matrix A

SYNOPSIS

```
SUBROUTINE ZGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
DOUBLE COMPLEX A(LDA,*)  
INTEGER N, LDA, ILO, IHI, INFO  
DOUBLE PRECISION SCALE(*)
```

```
SUBROUTINE ZGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
```

```
CHARACTER * 1 JOB  
DOUBLE COMPLEX A(LDA,*)  
INTEGER*8 N, LDA, ILO, IHI, INFO  
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, ILO, IHI, INFO  
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: JOB  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, ILO, IHI, INFO
```

```
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgebal(char job, int n, doublecomplex *a, int lda, int  
            *ilo, int *ihi, double *scale, int *info);
```

```
void zgebal_64(char job, long n, doublecomplex *a, long lda,  
               long *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

zgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)

Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N,
SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute
only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the input matrix A. On exit, A is
overwritten by the balanced matrix. If JOB = 'N',
A is not referenced. See Further Details.

LDA (input)

The leading dimension of the array A. LDA >=
max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit
 $A(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If $JOB = 'N'$ or $'S'$, $ILO = 1$ and $IHI = N$.

IHI (output)

ILO and IHI are set to integers such that on exit
 $A(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If $JOB = 'N'$ or $'S'$, $ILO = 1$ and $IHI = N$.

SCALE (output)

Details of the permutations and scaling factors applied to A. If $P(j)$ is the index of the row and column interchanged with row and column j and $D(j)$ is the scaling factor applied to row and column j , then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1 = D(j)$ for $j = ILO, \dots, IHI = P(j)$ for $j = IHI+1, \dots, N$. The order in which the interchanges are made is N to $IHI+1$, then 1 to $ILO-1$.

INFO (output)

$= 0$: successful exit.
 < 0 : if $INFO = -i$, the i -th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

$$P A P = \begin{pmatrix} T1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T2 \end{pmatrix}$$

where $T1$ and $T2$ are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B . Balancing consists of applying a diagonal similarity transformation $\text{inv}(D) * B * D$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T1 & X*D & Y \\ 0 & \text{inv}(D)*B*D & \text{inv}(D)*Z \\ 0 & 0 & T2 \end{pmatrix}.$$

Information about the permutations P and the diagonal matrix D is returned in the vector $SCALE$.

This subroutine is based on the EISPACK routine CBAL.

Modified by Tzu-Yi Chen, Computer Science Division, University of
California at Berkeley, USA

```

```
SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
[LWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAUQ, TAUP, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LWORK, INFO  
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>

void zgebrd(int m, int n, doublecomplex *a, int lda, double
           *d, double *e, doublecomplex *tauq, doublecomplex
           *taup, int *info);

void zgebrd_64(long m, long n, doublecomplex *a, long lda,
              double *d, double *e, doublecomplex *tauq, doublecomplex
              *taup, long *info);
```

PURPOSE

zgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: $Q^*H * A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. $M \geq 0$.

N (input) The number of columns in the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

D (output)

The diagonal elements of the bidiagonal matrix B:
 $D(i) = A(i,i)$.

E (output)

The off-diagonal elements of the bidiagonal matrix B:
if $m \geq n$, $E(i) = A(i,i+1)$ for $i = 1, 2, \dots, n-1$;
if $m < n$, $E(i) = A(i+1,i)$ for $i = 1, 2, \dots, m-1$.

TAUQ (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP (output)

The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. LWORK $\geq \max(1, M, N)$. For optimum performance LWORK $\geq (M+N)*NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) H(2) \dots H(n) \quad \text{and} \quad P = G(1) G(2) \dots G(n-1)$$

Each H(i) and G(i) has the form:

$$H(i) = I - \tau_q * v * v' \quad \text{and} \quad G(i) = I - \tau_p * u * u'$$

where τ_q and τ_p are complex scalars, and v and u are complex vectors; $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(i,i+2:n)$; τ_q is stored in

TAUQ(i) and taup in TAUP(i).
 If $m < n$,

$$Q = H(1) H(2) \dots H(m-1) \quad \text{and} \quad P = G(1) G(2) \dots G(m)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \text{tauq} * v * v' \quad \text{and} \quad G(i) = I - \text{taup} * u * u'$$

where tauq and taup are complex scalars, and v and u are complex vectors; $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(i+2:m,i)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(i,i+1:n)$; tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

$m = 6$ and $n = 5$ ($m > n$):

```
( d  e  u1 u1 u1 )
u1 )
( v1 d  e  u2 u2 )
u2 )
( v1 v2 d  e  u3 )
u3 )
( v1 v2 v3 d  e )
u4 )
( v1 v2 v3 v4 d )
u5 )
( v1 v2 v3 v4 v5 )
```

$m = 5$ and $n = 6$ ($m < n$):

```
( d  u1  u1  u1  u1
( e  d  u2  u2  u2
( v1 e  d  u3  u3
( v1 v2 e  d  u4
( v1 v2 v3 e  d
```

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

            double anorm, double *rcond, int *info);  
  
void zgecon_64(char norm, long n, doublecomplex *a, long  
               lda, double anorm, double *rcond, long *info);
```

PURPOSE

zgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by ZGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by ZGETRF.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER*8 M, N, LDA, INFO  
DOUBLE PRECISION ROWCND, COLCND, AMAX  
DOUBLE PRECISION R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU([M], [N], A, [LDA], R, C, ROWCND, COLCND,  
                AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, INFO  
REAL(8) :: ROWCND, COLCND, AMAX  
REAL(8), DIMENSION(:) :: R, C
```

```
SUBROUTINE GEEQU_64([M], [N], A, [LDA], R, C, ROWCND, COLCND,  
                   AMAX, [INFO])
```

```

COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INFO
REAL(8) :: ROWCND, COLCND, AMAX
REAL(8), DIMENSION(:) :: R, C

```

C INTERFACE

```

#include <sunperf.h>

void zggequ(int m, int n, doublecomplex *a, int lda, double
            *r, double *c, double *rowcnd, double *colcnd,
            double *amax, int *info);

void zggequ_64(long m, long n, doublecomplex *a, long lda,
               double *r, double *c, double *rowcnd, double
               *colcnd, double *amax, long *info);

```

PURPOSE

zggequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)

If INFO = 0, C contains the column scale factors for A.

ROWCND (output)

If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND (output)

If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

                   *a, long lda, long *nout, doublecomplex *w,
                   doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^*H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
 = 'N': Schur vectors are not computed;
 = 'V': Schur vectors are computed.

SORTEV (input)
 Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered:
 = 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
 LOGICAL FUNCTION of one DOUBLE COMPLEX argument
 SELECT must be declared EXTERNAL in the calling

subroutine. If `SORTEV = 'S'`, `SELECT` is used to select eigenvalues to order to the top left of the Schur form. If `SORTEV = 'N'`, `SELECT` is not referenced. The eigenvalue `W(j)` is selected if `SELECT(W(j))` is true.

N (input) The order of the matrix `A`. `N >= 0`.

A (input/output)
 DOUBLE COMPLEX array, dimension(`LDA`,`N`) On entry, the `N`-by-`N` matrix `A`. On exit, `A` has been overwritten by its Schur form `T`.

LDA (input)
 The leading dimension of the array `A`. `LDA >= max(1,N)`.

NOUT (output)
 If `SORTEV = 'N'`, `NOUT = 0`. If `SORTEV = 'S'`, `NOUT` = number of eigenvalues for which `SELECT` is true.

W (output)
 DOUBLE COMPLEX array, dimension(`N`) `W` contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form `T`.

Z (output)
 DOUBLE COMPLEX array, dimension (`LDZ`, `N`) If `JOBZ = 'V'`, `Z` contains the unitary matrix `Z` of Schur vectors. If `JOBZ = 'N'`, `Z` is not referenced.

LDZ (input)
 The leading dimension of the array `Z`. `LDZ >= 1`; if `JOBZ = 'V'`, `LDZ >= N`.

WORK (workspace)
 DOUBLE COMPLEX array, dimension(`LWORK`) On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

LDWORK (input)
 The dimension of the array `WORK`. `LDWORK >= max(1,2*N)`. For good performance, `LDWORK` must generally be larger.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

WORK2 (workspace)
 DOUBLE PRECISION array, dimension(`N`)

WORK3 (workspace)
 LOGICAL array, dimension(`N`) Not referenced if `SORTEV = 'N'`.

INFO (output)
 = 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is
 <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE..
 This could also be caused by underflow due to scaling.

    *rcone, double *rconv, long *info);

```

PURPOSE

zgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z * T * (Z^* * H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users'

Guide (where these quantities are called `s` and `sep` respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

`JOBZ` (input)

= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

`SORTEV` (input)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see `SELECT`).

`SELECT` (input)

LOGICAL FUNCTION of one `DOUBLE COMPLEX` argument `SELECT` must be declared `EXTERNAL` in the calling subroutine. If `SORTEV` = 'S', `SELECT` is used to select eigenvalues to order to the top left of the Schur form. If `SORTEV` = 'N', `SELECT` is not referenced. An eigenvalue `W(j)` is selected if `SELECT(W(j))` is true.

`SENSE` (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If `SENSE` = 'E', 'V' or 'B', `SORTEV` must equal 'S'.

`N` (input) The order of the matrix `A`. `N` \geq 0.

`A` (input/output)

`DOUBLE COMPLEX` array, dimension(`LDA`, `N`) On entry, the `N`-by-`N` matrix `A`. On exit, `A` is overwritten by its Schur form `T`.

`LDA` (input)

The leading dimension of the array `A`. `LDA` \geq `max(1,N)`.

`NOUT` (output)

If `SORTEV` = 'N', `NOUT` = 0. If `SORTEV` = 'S', `NOUT` = number of eigenvalues for which `SELECT` is true.

`W` (output)

`DOUBLE COMPLEX` array, dimension(`N`) `W` contains the computed eigenvalues, in the same order that they

appear on the diagonal of the output Schur form T.

Z (output)
 DOUBLE COMPLEX array, dimension(LDZ,N) If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

RCONE (output)
 If SENSE = 'E' or 'B', RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
 If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
 DOUBLE COMPLEX array, dimension(LDWORK) On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
 The dimension of the array WORK. LDWORK >= max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= 2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that 2*NOUT*(N-NOUT) <= N*N/2. For good performance, LDWORK must generally be larger.

WORK2 (workspace)
 DOUBLE PRECISION array, dimension(N)

BWORK3 (workspace)
 LOGICAL array, dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: if INFO = i, and i is
 <= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
 = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned);
 = N+2: after reordering, roundoff changed values of

some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE.. This could also be caused by underflow due to scaling.

           int lda, doublecomplex *w, doublecomplex *vl, int  
           ldvl, doublecomplex *vr, int ldvr, int *info);  
  
void zgeev_64(char jobvl, char jobvr, long n, doublecomplex  
              *a, long lda, doublecomplex *w, doublecomplex *vl,  
              long ldvl, doublecomplex *vr, long ldvr, long  
              *info);
```

PURPOSE

zgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)

= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of are computed.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

W (output)
W contains the computed eigenvalues.

VL (output)
If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:,j)$, the j-th column of VL.

LDVL (input)
The leading dimension of the array VL. LDVL \geq 1; if JOBVL = 'V', LDVL \geq N.

VR (input)
If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:,j)$, the j-th column of VR.

LDVR (input)
The leading dimension of the array VR. LDVR \geq 1; if JOBVR = 'V', LDVR \geq N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

```

PURPOSE

zgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diago-

nal similarity transformation $D * A * D^{**}(-1)$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;

= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by $D*A*D^{**}(-1)$, where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': left eigenvectors of A are not computed;

= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)

= 'N': right eigenvectors of A are not computed;

= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': None are computed;

= 'E': Computed for eigenvalues only;

= 'V': Computed for right eigenvectors only;

= 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)
 W contains the computed eigenvalues.

VL (output)
 If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:, j)$, the j-th column of VL.

LDVL (input)
 The leading dimension of the array VL. $LDVL \geq 1$; if JOBVL = 'V', $LDVL \geq N$.

VR (input)
 If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:, j)$, the j-th column of VR.

LDVR (input)
 The leading dimension of the array VR. $LDVR \geq 1$; if JOBVR = 'V', $LDVR \geq N$.

ILO (output)
 ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

IHI (output)
 ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

SCALE (output)
 Details of the permutations and scaling factors applied when balancing A. If $P(j)$ is the index of the row and column interchanged with row and column j, and $D(j)$ is the scaling factor applied to row and column j, then $SCALE(J) = P(J)$, for $J = 1, \dots, ILO-1 = D(J)$, for $J = ILO, \dots, IHI = P(J)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to

ILO-1.

ABNRM (output)

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)

RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)

RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK $\geq \max(1, 2*N)$, and if SENSE = 'V' or 'B', LDWORK $\geq N*N+2*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension($2*N$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

```

PURPOSE

zgegs routine is deprecated and has been replaced by routine CGGES.

ZGEGS computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver ZGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and VSR. N
>= 0.

A (input/output)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

LDA (input)

The leading dimension of A. LDA >= max(1,N).

B (input/output)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B.

LDB (input)

The leading dimension of B. LDB >= max(1,N).

ALPHA (output)

On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by ZGEGS. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in

magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)

See the description of ALPHA.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL \geq 1, and if JOBVSL = 'V', LDVSL \geq N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR \geq 1, and if JOBVSR = 'V', LDVSR \geq N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for ZGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for ZGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is N*(NB+1).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that

usually indicate LAPACK problems:

- =N+1: error return from CGGBAL
- =N+2: error return from ZGEQRF
- =N+3: error return from CUNMQR
- =N+4: error return from CUNGQR
- =N+5: error return from CGGHRD
- =N+6: error return from CHGEQZ (other than failed iteration)
- =N+7: error return from CGGBAK (computing VSL)
- =N+8: error return from CGGBAK (computing VSR)
- =N+9: error return from CLASCL (various places)

PURPOSE

zgegv routine is deprecated and has been replaced by routine CGGEV.

ZGEGV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - w B) r = 0$. A left generalized eigenvector is a vector l such that $l^*H * (A - w B) = 0$, where l^*H is the conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)
The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)
The leading dimension of B. $LDB \geq \max(1, N)$.

ALPHA (output)
On exit, $ALPHA(j)/VL(j)$, $j=1, \dots, N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/VL(j)$ may easily overflow or underflow, and $VL(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and VL always less than and usually comparable with $\text{norm}(B)$.

BETA (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not

referenced if `JOBVL = 'N'`.

VL (output)
 If `JOBVL = 'V'`, the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have `abs(real part) + abs(imag. part) = 1`, *except* that for eigenvalues with `alpha=beta=0`, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVL = 'N'`.

LDVL (input)
 The leading dimension of the matrix VL. `LDVL >= 1`, and if `JOBVL = 'V'`, `LDVL >= N`.

VR (output)
 If `JOBVR = 'V'`, the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have `abs(real part) + abs(imag. part) = 1`, *except* that for eigenvalues with `alpha=beta=0`, a zero vector will be returned as the corresponding eigenvector. Not referenced if `JOBVR = 'N'`.

LDVR (input)
 The leading dimension of the matrix VR. `LDVR >= 1`, and if `JOBVR = 'V'`, `LDVR >= N`.

WORK (workspace)
 On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

LDWORK (input)
 The dimension of the array `WORK`. `LDWORK >= max(1,2*N)`. For good performance, `LDWORK` must generally be larger. To compute the optimal value of `LDWORK`, call `ILAENV` to get blocksizes (for `ZGEQRF`, `CUNMQR`, and `CUNGQR`.) Then compute: `NB` as the `MAX` of the blocksizes for `ZGEQRF`, `CUNMQR`, and `CUNGQR`; The optimal `LDWORK` is `MAX(2*N, N*(NB+1))`.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

WORK2 (workspace)
 dimension(8*N)

INFO (output)
 = 0: successful exit
 < 0: if `INFO = -i`, the `i`-th argument had an illegal value.
 =1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but `ALPHA(j)` and `VL(j)`

```

should be correct for j=INFO+1,...,N. > N:
errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from ZGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed
iteration) =N+7: error return from CTGEVC
=N+8: error return from CGGBAK (computing VL)

=N+10: error return from CLASCL (various calls)

```

FURTHER DETAILS

Balancing -----

This driver calls CGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL^*A^*PR and PL^*B^*R will be upper triangular except for the diagonal blocks $A(i:j,i:j)$ and $B(i:j,i:j)$, with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair $DL^*PL^*A^*PR^*DR$, $DL^*PL^*B^*PR^*DR$ have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, CGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit -----

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the complex Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] In other words, upper triangular form.

```

```
DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)  
INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
```

F95 INTERFACE

```
SUBROUTINE GEHRD([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],  
[INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORKIN  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
```

```
SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],  
[INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORKIN  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgehrd(int n, int ilo, int ihi, doublecomplex *a, int
```

```

        lda, doublecomplex *tau, int *info);

void zgehrd_64(long n, long ilo, long ihi, doublecomplex *a,
              long lda, doublecomplex *tau, long *info);

```

PURPOSE

zgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)

See the description of ILO.

A (input/output)

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq$

$N \times NB$, where NB is the optimal blocksize.

If `LWORKIN` = -1, then a workspace query is assumed; the routine only calculates the optimal size of the `WORKIN` array, returns this value as the first entry of the `WORKIN` array, and no error message related to `LWORKIN` is issued by `XERBLA`.

`INFO` (output)

= 0: successful exit

< 0: if `INFO` = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo) H(ilo+1) \dots H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(i+2:ihi,i)$, and τ in $TAU(i)$.

The contents of A are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry,

on exit,

(a	a	a	a	a	a	a)	(a	a	h	h	h	h
a)	(a	a	a	a a)	(a	h	h	h
h a)	(a	a	a	a a)	(h	h	h	h
h h h)	(a	a	a	a a a)	(v2	h	h
h h h h)	(a	a	a	a a a)	(v2	h	h
v3 h h h h)	(a	a	a	a a a)	(
v2 v3 v4 h h h)	(a)	(
a)												

where a denotes an element of the original matrix A , h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GELQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgelf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgelsf_64(long m, long n, doublecomplex *a, long lda,
               doublecomplex *tau, long *info);
```

PURPOSE

zgelsf computes an LQ factorization of a complex M-by-N matrix A: $A = L * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
 < 0: if $INFO = -i$, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)', \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $\text{conjg}(v(i+1:n))$ is stored on exit in $A(i,i+1:n)$, and τ in $TAU(i)$.

void zgels (char, int, int, int, doublecomplex*, int, doublecomplex*, int, int*);
```

```
void zgels_64 (char, long, long, long, doublecomplex*, long, doublecomplex*, long, long*);
```

PURPOSE

zgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of
an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } || B - A * X ||.$$

2. If TRANS = 'N' and m < n: find the minimum norm solution of
an underdetermined system $A * X = B$.

3. If TRANS = 'C' and m >= n: find the minimum norm solution of
an undetermined system $A^{**H} * X = B$.

4. If TRANS = 'C' and m < n: find the least squares solution of
an overdetermined system, i.e., solve the least squares problem

$$\text{minimize } || B - A^{**H} * X ||.$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

TRANSA (input)

- = 'N': the linear system involves A;
- = 'C': the linear system involves A^{**H} .

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. if $M \geq N$, A is overwritten by details of its QR factorization as returned by ZGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by ZGELQF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if $TRANSA = 'N'$, or N-by-NRHS if $TRANSA = 'C'$. On exit, B is overwritten by the solution vectors, stored columnwise: if $TRANSA = 'N'$ and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if $TRANSA = 'N'$ and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if $TRANSA = 'C'$ and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if $TRANSA = 'C'$ and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If $LDWORK = -1$, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: S, RWORK

```

C INTERFACE

```

#include <sunperf.h>
void zgelsd(int m, int n, int nrhs, doublecomplex *a, int
    lda, doublecomplex *b, int ldb, double *s, double
    rcond, int *rank, int *info);

void zgelsd_64(long m, long n, long nrhs, doublecomplex *a,
    long lda, doublecomplex *b, long ldb, double *s,
    double rcond, long *rank, long *info);

```

PURPOSE

zgelsd computes the minimum-norm solution to a real linear least squares problem:

minimize 2-norm($| b - A \cdot x |$)

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines

with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $RANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m, n))$.

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

WORK (workspace)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK ≥ 1 . The exact minimum amount of workspace needed depends on M, N and NRHS. If $M \geq N$, LWORK $\geq 2*N + N*NRHS$. If $M < N$, LWORK $\geq 2*M + M*NRHS$. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
 If $M \geq N$, LRWORK $\geq 8*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS$. If $M < N$, LRWORK $\geq 8*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS$. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1

IWORK (workspace)
 LIWORK $\geq 3 * MINMN * NLVL + 11 * MINMN$, where MINMN = MIN(M,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.
 > 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```

PURPOSE

zgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm($| b - A*x |$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right

singular vectors, stored rowwise.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,M).

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,M,N).

SING (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values SING(i) \leq RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK \geq 1, and also: LDWORK \geq 2*min(M,N) + max(M,N,NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(5*min(M,N))

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```

PURPOSE

zgelsx routine is deprecated and has been replaced by routine ZGELSY.

ZGELSX computes the minimum-norm solution to a complex linear least squares problem:

minimize || A * X - B ||

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' [\text{inv}(T11) * Q1' * B]$$

[0]

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS ≥ 0 .

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
The leading dimension of the array A. LDA $\geq \max(1, M)$.

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1, M, N)$.

JPIVOT (input/output)
On entry, if JPIVOT(i) $\neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND (input)
RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/\text{RCOND}$.

IRANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
 (min(M,N) + max(N, 2*min(M,N)+NRHS)),

WORK2 (workspace)
 dimension(2*N)

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

               double rcond, long *rank, long *info);

```

PURPOSE

zgelsy computes the minimum-norm solution to a complex linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

$$A * P = Q * \begin{bmatrix} R11 & R12 \\ 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \end{bmatrix}$$

[0]

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The permutation of matrix B (the right hand side) is faster and more simple.
- o The call to the subroutine xGEQPF has been substituted by the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
- o Matrix B (the right hand side) is updated with Blas-3.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,M,N).

JPVT (input/output)
On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND (input)
RCOND is used to determine the effective rank of

A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/\text{RCOND}$.

RANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. The unblocked strategy requires that: $\text{LWORK} \geq \text{MN} + \text{MAX}(2*\text{MN}, \text{N}+1, \text{MN}+\text{NRHS})$ where $\text{MN} = \text{min}(\text{M}, \text{N})$. The block algorithm requires that: $\text{LWORK} \geq \text{MN} + \text{MAX}(2*\text{MN}, \text{NB}*(\text{N}+1), \text{MN}+\text{MN}*\text{NB}, \text{MN}+\text{NB}*\text{NRHS})$ where NB is an upper bound on the blocksize returned by ILAENV for the routines ZGEP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension($2*\text{N}$)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void zgemm(char transa, char transb, int m, int n, int k,
           doublecomplex *alpha, doublecomplex *a, int lda,
           doublecomplex *b, int ldb, doublecomplex *beta,
           doublecomplex *c, int ldc);
void zgemm_64(char transa, char transb, long m, long n, long k,
              doublecomplex *alpha, doublecomplex *a, long lda,
              doublecomplex *b, long ldb, doublecomplex *beta,
              doublecomplex *c, long ldc);
```

PURPOSE

zgemm performs one of the matrix-matrix operations

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$$

where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$ or $\text{op}(X) = \text{conjg}(X')$, α and β are scalars, and A , B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', op(B) = B'.

TRANSB = 'C' or 'c', op(B) = conjg(B').

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N >= 0. Unchanged on exit.

K (input)

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is K when TRANSA = 'N' or 'n', and is M otherwise. Before entry with TRANSA = 'N' or 'n', the leading M by K part of the array A must contain the matrix A, otherwise the leading K by M part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA >= max(1, M), otherwise LDA >= max(1, K). Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, kb), where kb is n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When

TRANSB = 'N' or 'n' then LDB \geq max(1, k), otherwise LDB \geq max(1, n). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC \geq max(1, m). Unchanged on exit.

```

```

CHARACTER(LEN=1) :: TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INCX, INCY

```

C INTERFACE

```

#include <sunperf.h>

void zgemv(char transa, int m, int n, doublecomplex *alpha,
           doublecomplex *a, int lda, doublecomplex *x, int
           incx, doublecomplex *beta, doublecomplex *y, int
           incy);
void zgemv_64(char transa, long m, long n, doublecomplex
              *alpha, doublecomplex *a, long lda, doublecomplex
              *x, long incx, doublecomplex *beta, doublecomplex
              *y, long incy);

```

PURPOSE

zgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A' x + \beta y$, or $y := \alpha \text{conjg}(A') x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A' x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A') x + \beta y$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)
 On entry, ALPHA specifies the scalar alpha.
 Unchanged on exit.

A (input)
 Before entry, the leading m by n part of the array A must contain the matrix of coefficients.
 Unchanged on exit.

LDA (input)
 On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

X (input)
 $(1 + (n - 1) * \text{abs}(INCX))$ when TRANS = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
 On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
 On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
 $(1 + (m - 1) * \text{abs}(INCY))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(INCY))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
 On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqlf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgeqlf_64(long m, long n, doublecomplex *a, long lda,
               doublecomplex *tau, long *info);
```

PURPOSE

zgeqlf computes a QL factorization of a complex M-by-N matrix A: $A = Q * L$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m \leq n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an ille-

gal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(k) \dots H(2) H(1)$, where $k = \min(m,n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(1:m-k+i-1, n-k+i)$, and τ in $TAU(i)$.

```
SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
                    [RWORK], [INFO])
```

```

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: RWORK

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqp3(int m, int n, doublecomplex *a, int lda, int
            *jpvt, doublecomplex *tau, int *info);
```

```
void zgeqp3_64(long m, long n, doublecomplex *a, long lda,
               long *jpvt, doublecomplex *tau, long *info);
```

PURPOSE

zgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M, N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(M, N)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

JPVT (input/output)

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A^*P (a leading column); if $JPVT(J) = 0$, the J-th column of A is a free column. On exit, if $JPVT(J) = K$, then the J-th column of A^*P was the K-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)
 On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK \geq N+1. For optimal performance LWORK \geq (N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
 dimension(2*N)

INFO (output)
 = 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and τ in $TAU(i)$.

#include <sunperf.h>

void zgeqpf(int m, int n, doublecomplex *a, int lda, int
           *jpivot, doublecomplex *tau, int *info);

void zgeqpf_64(long m, long n, doublecomplex *a, long lda,
              long *jpivot, doublecomplex *tau, long *info);

```

PURPOSE

zgeqpf routine is deprecated and has been replaced by routine ZGEQP3.

ZGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$

A (input/output)

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M, N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(m, n)$ elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

JPIVOT (input/output)

On entry, if JPIVOT(i) $\neq 0$, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU (output)

The scalar factors of the elementary reflectors.

```

WORK (workspace)
    dimension(N)

WORK2 (workspace)
    dimension(2*N)

INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an
          illegal value

```

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n)$$

Each $H(i)$ has the form

$$H = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$.

The matrix P is represented in `jpvt` as follows: If

$$\text{jpvt}(j) = i$$

then the j th column of P is the i th canonical unit vector.

```

```
SUBROUTINE GEQRF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqrf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgeqrf_64(long m, long n, doublecomplex *a, long lda,
               doublecomplex *tau, long *info);
```

PURPOSE

zgeqrf computes a QR factorization of a complex M-by-N matrix A: $A = Q * R$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(i+1:m,i)$, and τ in $TAU(i)$.

NAME

zgerc - perform the rank 1 operation $A := \alpha x \text{conjg}(y') + A$

SYNOPSIS

```
SUBROUTINE ZGERC(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE ZGERC_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void zgerc(int m, int n, doublecomplex *alpha, doublecomplex
          *x, int incx, doublecomplex *y, int incy, doublecomplex *a, int lda);

void zgerc_64(long m, long n, doublecomplex *alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zgerc performs the rank 1 operation $A := \alpha x \text{conjg}(y')$ + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1) * abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged

on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, m). Unchanged on exit.

    *ipivot, doublecomplex *b, long ldb, doublecomplex
    *x, long ldx, double *ferr, double *berr, long
    *info);

```

PURPOSE

zgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The original N-by-N matrix A.

LDA (input)
 The leading dimension of the array A. $LDA \geq$

max(1,N).

AF (input)
The factors L and U from the factorization $A = P * L * U$ as computed by ZGETRF.

LDAF (input)
The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input)
The pivot indices from ZGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by ZGETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GERQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgerqf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);
```

```
void zgerqf_64(long m, long n, doublecomplex *a, long lda,
               doublecomplex *tau, long *info);
```

PURPOSE

zgerqf computes an RQ factorization of a complex M-by-N matrix A: $A = R * Q$.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if $m \geq n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an ille-

gal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$Q = H(1)' H(2)' \dots H(k)'$, where $k = \min(m,n)$.
Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $\text{conjg}(v(1:n-k+i-1))$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and τ in $TAU(i)$.

NAME

zgeru - perform the rank 1 operation $A := \alpha x y' + A$

SYNOPSIS

```
SUBROUTINE ZGERU(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE ZGERU_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)  
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void zgeru(int m, int n, doublecomplex *alpha, doublecomplex
          *x, int incx, doublecomplex *y, int incy, doublecomplex *a, int lda);

void zgeru_64(long m, long n, doublecomplex *alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zgeru performs the rank 1 operation $A := \alpha x y' + A$ where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)
($1 + (m - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
($1 + (n - 1) * \text{abs}(\text{INCY})$). Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the

elements of Y. INCY must not be zero. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

    doublecomplex *vt, long ldvt, long *info);

```

PURPOSE

zgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written

$$A = U * SIGMA * conjugate-transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**H, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)

Specifies options for computing all or part of the matrix U:

= 'A': all M columns of U and all N rows of V^*H are returned in the arrays U and VT; = 'S': the first $\min(M,N)$ columns of U and the first $\min(M,N)$ rows of V^*H are returned in the arrays U and VT; = 'O': If $M \geq N$, the first N columns of U are overwritten on the array A and all rows of V^*H are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V^*H are overwritten on the array A; = 'N': no columns of U or rows of V^*H are computed.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of V^*H (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

S (output)

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

U (output)

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = $\min(M,N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first $\min(M,N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq 1$; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

VT (output)

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N unitary matrix V^*H ; if JOBZ =

'S', VT contains the first $\min(M,N)$ rows of V^*H (the right singular vectors, stored rowwise); if $JOBZ = 'O'$ and $M < N$, or $JOBZ = 'N'$, VT is not referenced.

LDVT (input)

The leading dimension of the array VT. $LDVT \geq 1$;
 if $JOBZ = 'A'$ or $JOBZ = 'O'$ and $M \geq N$, $LDVT \geq N$;
 if $JOBZ = 'S'$, $LDVT \geq \min(M,N)$.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq 1$. If $LWORK = -1$, then a workspace query is assumed. In this case, the routine only calculates the optimal size of the work array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued. The minimum workspace size requirement is as follows:

If M is much larger than N such that $M \geq (N*17/9)$:

if $JOBZ = 'N'$, $LWORK \geq 3*N$
 if $JOBZ = 'O'$, $LWORK \geq 2*N*N + 3*N$
 if $JOBZ = 'S'$, $LWORK \geq N*N + 3*N$
 if $JOBZ = 'A'$, $LWORK \geq N*N + 2*N + M$ Else if $((N*17/9) > M \geq N)$:

if $JOBZ = 'N'$, $LWORK \geq 2*N + M$
 if $JOBZ = 'O'$, $LWORK \geq 2*N + M + N*N$
 if $JOBZ = 'S'$, $LWORK \geq 2*N + M$
 if $JOBZ = 'A'$, $LWORK \geq 2*N + M$ Else if N is much larger than M such that $N \geq (M*17/9)$:

if $JOBZ = 'N'$, $LWORK \geq 3*M$
 if $JOBZ = 'O'$, $LWORK \geq 2*M*M + 3*M$
 if $JOBZ = 'S'$, $LWORK \geq M*M + 3*M$
 if $JOBZ = 'A'$, $LWORK \geq M*M + 2*M + N$ Else if $((M*17/9) > N \geq M)$:

if $JOBZ = 'N'$, $LWORK \geq 2*M + N$
 if $JOBZ = 'O'$, $LWORK \geq 2*M+N + M*M$
 if $JOBZ = 'S'$, $LWORK \geq 2*M + N$
 if $JOBZ = 'A'$, $LWORK \geq 2*M + N$

RWORK (workspace)

If $JOBZ = 'N'$, RWORK must be at least $7*\min(M,N)$.
 Otherwise, RWORK must be at least $5*\min(M,N)*\min(M,N) + 5*\min(M,N)$

IWORK (workspace)

dimension($8*\min(M,N)$)

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The updating process of SBDSDC did not converge.

```

```
COMPLEX(8), DIMENSION(:, :) :: A, B  
INTEGER :: N, NRHS, LDA, LDB, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GESV_64([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A, B  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zgesv(int n, int nrhs, doublecomplex *a, int lda, int
          *ipivot, doublecomplex *b, int ldb, int *info);

void zgesv_64(long n, long nrhs, doublecomplex *a, long lda,
              long *ipivot, doublecomplex *b, long ldb, long
              *info);

```

PURPOSE

zgesv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)
On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

               *u, long ldu, doublecomplex *vt, long ldvt,
               long *info);

```

PURPOSE

zgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

$$A = U * SIGMA * conjugate-transpose(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**H, not V.

ARGUMENTS

JOBU (input)

Specifies options for computing all or part of the matrix U:

= 'A': all M columns of U are returned in array U:

= 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; =

'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;

= 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)
 Specifies options for computing all or part of the matrix V^*H :
 = 'A': all N rows of V^*H are returned in the array VT;
 = 'S': the first $\min(m,n)$ rows of V^*H (the right singular vectors) are returned in the array VT; =
 'O': the first $\min(m,n)$ rows of V^*H (the right singular vectors) are overwritten on the array A;
 = 'N': no rows of V^*H (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A. $M \geq 0$.

N (input) The number of columns of the input matrix A. $N \geq 0$.

A (input/output)
 On entry, the M -by- N matrix A. On exit, if JOBU = 'O', A is overwritten with the first $\min(m,n)$ columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first $\min(m,n)$ rows of V^*H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,M)$.

SING (output)
 The singular values of A, sorted so that $SING(i) \geq SING(i+1)$.

U (input) (LDU,M) if JOBU = 'A' or (LDU, $\min(M,N)$) if JOBU = 'S'. If JOBU = 'A', U contains the M -by- M unitary matrix U; if JOBU = 'S', U contains the first $\min(m,n)$ columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)
 The leading dimension of the array U. $LDU \geq 1$; if JOBU = 'S' or 'A', $LDU \geq M$.

VT (input)
 If JOBVT = 'A', VT contains the N -by- N unitary matrix V^*H ; if JOBVT = 'S', VT contains the first $\min(m,n)$ rows of V^*H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. LDVT ≥ 1 ;
if JOBVT = 'A', LDVT $\geq N$; if JOBVT = 'S', LDVT \geq
min(M,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal
LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK ≥ 1 .
LDWORK $\geq 2 \cdot \text{MIN}(M,N) + \text{MAX}(M,N)$ For good perfor-
mance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LDWORK is issued by XERBLA.

WORK2 (workspace)

DIMENSION(5*MIN(M,N)). On exit, if INFO > 0,
WORK2(1:MIN(M,N)-1) contains the unconverged
superdiagonal elements of an upper bidiagonal
matrix B whose diagonal is in SING (not neces-
sarily sorted). B satisfies $A = U * B * VT$, so it
has the same singular values as A, and singular
vectors related by U and VT.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an ille-
gal value.
> 0: if CBDSQR did not converge, INFO specifies
how many superdiagonals of an intermediate bidiag-
onal form B did not converge to zero. See the
description of WORK2 above for details.

PURPOSE

zgesvx uses the LU factorization to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

$$\text{TRANS} = \text{'N'}: \text{diag(R)} * A * \text{diag(C)} \quad * \text{inv}(\text{diag(C)}) * X =$$

```

diag(R)*B
    TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X =
diag(C)*B
    TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X =
diag(C)*B
    Whether or not the system will be equilibrated depends on
the
    scaling of the matrix A, but if equilibration is used, A
is
    overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if
TRANS='N')
    or diag(C)*B (if TRANS = 'T' or 'C').
2. If FACT = 'N' or 'E', the LU decomposition is used to
factor the
    matrix A (after equilibration if FACT = 'E') as
    A = P * L * U,
    where P is a permutation matrix, L is a unit lower tri-
angular
    matrix, and U is upper triangular.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
    returns with INFO = i. Otherwise, the factored form of A
is used
    to estimate the condition number of the matrix A. If the
    reciprocal of the condition number is less than machine
precision,
    INFO = N+1 is returned as a warning, but the routine
still goes on
    to solve for X and compute error bounds as described
below.

4. The system of equations is solved for X using the fac-
tored form
    of A.

5. Iterative refinement is applied to improve the computed
solution
    matrix and calculate error bounds and backward error
estimates
    for it.

6. If equilibration was used, the matrix X is premultiplied
by
    diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or
'C') so
    that it solves the original system before equilibration.

```

ARGUMENTS

```

FACT (input)
    Specifies whether or not the factored form of the

```

matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^*T * X = B$ (Transpose)

= 'C': $A^*H * X = B$ (Conjugate transpose)

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': $A := \text{diag}(R) * A$

EQUED = 'C': $A := A * \text{diag}(C)$

EQUED = 'B': $A := \text{diag}(R) * A * \text{diag}(C)$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by ZGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the

equilibrated matrix).

LDAF (input)
 The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input or output)
 If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P*L*U$ as computed by ZGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the equilibrated matrix A.

EQUED (input or output)
 Specifies the form of equilibration that was done.
 = 'N': No equilibration (always true if FACT = 'N').
 = 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by $\text{diag(R)} * A * \text{diag(C)}$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input or output)
 The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input or output)
 The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by $\text{diag(R)}*B$; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by

`diag(C)*B.`

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(C)) * X$ if TRANSA = 'N' and EQUED = 'C' or 'B', or $\text{inv}(\text{diag}(R)) * X$ if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(2*N) On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the

solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then `WORK2(1)` contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, and i is
 - <= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned.
 - = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```

```
SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zgetf2(int m, int n, doublecomplex *a, int lda, int
            *ipiv, int *info);

void zgetf2_64(long m, long n, doublecomplex *a, long lda,
               long *ipiv, long *info);

```

PURPOSE

zgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIV (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur
if it is used to solve a system of equations.

```

void zgetrf(int m, int n, doublecomplex *a, int lda, int
            *ipivot, int *info);

void zgetrf_64(long m, long n, doublecomplex *a, long lda,
               long *ipivot, long *info);

```

PURPOSE

zgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME

zgetri - compute the inverse of a matrix using the LU factorization computed by ZGETRF

SYNOPSIS

```
SUBROUTINE ZGETRI(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER N, LDA, LDWORK, INFO  
INTEGER IPIVOT(*)
```

```
SUBROUTINE ZGETRI_64(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, LDA, LDWORK, INFO  
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, LDWORK, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, LDWORK, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zgetri(int n, doublecomplex *a, int lda, int *ipivot,
            int *info);

void zgetri_64(long n, doublecomplex *a, long lda, long
               *ipivot, long *info);
```

PURPOSE

zgetri computes the inverse of a matrix using the LU factorization computed by ZGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by ZGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from ZGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row $\text{IPIVOT}(i)$.

WORK (workspace)

On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N*\text{NB}$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetrs(char transa, int n, int nrhs, doublecomplex *a,  
            int lda, int *ipivot, doublecomplex *b, int ldb,  
            int *info);
```

```
void zgetrs_64(char transa, long n, long nrhs, doublecomplex  
               *a, long lda, long *ipivot, doublecomplex *b, long  
               ldb, long *info);
```

PURPOSE

zgetrs solves a system of linear equations

$A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N -by- N matrix A using the LU factorization computed by ZGETRF.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations:

= 'N': $A * X = B$ (No transpose)

= 'T': $A^{**T} * X = B$ (Transpose)

= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The factors L and U from the factorization $A = P * L * U$ as computed by ZGETRF.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)

The pivot indices from ZGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row $IPIVOT(i)$.

B (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8), DIMENSION(:) :: LSCALE, RSCALE

```

C INTERFACE

```

#include <sunperf.h>

void zggbak(char job, char side, int n, int ilo, int ihi,
            double *lscale, double *rscale, int m, doublecom-
            plex *v, int ldv, int *info);
void zggbak_64(char job, char side, long n, long ilo, long
               ihi, double *lscale, double *rscale, long m, doub-
               lecomplex *v, long ldv, long *info);

```

PURPOSE

zggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem $Ax = \lambda Bx$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by ZGGBAL.

ARGUMENTS

JOB (input)
 Specifies the type of backward transformation required:
 = 'N': do nothing, return immediately;
 = 'P': do backward transformation for permutation only;
 = 'S': do backward transformation for scaling only;
 = 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to ZGGBAL.

SIDE (input)
 = 'R': V contains right eigenvectors;
 = 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. $N \geq 0$.

ILO (input)
 The integers ILO and IHI determined by ZGGBAL. 1
 $\leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

IHI (input)
 The integers ILO and IHI determined by ZGGBAL. 1
 \leq ILO \leq IHI \leq N, if N > 0; ILO=1 and IHI=0, if
 N=0.

LSCALE (input)
 Details of the permutations and/or scaling factors
 applied to the left side of A and B, as returned
 by ZGGBAL.

RSCALE (input)
 Details of the permutations and/or scaling factors
 applied to the right side of A and B, as returned
 by ZGGBAL.

M (input) The number of columns of the matrix V. M \geq 0.

V (input/output)
 On entry, the matrix of right or left eigenvectors
 to be transformed, as returned by CTGEVC. On
 exit, V is overwritten by the transformed eigen-
 vectors.

LDV (input)
 The leading dimension of the matrix V. LDV \geq
 max(1,N).

INFO (output)
 = 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value.

FURTHER DETAILS

#include <sunperf.h>

void zggbal(char job, int n, doublecomplex *a, int lda,
            doublecomplex *b, int ldb, int *ilo, int *ihi,
            double *lscale, double *rscale, int *info);

void zggbal_64(char job, long n, doublecomplex *a, long lda,
               doublecomplex *b, long ldb, long *ilo, long *ihi,
               double *lscale, double *rscale, long *info);

```

PURPOSE

zggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO\$-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

JOB (input)
 Specifies the operations to be performed on A and B:
 = 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N;
 = 'P': permute only;
 = 'S': scale only;
 = 'B': both permute and scale.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

ILO (output)
ILO and IHI are set to integers such that on exit $A(i, j) = 0$ and $B(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', $ILO = 1$ and $IHI = N$.

IHI (output)
ILO and IHI are set to integers such that on exit $A(i, j) = 0$ and $B(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.

LSCALE (input)
Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $D(j)$ for $J = ILO, \dots, IHI$ and $P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (input)
Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$ and $D(j)$ for $J = ILO, \dots, IHI$ and $P(j)$ for $J = IHI+1, \dots, N$. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK (workspace)
dimension(6*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

```

PURPOSE

zggges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A,B) = ((VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H)$$

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then

form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver ZGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α,β), as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

JOBVSL (input)

= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)

= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELZTG).

DELZTG (input)

LOGICAL FUNCTION of two DOUBLE COMPLEX arguments
DELZTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELZTG is not referenced. If SORT = 'S', DELZTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue $\text{ALPHA}(j)/\text{BETA}(j)$ is selected if $\text{DELZTG}(\text{ALPHA}(j),\text{BETA}(j))$ is true.

Note that a selected complex eigenvalue may no longer satisfy $\text{DELZTG}(\text{ALPHA}(j),\text{BETA}(j)) = \text{.TRUE.}$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N (input) The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

A (input/output)

DOUBLE COMPLEX array, dimension(LDA, N) On entry,

the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA \geq max(1,N).

B (input/output)
DOUBLE COMPLEX array, dimension(LDB,N) On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB \geq max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELZTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by ZGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VSL (input)
DOUBLE COMPLEX array, dimension(LDVSL, N) If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL \geq 1, and if JOBVSL = 'V', LDVSL \geq N.

VSR (input)
DOUBLE COMPLEX array, dimension(LDVSR,N) If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR \geq 1, and if JOBVSR = 'V', LDVSR \geq N.

WORK (workspace)

DOUBLE COMPLEX array, dimension(LWORK) On exit, if
INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq
max(1,2*N). For good performance, LWORK must gen-
erally be larger.

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

RWORK (workspace)

DOUBLE PRECISION array, dimension(8*N)

BWORK (workspace)

LOGICAL array, dimension(N) Not referenced if SORT
= 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value.
=1,...,N: The QZ iteration failed. (A,B) are not
in Schur form, but ALPHA(j) and BETA(j) should be
correct for j=INFO+1,...,N. > N: =N+1: other
than QZ iteration failed in CHGEQZ
=N+2: after reordering, roundoff changed values of
some complex eigenvalues so that leading eigen-
values in the Generalized Schur form no longer
satisfy DELZTG=.TRUE. This could also be caused
due to scaling. =N+3: reordering failed in
CTGSEN.

    lecomplex *b, long ldb, long *sdim, doublecomplex
    *alpha, doublecomplex *beta, doublecomplex *vsl,
    long ldvsl, doublecomplex *vsr, long ldvsr, double
    *rconde, double *rcondv, long *info);
```

PURPOSE

zggex computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization $A,B = (VSL) S (VSR)^* H$, $(VSL) T (VSR)^* H$

where $(VSR)^{**H}$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (α,β) , as there is a reasonable interpretation for $\beta=0$ or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =
'N': Eigenvalues are not ordered;
'S': Eigenvalues are ordered (see DELCTG).

DELCTG (input)
LOGICAL FUNCTION of two DOUBLE COMPLEX arguments
DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy $DELCTG(ALPHA(j),BETA(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE (input)
Determines which reciprocal condition numbers are

computed. = 'N' : None are computed;
 = 'E' : Computed for average of selected eigenvalues only;
 = 'V' : Computed for selected deflating subspaces only;
 = 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N \geq 0.

A (input/output)
 DOUBLE COMPLEX array, dimension(LDA,N) On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
 The leading dimension of A. LDA \geq max(1,N).

B (input/output)
 DOUBLE COMPLEX array, dimension(LDB,N) On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
 The leading dimension of B. LDB \geq max(1,N).

SDIM (output)
 If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true.

ALPHA (output)
 On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j) and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
 See description of ALPHA.

VSL (input)
 If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL
>=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur
vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE (output)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2)
contain the reciprocal condition numbers for the
average of the selected eigenvalues. Not refer-
enced if SENSE = 'N' or 'V'.

RCONDV (output)

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2)
contain the reciprocal condition number for the
selected deflating subspaces. Not referenced if
SENSE = 'N' or 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal
LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 2*N.
If SENSE = 'E', 'V', or 'B', LWORK >= MAX(2*N,
2*SDIM*(N-SDIM)).

RWORK (workspace)

dimension(8*N) Real workspace.

IWORK (workspace/output)

Not referenced if SENSE = 'N'. On exit, if INFO =
0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array WORK. LIWORK >= N+2.

BWORK (workspace)

dimension(N) Not referenced if SORT = 'N'.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value.
= 1,...,N: The QZ iteration failed. (A,B) are
not in Schur form, but ALPHA(j) and BETA(j) should
be correct for j=INFO+1,...,N. > N: =N+1: other
than QZ iteration failed in CHGEQZ
=N+2: after reordering, roundoff changed values of
some complex eigenvalues so that leading eigen-
values in the Generalized Schur form no longer
satisfy DELCTG=.TRUE. This could also be caused

due to scaling. =N+3: reordering failed in
CTGSEN.

void zggev(char jobvl, char jobvr, int n, doublecomplex *a,  
           int lda, doublecomplex *b, int ldb, doublecomplex  
           *alpha, doublecomplex *beta, doublecomplex *vl,  
           int ldvl, doublecomplex *vr, int ldvr, int *info);  
  
void zggev_64(char jobvl, char jobvr, long n, doublecomplex  
              *a, long lda, doublecomplex *b, long ldb, doublecom-  
              plex *alpha, doublecomplex *beta, doublecom-  
              plex *vl, long ldvl, doublecomplex *vr, long ldvr,  
              long *info);
```

PURPOSE

zggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalues $\lambda(j)$ of (A,B) satisfies

$$u(j)**H * A = \lambda(j) * u(j)**H * B$$

where $u(j)**H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

```
JOBVL (input)  
= 'N': do not compute the left generalized eigen-  
vectors;
```

= 'V': compute the left generalized eigenvectors.

JOBVR (input)
 = 'N': do not compute the right generalized eigenvectors;
 = 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
 On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)
 The leading dimension of A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

LDB (input)
 The leading dimension of B. $LDB \geq \max(1, N)$.

ALPHA (output)
 On exit, $ALPHA(j)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $alpha/beta$. However, ALPHA will be always less than and usually comparable with $norm(A)$ in magnitude, and BETA always less than and usually comparable with $norm(B)$.

BETA (output)
 See description of ALPHA.

VL (output)
 If $JOBVL = 'V'$, the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(real\ part) + abs(imag.\ part) = 1$. Not referenced if $JOBVL = 'N'$.

LDVL (input)
 The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

VR (output)
 If $JOBVR = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns

of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq \max(1, 2*N)$. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(8*N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for $j=\text{INFO}+1, \dots, N$.
> N: =N+1: other than QZ iteration failed in SHGEQZ,
=N+2: error return from STGEVC.

PURPOSE

zggevz computes for a pair of N-by-N complex nonsymmetric

matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero.

The right eigenvector $v(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A * v(j) = \lambda(j) * B * v(j) .$$

The left eigenvector $u(j)$ corresponding to the eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^*H * A = \lambda(j) * u(j)^*H * B .$$

where $u(j)^*H$ is the conjugate-transpose of $u(j)$.

ARGUMENTS

BALANC (input)

Specifies the balance option to be performed:

= 'N': do not diagonally scale or permute;

= 'P': permute only;

= 'S': scale only;

= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)

= 'N': do not compute the left generalized eigenvectors;

= 'V': compute the left generalized eigenvectors.

JOBVR (input)

= 'N': do not compute the right generalized eigenvectors;

= 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;

= 'E': computed for eigenvalues only;

= 'V': computed for eigenvectors only;

= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. $N \geq 0$.

A (input/output)
 On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

LDA (input)
 The leading dimension of A. $LDA \geq \max(1,N)$.

B (input/output)
 On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

LDB (input)
 The leading dimension of B. $LDB \geq \max(1,N)$.

ALPHA (output)
 On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotient $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $ALPHA/BETA$. However, $ALPHA$ will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $BETA$ always less than and usually comparable with $\text{norm}(B)$.

BETA (output)
 See description of ALPHA.

VL (output)
 If JOBVL = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVL = 'N'.

LDVL (input)
 The leading dimension of the matrix VL. $LDVL \geq 1$, and if JOBVL = 'V', $LDVL \geq N$.

VR (output)
 If JOBVR = 'V', the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest

component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if `JOBVR = 'N'`.

`LDVR` (input)

The leading dimension of the matrix `VR`. `LDVR` ≥ 1 , and if `JOBVR = 'V'`, `LDVR` $\geq N$.

`ILO` (output)

`ILO` is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, \text{ILO}-1$ or $i = \text{IHI}+1, \dots, N$. If `BALANC = 'N'` or `'S'`, `ILO` = 1 and `IHI` = `N`.

`IHI` (output)

`IHI` is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, \text{ILO}-1$ or $i = \text{IHI}+1, \dots, N$. If `BALANC = 'N'` or `'S'`, `ILO` = 1 and `IHI` = `N`.

`LSCALE` (output)

Details of the permutations and scaling factors applied to the left side of `A` and `B`. If `PL(j)` is the index of the row interchanged with row j , and `DL(j)` is the scaling factor applied to row j , then `LSCALE(j) = PL(j)` for $j = 1, \dots, \text{ILO}-1$ = `DL(j)` for $j = \text{ILO}, \dots, \text{IHI}$ = `PL(j)` for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is `N` to `IHI+1`, then 1 to `ILO-1`.

`RSCALE` (output)

Details of the permutations and scaling factors applied to the right side of `A` and `B`. If `PR(j)` is the index of the column interchanged with column j , and `DR(j)` is the scaling factor applied to column j , then `RSCALE(j) = PR(j)` for $j = 1, \dots, \text{ILO}-1$ = `DR(j)` for $j = \text{ILO}, \dots, \text{IHI}$ = `PR(j)` for $j = \text{IHI}+1, \dots, N$. The order in which the interchanges are made is `N` to `IHI+1`, then 1 to `ILO-1`.

`ABNRM` (output)

The one-norm of the balanced matrix `A`.

`BBNRM` (output)

The one-norm of the balanced matrix `B`.

`RCONDE` (output)

If `SENSE = 'E'` or `'B'`, the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If `SENSE = 'V'`, `RCONDE` is not referenced.

`RCONDV` (output)

If `JOB = 'V'` or `'B'`, the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute

RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK \geq max(1,2*N). If SENSE = 'N' or 'E', LWORK \geq 2*N. If SENSE = 'V' or 'B', LWORK \geq 2*N*N+2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(6*N) Real workspace.

IWORK (workspace)

dimension(N+2) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)

dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N:
=N+1: other than QZ iteration failed in CHGEQZ.
=N+2: error return from CTGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between

the i -th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{hord}(w, \lambda) \leq \text{EPS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{RCONDE}(I)$$

An approximate error bound for the angle between the i -th computed eigenvector $\text{VL}(i)$ or $\text{VR}(i)$ is given by

$$\text{PS} * \text{norm}(\text{ABNRM}, \text{BBNRM}) / \text{DIF}(i).$$

For further explanation of the reciprocal condition numbers RCONDE and RCONDV , see section 4.11 of LAPACK User's Guide.

#include <sunperf.h>
```

```

void zgglm(int n, int m, int p, doublecomplex *a, int lda,
           doublecomplex *b, int ldb, doublecomplex *d, doublecomplex *x, doublecomplex *y, int *info);

void zgglm_64(long n, long m, long p, doublecomplex *a,
              long lda, doublecomplex *b, long ldb, doublecomplex *d, doublecomplex *x, doublecomplex *y, long *info);

```

PURPOSE

zgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad ||y||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad ||\text{inv}(B)*(d-A*x)||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $0 \leq M \leq N$.

P (input) The number of columns of the matrix B. $P \geq N-M$.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1, N)$.

D (input/output)
 On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
 On exit, X and Y are the solutions of the GLM problem.

Y (output)
 On exit, X and Y are the solutions of the GLM problem.

WORK (workspace)
 On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)
 The dimension of the array WORK. $LDWORK \geq \max(1, N+M+P)$. For optimum performance, $LDWORK \geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

INFO (output)
 = 0: successful exit.
 < 0: if $INFO = -i$, the i-th argument had an illegal value.

               doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1 * Q) * H * (Z1 * Z)'$$

ARGUMENTS

COMPQ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product $Q1 * Q$ is returned.

COMPZ (input)

= 'N': do not compute Q;
 = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product $Q1 * Q$ is returned.

N (input) The order of the matrices A and B. $N \geq 0$.

ILO (input)
 It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to ZGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)
 See description of ILO.

A (input/output)
 On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)
 The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input/output)
 On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

LDB (input)
 The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

Q (input/output)
 If $\text{COMPQ}='N'$: Q is not referenced.
 If $\text{COMPQ}='I'$: on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If $\text{COMPQ}='V'$: on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by $Q1*Q$.

LDQ (input)
 The leading dimension of the array Q. $\text{LDQ} \geq N$ if $\text{COMPQ}='V'$ or $'I'$; $\text{LDQ} \geq 1$ otherwise.

Z (input/output)
 If $\text{COMPZ}='N'$: Z is not referenced.
 If $\text{COMPZ}='I'$: on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is the product of the Givens transformations which are applied to A and B on the right. If $\text{COMPZ}='V'$: on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by $Z1*Z$.

LDZ (input)
The leading dimension of the array Z. LDZ \geq N if
COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in Matrix Computations, by Golub and van Loan (Johns Hopkins Press).

COMPLEX(8), DIMENSION(:, :) :: A, B  
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zgglse(int m, int n, int p, doublecomplex *a, int lda,
            doublecomplex *b, int ldb, doublecomplex *c, doublecomplex *d, doublecomplex *x, int *info);

void zgglse_64(long m, long n, long p, doublecomplex *a,
               long lda, doublecomplex *b, long ldb, doublecomplex *c, doublecomplex *d, doublecomplex *x, long *info);

```

PURPOSE

zgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } ||c - A*x||_2 \quad \text{subject to} \quad B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that

$P \leq N \leq M+P$, and

$$\text{rank}(B) = P \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

P (input) The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

C (input/output)

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements $N-P+1$ to M of vector C.

D (input/output)

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)

On exit, X is the solution of the LSE problem.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

$LDWORK$ (input)

The dimension of the array WORK. $LDWORK \geq \max(1, M+N+P)$. For optimum performance $LDWORK \geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if $INFO = -i$, the i -th argument had an illegal value.

INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zggqrf(int n, int m, int p, doublecomplex *a, int lda,
           doublecomplex *taua, doublecomplex *b, int ldb,
           doublecomplex *taub, int *info);
```

```
void zggqrf_64(long n, long m, long p, doublecomplex *a,
               long lda, doublecomplex *taua, doublecomplex *b,
               long ldb, doublecomplex *taub, long *info);
```

PURPOSE

zggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

$$\begin{array}{l} \text{if } N \geq M, \quad R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} M \\ N-M \end{matrix}, \quad \text{or if } N < M, \quad R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} N \\ M-N \end{matrix} \\ \text{if } N \leq M, \quad R = \begin{pmatrix} R_{11} & \\ & 0 \end{pmatrix} \begin{matrix} N \\ M-N \end{matrix}, \quad \text{or if } N > M, \quad R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} N \\ M-N \end{matrix} \end{array}$$

where R11 is upper triangular, and

$$\begin{array}{l} \text{if } N \leq P, \quad T = \begin{pmatrix} 0 & T_{12} \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } N > P, \quad T = \begin{pmatrix} T_{11} \\ & \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix} \\ \text{if } N > P, \quad T = \begin{pmatrix} T_{11} \\ & \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix}, \quad \text{or if } N \leq P, \quad T = \begin{pmatrix} T_{11} \\ & \end{pmatrix} \begin{matrix} N \\ P-N \end{matrix} \end{array}$$

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'^*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of matrix Z.

ARGUMENTS

N (input) The number of rows of the matrices A and B. $N \geq 0$.

M (input) The number of columns of the matrix A. $M \geq 0$.

P (input) The number of columns of the matrix B. $P \geq 0$.

A (input/output)

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N,M)-by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAU_A, represent the unitary matrix Q as a product of min(N,M) elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

TAU_A (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray B(1:N, P-N+1:P) contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAU_B, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

TAU_B (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(n, m).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}a * v * v'$$

where $\text{tau}a$ is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(i+1:n, i)$, and $\text{tau}a$ in $\text{TAUA}(i)$.

To form Q explicitly, use LAPACK subroutine CUNGQR.

To use Q to update another matrix, use LAPACK subroutine CUNMQR.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \text{tau}b * v * v'$$

where $\text{tau}b$ is a complex scalar, and v is a complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(n-k+i, 1:p-k+i-1)$, and $\text{tau}b$ in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine CUNGRQ.

To use Z to update another matrix, use LAPACK subroutine CUNMRQ.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zggrqf(int m, int p, int n, doublecomplex *a, int lda,
            doublecomplex *taua, doublecomplex *b, int ldb,
            doublecomplex *taub, int *info);
```

```
void zggrqf_64(long m, long p, long n, doublecomplex *a,
               long lda, doublecomplex *taua, doublecomplex *b,
               long ldb, doublecomplex *taub, long *info);
```

PURPOSE

zggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

$$\begin{array}{l} \text{if } M \leq N, \quad R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} \begin{matrix} M \\ M-N \end{matrix}, \quad \text{or if } M > N, \quad R = \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix} \begin{matrix} N \\ N \end{matrix} \\ \text{where } R_{12} \text{ or } R_{21} \text{ is upper triangular, and} \end{array}$$

where R12 or R21 is upper triangular, and

$$\begin{array}{l} \text{if } P \geq N, \quad T = \begin{pmatrix} T_{11} \end{pmatrix} \begin{matrix} N \\ P \end{matrix}, \quad \text{or if } P < N, \quad T = \begin{pmatrix} T_{11} & T_{12} \\ 0 & \end{pmatrix} \begin{matrix} P \\ N-P \end{matrix} \\ \text{where } T_{11} \text{ is upper triangular.} \end{array}$$

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*\text{inv}(B)$:

$$A*\text{inv}(B) = (R*\text{inv}(T))*Z'$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of the matrix Z.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

TAUUA (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P,N)-by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAUUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,P)$.

TAUB (output)

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1,N,M,P)$. For optimum performance $LWORK \geq \max(N,M,P) * \max(NB1,NB2,NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

```

= 0:  successful exit
< 0:  if INFO=-i, the i-th argument had an illegal
value.

```

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(k), \text{ where } k = \min(m,n).$$

Each $H(i)$ has the form

$$H(i) = I - \text{taua} * v * v'$$

where taua is a complex scalar, and v is a complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(m-k+i,1:n-k+i-1)$, and taua in $\text{TAUA}(i)$.

To form Q explicitly, use LAPACK subroutine CUNGRQ.

To use Q to update another matrix, use LAPACK subroutine CUNMRQ.

The matrix Z is represented as a product of elementary reflectors

$$Z = H(1) H(2) \dots H(k), \text{ where } k = \min(p,n).$$

Each $H(i)$ has the form

$$H(i) = I - \text{taub} * v * v'$$

where taub is a complex scalar, and v is a complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i+1:p,i)$, and taub in $\text{TAUB}(i)$.

To form Z explicitly, use LAPACK subroutine CUNGQR.

To use Z to update another matrix, use LAPACK subroutine CUNMQR.

    *alpha, double *beta, doublecomplex *u, long ldu,
    doublecomplex *v, long ldv, doublecomplex *q, long
    ldq, long *iwork3, long *info);

```

PURPOSE

zggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

$$U' A Q = D1 * (\begin{smallmatrix} 0 & R \end{smallmatrix}), \quad V' B Q = D2 * (\begin{smallmatrix} 0 & R \end{smallmatrix})$$

where U, V and Q are unitary matrices, and Z' means the conjugate transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B')', then R is a (K+L)-by-(K+L) non-singular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D1 = \begin{matrix} & K & L \\ \begin{matrix} K \\ L \\ M-K-L \end{matrix} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & K & L \\ \begin{matrix} L \\ P-L \end{matrix} & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & N-K-L & K & L \\ K & \begin{pmatrix} 0 & R_{11} & R_{12} \end{pmatrix} \\ L & \begin{pmatrix} 0 & 0 & R_{22} \end{pmatrix} \end{matrix}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)),$
 $S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)),$
 $C^{**2} + S^{**2} = I.$
 R is stored in $A(1:K+L, N-K-L+1:N)$ on exit.

If $M-K-L < 0,$

$$D1 = \begin{matrix} & K & M-K & K+L-M \\ K & \begin{pmatrix} I & 0 & 0 \end{pmatrix} \\ M-K & \begin{pmatrix} 0 & C & 0 \end{pmatrix} \end{matrix}$$

$$D2 = \begin{matrix} & K & M-K & K+L-M \\ M-K & \begin{pmatrix} 0 & S & 0 \end{pmatrix} \\ K+L-M & \begin{pmatrix} 0 & 0 & I \end{pmatrix} \\ P-L & \begin{pmatrix} 0 & 0 & 0 \end{pmatrix} \end{matrix}$$

$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{matrix} & N-K-L & K & M-K & K+L-M \\ K & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \end{pmatrix} \\ M-K & \begin{pmatrix} 0 & 0 & R_{22} & R_{23} \end{pmatrix} \\ K+L-M & \begin{pmatrix} 0 & 0 & 0 & R_{33} \end{pmatrix} \end{matrix}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$
 $S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$
 $C^{**2} + S^{**2} = I.$

$(R_{11} \ R_{12} \ R_{13})$ is stored in $A(1:M, N-K-L+1:N),$ and R_{33} is stored

$(0 \ R_{22} \ R_{23})$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The routine computes $C, S, R,$ and optionally the unitary transformation matrices U, V and $Q.$

In particular, if B is an N -by- N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of $A \cdot \text{inv}(B):$

$$A \cdot \text{inv}(B) = U \cdot (D1 \cdot \text{inv}(D2)) \cdot V'.$$

If (A', B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and $B.$ Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

$$A' \cdot A \cdot x = \text{lambda} \cdot B' \cdot B \cdot x.$$

In some literature, the GSVD of A and B is presented in the form

$$U' \cdot A \cdot X = (0 \ D1), \quad V' \cdot B \cdot X = (0 \ D2)$$

where U and V are orthogonal and X is nonsingular, and $D1$ and $D2$ are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q * \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}$$

ARGUMENTS

JOBV (input)
 = 'U': Unitary matrix U is computed;
 = 'N': U is not computed.

JOBQ (input)
 = 'V': Unitary matrix V is computed;
 = 'N': V is not computed.

JOBQ (input)
 = 'Q': Unitary matrix Q is computed;
 = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)
 On exit, K and L specify the dimension of the sub-blocks described in Purpose. K + L = effective numerical rank of (A',B')'.

L (output)
 On exit, K and L specify the dimension of the sub-blocks described in Purpose. K + L = effective numerical rank of (A',B')'.

A (input/output)
 On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
 On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,P).

ALPHA (output)
 On exit, ALPHA and BETA contain the generalized

singular value pairs of A and B; ALPHA(1:K) = 1,
 ALPHA(1:K) = 1,
 BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L)
 = C,
 BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)=
 C, ALPHA(M+1:K+L)= 0
 BETA(K+1:M) = S, BETA(M+1:K+L) = 1 and
 ALPHA(K+L+1:N) = 0
 BETA(K+L+1:N) = 0

BETA (output)

See description of ALPHA.

U (output)

If JOBU = 'U', U contains the M-by-M unitary
 matrix U. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU >=
 max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)

If JOBV = 'V', V contains the P-by-P unitary
 matrix V. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. LDV >=
 max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)

If JOBQ = 'Q', Q contains the N-by-N unitary
 matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >=
 max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)

dimension(MAX(3*N,M,P)+N)

WORK2 (workspace)

dimension(2*N)

IWORK3 (output)

dimension(N) On exit, IWORK3 stores the sorting
 information. More precisely, the following loop
 will sort ALPHA for I = K+1, min(M,K+L) swap
 ALPHA(I) and ALPHA(IWORK3(I)) endfor such that
 ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)

= 0: successful exit.
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value.
 > 0: if INFO = 1, the Jacobi-type procedure
 failed to converge. For further details, see sub-

routine CTGSJA.

```

PURPOSE

zggsvp computes unitary matrices U, V and Q such that

$$\begin{array}{c}
 \begin{array}{ccc}
 & L & (\begin{array}{ccc} 0 & 0 & A23 \end{array}) \\
 M-K-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array} \\
 \\
 = \begin{array}{ccc}
 & N-K-L & \begin{array}{cc} K & L \end{array} \\
 K & (\begin{array}{ccc} 0 & A12 & A13 \end{array}) & \text{if } M-K-L < 0; \\
 M-K & (\begin{array}{ccc} 0 & 0 & A23 \end{array})
 \end{array} \\
 \\
 V' * B * Q = \begin{array}{ccc}
 & N-K-L & \begin{array}{cc} K & L \end{array} \\
 L & (\begin{array}{ccc} 0 & 0 & B13 \end{array}) \\
 P-L & (\begin{array}{ccc} 0 & 0 & 0 \end{array})
 \end{array}
 \end{array}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L ≥ 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix

(A',B')'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine ZGGSVD.

ARGUMENTS

JOBV (input)

= 'U': Unitary matrix U is computed;
= 'N': U is not computed.

JOBQ (input)

= 'V': Unitary matrix V is computed;
= 'N': V is not computed.

JOBQ (input)

= 'Q': Unitary matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. $M \geq 0$.

P (input) The number of rows of the matrix B. $P \geq 0$.

N (input) The number of columns of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input/output)

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

TOLA (input)

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
 See description of TOLA.

K (output)
 On exit, K and L specify the dimension of the sub-
 blocks described in Purpose section. $K + L =$
 effective numerical rank of $(A', B')'$.

L (output)
 See the description of K.

U (input) If JOBU = 'U', U contains the unitary matrix U.
 If JOBU = 'N', U is not referenced.

LDU (input)
 The leading dimension of the array U. $LDU \geq$
 $\max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

V (input) If JOBV = 'V', V contains the unitary matrix V.
 If JOBV = 'N', V is not referenced.

LDV (input)
 The leading dimension of the array V. $LDV \geq$
 $\max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

Q (input) If JOBQ = 'Q', Q contains the unitary matrix Q.
 If JOBQ = 'N', Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. $LDQ \geq$
 $\max(1, N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

IWORK (workspace)
 dimension(N)

RWORK (workspace)
 dimension(2*N)

TAU (workspace)
 dimension(N)

WORK (workspace)
 dimension(MAX(3*N, M, P))

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine CGEQPF for the QR fac-
 torization with column pivoting to detect the effective
 numerical rank of the a matrix. It may be replaced by a

better rank determination strategy.

NAME

zgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE ZGSSCO ( COND, HANDLE, IER )
```

```
INTEGER          IER
DOUBLE PRECISION COND
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSCO - Condition number estimate.

PARAMETERS

COND - DOUBLE PRECISION

On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, [ZGSSFA](#)().

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-700 : Invalid calling sequence - need to call ZGSSFA first.

-710 : Condition number estimate not available (not implemented for this HANDLE's matrix type).

NAME

zgssda - Deallocate working storage for the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSDA ( HANDLE, IER )
```

```
INTEGER                IER  
DOUBLE PRECISION      HANDLE(150)
```

PURPOSE

ZGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array
On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

- [PARAMETERS](#)

NAME

zgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE ZGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )
```

```
INTEGER          NEQNS, COLSTR(*), ROWIND(*), IER  
DOUBLE COMPLEX   VALUES(*)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER
On entry, **NEQNS** specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, **COLSTR**(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, **ROWIND**(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE COMPLEX array
On entry, **VALUES**(*) is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on

exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 300 : Invalid calling sequence - need to call ZGSSOR first.
- 301 : Failure to dynamically allocate memory.
- 666 : Internal error.

                OUTUNT, MSGGLVL, IER
CHARACTER*3      ORDMTHD
DOUBLE COMPLEX   VALUES(*), RHS(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSFS - General sparse solver one call interface.

PARAMETERS

MTXTYP - CHARACTER*2

On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

'sp' or 'SP' - symmetric structure, Hermitian positive definite values
'ss' or 'SS' - symmetric structure, symmetric values
'su' or 'SU' - symmetric structure, unsymmetric values
'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1

On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER
 On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array
 On entry, *COLSTR*(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
 On entry, *ROWIND*(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE COMPLEX array
 On entry, *VALUES*(*) is an array of size COLSTR(NEQNS+1)-1, containing the non-zero numeric values of the sparse matrix to be factored. Unchanged on exit.

NRHS - INTEGER
 On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(*) - DOUBLE COMPLEX array
 On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
 On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

ORDMTHD - CHARACTER*3
 On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
 'mmd' or 'MMD' - multiple minimum degree
 'gnd' or 'GND' - general nested dissection
 'uso' or 'USO' - user specified ordering (see ZGSSUO)

Unchanged on exit.

OUTUNT - INTEGER
 Output unit. Unchanged on exit.

MSGLVL - INTEGER
 Message level.

0 - no output from solver.
 (No messages supported for this release.)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
 On entry, *HANDLE*(*) is an array of containing information needed by the solver, and must be passed

unchanged to each sparse solver subroutine.

Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 101 : Failure to dynamically allocate memory.
- 102 : Invalid matrix type.
- 103 : Invalid pivot option.
- 104 : Number of nonzeros is less than NEQNS.
- 105 : NEQNS < 1
- 106 : Invalid matrix structure.
- 201 : Failure to dynamically allocate memory.
- 301 : Failure to dynamically allocate memory.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS
- 666 : Internal error.

Contents

- [NAME](#)
- [SYNOPSIS](#)
- [PURPOSE](#)
- [PARAMETERS](#)

NAME

zgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,  
                  MSGLVL, HANDLE, IER )  
  
CHARACTER*2      MTXTYP  
CHARACTER*1      PIVOT  
INTEGER          NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2
On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

 'sp' or 'SP' - symmetric structure, Hermitian positive definite values
 'ss' or 'SS' - symmetric structure, symmetric values
 'su' or 'SU' - symmetric structure, unsymmetric values
 'uu' or 'UU' - unsymmetric structure, unsymmetric values

Unchanged on exit.

PIVOT - CHARACTER*1
On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

 'n' or 'N' - no pivoting is used
 (Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, **COLSTR**(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, **ROWIND**(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, **HANDLE**(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGLVL - INTEGER

Message level.

0 - no output from solver.

(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.

-102 : Invalid matrix type.

-103 : Invalid pivot option.

-104 : Number of nonzeros less than NEQNS.

-105 : NEQNS < 1

-106 : Invalid matrix structure.

```

```
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'gnd' or 'GND' - general nested dissection
'uso' or 'USO' - user specified ordering (see ZGSSUO)

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 200 : Invalid calling sequence - need to call ZGSSIN first.
- 201 : Failure to dynamically allocate memory.
- 666 : Internal error.

Contents

NAME

zgssps - Print general sparse solver statics.

SYNOPSIS

```
SUBROUTINE ZGSSPS ( HANDLE, IER )
```

```
INTEGER          IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-800 : Invalid calling sequence - need to call ZGSSSL first.
-899 : Printed solver statistics not supported this release.

Contents

- [NAME](#)
- [SYNOPSIS](#)

NAME

zgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSRP ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call ZGSSOR first.

Contents

NAME

zgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )
```

```
INTEGER          NRHS, LDRHS, IER  
DOUBLE COMPLEX   RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER
On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - DOUBLE COMPLEX array
On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER
On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER

- INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call ZGSSFA first.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS

Contents

NAME

zgssuo - User supplied permutation for ordering used in the general sparse solver.

SYNOPSIS

```
SUBROUTINE ZGSSUO ( PERM, HANDLE, IER )
```

```
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

ZGSSUO - User supplied permutation for ordering. Must be called after [ZGSSIN\(\)](#) (sparse solver initialization) and before [ZGSSOR\(\)](#) (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array

On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, [HANDLE](#)(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call ZGSSIN first.

    RCOND, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: NORM
```

```
COMPLEX(8), DIMENSION(:) :: LOW, D, UP1, UP2, WORK
```

```
INTEGER(8) :: N, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIVOT
```

```
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgtcon(char norm, int n, doublecomplex *low, doublecom-  
    plex *diag, doublecomplex *up1, doublecomplex  
    *up2, int *ipivot, double anorm, double *rcond,  
    int *info);
```

```
void zgtcon_64(char norm, long n, doublecomplex *low, doub-  
    lecomplex *diag, doublecomplex *up1, doublecomplex  
    *up2, long *ipivot, double anorm, double *rcond,  
    long *info);
```

PURPOSE

zgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by ZGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. $N \geq 0$.

LOW (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

D (input) The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first superdiagonal of U.

UP2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

zgthr - Gathers specified elements from y into x.

SYNOPSIS

```
SUBROUTINE ZGTHR(NZ, Y, X, INDX)
```

```
DOUBLE COMPLEX Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE ZGTHR_64(NZ, Y, X, INDX)
```

```
DOUBLE COMPLEX Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE GTHR([NZ], Y, X, INDX)
```

```
  COMPLEX(8), DIMENSION(:) :: Y, X  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE GTHR_64([NZ], Y, X, INDX)
```

```
  COMPLEX(8), DIMENSION(:) :: Y, X  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

ZGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only

the elements of `y` whose indices are listed in `indx` are referenced.

```
do i = 1, n
    x(i) = y(indx(i))
enddo
```

ARGUMENTS

`NZ (input)` - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

`Y (input)`

Vector in full storage form. Unchanged on exit.

`X (output)`

Vector in compressed form. Contains elements of `y` whose indices are listed in `indx` on exit.

`INDX (input)` - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in `INDX` are distinct and greater than zero. Unchanged on exit.

Contents

NAME

zgthrz - Gather and zero.

SYNOPSIS

```
SUBROUTINE ZGTHRZ(NZ, Y, X, INDX)
```

```
DOUBLE COMPLEX Y(*), X(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE ZGTHRZ_64(NZ, Y, X, INDX)
```

```
DOUBLE COMPLEX Y(*), X(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE GTHRZ([NZ], Y, X, INDX)
```

```
COMPLEX(8), DIMENSION(:) :: Y, X  
INTEGER :: NZ  
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)
```

```
COMPLEX(8), DIMENSION(:) :: Y, X  
INTEGER(8) :: NZ  
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

ZGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The

gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)

Vector in full storage form. Gathered elements are set to zero.

X (output)

Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

    *ipivot, doublecomplex *b, long ldb, doublecomplex
    *x, long ldx, double *ferr, double *berr, long
    *info);

```

PURPOSE

zgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)
The (n-1) subdiagonal elements of A.

D (input) The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

DF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X, as computed by ZGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

```

```

        int ldb, int *info);

void zgtsv_64(long n, long nrhs, doublecomplex *low, doublecomplex
              *diag, doublecomplex *up, doublecomplex
              *b, long ldb, long *info);

```

PURPOSE

zgtsv solves the equation

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A'X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input/output)
On entry, LOW must contain the (n-1) subdiagonal elements of A. On exit, LOW is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

D (input/output)
On entry, D must contain the diagonal elements of A. On exit, D is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) superdiagonal elements of A. On exit, UP is overwritten by the (n-1) elements of the first superdiagonal of U.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
 $\max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

```

PURPOSE

zgtsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a tridiagonal matrix of order N and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
as $A = L * U$, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with
nonzeros in
only the main diagonal and first two superdiagonals.
2. If some $U(i,i)=0$, so that U is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine
precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.
3. The system of equations is solved for X using the fac-
tored form
of A.
4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A
has been supplied on entry. = 'F': LOWF, DF,
UPF1, UPF2, and IPIVOT contain the factored form
of A; LOW, D, UP, LOWF, DF, UPF1, UPF2 and IPIVOT
will not be modified. = 'N': The matrix will be
copied to LOWF, DF, and UPF1 and factored.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

LOW (input)
The (n-1) subdiagonal elements of A.

D (input) The n diagonal elements of A.

UP (input/output)
The (n-1) superdiagonal elements of A.

LOWF (input or output)
If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by ZGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DF (input or output)
If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input or output)
If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input or output)
If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by ZGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

```
WORK2 (workspace)
    dimension(N)
```

```
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an illegal value
    > 0:  if INFO = i, and i is
    <= N:  U(i,i) is exactly zero.  The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed.  RCOND = 0 is returned.
    = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.
```

SUBROUTINE GTTRF([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: LOW, D, UP1, UP2  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GTTRF_64([N], LOW, D, UP1, UP2, IPIVOT, [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: LOW, D, UP1, UP2  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zgtrrf(int n, doublecomplex *low, doublecomplex *diag,
            doublecomplex *up1, doublecomplex *up2, int
            *ipivot, int *info);

void zgtrrf_64(long n, doublecomplex *low, doublecomplex
               *diag, doublecomplex *up1, doublecomplex *up2,
               long *ipivot, long *info);
```

PURPOSE

zgtrrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

D (input/output)

On entry, D must contain the diagonal elements of A.

On exit, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or $i+1$; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit
< 0: if INFO = - k , the k -th argument had an illegal value
> 0: if INFO = k , $U(k,k)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

    *b, long ldb, long *info);
```

PURPOSE

zgtrfs solves one of the systems of equations

$A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, with a tri-diagonal matrix A using the LU factorization computed by ZGTTRF.

ARGUMENTS

TRANSA (input)

Specifies the form of the system of equations. =
'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)

The (n-1) multipliers that define the matrix L from the LU factorization of A.

D (input) The n diagonal elements of the upper triangular matrix U from the LU factorization of A .

UP1 (input)
The $(n-1)$ elements of the first super-diagonal of U .

UP2 (input)
The $(n-2)$ elements of the second super-diagonal of U .

IPIVOT (input)
The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row $IPIVOT(i)$.
 $IPIVOT(i)$ will always be either i or $i+1$;
 $IPIVOT(i) = i$ indicates a row interchange was not required.

B (input/output)
On entry, the matrix of right hand side vectors B .
On exit, B is overwritten by the solution vectors X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if $INFO = -k$, the k -th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```

void zhbev(char jobz, char uplo, int n, int kd, doublecom-
    plex *a, int lda, double *w, doublecomplex *z, int
    ldz, int *info);
void zhbev_64(char jobz, char uplo, long n, long kd, doub-
    lecomplex *a, long lda, double *w, doublecomplex
    *z, long ldz, long *info);

```

PURPOSE

zhbev computes all the eigenvalues and, optionally, eigen-
vectors of a complex Hermitian band matrix A.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. KD >= 0.

A (input/output)
 On entry, the upper or lower triangle of the Her-
 mitian band matrix A, stored in the first KD+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array A as follows: if
 UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-
 kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j)
 for j<=i<=min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

LDA (input)

The leading dimension of the array A. LDA \geq KD + 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1,N).

WORK (workspace)

dimension(N)

WORK2 (workspace)

dimension(max(1,3*N-2))

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>  
void zhbevd(char jobz, char uplo, int n, int kd, doublecom-  
plex *ab, int ldab, double *w, doublecomplex *z,  
int ldz, int *info);  
  
void zhbevd_64(char jobz, char uplo, long n, long kd, doub-  
lecomplex *ab, long ldab, double *w, doublecomplex  
*z, long ldz, long *info);
```

PURPOSE

zhbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KD >= 0.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD + 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ \geq 1, and if JOBZ = 'V', LDZ \geq max(1, N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If N \leq 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If N \leq 1,

LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N . If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```

#include <sunperf.h>

void zhbevz(char jobz, char range, char uplo, int n, int kd,
    doublecomplex *a, int lda, doublecomplex *q, int
    ldq, double vl, double vu, int il, int iu, double
    abtol, int *nfound, double *w, doublecomplex *z,
    int ldz, int *ifail, int *info);

void zhbevz_64(char jobz, char range, char uplo, long n,
    long kd, doublecomplex *a, long lda, doublecomplex
    *q, long ldq, double vl, double vu, long il, long
    iu, double abtol, long *nfound, double *w, doub-
    lecomplex *z, long ldz, long *ifail, long *info);

```

PURPOSE

zhbevz computes selected eigenvalues and, optionally, eigen-
vectors of a complex Hermitian band matrix A. Eigenvalues
and eigenvectors can be selected by specifying either a
range of values or a range of indices for the desired eigen-
values.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval
(VL,VU] will be found; = 'I': the IL-th through
IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

A (input/output)
 On entry, the upper or lower triangle of the Her-
 mitian band matrix A, stored in the first KD+1
 rows of the array. The j-th column of A is stored
 in the j-th column of the array A as follows: if
 UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-$
 $kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$
 for $j \leq i \leq \min(n, j+kd)$.

 On exit, A is overwritten by values generated dur-
 ing the reduction to tridiagonal form.

LDA (input)
 The leading dimension of the array A. $LDA \geq KD +$
 1.

Q (output)
 If JOBZ = 'V', the N-by-N unitary matrix used in
 the reduction to tridiagonal form. If JOBZ = 'N',
 the array Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. If JOBZ =
 'V', then $LDQ \geq \max(1, N)$.

VL (input)
 If RANGE='V', the lower and upper bounds of the
 interval to be searched for eigenvalues. $VL < VU$.
 Not referenced if RANGE = 'A' or 'I'.

VU (input)
 If RANGE='V', the lower and upper bounds of the
 interval to be searched for eigenvalues. $VL < VU$.
 Not referenced if RANGE = 'A' or 'I'.

IL (input)
 If RANGE='I', the indices (in ascending order) of
 the smallest and largest eigenvalues to be
 returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$
 and $IU = 0$ if $N = 0$. Not referenced if RANGE =
 'A' or 'V'.

IU (input)
 If RANGE='I', the indices (in ascending order) of

the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If $ABTOL$ is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $ABTOL$ is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting $ABTOL$ to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If $RANGE = 'A'$, $NFOUND = N$, and if $RANGE = 'I'$, $NFOUND = IU - IL + 1$.

W (output)

The first $NFOUND$ elements contain the selected eigenvalues in ascending order.

Z (input) If $JOBZ = 'V'$, then if $INFO = 0$, the first $NFOUND$ columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $IFAIL$. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of $NFOUND$ is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace)
 dimension(N)

WORK2 (workspace)
 dimension(7*N)

IWORK3 (workspace)
 dimension(5*N)

IFAIL (output)
 If JOBZ = 'V', then if INFO = 0, the first NFOUND
 elements of IFAIL are zero. If INFO > 0, then
 IFAIL contains the indices of the eigenvectors
 that failed to converge. If JOBZ = 'N', then
 IFAIL is not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: if INFO = i, then i eigenvectors failed to
 converge. Their indices are stored in array
 IFAIL.

                *bb, long ldbb, doublecomplex *x, long ldx, long
                *info);

```

PURPOSE

zhbgsst reduces a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A .

B must have been previously factorized as S^*H*S by CPBSTF, using a split Cholesky factorization. A is overwritten by $C = X^*H*A*X$, where $X = S^{*(-1)}*Q$ and Q is a unitary matrix chosen to preserve the bandwidth of A .

ARGUMENTS

```

VECT (input)
    = 'N': do not form the transformation matrix X;
    = 'V': form X.

UPLO (input)
    = 'U': Upper triangle of A is stored;
    = 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
    The number of superdiagonals of the matrix A if
    UPLO = 'U', or the number of subdiagonals if UPLO
    = 'L'. KA >= 0.

KB (input)
    The number of superdiagonals of the matrix B if

```

UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka) <= i <= j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j <= i <= min(n,j+ka).

On exit, the transformed matrix X^*HAX , stored in the same format as A.

LDAB (input)

The leading dimension of the array AB. LDAB >= KA+1.

BB (input)

The banded factor S from the split Cholesky factorization of B, as returned by CPBSTF, stored in the first kb+1 rows of the array.

LDBB (input)

The leading dimension of the array BB. LDBB >= KB+1.

X (output)

If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N) if VECT = 'V'; LDX >= 1 otherwise.

WORK (workspace)

dimension(N)

RWORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

              *bb, long ldbb, double *w, doublecomplex *z, long
              ldz, long *info);

```

PURPOSE

zhbqv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $Ax = (\lambda)Bx$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KA \geq 0$.

KB (input)
 The number of superdiagonals of the matrix B if
 UPLO = 'U', or the number of subdiagonals if UPLO

= 'L'. KB >= 0.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)

The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

LDBB (input)

The leading dimension of the array BB. LDBB >= KB+1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)

dimension(N)

RWORK (workspace)

dimension(3*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
 <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero;
 > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

    kb, doublecomplex *ab, long ldab, doublecomplex
    *bb, long ldbb, double *w, doublecomplex *z, long
    ldz, long *info);

```

PURPOSE

zhbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```

JOBZ (input)
    = 'N': Compute eigenvalues only;
    = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
    = 'U': Upper triangles of A and B are stored;

```

= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

KA (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KA \geq 0$.

KB (input)
The number of superdiagonals of the matrix B if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. $KB \geq 0$.

AB (input/output)
On entry, the upper or lower triangle of the Her-
mitian band matrix A, stored in the first $ka+1$
rows of the array. The j-th column of A is stored
in the j-th column of the array AB as follows: if
UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$
for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. $LDAB \geq KA+1$.

BB (input/output)
On entry, the upper or lower triangle of the Her-
mitian band matrix B, stored in the first $kb+1$
rows of the array. The j-th column of B is stored
in the j-th column of the array BB as follows: if
UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$
for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky fac-
torization $B = S^*H^*S$, as returned by CPBSTF.

LDBB (input)
The leading dimension of the array BB. $LDBB \geq KB+1$.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the
matrix Z of eigenvectors, with the i-th column of
Z holding the eigenvector associated with $W(i)$.
The eigenvectors are normalized so that $Z^*H^*B^*Z = I$.
If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$,
and if JOBZ = 'V', $LDZ \geq N$.

WORK (workspace)
 On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
 On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
 The dimension of array RWORK. If $N \leq 1$, LRWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LRWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
 On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
 The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, and i is:
 <= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then CPBSTF returned INFO = i: B is not positive definite.

The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

void zhbgvx_64(char jobz, char range, char uplo, long n,
    long ka, long kb, doublecomplex *ab, long ldab,
    doublecomplex *bb, long ldbb, doublecomplex *q,
    long ldq, double vl, double vu, long il, long iu,
    double abstol, long *m, double *w, doublecomplex
    *z, long ldz, long *ifail, long *info);

```

PURPOSE

zhbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $Ax = (\lambda)Bx$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)

```

        = 'N':  Compute eigenvalues only;
        = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
    = 'A': all eigenvalues will be found;
    = 'V': all eigenvalues in the half-open interval
            (VL,VU] will be found; = 'I': the IL-th through
            IU-th eigenvalues will be found.

UPLO (input)
    = 'U':  Upper triangles of A and B are stored;
    = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
    The number of superdiagonals of the matrix A if
    UPLO = 'U', or the number of subdiagonals if UPLO
    = 'L'. KA >= 0.

KB (input)
    The number of superdiagonals of the matrix B if
    UPLO = 'U', or the number of subdiagonals if UPLO
    = 'L'. KB >= 0.

AB (input/output)
    On entry, the upper or lower triangle of the Her-
    mitian band matrix A, stored in the first ka+1
    rows of the array. The j-th column of A is stored
    in the j-th column of the array AB as follows: if
    UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-
    ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j)
    for j<=i<=min(n,j+ka).

    On exit, the contents of AB are destroyed.

LDAB (input)
    The leading dimension of the array AB. LDAB >=
    KA+1.

BB (input/output)
    On entry, the upper or lower triangle of the Her-
    mitian band matrix B, stored in the first kb+1
    rows of the array. The j-th column of B is stored
    in the j-th column of the array BB as follows: if
    UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-
    kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j)
    for j<=i<=min(n,j+kb).

    On exit, the factor S from the split Cholesky fac-
    torization  $B = S^*H^*S$ , as returned by CPBSTF.

LDBB (input)
    The leading dimension of the array BB. LDBB >=
    KB+1.

```

Q (output)

If JOBZ = 'V', the n-by-n matrix used in the reduction of $A*x = (\text{lambda})*B*x$ to standard form, i.e. $C*x = (\text{lambda})*x$, and consequently C to tri-diagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'N', LDQ ≥ 1 . If JOBZ = 'V', LDQ $\geq \max(1,N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; IL = 1 and IU = 0 if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tri-diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

M (output)
The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that $Z^H B Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

WORK (workspace)
dimension(N)

RWORK (workspace)
dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: then i eigenvectors failed to converge. Their indices are stored in array IFAIL.
> N: if INFO = N + i, for $1 \leq i \leq N$, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

```
SUBROUTINE HBMV_64(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX],
```

```
BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, K, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbmv(char uplo, int n, int k, doublecomplex *alpha,  
           doublecomplex *a, int lda, doublecomplex *x, int  
           incx, doublecomplex *beta, doublecomplex *y, int  
           incy);  
void zhbmv_64(char uplo, long n, long k, doublecomplex  
              *alpha, doublecomplex *a, long lda, doublecomplex  
              *x, long incx, doublecomplex *beta, doublecomplex  
              *y, long incy);
```

PURPOSE

zhbmv performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

K (input)

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy $0 \leq K$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

COMPLEX(8), DIMENSION(:,:) :: AB, Q  
INTEGER(8) :: N, KD, LDAB, LDQ, INFO  
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhbtrd(char vect, char uplo, int n, int kd, doublecom-  
plex *ab, int ldab, double *d, double *e, doub-  
lecomplex *q, int ldq, int *info);  
void zhbtrd_64(char vect, char uplo, long n, long kd, doub-  
lecomplex *ab, long ldab, double *d, double *e,  
doublecomplex *q, long ldq, long *info);
```

PURPOSE

zhbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^* H * A * Q = T$.

ARGUMENTS

VECT (input)

- = 'N': do not form Q;
- = 'V': form Q;
- = 'U': update a matrix X, by forming $X*Q$.

UPLO (input)

- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$

for $j \leq i \leq \min(n, j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the elements on the first superdiagonal (if $UPLO = 'U'$) or the first subdiagonal (if $UPLO = 'L'$) are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)

The leading dimension of the array AB. $LDAB \geq KD+1$.

D (output)

The diagonal elements of the tridiagonal matrix T.

E (output)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i, i+1)$ if $UPLO = 'U'$; $E(i) = T(i+1, i)$ if $UPLO = 'L'$.

Q (input/output)

On entry, if $VECT = 'U'$, then Q must contain an N-by-N matrix X; if $VECT = 'N'$ or $'V'$, then Q need not be set.

On exit: if $VECT = 'V'$, Q contains the N-by-N unitary matrix Q; if $VECT = 'U'$, Q contains the product $X*Q$; if $VECT = 'N'$, the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq 1$, and $LDQ \geq N$ if $VECT = 'V'$ or $'U'$.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an illegal value

               lda, long *ipivot, double anorm, double *rcond,
               long *info);
```

PURPOSE

zhecon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U^*D U^{**H}$ or $A = L^*D L^{**H}$ computed by ZHETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U^*D U^{**H}$;
= 'L': Lower triangular, form is $A = L^*D L^{**H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZHETRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

C INTERFACE

```

#include <sunperf.h>

void zheev(char jobz, char uplo, int n, doublecomplex *a,
           int lda, double *w, int *info);

void zheev_64(char jobz, char uplo, long n, doublecomplex
              *a, long lda, double *w, long *info);

```

PURPOSE

zheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK \geq max(1,2*N-1). For optimal efficiency, LDWORK \geq (NB+1)*N, where NB is the blocksize for ZHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(max(1,3*N-2))

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

C INTERFACE

```

#include <sunperf.h>
void zheevd(char jobz, char uplo, int n, doublecomplex *a,
            int lda, double *w, int *info);

void zheevd_64(char jobz, char uplo, long n, doublecomplex
               *a, long lda, double *w, long *info);

```

PURPOSE

zheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $N + 1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N + N^2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of the array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N. If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N^2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal
LIWORK.

LIWORK (input)
The dimension of the array IWORK. If $N \leq 1$,
LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$,
LIWORK must be at least 1. If JOBZ = 'V' and
 $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the IWORK array, returns this value as the first
entry of the IWORK array, and no error message
related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, the algorithm failed to con-
verge; i off-diagonal elements of an intermediate
tridiagonal form did not converge to zero.

```

PURPOSE

zheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, ZHEEVR calls CSTEGR to compute the eigenspectrum using Relatively Robust Representations. CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$

to high
 relative accuracy by the dqds algorithm,
 (c) If there is a cluster of close eigenvalues, "choose"
 sigma_i
 close to the cluster, and go to step (a),
 (d) Given the approximate eigenvalue lambda_j of L_i D_i
 L_i^T,
 compute the corresponding eigenvector by forming a
 rank-revealing twisted factorization.
 The desired accuracy of the output can be specified by the
 input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : ZHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. ZHEEVR calls SSTEGBZ and CSTEIN on non-ieee machines and when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
 = 'A': all eigenvalues will be found.
 = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their

eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. $LWORK \geq \max(1, 2*N)$. For optimal efficiency, $LWORK \geq (NB+1)*N$, where NB is the max of the blocksize for ZHETRD and for CUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK (input)

The length of the array RWORK. $LRWORK \geq \max(1, 24*N)$.

If LRWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK \geq max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: Internal error

    *info);

```

PURPOSE

zheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

JOBZ (input)
    = 'N': Compute eigenvalues only;
    = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
    = 'A': all eigenvalues will be found.
    = 'V': all eigenvalues in the half-open interval
    (VL,VU] will be found. = 'I': the IL-th through
    IU-th eigenvalues will be found.

UPLO (input)
    = 'U': Upper triangle of A is stored;
    = 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold

2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)

On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. $\text{LDWORK} \geq \max(1, 2*N)$. For optimal efficiency, $\text{LDWORK} \geq (\text{NB}+1)*N$, where NB is the max of the blocksize for ZHETRD and for CUNMTR as returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(7*N)

IWORK3 (workspace)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```

C INTERFACE

```
#include <sunperf.h>
```

```

void zhegs2(int itype, char uplo, int n, doublecomplex *a,
            int lda, doublecomplex *b, int ldb, int *info);

void zhegs2_64(long itype, char uplo, long n, doublecomplex
               *a, long lda, doublecomplex *b, long ldb, long
               *info);

```

PURPOSE

zhegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U')*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$.
 If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U'*U$ or $L'*L$ by CPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U')*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$;
 = 2 or 3: compute $U*A*U'$ or $L'*A*L$.

UPLO (input)
 Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular
 = 'L': Lower triangular

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

               *a, long lda, doublecomplex *b, long ldb, long
               *info);

```

PURPOSE

zhegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$

If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by CPOTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$;
 = 2 or 3: compute $U*A*U^{**H}$ or $L^{**H}*A*L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**H}*U$; = 'L': Lower triangle of A is stored and B is factored as $L*L^{**H}$.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,
stored in the same format as A.

LDA (input)

The leading dimension of the array A. LDA \geq
max(1,N).

B (input) The triangular factor from the Cholesky factoriza-
tion of B, as returned by CPOTRF.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

#include <sunperf.h>

void zhegv(int itype, char jobz, char uplo, int n, doublecomplex *a, int lda, doublecomplex *b, int ldb, double *w, int *info);

void zhegv_64(long itype, char jobz, char uplo, long n, doublecomplex *a, long lda, doublecomplex *b, long ldb, double *w, long *info);

```

PURPOSE

zhegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $Ax = (\lambda)Bx$, $A*Bx = (\lambda)x$, or $B*Ax = (\lambda)x$. Here A and B are assumed to be Hermitian and B is also positive definite.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:
 = 1: $Ax = (\lambda)Bx$
 = 2: $A*Bx = (\lambda)x$
 = 3: $B*Ax = (\lambda)x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)
 On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of

the matrix A.

On exit, if `JOBZ = 'V'`, then if `INFO = 0`, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if `ITYPE = 1` or `2`, $Z^*H*B*Z = I$; if `ITYPE = 3`, $Z^*H*inv(B)*Z = I$. If `JOBZ = 'N'`, then on exit the upper triangle (if `UPLO='U'`) or the lower triangle (if `UPLO='L'`) of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. `LDA` $\geq \max(1,N)$.

B (input/output)

On entry, the Hermitian positive definite matrix B. If `UPLO = 'U'`, the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If `UPLO = 'L'`, the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if `INFO` $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

LDB (input)

The leading dimension of the array B. `LDB` $\geq \max(1,N)$.

W (output)

If `INFO = 0`, the eigenvalues in ascending order.

WORK (workspace)

On exit, if `INFO = 0`, `WORK(1)` returns the optimal `LDWORK`.

LDWORK (input)

The length of the array `WORK`. `LDWORK` $\geq \max(1,2*N-1)$. For optimal efficiency, `LDWORK` $\geq (NB+1)*N$, where `NB` is the blocksize for `ZHETRD` returned by `ILAENV`.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

WORK2 (workspace)

`dimension(max(1,3*N-2))`

INFO (output)

`= 0`: successful exit
`< 0`: if `INFO = -i`, the i-th argument had an ille-

gal value

> 0: CPOTRF or ZHEEV returned an error code:

<= N: if INFO = i, ZHEEV failed to converge; i
off-diagonal elements of an intermediate tridiagonal
form did not converge to zero; > N: if INFO
= N + i, for $1 \leq i \leq N$, then the leading minor
of order i of B is not positive definite. The
factorization of B could not be completed and no
eigenvalues or eigenvectors were computed.

    *a, int lda, doublecomplex *b, int ldb, double *w, int *info);

void zhegvd_64(long itype, char jobz, char uplo, long n, doublecomplex
    *a, long lda, doublecomplex *b, long ldb, double *w, long *info);

```

PURPOSE

zhegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```

ITYPE (input)
    Specifies the problem type to be solved:
    = 1:   $A*x = (\lambda)B*x$ 
    = 2:   $A*B*x = (\lambda)x$ 
    = 3:   $B*A*x = (\lambda)x$ 

JOBZ (input)
    = 'N':  Compute eigenvalues only;

```

= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

- = 'U': Upper triangles of A and B are stored;
- = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq N + 1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N +$

N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of the array RWORK. If $N \leq 1$, LRWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LRWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or ZHEEVD returned an error code:
<= N: if INFO = i, ZHEEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

zhegvx computes selected eigenvalues, and optionally, eigen-
vectors of a complex generalized Hermitian-definite eigen-
problem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or
 $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian
and B is also positive definite. Eigenvalues and eigenvec-
tors can be selected by specifying either a range of values
or a range of indices for the desired eigenvalues.

ARGUMENTS

```

ITYPE (input)
    Specifies the problem type to be solved:
    = 1:  $A*x = (\lambda)B*x$ 
    = 2:  $A*B*x = (\lambda)x$ 

```

= 3: $B^*A*x = (\text{lambda})*x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found.
- = 'V': all eigenvalues in the half-open interval $(VL, VU]$ will be found.
- = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangles of A and B are stored;
- = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)
 If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
 If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
 The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with INFO > 0, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

M (output)
 The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output)
 The first M elements contain the selected eigenvalues in ascending order.

Z (output)
 If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^* T^* B^* Z = I$; if

ITYPE = 3, $Z^*T \text{inv}(B) * Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z ; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z . LDZ ≥ 1 , and if JOBZ = 'V', LDZ $\geq \max(1,N)$.

WORK (workspace/output)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. LWORK $\geq \max(1, 2*N-1)$. For optimal efficiency, LWORK $\geq (NB+1)*N$, where NB is the blocksize for ZHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(7*N)

IWORK (workspace)

dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0 , then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or ZHEEVX returned an error code:
 $\leq N$: if INFO = i, ZHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL.
 $> N$: if INFO = $N + i$, for $1 \leq i \leq N$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no

eigenvalues or eigenvectors were computed.

FURTHER DETAILS

              doublecomplex *b, long ldb, doublecomplex *beta,
              doublecomplex *c, long ldc);

```

PURPOSE

zhemm performs one of the matrix-matrix operations $C := \alpha A B + \beta C$ or $C := \alpha B A + \beta C$ where α and β are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha A B + \beta C$,

SIDE = 'R' or 'r' $C := \alpha B A + \beta C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least $\max(1, m)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, m)$. Unchanged on exit.

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y  
COMPLEX(8), DIMENSION(:, :) :: A
```

```
INTEGER(8) :: N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhmv(char uplo, int n, doublecomplex *alpha, doublecomplex *a, int lda, doublecomplex *x, int incx, doublecomplex *beta, doublecomplex *y, int incy);
```

```
void zhmv_64(char uplo, long n, doublecomplex *alpha, doublecomplex *a, long lda, doublecomplex *x, long incx, doublecomplex *beta, doublecomplex *y, long incy);
```

PURPOSE

zhmv performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular

part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

```

```

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, INCX, LDA
REAL(8) :: ALPHA

```

C INTERFACE

```

#include <sunperf.h>

void zher(char uplo, int n, double alpha, doublecomplex *x,
          int incx, doublecomplex *a, int lda);

void zher_64(char uplo, long n, double alpha, doublecomplex
             *x, long incx, doublecomplex *a, long lda);

```

PURPOSE

zher performs the hermitian rank 1 operation $A := \alpha x x^* \text{conjg}(x) + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

```

```
void zher2_64(char uplo, long n, doublecomplex *alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *a, long lda);
```

PURPOSE

zher2 performs the hermitian rank 2 operation $A := \alpha x \text{conjg}(y') + \text{conjg}(\alpha) y \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

Y (input)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

```

```

SUBROUTINE HER2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
                   [LDB], BETA, C, [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL(8) :: BETA

```

C INTERFACE

```

#include <sunperf.h>
void zher2k(char uplo, char transa, int n, int k, doublecom-
           plex *alpha, doublecomplex *a, int lda, doublecom-
           plex *b, int ldb, double beta, doublecomplex *c,
           int ldc);

void zher2k_64(char uplo, char transa, long n, long k, doub-
              lecomplex *alpha, doublecomplex *a, long lda,
              doublecomplex *b, long ldb, double beta, doub-
              lecomplex *c, long ldc);

```

PURPOSE

zher2k performs one of the Hermitian rank 2k operations $C := \alpha A \text{conjg}(B') + \text{conjg}(\alpha) B \text{conjg}(A') + \beta C$ or $C := \alpha \text{conjg}(A') B + \text{conjg}(\alpha) \text{conjg}(B') A + \beta C$ where α and β are scalars with β real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be

performed as follows:

```
TRANSA = 'N' or 'n'      C := alpha*A*conjg( B' )  
+ conjg( alpha )*B*conjg( A' ) + beta*C.
```

```
TRANSA = 'C' or 'c'      C := alpha*conjg( A' )*B  
+ conjg( alpha )*conjg( B' )*A + beta*C.
```

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C.
N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies
the number of columns of the matrices A and B,
and on entry with TRANSA = 'C' or 'c', K
specifies the number of rows of the matrices A
and B. K must be at least zero. Unchanged on
exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka),
where ka is k when TRANSA = 'N' or 'n', and is
n otherwise. Before entry with TRANSA = 'N' or
'n', the leading n by k part of the array A
must contain the matrix A, otherwise the leading
k by n part of the array A must contain the
matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A
as declared in the calling (sub) program.
When TRANSA = 'N' or 'n' then LDA must be at
least max(1, n), otherwise LDA must be at
least max(1, k). Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, kb),
where kb is k when TRANSA = 'N' or 'n', and is
n otherwise. Before entry with TRANSA = 'N' or
'n', the leading n by k part of the array B
must contain the matrix B, otherwise the leading
k by n part of the array B must contain the
matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

    *info);

```

PURPOSE

zherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the

strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

AF (input)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by ZHETRF.

LDAF (input)

The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZHETRF.

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)

On entry, the solution matrix X, as computed by ZHETRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an

```
exact solution).  
  
WORK (workspace)  
    dimension(2*N)  
  
WORK2 (workspace)  
    dimension(N)  
  
INFO (output)  
    = 0:  successful exit  
    < 0:  if INFO = -i, the i-th argument had an ille-  
          gal value
```

INTEGER(8) :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA

```

C INTERFACE

```
#include <sunperf.h>
```

```

void zherk(char uplo, char transa, int n, int k, double
           alpha, doublecomplex *a, int lda, double beta,
           doublecomplex *c, int ldc);

```

```

void zherk_64(char uplo, char transa, long n, long k, double
              alpha, doublecomplex *a, long lda, double beta,
              doublecomplex *c, long ldc);

```

PURPOSE

zherk performs one of the Hermitian rank k operations $C := \alpha A \text{conjg}(A') + \beta C$ or $C := \alpha \text{conjg}(A') A + \beta C$ where α and β are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A \text{conjg}(A') + \beta C$.

TRANSA = 'C' or 'c' $C := \alpha \text{conjg}(A') A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangu-

lar part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

```

#include <sunperf.h>

void zhesv(char uplo, int n, int nrhs, doublecomplex *a, int
           lda, int *ipivot, doublecomplex *b, int ldb, int
           *info);
void zhesv_64(char uplo, long n, long nrhs, doublecomplex
              *a, long lda, long *ipivot, doublecomplex *b, long
              ldb, long *info);

```

PURPOSE

zhesv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*H}$, if UPLO = 'U', or

$A = L * D * L^{*H}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N

lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^H$ or $A = L*D*L^H$ as computed by ZHETRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by ZHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of WORK. $LDWORK \geq 1$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for ZHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The

factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

```

PURPOSE

zhesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A .

The form of the factorization is

$A = U * D * U^{*H}$, if $UPLO = 'U'$, or

$A = L * D * L^{*H}$, if $UPLO = 'L'$,

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is Hermitian and block diago-

nal with
 1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine
 returns with $INFO = i$. Otherwise, the factored form of A
 is used
 to estimate the condition number of the matrix A . If the
 reciprocal of the condition number is less than machine
 precision,
 $INFO = N+1$ is returned as a warning, but the routine
 still goes on
 to solve for X and compute error bounds as described
 below.

3. The system of equations is solved for X using the fac-
 tored form
 of A .

4. Iterative refinement is applied to improve the computed
 solution
 matrix and calculate error bounds and backward error
 estimates
 for it.

ARGUMENTS

FACT (input)
 Specifies whether or not the factored form of A
 has been supplied on entry. = 'F': On entry, AF
 and $IPIVOT$ contain the factored form of A . A , AF
 and $IPIVOT$ will not be modified. = 'N': The
 matrix A will be copied to AF and factored.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
 the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrices B and X . $NRHS \geq 0$.

A (input) The Hermitian matrix A . If $UPLO = 'U'$, the lead-
 ing N -by- N upper triangular part of A contains the
 upper triangular part of the matrix A , and the
 strictly lower triangular part of A is not refer-
 enced. If $UPLO = 'L'$, the leading N -by- N lower
 triangular part of A contains the lower triangular
 part of the matrix A , and the strictly upper tri-
 angular part of A is not referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^H$ or $A = L*D*L^H$ as computed by ZHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^H$ or $A = L*D*L^H$.

LDAF (input)
The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZHETRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZHETRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)
The estimate of the reciprocal condition number of

the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of WORK. LDWORK >= 2*N, and for best performance LDWORK >= N*Nb, where Nb is the optimal blocksize for ZHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest .

NAME

zhETF2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE ZHETF2(UPLO, N, A, LDA, IPIV, INFO)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX A(LDA,*)  
INTEGER N, LDA, INFO  
INTEGER IPIV(*)
```

```
SUBROUTINE ZHETF2_64(UPLO, N, A, LDA, IPIV, INFO)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX A(LDA,*)  
INTEGER*8 N, LDA, INFO  
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE HETF2(UPLO, [N], A, [LDA], IPIV, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE HETF2_64(UPLO, [N], A, [LDA], IPIV, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: A
```

```
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void zhetf2(char uplo, int n, doublecomplex *a, int lda, int
            *ipiv, int *info);

void zhetf2_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipiv, long *info);
```

PURPOSE

zhetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U*D*U' \quad \text{or} \quad A = L*D*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

IPIV (output)

Details of the interchanges and the block structure of D. If IPIV(k) > 0 , then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0 , then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0 , then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
 < 0 : if INFO = -k, the k-th argument had an illegal value
 > 0 : if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by

J. Lewis, Boeing Computer Services Company

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

If UPLO = 'U', then $A = U^*D^*U$, where

$U = P(n)^*U(n)^* \dots *P(k)U(k)^* \dots$,
i.e., U is a product of terms $P(k)^*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$. If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

REAL(8), DIMENSION(:) :: D, E

```

C INTERFACE

```
#include <sunperf.h>
```

```

void zhetrd(char uplo, int n, doublecomplex *a, int lda,
            double *d, double *e, doublecomplex *tau, int
            *info);

```

```

void zhetrd_64(char uplo, long n, doublecomplex *a, long
               lda, double *d, double *e, doublecomplex *tau,
               long *info);

```

PURPOSE

zhetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

UPLO (input)

```

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

A (input) On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent

the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

D (output)

The diagonal elements of the tridiagonal matrix T :
 $D(i) = A(i, i)$.

E (output)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i, i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1, i)$ if $UPLO = 'L'$.

TAU (output)

The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

LWORK (input)

The dimension of the array $WORK$. $LWORK \geq 1$. For optimum performance $LWORK \geq N \cdot NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

FURTHER DETAILS

If $UPLO = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit

in
 $A(1:i-1,i+1)$, and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$Q = H(1) H(2) \dots H(n-1)$.
Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where tau is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(i+2:n,i)$, and tau in TAU(i).

The contents of A on exit are illustrated by the following examples with $n = 5$:

<pre> if UPLO = 'U': (d e v2 v3 v4)) (d e v3 v4)) (d e v4)) (d e)) (d)) </pre>	<pre> if UPLO = 'L': (d) (e d) (v1 e d) (v1 v2 e d) (v1 v2 v3 e d) </pre>
---	---

where d and e denote diagonal and off-diagonal elements of T, and v_i denotes an element of the vector defining H(i).

INTEGER*8 N, LDA, LDWORK, INFO  
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HETRF(UPLO, [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, LDWORK, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE HETRF_64(UPLO, [N], A, [LDA], IPIVOT, [WORK], [LDWORK],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A
```

```
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zhetrf(char uplo, int n, doublecomplex *a, int lda, int
            *ipivot, int *info);

void zhetrf_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipivot, long *info);
```

PURPOSE

zhetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U^* D U^{**H} \quad \text{or} \quad A = L^* D L^{**H}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A . $LDA \geq$

max(1,N).

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of WORK. LDWORK >= 1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then $A = U^*D^*U$, where

$U = P(n)^*U(n)^* \dots *P(k)U(k)^* \dots$,
i.e., U is a product of terms $P(k)^*U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L^*D^*L$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by IPIVOT(k), and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \\ k-1 & s & n-k-s+1 & \end{pmatrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

C INTERFACE

```

#include <sunperf.h>

void zhetri(char uplo, int n, doublecomplex *a, int lda, int
            *ipivot, int *info);

void zhetri_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipivot, long *info);

```

PURPOSE

zhetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U^*D U^{**H}$ or $A = L^*D L^{**H}$ computed by ZHETRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U^*D U^{**H}$;
 = 'L': Lower triangular, form is $A = L^*D L^{**H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

 On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZHETRF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, $D(i,i) = 0$; the matrix is singular and its inverse could not be computed.

#include <sunperf.h>

void zhetrz(char uplo, int n, int nrhs, doublecomplex *a,
            int lda, int *ipivot, doublecomplex *b, int ldb,
            int *info);

void zhetrz_64(char uplo, long n, long nrhs, doublecomplex
               *a, long lda, long *ipivot, doublecomplex *b, long
               ldb, long *info);
```

PURPOSE

zhetrz solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by ZHETRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^* \cdot H$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^* \cdot H$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHETRF.

LDA (input)
The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by ZHETRF.

B (input/output)
On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

zhgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i)B) = 0$. If $\text{JOB}='S'$, then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right.

SYNOPSIS

```
SUBROUTINE ZHGEQZ(JOB, COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB,

    doublecomplex *beta, doublecomplex *q, long ldq,  
    doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation A are then $\text{ALPHA}(1), \dots, \text{ALPHA}(N)$, and of B are $\text{BETA}(1), \dots, \text{BETA}(N)$.

If $\text{JOB}='S'$ and COMPQ and COMPZ are $'V'$ or $'I'$, then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:
 $(in) A(in) Z(in)^* = Q(out) A(out) Z(out)^*$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix eigenvalue Problems", SIAM J. Numer. Anal., 10(1973), p. 241--256.

ARGUMENTS

JOB (input)
= $'E'$: compute only ALPHA and BETA . A and B will not necessarily be put into generalized Schur form. = $'S'$: put A and B into generalized Schur form, as well as computing ALPHA and BETA .

COMPQ (input)
= $'N'$: do not modify Q .

= 'V': multiply the array Q on the right by the conjugate transpose of the unitary transformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)

= 'N': do not modify Z.
= 'V': multiply the array Z on the right by the unitary transformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. $N \geq 0$.

ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

IHI (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit A will have been destroyed.

LDA (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit B will have been destroyed.

LDB (input)

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

ALPHA (output)

The diagonal elements of A when the pair (A,B) has been reduced to Schur form. $\text{ALPHA}(i)/\text{BETA}(i)$ $i=1, \dots, N$ are the generalized eigenvalues.

BETA (output)

The diagonal elements of B when the pair (A,B) has

been reduced to Schur form. ALPHA(i)/BETA(i) $i=1,\dots,N$ are the generalized eigenvalues. A and B are normalized so that BETA(1),...,BETA(N) are non-negative real numbers.

Q (input/output)

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)

The leading dimension of the array Q. LDQ ≥ 1 .
If COMPQ='V' or 'I', then LDQ $\geq N$.

Z (input/output)

If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)

The leading dimension of the array Z. LDZ ≥ 1 .
If COMPZ='V' or 'I', then LDZ $\geq N$.

WORK (workspace)

On exit, if INFO ≥ 0 , WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK $\geq \max(1,N)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), $i=$ INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), $i=$ INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

We assume that complex ABS works as long as its value is less than overflow.

C INTERFACE

```

#include <sunperf.h>

void zhpcon(char uplo, int n, doublecomplex *a, int *ipivot,
            double anorm, double *rcond, int *info);

void zhpcon_64(char uplo, long n, doublecomplex *a, long
               *ipivot, double anorm, double *rcond, long *info);

```

PURPOSE

zhpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by ZHPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U^*D^*U^{**H}$;
 = 'L': Lower triangular, form is $A = L^*D^*L^{**H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

IPIVOT (input) INTEGER array, dimension (N)
 Details of the interchanges and the block structure of D as determined by ZHPTRF.

ANORM (input)
 The 1-norm of the original matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

```
WORK (workspace)
      COMPLEX*16 array, dimension(2*N)

INFO (output)
      = 0:  successful exit
      < 0:  if INFO = -i, the i-th argument had an illegal value
```

#include <sunperf.h>

void zhpev(char jobz, char uplo, int n, doublecomplex *a,
           double *w, doublecomplex *z, int ldz, int *info);

void zhpev_64(char jobz, char uplo, long n, doublecomplex
              *a, double *w, doublecomplex *z, long ldz, long
              *info);

```

PURPOSE

zhpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output) DOUBLE PRECISION array, dimension (N)

If INFO = 0, the eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, N)
If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
COMPLEX*16 array, dimension(MAX(1,2*N-1))

WORK2 (workspace)
DOUBLE PRECISION array, dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

void zhpevd(char jobz, char uplo, int n, doublecomplex *ap,
            double *w, doublecomplex *z, int ldz, int *info);

void zhpevd_64(char jobz, char uplo, long n, doublecomplex
               *ap, double *w, doublecomplex *z, long ldz, long
               *info);

```

PURPOSE

zhpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output) COMPLEX*16 array, dimension (N*(N+1)/2)
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-

$1) * j / 2) = A(i, j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1) * (2 * n - j) / 2) = A(i, j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If $UPLO = 'U'$, the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if $UPLO = 'L'$, the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output) DOUBLE PRECISION array, dimension (N)
If $INFO = 0$, the eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, N)
If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

WORK (workspace) COMPLEX*16 array, dimension (LWORK)
On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

LWORK (input)
The dimension of array WORK. If $N \leq 1$, LWORK must be at least 1. If $JOBZ = 'N'$ and $N > 1$, LWORK must be at least N. If $JOBZ = 'V'$ and $N > 1$, LWORK must be at least $2 * N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
DOUBLE PRECISION array, dimension (LRWORK) On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If $N \leq 1$, LRWORK must be at least 1. If $JOBZ = 'N'$ and $N > 1$, LRWORK must be at least N. If $JOBZ = 'V'$ and $N > 1$, LRWORK must be at least $1 + 5 * N + 2 * N ** 2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of

the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output) INTEGER array, dimension (LIWORK)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

REAL(8) :: VL, VU, ABTOL
REAL(8), DIMENSION(:) :: W, WORK2

```

C INTERFACE

```

#include <sunperf.h>

void zhpevx(char jobz, char range, char uplo, int n, doublecomplex *a, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, doublecomplex *z, int ldz, int *ifail, int *info);

void zhpevx_64(char jobz, char range, char uplo, long n, doublecomplex *a, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, doublecomplex *z, long ldz, long *ifail, long *info);

```

PURPOSE

zhpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```

JOBZ (input)
    = 'N': Compute eigenvalues only;
    = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
    = 'A': all eigenvalues will be found;
    = 'V': all eigenvalues in the half-open interval (VL,VU] will be found;
    = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
    = 'U': Upper triangle of A is stored;
    = 'L': Lower triangle of A is stored.

```

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If $\text{RANGE} = 'A'$, $\text{NFOUND} = N$, and if $\text{RANGE} = 'I'$, $\text{NFOUND} = \text{IU} - \text{IL} + 1$.

W (output) DOUBLE PRECISION array, dimension (N)

If $\text{INFO} = 0$, the selected eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, $\max(1, M)$)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $\text{JOBZ} = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if $\text{RANGE} = 'V'$, the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if $\text{JOBZ} = 'V'$, $\text{LDZ} \geq \max(1, N)$.

WORK (workspace)

COMPLEX*16 array, dimension($2 * N$)

WORK2 (workspace)

DOUBLE PRECISION array, dimension($7 * N$)

IWORK3 (workspace)

INTEGER array, dimension($5 * N$)

IFAIL (output) INTEGER array, dimension (N)

If $\text{JOBZ} = 'V'$, then if $\text{INFO} = 0$, the first NFOUND elements of IFAIL are zero. If $\text{INFO} > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $\text{JOBZ} = 'N'$, then IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```
#include <sunperf.h>
```

```

void zhpgst(int itype, char uplo, int n, doublecomplex *ap,
            doublecomplex *bp, int *info);

void zhpgst_64(long itype, char uplo, long n, doublecomplex
               *ap, doublecomplex *bp, long *info);

```

PURPOSE

zhpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is $A*x = \lambda*B*x$, and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$.
 If ITYPE = 2 or 3, the problem is $A*B*x = \lambda*x$ or $B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by CPPTRF.

ARGUMENTS

ITYPE (input)
 = 1: compute $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$;
 = 2 or 3: compute $U*A*U^{**H}$ or $L^{**H}*A*L$.

UPLO (input)
 = 'U': Upper triangle of A is stored and B is factored as $U^{**H}*U$; = 'L': Lower triangle of A is stored and B is factored as $L*L^{**H}$.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output) COMPLEX*16 array, dimension $(N*(N+1))/2$
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

           doublecomplex *z, int ldz, int *info);
```

```
void zhpgv_64(long itype, char jobz, char uplo, long n,  
              doublecomplex *a, doublecomplex *b, double *w,  
              doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $Ax = (\lambda)Bx$, $A*Bx = (\lambda)x$, or $B*Ax = (\lambda)x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

= 1: $Ax = (\lambda)Bx$
= 2: $A*Bx = (\lambda)x$
= 3: $B*Ax = (\lambda)x$

JOBZ (input)

= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear

array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

B (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
On entry, the upper or lower triangle of the Hermitian matrix B , packed columnwise in a linear array. The j -th column of B is stored in the array B as follows: if $UPLO = 'U'$, $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$, in the same storage format as B .

W (output) DOUBLE PRECISION array, dimension (N)
If $INFO = 0$, the eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, N)
If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^*H*B*Z = I$; if $ITYPE = 3$, $Z^*H*inv(B)*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

LDZ (input)
The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

$WORK$ (workspace)
COMPLEX*16 array, dimension $(\max(1, 2*N-1))$

$WORK2$ (workspace)
DOUBLE PRECISION array, dimension $(\max(1, 3*N-2))$

$INFO$ (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: CPPTRF or ZHPEV returned an error code:
<= N : if $INFO = i$, ZHPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N : if $INFO = N + i$, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

void zhpgvd_64(long itype, char jobz, char uplo, long n, doublecomplex *ap, doublecomplex *bp, double *w, doublecomplex *z, long ldz, long *info);

```

PURPOSE

zhpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)
 Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)B*x$
- = 2: $A*B*x = (\lambda)x$
- = 3: $B*A*x = (\lambda)x$

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangles of A and B are stored;
 = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.
 On exit, the contents of AP are destroyed.

BP (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.
 On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

W (output) DOUBLE PRECISION array, dimension (N)
 If INFO = 0, the eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, N)
 If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**H*B*Z = I$; if ITYPE = 3, $Z**H*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

WORK (workspace) COMPLEX*16 array, dimension (LWORK)
 On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of array WORK. If $N \leq 1$, $LWORK \geq 1$. If JOBZ = 'N' and $N > 1$, $LWORK \geq N$.

If JOBZ = 'V' and $N > 1$, $LWORK \geq 2*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace) DOUBLE PRECISION array, dimension (LRWORK)
On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)

The dimension of array RWORK. If $N \leq 1$, $LRWORK \geq 1$. If JOBZ = 'N' and $N > 1$, $LRWORK \geq N$. If JOBZ = 'V' and $N > 1$, $LRWORK \geq 1 + 5*N + 2*N**2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output) INTEGER array, dimension (LIWORK)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, $LIWORK \geq 1$. If JOBZ = 'V' and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or ZHPEVD returned an error code:
<= N: if INFO = i, ZHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for $1 \leq i \leq n$, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

INTEGER(8), DIMENSION(:) :: IWORK, IFAIL
REAL(8) :: VL, VU, ABSTOL
REAL(8), DIMENSION(:) :: W, RWORK

```

C INTERFACE

```

#include <sunperf.h>

void zhpgvx(int itype, char jobz, char range, char uplo, int
    n, doublecomplex *ap, doublecomplex *bp, double
    vl, double vu, int il, int iu, double abstol, int
    *m, double *w, doublecomplex *z, int ldz, int
    *ifail, int *info);

void zhpgvx_64(long itype, char jobz, char range, char uplo,
    long n, doublecomplex *ap, doublecomplex *bp, dou-
    ble vl, double vu, long il, long iu, double
    abstol, long *m, double *w, doublecomplex *z, long
    ldz, long *ifail, long *info);

```

PURPOSE

zhpgvx computes selected eigenvalues and, optionally, eigen-
vectors of a complex generalized Hermitian-definite eigen-
problem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or
 $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian,
stored in packed format, and B is also positive definite.
Eigenvalues and eigenvectors can be selected by specifying
either a range of values or a range of indices for the
desired eigenvalues.

ARGUMENTS

ITYPE (input)
Specifies the problem type to be solved:

- = 1: $A*x = (\lambda)B*x$
- = 2: $A*B*x = (\lambda)x$
- = 3: $B*A*x = (\lambda)x$

JOBZ (input)

- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

- = 'A': all eigenvalues will be found;
- = 'V': all eigenvalues in the half-open interval $(VL, VU]$ will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

- = 'U': Upper triangles of A and B are stored;
- = 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. $N \geq 0$.

AP (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

BP (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i, j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$, in the same storage format as B.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

W (output) DOUBLE PRECISION array, dimension (N)

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) COMPLEX*16 array, dimension (LDZ, N)

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^*H*B*Z = I$; if $ITYPE = 3$, $Z^*H*inv(B)*Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1,
and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

COMPLEX*16 array, dimension(2*N)

RWORK (workspace)

DOUBLE PRECISION array, dimension(7*N)

IWORK (workspace)

INTEGER array, dimension(5*N)

IFAIL (output)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: CPPTRF or ZHPEVX returned an error code:

<= N: if INFO = i, ZHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

zhpmv - perform the matrix-vector operation $y := \alpha A x + \beta y$

SYNOPSIS

```
SUBROUTINE ZHPMV(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(*), X(*), Y(*)  
INTEGER N, INCX, INCY
```

```
SUBROUTINE ZHPMV_64(UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(*), X(*), Y(*)  
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HPMV(UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: A, X, Y  
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE HPMV_64(UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: A, X, Y  
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpmv(char uplo, int n, doublecomplex *alpha, doublecomplex *a, doublecomplex *x, int incx, doublecomplex *beta, doublecomplex *y, int incy);
```

```
void zhpmv_64(char uplo, long n, doublecomplex *alpha, doublecomplex *a, doublecomplex *x, long incx, doublecomplex *beta, doublecomplex *y, long incy);
```

PURPOSE

zhpmv performs the matrix-vector operation $y := \alpha A x + \beta y$ where α and β are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

A (input)

(($n * (n + 1) / 2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a($

1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          int incx, doublecomplex *a);
```

```
void zhpr_64(char uplo, long n, double alpha, doublecomplex  
             *x, long incx, doublecomplex *a);
```

PURPOSE

zhpr performs the hermitian rank 1 operation $A := \alpha x x^* \text{conjg}(x) + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A .
 $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α .
Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

A (input/output)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

```
void zhpr2(char uplo, int n, doublecomplex *alpha, doublecomplex *x, int incx, doublecomplex *y, int incy, doublecomplex *ap);
```

```
void zhpr2_64(char uplo, long n, doublecomplex *alpha, doublecomplex *x, long incx, doublecomplex *y, long incy, doublecomplex *ap);
```

PURPOSE

zhpr2 performs the Hermitian rank 2 operation $A := \alpha x \text{conjg}(y') + \text{conjg}(\alpha) y \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP .

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

X (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX \neq 0. Unchanged on exit.

Y (input)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

AP (input/output)

((n * (n + 1)) / 2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

    *ferr, double *berr, long *info);

```

PURPOSE

zhprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^H$ or $A = L*D*L^H$ as computed by ZHPTRF, stored as a packed triangular matrix.

IPIVOT (input) INTEGER array, dimension (N)
Details of the interchanges and the block structure of D as determined by ZHPTRF.

B (input) COMPLEX*16 array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (input/output) COMPLEX*16 array, dimension (LDX,NRHS)
On entry, the solution matrix X, as computed by ZHPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1,N)$.

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)
The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
COMPLEX*16 array, dimension $(2*N)$

WORK2 (workspace)
DOUBLE PRECISION array, dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

void zhpsv(char uplo, int n, int nrhs, doublecomplex *a, int
           *ipivot, doublecomplex *b, int ldb, int *info);

void zhpsv_64(char uplo, long n, long nrhs, doublecomplex
              *a, long *ipivot, doublecomplex *b, long ldb, long
              *info);

```

PURPOSE

zhpsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*H}$, if UPLO = 'U', or

$A = L * D * L^{*H}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear

array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A .

IPIVOT (output) INTEGER array, dimension (N)

Details of the interchanges and the block structure of D , as determined by ZHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

B (input/output) COMPLEX*16 array, dimension (LDB,NRHS)

On entry, the N-by-NRHS right hand side matrix B . On exit, if $INFO = 0$, the N-by-NRHS solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit
 < 0 : if $INFO = -i$, the i -th argument had an illegal value
 > 0 : if $INFO = i$, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A :

a11 a12 a13 a14

```
    a22 a23 a24
      a33 a34      (aij = conjg(aji))
        a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

```

C INTERFACE

```

#include <sunperf.h>

void zhpsvx(char fact, char uplo, int n, int nrhs, doublecomplex
    *a, doublecomplex *af, int *ipivot, doublecomplex *b, int ldb, doublecomplex
    *x, int ldx, double *rcond, double *ferr, double *berr, int *info);

void zhpsvx_64(char fact, char uplo, long n, long nrhs, doublecomplex
    *a, doublecomplex *af, long *ipivot, doublecomplex *b, long ldb, doublecomplex
    *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

```

PURPOSE

zhpsvx uses the diagonal pivoting factorization $A = U^*D U^{**H}$ or $A = L^*D L^{**H}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$$A = U * D * U^{**H}, \quad \text{if } UPLO = 'U', \text{ or}$$

$$A = L * D * L^{**H}, \quad \text{if } UPLO = 'L',$$

where U (or L) is a product of permutation and unit upper

(lower)
triangular matrices and D is Hermitian and block diagonal
with
1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine
precision,
INFO = N+1 is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.

3. The system of equations is solved for X using the fac-
tored form
of A.

4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, AF
and IPIVOT contain the factored form of A. AF and
IPIVOT will not be modified. = 'N': The matrix A
will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrices B and X. $NRHS \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
The upper or lower triangle of the Hermitian
matrix A, packed columnwise in a linear array.
The j-th column of A is stored in the array A as

follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

AF (input or output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by ZHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output) INTEGER array, dimension (N)
 If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZHPTRF.

B (input) COMPLEX*16 array, dimension (LDB,NRHS)
 The N-by-NRHS right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (output) COMPLEX*16 array, dimension (LDX,NRHS)
 If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
 The leading dimension of the array X. $LDX \geq \max(1,N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output) DOUBLE PRECISION array, dimension (NRHS)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

COMPLEX*16 array, dimension(2*N)

DOUBLE PRECISION array, WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following

example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A :

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

#include <sunperf.h>

void zhptrd(char uplo, int n, doublecomplex *ap, double *d,
            double *e, doublecomplex *tau, int *info);

void zhptrd_64(char uplo, long n, doublecomplex *ap, double
               *d, double *e, doublecomplex *tau, long *info);

```

PURPOSE

zhptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

D (output) DOUBLE PRECISION array, dimension (N)
The diagonal elements of the tridiagonal matrix T:
 $D(i) = A(i,i)$.

E (output) DOUBLE PRECISION array, dimension (N-1)
The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

TAU (output) COMPLEX*16 array, dimension (N-1)
The scalar factors of the elementary reflectors (see Further Details).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) \dots H(2) H(1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in AP, overwriting $A(1:i-1,i+1)$, and τ is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) H(2) \dots H(n-1).$$

Each H(i) has the form

$$H(i) = I - \tau * v * v'$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in AP, overwriting $A(i+2:n,i)$, and τ is stored in TAU(i).

INTEGER(8), DIMENSION(:) :: IPIVOT

```

C INTERFACE

```

#include <sunperf.h>

void zhpstrf(char uplo, int n, doublecomplex *a, int *ipivot,
             int *info);

void zhpstrf_64(char uplo, long n, doublecomplex *a, long
                *ipivot, long *info);

```

PURPOSE

zhpstrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^* D U^* H \quad \text{or} \quad A = L^* D L^* H$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output) INTEGER array, dimension (N)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
 Company

If UPLO = 'U', then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,
 i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & & & \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \\ k-s \quad s \quad n-k \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L * D * L'$, where

$L = P(1) * L(1) * \dots * P(k) * L(k) * \dots$,
 i.e., L is a product of terms $P(k) * L(k)$, where k increases

from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \\ & & & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \\ \end{matrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

               *ipivot, long *info);
```

PURPOSE

zhptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by ZHPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U^*D^*U^{**H}$;
= 'L': Lower triangular, form is $A = L^*D^*L^{**H}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input) INTEGER array, dimension (N)
Details of the interchanges and the block structure of D as determined by ZHPTRF.

WORK (workspace)
COMPLEX*16 array, dimension(N)

INFO (output)

- = 0: successful exit

```

C INTERFACE

```

#include <sunperf.h>

void zhptrs(char uplo, int n, int nrhs, doublecomplex *a,
            int *ipivot, doublecomplex *b, int ldb, int
            *info);

void zhptrs_64(char uplo, long n, long nrhs, doublecomplex
               *a, long *ipivot, doublecomplex *b, long ldb, long
               *info);

```

PURPOSE

zhptrs solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**H}$ or $A = L \cdot D \cdot L^{**H}$ computed by ZHPTRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**H}$;
 = 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**H}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) COMPLEX*16 array, dimension $(N \cdot (N+1)/2)$
 The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZHPTRF, stored as a packed triangular matrix.

IPIVOT (input) INTEGER array, dimension (N)
 Details of the interchanges and the block structure of D as determined by ZHPTRF.

B (input/output) COMPLEX*16 array, dimension (LDB, NRHS)
 On entry, the right hand side matrix B . On exit,

the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-
gal value

```

#include <sunperf.h>

void zhsein(char side, char eigsrc, char initv, int *select,
    int n, doublecomplex *h, int ldh, doublecomplex
    *w, doublecomplex *vl, int ldvl, doublecomplex
    *vr, int ldvr, int mm, int *m, int *ifaill, int
    *ifailr, int *info);

void zhsein_64(char side, char eigsrc, char initv, long
    *select, long n, doublecomplex *h, long ldh, doub-
    lecomplex *w, doublecomplex *vl, long ldvl, doub-
    lecomplex *vr, long ldvr, long mm, long *m, long
    *ifaill, long *ifailr, long *info);

```

PURPOSE

zhsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y .

ARGUMENTS

SIDE (input)
 = 'R': compute right eigenvectors only;
 = 'L': compute left eigenvectors only;
 = 'B': compute both right and left eigenvectors.

EIGSRC (input)
 Specifies the source of eigenvalues supplied in W:
 = 'Q': the eigenvalues were found using ZHSEQR;

thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows ZHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, ZHSEIN must always perform inverse iteration using the whole matrix H.

INITV (input)

= 'N': no initial vectors are supplied;
= 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT (input)

Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue W(j), SELECT(j) must be set to .TRUE..

N (input) The order of the matrix H. $N \geq 0$.

H (input) The upper Hessenberg matrix H.

LDH (input)

The leading dimension of the array H. $LDH \geq \max(1, N)$.

W (input/output)

On entry, the eigenvalues of H. On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

VL (input/output)

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. $LDVL \geq \max(1, N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

VR (input/output)

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored.

On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

WORK (workspace)

dimension(N*N)

RWORK (workspace)

dimension(N)

IFAILL (output)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x|+|y|$.

                   [WORK], LWORK, [INFO])
```

```

CHARACTER(LEN=1) :: JOB, COMPZ
COMPLEX(8), DIMENSION(:) :: W, WORK
COMPLEX(8), DIMENSION(:, :) :: H, Z
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO

```

C INTERFACE

```

#include <sunperf.h>

void zhseqr (char, char, int, int, int, doublecomplex*, int,
             doublecomplex*, doublecomplex*, int, int*);

void zhseqr_64 (char, char, long, long, long, doublecom-
                plex*, long, doublecomplex*, doublecomplex*, long,
                long*);

```

PURPOSE

zhseqr computes the eigenvalues of a complex upper Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^* H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q , so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q : $A = Q^* H Q = (QZ)^* T (QZ)$.

ARGUMENTS

JOB (input)
 = 'E': compute eigenvalues only;
 = 'S': compute eigenvalues and the Schur form T .

COMPZ (input)
 = 'N': no Schur vectors are computed;
 = 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product $Q^* Z$ is returned.

N (input) The order of the matrix H . $N \geq 0$.

ILO (input)
 It is assumed that H is already upper triangular in rows and columns $1:ILO-1$ and $IHI+1:N$. ILO and

IHI are normally set by a previous call to CGEBAL, and then passed to CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq \text{ILO} \leq \text{IHI} \leq \text{N}$, if $\text{N} > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $\text{N}=0$.

IHI (input)

See the description of ILO.

H (input/output)

On entry, the upper Hessenberg matrix H. On exit, if $\text{JOB} = 'S'$, H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If $\text{JOB} = 'E'$, the contents of H are unspecified on exit.

LDH (input)

The leading dimension of the array H. $\text{LDH} \geq \max(1, \text{N})$.

W (output)

The computed eigenvalues. If $\text{JOB} = 'S'$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with $W(i) = H(i, i)$.

Z (input) If $\text{COMPZ} = 'N'$: Z is not referenced.

If $\text{COMPZ} = 'I'$: on entry, Z need not be set, and on exit, Z contains the unitary matrix Z of the Schur vectors of H. If $\text{COMPZ} = 'V'$: on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix $Z(\text{ILO}:\text{IHI}, \text{ILO}:\text{IHI})$; on exit Z contains Q^*Z . Normally Q is the unitary matrix generated by CUNGHR after the call to CGEHRD which formed the Hessenberg matrix H.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq \max(1, \text{N})$ if $\text{COMPZ} = 'I'$ or $'V'$; $\text{LDZ} \geq 1$ otherwise.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK.

LWORK (output)

The dimension of the array WORK. $\text{LWORK} \geq \max(1, \text{N})$.

If $\text{LWORK} = -1$, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, ZHSEQR failed to compute all the eigenvalues in a total of $30 \cdot (\text{IHI} - \text{ILO} + 1)$ iterations; elements 1:i-1 and i+1:n of W contain those eigenvalues which have been successfully computed.

doublecomplex *beta, doublecomplex *c, int ldc)
```

```
void zjadmm_64(long transa, long m, long n, long k,
doublecomplex *alpha, long *descra, doublecomplex *val, long
*indx, long *pntr, long maxnz, long *iperm, doublecomplex
*b, long ldb, doublecomplex *beta, doublecomplex *c, long
ldc);
```

DESCRIPTION

zjadmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the jagged diagonal format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$) 3 : Triangular 4 : Skew(Anti)-Symmetric ($A=-A'$)

5 : Diagonal
 6 : Skew-Hermitian (A= -CONJG(A'))
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length
 NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A.
 VAL can be viewed as a column major ordering of a
 row permutation of the Ellpack representation of A,
 where the Ellpack representation is permuted so that
 the rows are non-increasing in the number of nonzero
 entries. Values added for padding in Ellpack are
 not included in the Jagged-Diagonal format.
 Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length
 NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column
 indices of the corresponding entries in VAL.
 Unchanged on exit.

PNTR(input) On entry, PNTR is an integer array of length
 MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to
 the location in VAL of the first element
 in the row-permuted Ellpack representation of A.
 Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of
 nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length M
 such that I = IPERM(I'), where row I in the
 original Ellpack representation corresponds
 to row I' in the permuted representation.
 If IPERM(1) = 0, it is assumed by convention that
 IPERM(I) = I. IPERM is used to determine the order
 in which rows of C are updated. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
 Before entry with TRANSA = 0, the leading k by n
 part of the array B must contain the matrix B, otherwise
 the leading m by n part of the array B must contain the
 matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared
 in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n
 part of the array C must contain the matrix C, otherwise

the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * op(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

DOUBLE COMPLEX, DIMENSION(:) :: VAL

SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                  IPERM, [WORK], [LWORK] )
INTEGER*8 TRANSP, M, K, MAXNZ
INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
DOUBLE COMPLEX, DIMENSION(:) :: VAL
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zjadrp (int transp, int m, int k, doublecomplex *val,
int *indx, int *pntr, int maxnz, int *iperm);
```

```
void zjadrp_64 (long transp, long m, long k, doublecomplex
*val, long *indx, long *pntr, long maxnz, long *iperm);
```

DESCRIPTION

zjadrp performs one of the matrix-matrix operations

```
A <- A P    or    A <- A P'
                                ( ' indicates matrix transpose)
```

where A is an M-by-K sparse matrix represented in the jagged diagonal format, the permutation matrix P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symmetrically permuted jagged diagonal matrix $P A P'$, one can explicitly permute the columns P A by calling

```
ZJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP(input)	TRANSP indicates how to operate with the permutation matrix: 0 : operate with matrix 1 : operate with transpose matrix Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
K(input)	On entry, K specifies the number of columns in the matrix A. Unchanged on exit.
VAL(input/output)	On entry, VAL is a scalar array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format. On exit, VAL contains non-zero entries of the output permuted jagged diagonal matrix.
INDX(input/output)	On entry, INDX is an integer array of length $NNZ=PNTR(MAXNZ+1)-PNTR(1)+1$ consisting of the column indices of the corresponding entries in VAL. On exit, INDX is overwritten by the column indices of the output permuted jagged diagonal matrix.

PNTR(input) On entry, PNTR is an integer array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length K such that $I = IPERM(I')$. Array IPERM represents a permutation P, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P. For example, if

$$P = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

then IPERM = (3, 1, 2). Unchanged on exit.

WORK(workspace) Scratch array of length LWORK. LWORK should be at least K.

LWORK(input) On entry, LWORK specifies the length of the array WORK. If LWORK=0, the routine is to allocate workspace needed. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the array WORK, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

doublecomplex *val, long *indx, long *pntr, long maxnz,  
long *iperm, doublecomplex *b, long ldb, doublecomplex  
*beta, doublecomplex *c, long ldc);
```

DESCRIPTION

cjadsm performs one of the matrix-matrix operations

```
C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,  
C <- alpha op(A) D B + beta C,
```

where alpha and beta are scalars, C and B are m by n dense matrices,
D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit,
upper or lower triangular matrix represented in the jagged-diagonal format
and op(A) is one of

```
op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))  
(inv denotes matrix inverse, ' indicates matrix transpose).
```

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row scaling (see section NOTES for further details) Unchanged on exit.

DV(input) On entry, DV is an array of length M consisting of the diagonal entries of the diagonal scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the rows have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:
DESCRA(1) matrix structure
0 : general
1 : symmetric (A=A')
2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
Note: For the routine, DESCRA(1)=3 is only supported.
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input) On entry, VAL is a scalar array of length NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format. Unchanged on exit if UNITD is not equal to 4.

INDX(input) On entry, INDX is an integer array of length NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 consisting of the column indices of the corresponding entries in VAL. Unchanged on exit.

PNTR(input) On entry, PNTR is an integer array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack representation of A. Unchanged on exit.

MAXNZ(input) On entry, MAXNZ specifies the max number of nonzeros elements per row. Unchanged on exit.

IPERM(input) On entry, IPERM is an integer array of length M such that I = IPERM(I'), where row I in the original Ellpack representation corresponds to row I' in the permuted representation. If IPERM(1) = 0, it is assumed by convention that IPERM(I) = I. IPERM is used to determine the order in which rows of C are updated. Unchanged on exit.

B (input)	Array of DIMENSION (LDB, N). On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.
LDB (input)	On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.
BETA (input)	On entry, BETA specifies the scalar beta. Unchanged on exit.
C(input/output)	Array of DIMENSION (LDC, N). On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.
LDC (input)	On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.
WORK(workspace)	Scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.
LWORK (input)	On entry, LWORK specifies the length of WORK array. LWORK should be at least 2*M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK $\geq 2 \times M \times N_{\text{CPUS}}$ where N_{CPUS} is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:
<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of the sparse matrix A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise WORK(1) = - i where i is the row number which 2-norm is exactly zero.

3. If DESCRA(3)=1 and UNITD < 4, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the JAD representation of a sparse matrix do not need to be 1.0 in this usage. They are not used by the routine in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine is designed so that it checks the validity of each sparse entry given in the sparse blas representation. Entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower triangle of A. But DESCRA(1) MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly lower triangle of A, U is the strictly upper triangle of A, D is the diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of DESCRA and the result matrix for the sparse representation of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	alpha*op(L+I)*B+beta*C
3	1	0	alpha*op(L+D)*B+beta*C
3	2	1	alpha*op(U+I)*B+beta*C
3	2	0	alpha*op(U+D)*B+beta*C

COMPLEX(8), DIMENSION(:, :) :: C
```

INTEGER(8) :: M, N, L, INCV, LDC

C INTERFACE

```
#include <sunperf.h>
```

```
void zlarz(char side, int m, int n, int l, doublecomplex *v,  
          int incv, doublecomplex *tau, doublecomplex *c,  
          int ldc);
```

```
void zlarz_64(char side, long m, long n, long l, doublecom-  
             plex *v, long incv, doublecomplex *tau, doublecom-  
             plex *c, long ldc);
```

PURPOSE

zlarz applies a complex elementary reflector H to a complex M -by- N matrix C , from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply $\text{conj}(\tau)$ instead τ .

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

SIDE (input)

= 'L': form $H * C$
= 'R': form $C * H$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

V (input) The vector v in the representation of H as returned by CTZRZF. V is not used if $\tau = 0$.

INCV (input)

The increment between elements of v . INCV $\neq 0$.

TAU (input)
The value tau in the representation of H.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix $H * C$ if SIDE = 'L', or $C * H$ if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

C INTERFACE

```
#include <sunperf.h>

void zlarzb(char side, char trans, char direct, char storev,
            int m, int n, int k, int l, doublecomplex *v, int
            ldv, doublecomplex *t, int ldt, doublecomplex *c,
            int ldc, int ldwork);

void zlarzb_64(char side, char trans, char direct, char
               storev, long m, long n, long k, long l, doublecom-
               plex *v, long ldv, doublecomplex *t, long ldt,
               doublecomplex *c, long ldc, long ldwork);
```

PURPOSE

zlarzb applies a complex block reflector H or its transpose H^*H to a complex distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Conjugate transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)
= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not supported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block

```

        reflector).

L (input) The number of columns of the matrix V containing
          the meaningful part of the Householder reflectors.
          If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L
          >= 0.
V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
          The leading dimension of the array V. If STOREV =
          'C', LDV >= L; if STOREV = 'R', LDV >= K.

T (input) The triangular K-by-K matrix T in the representa-
          tion of the block reflector.

LDT (input)
          The leading dimension of the array T. LDT >= K.

C (input/output)
          On entry, the M-by-N matrix C. On exit, C is
          overwritten by H*C or H'*C or C*H or C*H'.

LDC (input)
          The leading dimension of the array C. LDC >=
          max(1,M).

WORK (workspace)
          dimension(MAX(M,N),K)

LDWORK (input)
          The leading dimension of the array WORK. If SIDE
          = 'L', LDWORK >= max(1,N); if SIDE = 'R', LDWORK
          >= max(1,M).

```

NAME

zlarzt - form the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE ZLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

```
CHARACTER * 1 DIRECT, STOREV  
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)  
INTEGER N, K, LDV, LDT
```

```
SUBROUTINE ZLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
```

```
CHARACTER * 1 DIRECT, STOREV  
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)  
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
```

```
CHARACTER(LEN=1) :: DIRECT, STOREV  
COMPLEX(8), DIMENSION(:) :: TAU  
COMPLEX(8), DIMENSION(:, :) :: V, T  
INTEGER :: N, K, LDV, LDT
```

```
SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
```

```
CHARACTER(LEN=1) :: DIRECT, STOREV  
COMPLEX(8), DIMENSION(:) :: TAU  
COMPLEX(8), DIMENSION(:, :) :: V, T
```

```
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zlarzt(char direct, char storev, int n, int k, doublecomplex *v, int ldv, doublecomplex *tau, doublecomplex *t, int ldt);
```

```
void zlarzt_64(char direct, char storev, long n, long k, doublecomplex *v, long ldv, doublecomplex *tau, doublecomplex *t, long ldt);
```

PURPOSE

zlarzt forms the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If $DIRECT = 'F'$, $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If $DIRECT = 'B'$, $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If $STOREV = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the array V , and

$$H = I - V * T * V'$$

If $STOREV = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the array V , and

$$H = I - V' * T * V$$

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

DIRECT (input)

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

= 'F': $H = H(1) H(2) \dots H(k)$ (Forward, not supported yet)

= 'B': $H = H(k) \dots H(2) H(1)$ (Backward)

STOREV (input)
 Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):
 = 'R': rowwise

N (input) The order of the block reflector H. $N \geq 0$.

K (input) The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R'
 The matrix V. See further details.

LDV (input)
 The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

TAU (input)
 TAU(i) must contain the scalar factor of the elementary reflector H(i).

T (input) The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT (input)
 The leading dimension of the array T. $LDT \geq K$.

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and
 STOREV = 'R':

$$V = \begin{pmatrix} & v_1 & v_2 & v_3 & & \\ (v_1 & v_2 & v_3) & & & \\ & & & & & \\ & & & & & \\ & & & & & \end{pmatrix} \quad \begin{matrix} \text{-----} V \text{-----} \\ / \\ (v_1 & v_1 & v_1 & v_1 & v_1 & . & . & . & 1 \\ \\ (v_2 & v_2 & v_2 & v_2 & v_2 & . & . & . & 1 \end{matrix}$$

void zlatzm_64(char side, long m, long n, doublecomplex *v,
               long incv, doublecomplex *tau, doublecomplex *c1,
               doublecomplex *c2, long ldc);
```

PURPOSE

zlatzm routine is deprecated and has been replaced by routine CUNMRZ.

CLATZM applies a Householder matrix generated by CTZRQF to a matrix.

Let $P = I - \tau u u'$, $u = \begin{pmatrix} 1 \\ v \end{pmatrix}$,

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals $'L'$, let

$$C = \begin{bmatrix} C1 & 1 \\ C2 & m-1 \end{bmatrix} \begin{matrix} \\ n \end{matrix}$$

Then C is overwritten by $P * C$.

If $SIDE$ equals $'R'$, let

$$C = \begin{bmatrix} C1 & C2 \end{bmatrix} \begin{matrix} m \\ 1 \quad n-1 \end{matrix}$$

Then C is overwritten by $C * P$.

ARGUMENTS

$SIDE$ (input)

= $'L'$: form $P * C$

= $'R'$: form $C * P$

M (input) The number of rows of the matrix C .

N (input) The number of columns of the matrix C .

V (input) $(1 + (M-1)*abs(INCV))$ if $SIDE = 'L'$ $(1 + (N-1)*abs(INCV))$ if $SIDE = 'R'$ The vector v in the representation of P . V is not used if $TAU = 0$.

INCV (input)
The increment between elements of v. INCV \neq 0

TAU (input)
The value tau in the representation of P.

C1 (input/output)
(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)
(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)
The leading dimension of the arrays C1 and C2.
LDC \geq max(1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

    lda, double anorm, double *rcond, int *info);

void zpbcon_64(char uplo, long n, long kd, doublecomplex *a,
    long lda, double anorm, double *rcond, long
    *info);

```

PURPOSE

zpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by ZPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $KD \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
The leading dimension of the array A. $LDA \geq KD+1$.

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,  
                [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, KD, LDA, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
    [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, KD, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpbequ(char uplo, int n, int kd, doublecomplex *a, int
    lda, double *scale, double *scond, double *amax,
    int *info);
```

```
void zpbequ_64(char uplo, long n, long kd, doublecomplex *a,
    long lda, double *scale, double *scond, double
    *amax, long *info);
```

PURPOSE

zpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)

```
= 'U': Upper triangular of A is stored;
= 'L': Lower triangular of A is stored.
```

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

```
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'.  $KD \geq 0$ .
```

A (input) The upper or lower triangle of the Hermitian band

matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)

The leading dimension of the array A. LDA \geq KD+1.

SCALE (output)

If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND \geq 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the i-th diagonal element is nonpositive.

    ldaf, doublecomplex *b, long ldb, doublecomplex
    *x, long ldx, double *ferr, double *berr, long
    *info);

```

PURPOSE

zpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number

of columns of the matrices B and X. NRHS ≥ 0 .

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
The leading dimension of the array A. LDA \geq KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A as computed by ZPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF \geq KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1, N).

X (input/output)
On entry, the solution matrix X, as computed by ZPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1, N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

```

F95 INTERFACE

```
SUBROUTINE PBSTF(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: AB  
INTEGER :: N, KD, LDAB, INFO
```

```
SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: AB  
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbstf(char uplo, int n, int kd, doublecomplex *ab, int
            ldab, int *info);

void zpbstf_64(char uplo, long n, long kd, doublecomplex
               *ab, long ldab, long *info);
```

PURPOSE

zpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.

The factorization has the form $A = S^*H^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & (M \ L) \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

AB (input/output)
 On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^*H^*S$. See Further Details.

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13           )
      (      s22  s23  s24      )
      (           s33  s34      )
      (               s44      )
      (           s53  s54  s55  )
      (               s64  s65  s66 )
      (                   s75  s76 s77 )
```

If UPLO = 'U', the array AB holds:

on entry:							on exit:					
*	*	a13	a24	a35	a46	a57	*	*	s13	s24	s53'	
s64'	s75'											
*	a12	a23	a34	a45	a56	a67	*	s12	s23	s34	s54'	
s65'	s76'	a11	a22	a33	a44	a55	a66	a77	s11	s22	s33	
s44	s55	s66	s77									

If UPLO = 'L', the array AB holds:

on entry:							on exit:					
a11	a22	a33	a44	a55	a66	a77	s11	s22	s33	s44	s55	
s66	s77	a21	a32	a43	a54	a65	a76	*	s12'	s23'	s34'	
s54	s65	s76	*	a31	a42	a53	a64	a64	*	*	s13'	
s24'	s53	s64	s75	*	*							

Array elements marked * are not used by the routine; s12' denotes conjg(s12); the diagonal elements of S are real.

```

C INTERFACE

```
#include <sunperf.h>

void zpbsv(char uplo, int n, int kd, int nrhs, doublecomplex
           *a, int lda, doublecomplex *b, int ldb, int
           *info);

void zpbsv_64(char uplo, long n, long kd, long nrhs, doublecomplex
              *a, long lda, doublecomplex *b, long
              ldb, long *info);
```

PURPOSE

zpbsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite band matrix and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$A = U^{*H} * U$, if $UPLO = 'U'$, or

$A = L * L^{*H}$, if $UPLO = 'L'$,

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KD \geq 0$.

$NRHS$ (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $KD+1$

rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(KD+1+i-j,j) = A(i,j)$ for $\max(1,j-KD) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+KD)$. See below for further details.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A , in the same storage format as A .

LDA (input)

The leading dimension of the array A . $LDA \geq KD+1$.

B (input/output)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

INFO (output)

$= 0$: successful exit
 < 0 : if $INFO = -i$, the i -th argument had an illegal value
 > 0 : if $INFO = i$, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if $UPLO = 'L'$ the format of A is as follows:

On entry:

On exit:

	a11	a22	a33	a44	a55	a66	111	122	133	144	155
166											
	a21	a32	a43	a54	a65	*	121	132	143	154	165
*											
	a31	a42	a53	a64	*	*	131	142	153	164	*
*											

Array elements marked * are not used by the routine.

```

PURPOSE

zpbsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite band matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate

the system:
 $\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$
Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U^{*H} * U, \quad \text{if UPLO} = 'U', \text{ or}$$

$$A = L * L^{*H}, \quad \text{if UPLO} = 'L',$$
where U is an upper triangular band matrix, and L is a lower triangular band matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether

the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored. = 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

NRHS (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(KD+1+i-j, j) = A(i, j)$ for $\max(1, j-KD) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+KD)$. See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq KD+1$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U*H*U$ or $A = L*L*H$ of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and

on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF \geq KD+1.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)

The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If

RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
 $\leq N$: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned.
 $= N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A :

```

a11  a12  a13
      a22  a23  a24
            a33  a34  a35
                  a44  a45  a46
                        a55  a56
(aij=conjg(aji))          a66

```

Band storage of the upper triangle of A:

```

*      *   a13  a24  a35  a46
*      a12  a23  a34  a45  a56
a11  a22  a33  a44  a55  a66

```

Similarly, if UPLO = 'L' the format of A is as follows:

```

a11  a22  a33  a44  a55  a66
a21  a32  a43  a54  a65  *
a31  a42  a53  a64  *    *

```

Array elements marked * are not used by the routine.

COMPLEX(8), DIMENSION(:, :) :: AB  
INTEGER :: N, KD, LDAB, INFO
```

```
SUBROUTINE PBTF2_64(UPLO, [N], KD, AB, [LDAB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: AB  
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbtbf2(char uplo, int n, int kd, doublecomplex *ab, int
             ldab, int *info);

void zpbtbf2_64(char uplo, long n, long kd, doublecomplex
                *ab, long ldab, long *info);
```

PURPOSE

zpbtbf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

= 'U': Upper triangular

= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. $KD \geq 0$.

AB (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization $A = U^*U$ or $A = L^*L'$ of the band matrix A , in the same storage format as A .

LDAB (input)

The leading dimension of the array AB. LDAB \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when $N = 6$, $KD = 2$, and $UPLO = 'U'$:

On entry:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35
u46												
	*	a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56												
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55
u66												

On exit:

Similarly, if $UPLO = 'L'$ the format of A is as follows:

On entry:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55
l66												
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65
*												
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*
*												

On exit:

Array elements marked * are not used by the routine.

#include <sunperf.h>

void zpbtrf(char uplo, int n, int kd, doublecomplex *a, int
            lda, int *info);

void zpbtrf_64(char uplo, long n, long kd, doublecomplex *a,
               long lda, long *info);
```

PURPOSE

zpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$A = U^*H * U$, if UPLO = 'U', or

$A = L * L^*H$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$ of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA \geq KD+1.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

On entry:

On exit:

	*	*	a13	a24	a35	a46		*	*	u13	u24	u35	
u46													
	*		a12	a23	a34	a45	a56		*	u12	u23	u34	u45
u56													
	a11	a22	a33	a44	a55	a66		u11	u22	u33	u44	u55	
u66													

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:

On exit:

	a11	a22	a33	a44	a55	a66		l11	l22	l33	l44	l55	
l66													
	a21	a32	a43	a54	a65	*		l21	l32	l43	l54	l65	
*													
	a31	a42	a53	a64	*	*		l31	l42	l53	l64	*	
*													

Array elements marked * are not used by the routine.

INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbtrs(char uplo, int n, int kd, int nrhs, doublecomplex
            *a, int lda, doublecomplex *b, int ldb, int
            *info);

void zpbtrs_64(char uplo, long n, long kd, long nrhs, doublecomplex
               *a, long lda, doublecomplex *b, long
               ldb, long *info);
```

PURPOSE

zpbtrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by ZPBTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor stored in A;
 = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals of the matrix A if
 UPLO = 'U', or the number of subdiagonals if UPLO
 = 'L'. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky
 factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ of the band
 matrix A, stored in the first $KD+1$ rows of the
 array. The j-th column of U or L is stored in the
 j-th column of the array A as follows: if UPLO
 = 'U', $A(kd+1+i-j, j) = U(i, j)$ for $\max(1, j-
 kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$
 for $j \leq i \leq \min(n, j+kd)$.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $KD+1$.

B (input/output)
 On entry, the right hand side matrix B. On exit,

the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an
illegal value

void zpocon_64(char uplo, long n, doublecomplex *a, long
    lda, double anorm, double *rcond, long *info);
```

PURPOSE

zpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$ computed by ZPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$, as computed by ZPOTRF.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

ANORM (input)
 The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)
 The reciprocal of the condition number of the

matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$,
where AINVNM is an estimate of the 1-norm of
inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)

```

```
SUBROUTINE ZPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)
```

```
DOUBLE COMPLEX A(LDA,*)  
INTEGER*8 N, LDA, INFO  
DOUBLE PRECISION SCOND, AMAX  
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO
```

```
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void zpoequ(int n, doublecomplex *a, int lda, double *scale,
            double *scond, double *amax, int *info);

void zpoequ_64(long n, doublecomplex *a, long lda, double
               *scale, double *scond, double *amax, long *info);
```

PURPOSE

zpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

A (input) The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1,N)$.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

               lecomplex *b, long ldb, doublecomplex *x, long
               ldx, double *ferr, double *berr, long *info);

```

PURPOSE

zporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
 The leading dimension of the array A. LDA >=

max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, as computed by ZPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF \geq max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by ZPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>
```

```

void zposv(char uplo, int n, int nrhs, doublecomplex *a, int
          lda, doublecomplex *b, int ldb, int *info);

void zposv_64(char uplo, long n, long nrhs, doublecomplex
              *a, long lda, doublecomplex *b, long ldb, long
              *info);

```

PURPOSE

zposv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{*}H * U$, if UPLO = 'U', or

$A = L * L^{*}H$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{*}H * U$ or $A = L * L^{*}H$.

LDA (input)
 The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
 On entry, the N-by-NRHS right hand side matrix B.
 On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

#include <sunperf.h>

void zposvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, char equed, double *s, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);

void zposvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, char equed, double *s, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

```

PURPOSE

zposvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the

scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$A = U^*H*U$, if UPLO = 'U', or

$A = L * L^*H$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i-by-i principal minor is not positive definite,

then the routine returns with INFO = i. Otherwise, the factored

form of A is used to estimate the condition number of the matrix

A. If the reciprocal of the condition number is less than machine

precision, INFO = N+1 is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by

$\text{diag}(S)$ so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the fac-

tored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output)

On entry, the Hermitian matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input or output)

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$, in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$ of the original matrix A.

If FACT = 'E', then AF is an output argument and

on exit returns the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF $\geq \max(1, N)$.

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)

The leading dimension of the array B. LDB $\geq \max(1, N)$.

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)

The leading dimension of the array X. LDX $\geq \max(1, N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by

a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension($2*N$)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = $-i$, the i -th argument had an illegal value
> 0: if INFO = i , and i is
<= N : the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. $RCOND = 0$ is returned. = $N+1$: U is non-singular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

```

```
SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zpotf2(char uplo, int n, doublecomplex *a, int lda, int
            *info);

void zpotf2_64(char uplo, long n, doublecomplex *a, long
               lda, long *info);

```

PURPOSE

zpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$A = U' * U$, if UPLO = 'U', or

$A = L * L'$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zpotrf(char uplo, int n, doublecomplex *a, int lda, int
            *info);

void zpotrf_64(char uplo, long n, doublecomplex *a, long
               lda, long *info);

```

PURPOSE

zpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$A = U^{*H} * U$, if UPLO = 'U', or

$A = L * L^{*H}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L^{*H}L$.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

void zpotri_64(char uplo, long n, doublecomplex *a, long
               lda, long *info);
```

PURPOSE

zpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by ZPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

A (input/output)
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$, as computed by ZPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A , overwriting the input factor U or L .

LDA (input)
 The leading dimension of the array A . $LDA \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value
 > 0: if $INFO = i$, the (i, i) element of the factor U or L is zero, and the inverse could not be computed.

               *a, long lda, doublecomplex *b, long ldb, long
               *info);
```

PURPOSE

zpotrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H \cdot U$ or $A = L \cdot L^*H$ computed by ZPOTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The triangular factor U or L from the Cholesky factorization $A = U^*H \cdot U$ or $A = L \cdot L^*H$, as computed by ZPOTRF.

LDA (input)
 The leading dimension of the array A . $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)
 The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)
 = 0: successful exit
 < 0: if $INFO = -i$, the i -th argument had an illegal value

```
SUBROUTINE PPCON_64(UPLO, [N], A, ANORM, RCOND, [WORK], [WORK2], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: A, WORK
```

```

INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2

```

C INTERFACE

```

#include <sunperf.h>

void zppcon(char uplo, int n, doublecomplex *a, double
            anorm, double *rcond, int *info);
void zppcon_64(char uplo, long n, doublecomplex *a, double
              anorm, double *rcond, long *info);

```

PURPOSE

zppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by ZPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

ANORM (input)
 The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

WORK (workspace)

```
COMPLEX*16 array, dimension(2*N)

WORK2 (workspace)
      DOUBLE PRECISION array, dimension(N)
INFO (output)
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SUBROUTINE ZPPEQU_64(UPLO, N, A, SCALE, SCOND, AMAX, INFO)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX A(*)  
INTEGER*8 N, INFO  
DOUBLE PRECISION SCOND, AMAX  
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: A  
INTEGER :: N, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: A  
INTEGER(8) :: N, INFO  
REAL(8) :: SCOND, AMAX  
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zppequ(char uplo, int n, doublecomplex *a, double  
            *scale, double *scond, double *amax, int *info);  
void zppequ_64(char uplo, long n, doublecomplex *a, double  
              *scale, double *scond, double *amax, long *info);
```

PURPOSE

zppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

SCALE (output) DOUBLE PRECISION array, dimension (N)

If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

               *berr, long *info);

```

PURPOSE

zpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i, j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i, j)$ for $j \leq i \leq n$.

AF (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 The triangular factor U or L from the Cholesky factorization $A = U^*H*U$ or $A = L*L^*H$, as computed by DPPTRF/ZPPTRF, packed columnwise in a

linear array in the same format as A (see A).

B (input) COMPLEX*16 array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output) COMPLEX*16 array, dimension (LDX,NRHS)
On entry, the solution matrix X, as computed by ZPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
COMPLEX*16 array, dimension(2*N)

WORK2 (workspace)
DOUBLE PRECISION array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void zppsv(char uplo, int n, int nrhs, doublecomplex *a,
           doublecomplex *b, int ldb, int *info);

void zppsv_64(char uplo, long n, long nrhs, doublecomplex
              *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zppsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$A = U^{*}H*U$, if UPLO = 'U', or

$A = L * L^{*}H$, if UPLO = 'L',

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, in the same storage format as A.

B (input/output) COMPLEX*16 array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B.
On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

    double *berr, long *info);

```

PURPOSE

zppsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations

$A * X = B$, where A is an N -by- N Hermitian positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

$$diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B$$
Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(S)*A*diag(S)$ and B by $diag(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = U' * U, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * L', \text{ if } UPLO = 'L',$$
 where U is an upper triangular matrix, L is a lower triangular matrix, and ' indicates conjugate transpose.
3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A.
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before equilibration.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.

= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(S)*A*\text{diag}(S)$. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$.

AF (input or output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$, in the same storage format as A. If EQUED = 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

EQUED (input or output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT =

'N').
= 'Y': Equilibration was done, i.e., A has been replaced by $\text{diag}(S) * A * \text{diag}(S)$. EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input or output) DOUBLE PRECISION array, dimension (N)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output) COMPLEX*16 array, dimension (LDB,NRHS)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(S) * B$.

LDB (input)
The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (output) COMPLEX*16 array, dimension (LDX,NRHS)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(S)) * X$.

LDX (input)
The leading dimension of the array X. LDX $\geq \max(1,N)$.

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

COMPLEX*16 array, dimension(2*N)

WORK2 (workspace)

DOUBLE PRECISION array, dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
 <= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned.
 = N+1: U is non-singular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A :

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A :

$A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]$

void zpptrf_64(char uplo, long n, doublecomplex *a, long
               *info);
```

PURPOSE

zpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

$A = U^{*H} * U$, if UPLO = 'U', or

$A = L * L^{*H}$, if UPLO = 'L',

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L*L^{*H}$, in the same storage format as A.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the Hermitian matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
      a33 a34    (aij = conjg(aji))
        a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

void zpptri_64(char uplo, long n, doublecomplex *a, long
               *info);
```

PURPOSE

zpptri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ computed by ZPPTRF.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangular factor is stored in A;
 = 'L': Lower triangular factor is stored in A.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

NAME

zptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**}H$ or $A = U^{**}H^*D^*U$ computed by ZPTTRF

SYNOPSIS

```
SUBROUTINE ZPTCON(N, D, E, ANORM, RCOND, WORK, INFO)
```

```
DOUBLE COMPLEX E(*)  
INTEGER N, INFO  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION D(*), WORK(*)
```

```
SUBROUTINE ZPTCON_64(N, D, E, ANORM, RCOND, WORK, INFO)
```

```
DOUBLE COMPLEX E(*)  
INTEGER*8 N, INFO  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION D(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCN([N], D, E, ANORM, RCOND, [WORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: E  
INTEGER :: N, INFO  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: D, WORK
```

```
SUBROUTINE PTCN_64([N], D, E, ANORM, RCOND, [WORK], [INFO])
```

```

COMPLEX(8), DIMENSION(:) :: E
INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: D, WORK

```

C INTERFACE

```

#include <sunperf.h>

void zptcon(int n, double *d, doublecomplex *e, double
            anorm, double *rcond, int *info);

void zptcon_64(long n, double *d, doublecomplex *e, double
              anorm, double *rcond, long *info);

```

PURPOSE

zptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L^*H$ or $A = U^*H*D*U$ computed by ZPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization of A, as computed by ZPTTRF.

E (input) The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by ZPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)

```
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX(8), DIMENSION(:, :) :: Z  
INTEGER :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```

CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK

```

C INTERFACE

```

#include <sunperf.h>

void zpteqr(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);

void zpteqr_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);

```

PURPOSE

zpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

```

COMPZ (input)
    = 'N': Compute eigenvalues only.
    = 'V': Compute eigenvectors of original Hermitian matrix also. Array Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.
    = 'I': Compute eigenvectors of tridiagonal matrix also.

```

N (input) The order of the matrix. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. $LDZ \geq 1$, and if COMPZ = 'V' or 'I', $LDZ \geq \max(1, N)$.

WORK (workspace)

dimension($4 \cdot N$)

INFO (output)

= 0: successful exit.

< 0: if INFO = $-i$, the i -th argument had an illegal value.

> 0: if INFO = i , and i is: $\leq N$ the Cholesky factorization of the matrix could not be performed because the i -th principal minor was not positive definite. $> N$ the SVD algorithm failed to converge; if INFO = $N+i$, i off-diagonal elements of the bidiagonal factor did not converge to zero.

               ldx, double *ferr, double *berr, long *info);

```

PURPOSE

zptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:
 = 'U': E is the superdiagonal of A, and $A = U^*H^*D^*U$;
 = 'L': E is the subdiagonal of A, and $A = L^*D^*L^{**}H$. (The two forms are equivalent if A is real.)

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n real diagonal elements of the tridiagonal matrix A .

E (input) The $(n-1)$ off-diagonal elements of the tridiagonal matrix A (see UPLO).

DF (input)
The n diagonal elements of the diagonal matrix D from the factorization computed by ZPTTRF.

EF (input)
The $(n-1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ZPTTRF (see UPLO).

B (input) The right hand side matrix B .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

X (input/output)
On entry, the solution matrix X , as computed by ZPTTRS. On exit, the improved solution matrix X .

LDX (input)
The leading dimension of the array X . $LDX \geq \max(1, N)$.

FERR (output)
The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

BERR (output)
The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zptsv(int n, int nrhs, double *d, doublecomplex *e,  
           doublecomplex *b, int ldb, int *info);
```

```
void zptsv_64(long n, long nrhs, double *d, doublecomplex  
              *e, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zptsv computes the solution to a complex system of linear equations $A \cdot X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

A is factored as $A = L \cdot D \cdot L^* \cdot H$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A . $N \geq 0$.

$NRHS$ (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix D from the factorization $A = L \cdot D \cdot L^* \cdot H$.

E (input/output)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L \cdot D \cdot L^* \cdot H$ factorization of A . E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^* \cdot H \cdot D \cdot U$ factorization of A .

B (input/output)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i -th argument had an illegal value

> 0: if $INFO = i$, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless $i = N$.

INTEGER(8) :: N, NRHS, LDB, LDX, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: D, DF, FERR, BERR, WORK2
C INTERFACE
#include <sunperf.h>

void zptsvx(char fact, int n, int nrhs, double *d, doublecomplex *e, double *df, doublecomplex *ef, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);

void zptsvx_64(char fact, long n, long nrhs, double *d, doublecomplex *e, double *df, doublecomplex *ef, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

```

PURPOSE

zptsvx uses the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the matrix A is factored as $A = L^*D^*L^{**}H$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^{**}H^*D^*U$.
2. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the

matrix

A. If the reciprocal of the condition number is less than machine

precision, INFO = N+1 is returned as a warning, but the routine

still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution

matrix and calculate error bounds and backward error estimates

for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DF and EF contain the factored form of A. D, E, DF, and EF will not be modified. = 'N': The matrix A will be copied to DF and EF and factored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix A.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF (input or output)

If FACT = 'F', then DF is an input argument and on entry contains the n diagonal elements of the diagonal matrix D from the $L^*D^*L^{**H}$ factorization of A. If FACT = 'N', then DF is an output argument and on exit contains the n diagonal elements of the diagonal matrix D from the $L^*D^*L^{**H}$ factorization of A.

EF (input or output)

If FACT = 'F', then EF is an input argument and on

entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^{**}H$ factorization of A. If FACT = 'N', then EF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*D^*L^{**}H$ factorization of A.

B (input) On entry, the N-by-NRHS right hand side matrix B. Unchanged on exit.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1, N)$.

RCOND (output)
The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is non-singular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

               *info);
```

PURPOSE

zpttrf computes the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

N (input) The order of the matrix A. $N \geq 0$.

D (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L^*D^*L' factorization of A.

E (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*D^*L' factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*D^*U factorization of A.

INFO (output)

= 0: successful exit
 < 0: if INFO = -k, the k-th argument had an illegal value
 > 0: if INFO = k, the leading minor of order k is not positive definite; if $k < N$, the factorization could not be completed, while if $k = N$, the factorization was completed, but $D(N) = 0$.

```

#include <sunperf.h>

void zpttrs(char uplo, int n, int nrhs, double *d, doublecomplex *e, doublecomplex *b, int ldb, int *info);

void zpttrs_64(char uplo, long n, long nrhs, double *d, doublecomplex *e, doublecomplex *b, long ldb, long *info);

```

PURPOSE

zpttrs solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by ZPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

UPLO (input)
 Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': $A = U' * D * U$, E is the superdiagonal of U
 = 'L': $A = L * D * L'$, E is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization $A = U' * D * U$ or $A = L * D * L'$.

E (input) If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U' * D * U$. If UPLO = 'L', the (n-1) subdi-

agonal elements of the unit bidiagonal factor L
from the factorization $A = L*D*L'$.

B (input/output)

On entry, the right hand side vectors B for the
system of linear equations. On exit, the solution
vectors, X .

LDB (input)

The leading dimension of the array B . $LDB \geq$
 $\max(1, N)$.

INFO (output)

= 0: successful exit
< 0: if $INFO = -k$, the k -th argument had an ille-
gal value

NAME

zptts2 - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by ZPTTRF

SYNOPSIS

```
SUBROUTINE ZPTTS2(IUPLO, N, NRHS, D, E, B, LDB)
```

```
DOUBLE COMPLEX E(*), B(LDB,*)  
INTEGER IUPLO, N, NRHS, LDB  
DOUBLE PRECISION D(*)
```

```
SUBROUTINE ZPTTS2_64(IUPLO, N, NRHS, D, E, B, LDB)
```

```
DOUBLE COMPLEX E(*), B(LDB,*)  
INTEGER*8 IUPLO, N, NRHS, LDB  
DOUBLE PRECISION D(*)
```

F95 INTERFACE

```
SUBROUTINE ZPTTS2(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX(8), DIMENSION(:) :: E  
COMPLEX(8), DIMENSION(:, :) :: B  
INTEGER :: IUPLO, N, NRHS, LDB  
REAL(8), DIMENSION(:) :: D
```

```
SUBROUTINE ZPTTS2_64(IUPLO, N, NRHS, D, E, B, LDB)
```

```
COMPLEX(8), DIMENSION(:) :: E  
COMPLEX(8), DIMENSION(:, :) :: B  
INTEGER(8) :: IUPLO, N, NRHS, LDB  
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>

void zptts2(int iuplo, int n, int nrhs, double *d, doublecomplex *e, doublecomplex *b, int ldb);

void zptts2_64(long iuplo, long n, long nrhs, double *d, doublecomplex *e, doublecomplex *b, long ldb);
```

PURPOSE

zptts2 solves a tridiagonal system of the form
 $A * X = B$ using the factorization $A = U' * D * U$ or $A = L * D * L'$ computed by ZPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

IUPLO (input)
Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: $A = U' * D * U$, E is the superdiagonal of U
= 0: $A = L * D * L'$, E is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

D (input) The n diagonal elements of the diagonal matrix D from the factorization $A = U' * D * U$ or $A = L * D * L'$.

E (input) If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U' * D * U$. If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L * D * L'$.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution

vectors, X.

LDB (input)

The leading dimension of the array B. LDB \geq
max(1,N).

NAME

zrot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

SYNOPSIS

```
SUBROUTINE ZROT(N, X, INCX, Y, INCY, C, S)
```

```
DOUBLE COMPLEX S  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER N, INCX, INCY  
DOUBLE PRECISION C
```

```
SUBROUTINE ZROT_64(N, X, INCX, Y, INCY, C, S)
```

```
DOUBLE COMPLEX S  
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 N, INCX, INCY  
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)
```

```
COMPLEX(8) :: S  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER :: N, INCX, INCY  
REAL(8) :: C
```

```
SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)
```

```
COMPLEX(8) :: S  
COMPLEX(8), DIMENSION(:) :: X, Y  
INTEGER(8) :: N, INCX, INCY
```

```
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zrot(int n, doublecomplex *x, int incx, doublecomplex  
         *y, int incy, double c, doublecomplex *s);
```

```
void zrot_64(long n, doublecomplex *x, long incx, doublecom-  
             plex *y, long incy, double c, doublecomplex *s);
```

PURPOSE

zrot applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex.

ARGUMENTS

N (input)

The number of elements in the vectors X and Y.

X (input/output)

On input, the vector X. On output, X is overwritten with $C*X + S*Y$.

INCX (input)

The increment between successive values of X.

Y (input/output)

On input, the vector Y. On output, Y is overwritten with $-CONJG(S)*X + C*Y$.

INCY (input)

The increment between successive values of Y.

C (input)

S (input)

C and S define a rotation

$$\begin{bmatrix} C & S \\ -\text{conjg}(S) & C \end{bmatrix}$$

where $C*C + S*CONJG(S) = 1.0$.

NAME

zrotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE ZROTG(A, B, C, S)
```

```
DOUBLE COMPLEX A, B, S
```

```
DOUBLE PRECISION C
```

```
SUBROUTINE ZROTG_64(A, B, C, S)
```

```
DOUBLE COMPLEX A, B, S
```

```
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)
```

```
COMPLEX(8) :: A, B, S
```

```
REAL(8) :: C
```

```
SUBROUTINE ROTG_64(A, B, C, S)
```

```
COMPLEX(8) :: A, B, S
```

```
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zrotg(doublecomplex *a, doublecomplex *b, double *c,  
          doublecomplex *s);
```

```
void zrotg_64(doublecomplex *a, doublecomplex *b, double *c,
```

```
doublecomplex *s);
```

PURPOSE

zrotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input)

On entry, B contains the entry to be annihilated in the second vector. Unchanged on exit.

C (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

zscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE ZSCAL(N, ALPHA, Y, INCY)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX Y(*)  
INTEGER N, INCY
```

```
SUBROUTINE ZSCAL_64(N, ALPHA, Y, INCY)
```

```
DOUBLE COMPLEX ALPHA  
DOUBLE COMPLEX Y(*)  
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: Y  
INTEGER :: N, INCY
```

```
SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])
```

```
COMPLEX(8) :: ALPHA  
COMPLEX(8), DIMENSION(:) :: Y  
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zscal(int n, doublecomplex *alpha, doublecomplex *y,
           int incy);

void zscal_64(long n, doublecomplex *alpha, doublecomplex
              *y, long incy);

```

PURPOSE

zscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

Y (input/output)

(1 + (n - 1) * INCY). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

INCY (input)

On entry, INCY specifies the increment for the elements of Y. This routine returns immediately if INCY is less than or equal to zero. Unchanged on exit.

NAME

zsctr - Scatters elements from x into y.

SYNOPSIS

```
SUBROUTINE ZSCTR(NZ, X, INDX, Y)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER NZ  
INTEGER INDX(*)
```

```
SUBROUTINE ZSCTR_64(NZ, X, INDX, Y)
```

```
DOUBLE COMPLEX X(*), Y(*)  
INTEGER*8 NZ  
INTEGER*8 INDX(*)
```

```
F95 INTERFACE
```

```
  SUBROUTINE SCTR([NZ], X, INDX, Y)
```

```
  COMPLEX(8), DIMENSION(:) :: X, Y  
  INTEGER :: NZ  
  INTEGER, DIMENSION(:) :: INDX
```

```
  SUBROUTINE SCTR_64([NZ], X, INDX, Y)
```

```
  COMPLEX(8), DIMENSION(:) :: X, Y  
  INTEGER(8) :: NZ  
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

ZSCTR - Scatters the components of a sparse vector x stored in compressed form into specified components of a vector y

in full storage form.

```
do i = 1, n
  y(indx(i)) = x(i)
enddo
```

ARGUMENTS

NZ (input) - INTEGER

Number of elements in the compressed form.
Unchanged on exit.

X (input)

Vector containing the values to be scattered from
compressed form into full storage form. Unchanged
on exit.

INDX (input) - INTEGER

Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

Y (output)

Vector whose elements specified by indx have been
set to the corresponding entries of x. Only the
elements corresponding to the indices in indx have
been modified.

```

```
void zskymm_64 (long transa, long m, long n, long k,
doublecomplex *alpha, long *descra, doublecomplex *val,
long *pntr, doublecomplex *b, long ldb, doublecomplex
*beta,
doublecomplex *c, long ldc);
```

DESCRIPTION

zskymm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where $\operatorname{op}(A)$ is one of

$\operatorname{op}(A) = A$ or $\operatorname{op}(A) = A'$ or $\operatorname{op}(A) = \operatorname{conjg}(A')$
(' indicates matrix transpose),

A is an M-by-K sparse matrix represented in the skyline format,
alpha and beta are scalars, C and B are dense matrices.

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of $\operatorname{op}(A)$ to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
K(input)	On entry, integer K specifies the number of columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array. DESCRA(1) matrix structure 0 : general (NOT SUPPORTED) 1 : symmetric ($A=A'$) 2 : Hermitian ($A= \operatorname{CONJG}(A')$)

```

3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, VAL is a scalar array consisting of the
                  nonzeros of A in skyline profile form.
                  Row-oriented if DESCRA(2) = 1 (lower triangular),
                  column oriented if DESCRA(2) = 2 (upper triangular).
                  Unchanged on exit.

PNTR (input)     On entry, INDX is an integer array of length
                  M+1 (lower triangular) or K+1 (upper triangular)
                  such that PNTR(I)-PNTR(1)+1 points to the
                  location in VAL of the first element of the skyline
                  profile in row (column) I. Unchanged on exit.

B (input)        Array of DIMENSION ( LDB, N ).
                  Before entry with  TRANSA = 0,  the leading k by n
                  part of the array B must contain the matrix B,  otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

LDB (input)      On entry, LDB specifies the first dimension of B as declared
                  in the calling (sub) program. Unchanged on exit.

BETA (input)     On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output)  Array of DIMENSION ( LDC, N ).
                  Before entry with  TRANSA = 0,  the leading m by n
                  part of the array C must contain the matrix C,  otherwise
                  the leading k by n part of the array C must contain the
                  matrix C. On exit, the array C is overwritten by the matrix
                  ( alpha*op( A )* B  + beta*C ).

LDC (input)      On entry, LDC specifies the first dimension of C as declared
                  in the calling (sub) program. Unchanged on exit.

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible
 with NIST FORTRAN Sparse Blas but the sources are different.
 Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN

Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

The SKY data structure is not supported for a general matrix structure (*DESCRA*(1)=0).

Also not supported:

1. lower triangular matrix A of size m by n where $m > n$
2. upper triangular matrix A of size m by n where $m < n$

doublecomplex *dv, doublecomplex *alpha, long *descra,
doublecomplex *val, long *pntr, doublecomplex *b, long ldb,
doublecomplex *beta, doublecomplex *c, long ldc);
```

DESCRIPTION

zskysm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C, \quad C \leftarrow \alpha D \operatorname{op}(A) B + \beta C,$$

$$C \leftarrow \alpha \operatorname{op}(A) D B + \beta C,$$

where alpha and beta are scalars, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the skyline format and op(A) is one of

op(A) = inv(A) or op(A) = inv(A') or op(A) = inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose).

ARGUMENTS

TRANSA(input)	On entry, integer TRANSA specifies the form of op(A) to be used in the sparse matrix inverse as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
M(input)	On entry, integer M specifies the number of rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
UNITD(input)	On entry, integer UNITD specifies the type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling) 4 : Automatic row or column scaling (see section NOTES for further details) Unchanged on exit.

DV(input) On entry, DV is an array of length M consisting of the diagonal entries of the scaling matrix D. If UNITD is 4, DV contains diagonal matrix by which the rows (columns) have been scaled (see section NOTES for further details). Otherwise, unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array.

DESCRA(1) matrix structure

- 0 : general (NOT SUPPORTED)
- 1 : symmetric (A=A')
- 2 : Hermitian (A= CONJG(A'))
- 3 : Triangular
- 4 : Skew(Anti)-Symmetric (A=-A')
- 5 : Diagonal
- 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL(input) On entry, VAL contains the nonzeros of A in skyline profile form. Row-oriented if DESCRA(2) = 1 (lower triangular), column oriented if DESCRA(2) = 2 (upper triangular). Unchanged on exit if UNITD is not 4. Otherwise, VAL contains entries of D*A or A*D (see section NOTES for further details).

PNTR (input) On entry, INDX is an integer array of length M+1 such that PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element of the skyline profile in row (column) I. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N).
On entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
On entry, the leading m by n part of the array C must contain the matrix C. On exit, the array C is overwritten.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M \cdot N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A if `DESCRA(2)=1` (lower triangular), and the columns of A if `DESCRA(2)=2` (upper triangular) such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On exit, DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if `DESCRA(2)=1` and UNITD=3 if `DESCRA(2)=2` should be used for the next calls to the routine with overwritten VAL and DV.

`WORK(1)=0` on return if the scaling has been completed successfully, otherwise `WORK(1) = -i` where i is the row (column) number which 2-norm is exactly zero.

3. If `DESCRA(3)=1` and `UNITD < 4`, the diagonal entries are each used with the mathematical value 1. The entries of the main diagonal in the skyline representation of a sparse matrix don't need to be referenced in this usage but they

need to be 1.0 if they are referenced. However if UNITD=4,
the unit diagonal elements with the mathematical value 1
MUST be referenced in the skyline representation.

```

```
SUBROUTINE SPCON_64(UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND

```

C INTERFACE

```

#include <sunperf.h>

void zspcon(char uplo, int n, doublecomplex *a, int *ipivot,
            double anorm, double *rcond, int *info);
void zspcon_64(char uplo, long n, doublecomplex *a, long
               *ipivot, double anorm, double *rcond, long *info);

```

PURPOSE

zspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by ZSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U*D*U^{**T}$;
 = 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) Double complex array, dimension $(N*(N+1)/2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

ANORM (input)
 The 1-norm of the original matrix A.

RCOND (output)
 The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVM})$, where AINVM is an estimate of the 1-norm of

inv(A) computed in this routine.

WORK (workspace)

Double complex array, dimension(2*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               *ferr, double *berr, long *info);

```

PURPOSE

zsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

A (input) Double complex array, dimension $(N*(N+1)/2)$ The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows:
 if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

AF (input)
 Double complex array, dimension $(N*(N+1)/2)$ The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used

to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

B (input) Double complex array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. $LDB \geq \max(1,N)$.

X (input/output)
Double complex array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by ZSPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. $LDX \geq \max(1,N)$.

FERR (output)
Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Double precision array, dimension(2*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

              long *info);

```

PURPOSE

zspsv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*T}$, if UPLO = 'U', or

$A = L * D * L^{*T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

AP (input/output)

Double complex array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear

array. The j -th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*T$ or $A = L*D*L^*T$ as computed by `ZSPTRF`, stored as a packed triangular matrix in the same storage format as A .

`IPIVOT` (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D , as determined by `ZSPTRF`. If `IPIVOT(k) > 0`, then rows and columns k and `IPIVOT(k)` were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and `IPIVOT(k) = IPIVOT(k-1) < 0`, then rows and columns $k-1$ and `-IPIVOT(k)` were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and `IPIVOT(k) = IPIVOT(k+1) < 0`, then rows and columns $k+1$ and `-IPIVOT(k)` were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

`B` (input/output)

Double complex array, dimension $(LDB, NRHS)$ On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if `INFO = 0`, the N -by- $NRHS$ solution matrix X .

`LDB` (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

`INFO` (output)

`= 0`: successful exit
`< 0`: if `INFO = -i`, the i -th argument had an illegal value
`> 0`: if `INFO = i`, $D(i,i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when $N = 4$, $UPLO = 'U'$:

Two-dimensional storage of the symmetric matrix A :

```

a11 a12 a13 a14
    a22 a23 a24
        a33 a34    (aij = aji)
            a44

```

Packed storage of the upper triangle of A:

```
AP = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

    *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

```

PURPOSE

zspsvx uses the diagonal pivoting factorization $A = U^*D U^{**T}$ or $A = L^*D L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as

$$A = U * D * U^{**T}, \text{ if } UPLO = 'U', \text{ or}$$

$$A = L * D * L^{**T}, \text{ if } UPLO = 'L',$$

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices and D is symmetric and block diagonal with

1-by-1 and 2-by-2 diagonal blocks.

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine
returns with $INFO = i$. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A . If the
reciprocal of the condition number is less than machine
precision,
 $INFO = N+1$ is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.
3. The system of equations is solved for X using the fac-
tored form
of A .
4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, AF
and $IPIVOT$ contain the factored form of A . A , AF
and $IPIVOT$ will not be modified. = 'N': The
matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X . $NRHS \geq 0$.

A (input) Double complex array, dimension $(N*(N+1)/2)$ The
upper or lower triangle of the symmetric matrix A ,
packed columnwise in a linear array. The j -th
column of A is stored in the array A as follows:
if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for
 $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) =$
 $A(i,j)$ for $j \leq i \leq n$. See below for further
details.

AF (input or output)

Double complex array, dimension $(N*(N+1)/2)$ If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZSPTRF.

B (input) Double complex array, dimension (LDB,NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB $\geq \max(1,N)$.

X (output)

Double complex array, dimension (LDX,NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)

The leading dimension of the array X. LDX $\geq \max(1,N)$.

RCOND (output)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This

condition is indicated by a return code of INFO > 0.

FERR (output)

Double complex array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

Double complex array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

Double complex array, dimension(2*N)

WORK2 (workspace)

Integer array, dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
```

a33 a34 (a_{ij} = a_{ji})
a44

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPTRF_64(UPLO, [N], AP, IPIVOT, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
```

```

COMPLEX(8), DIMENSION(:) :: AP
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT

```

C INTERFACE

```

#include <sunperf.h>

void zsptrf(char uplo, int n, doublecomplex *ap, int
            *ipivot, int *info);

void zsptrf_64(char uplo, long n, doublecomplex *ap, long
               *ipivot, long *info);

```

PURPOSE

zsptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double complex array, dimension $(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,
i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then $A = L * D * L'$, where

$$L = P(1) * L(1) * \dots * P(k) * L(k) * \dots,$$

i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \\ & & & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \\ \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

#include <sunperf.h>

void zsptri(char uplo, int n, doublecomplex *ap, int
            *ipivot, int *info);

void zsptri_64(char uplo, long n, doublecomplex *ap, long
               *ipivot, long *info);

```

PURPOSE

zsptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by ZSPTRF.

ARGUMENTS

UPLO (input)
 Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U^*D^*U^{**T}$;
 = 'L': Lower triangular, form is $A = L^*D^*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

AP (input/output)
 Double complex array, dimension $(N*(N+1)/2)$ On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = inv(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j)$ for $j \leq i \leq n$.

IPIVOT (input)
 Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

WORK (workspace)

Double complex array, dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

```

PURPOSE

zsptrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by ZSPTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
 = 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

AP (input)

Double complex array, dimension $(N \cdot (N+1)/2)$ The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

IPIVOT (input)

Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

B (input/output)

Double complex array, dimension (LDB,NRHS) On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB \geq max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```

SUBROUTINE STEDC_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK],
                   [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, RWORK

```

C INTERFACE

```

#include <sunperf.h>
void zstedc(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);

void zstedc_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);

```

PURPOSE

zstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)
 = 'N': Compute eigenvalues only.
 = 'I': Compute eigenvectors of tridiagonal matrix also.
 = 'V': Compute eigenvectors of original Hermitian matrix also. On entry, Z contains the unitary matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.
 N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If COMPZ = 'N' or 'I', or N <= 1, LWORK must be at least 1. If COMPZ = 'V' and N > 1, LWORK must be at least N*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If COMPZ = 'N' or N <= 1, LRWORK must be at least 1. If COMPZ = 'V' and N > 1, LRWORK must be at least $1 + 3*N + 2*N*\lg N + 3*N**2$, where $\lg(N)$ = smallest integer k such that $2**k \geq N$. If COMPZ = 'I' and N > 1, LRWORK must be at least $1 + 4*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If COMPZ = 'V' or $N > 1$, LIWORK must be at least $6 + 6*N + 5*N*\lg N$. If COMPZ = 'I' or $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

    *z, long ldz, long *isuppz, long *info);
```

PURPOSE

zstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
 (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
 (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently ZSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine ZSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. ZSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : ZSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of ZSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. $N \geq 0$.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$.
Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed

to an accuracy of $\text{EPS} * |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = \text{IU} - \text{IL} + 1$.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

ISUPPZ (output)

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)

The dimension of the array WORK. $\text{LWORK} \geq \max(1, 18 * N)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK \geq
 $\max(1, 10 \cdot N)$

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if
INFO = 2, internal error in CLARRV.

```

```

COMPLEX(8), DIMENSION(:, :) :: Z
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK

```

C INTERFACE

```

#include <sunperf.h>

void zstein(int n, double *d, double *e, int m, double *w,
            int *iblock, int *isplit, doublecomplex *z, int
            ldz, int *ifail, int *info);
void zstein_64(long n, double *d, double *e, long m, double
               *w, long *iblock, long *isplit, doublecomplex *z,
               long ldz, long *ifail, long *info);

```

PURPOSE

zstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

N (input) The order of the matrix. $N \geq 0$.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.

M (input) The number of eigenvectors to be found. $0 \leq M \leq N$.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the

block. (The output array W from SSTEBC with ORDER = 'B' is expected here.)

IBLOCK (input)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBC is expected here.)

ISPLIT (input)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBC is expected here.)

Z (output)

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

LDZ (input)

The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)

dimension(5*N)

IWORK (workspace)

dimension(N)

IFAIL (output)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

NAME

zsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE ZSTEQR(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
DOUBLE COMPLEX Z(LDZ,*)  
INTEGER N, LDZ, INFO  
DOUBLE PRECISION D(*), E(*), WORK(*)
```

```
SUBROUTINE ZSTEQR_64(COMPZ, N, D, E, Z, LDZ, WORK, INFO)
```

```
CHARACTER * 1 COMPZ  
DOUBLE COMPLEX Z(LDZ,*)  
INTEGER*8 N, LDZ, INFO  
DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX(8), DIMENSION(:, :) :: Z  
INTEGER :: N, LDZ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE STEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ  
COMPLEX(8), DIMENSION(:, :) :: Z
```

```

INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK

```

C INTERFACE

```

#include <sunperf.h>

void zsteqr(char compz, int n, double *d, double *e, doublecomplex *z, int ldz, int *info);

void zsteqr_64(char compz, long n, double *d, double *e, doublecomplex *z, long ldz, long *info);

```

PURPOSE

zsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
 = 'N': Compute eigenvalues only.
 = 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
 On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
 On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ =

'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ ≥ 1 , and if eigenvectors are desired, then LDZ $\geq \max(1, N)$.

WORK (workspace)

dimension($\max(1, 2*N-2)$) If COMPZ = 'N', then WORK is not referenced.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: the algorithm has failed to find all the eigenvalues in a total of $30*N$ iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is unitarily similar to the original matrix.

```
COMPLEX(8), DIMENSION(:) :: L, D, SUBL  
COMPLEX(8), DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void zstsv(int n, int nrhs, doublecomplex *l, doublecomplex
           *d, doublecomplex *subl, doublecomplex *b, int
           ldb, int *ipiv, int *info);

void zstsv_64(long n, long nrhs, doublecomplex *l, double-
              lecomplex *d, doublecomplex *subl, doublecomplex
              *b, long ldb, long *ipiv, long *info);
```

PURPOSE

zstsv computes the solution to a complex system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix.

ARGUMENTS

N (input)
The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides in B.

L (input/output)
COMPLEX array, dimension (N-1)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N-2)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

INFO (output)

INTEGER

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

void zsttrf(int n, doublecomplex *l, doublecomplex *d, doublecomplex *subl, int *ipiv, int *info);

void zsttrf_64(long n, doublecomplex *l, doublecomplex *d, doublecomplex *subl, long *ipiv, long *info);
```

PURPOSE

zsttrf computes the L^*D^*L' factorization of a complex symmetric tridiagonal matrix A using the Bunch-Kaufman diagonal pivoting method.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. $N \geq 0$.

L (input/output)
COMPLEX array, dimension (N-1)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N-2)
On exit, part of the factorization of A.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division

by zero will occur if it is used to solve a system of equations.

```
#include <sunperf.h>

void zsttrs(int n, int nrhs, doublecomplex *l, doublecomplex
            *d, doublecomplex *subl, doublecomplex *b, int
            ldb, int *ipiv, int *info);

void zsttrs_64(long n, long nrhs, doublecomplex *l, doub-
               lecomplex *d, doublecomplex *subl, doublecomplex
               *b, long ldb, long *ipiv, long *info);
```

PURPOSE

zsttrs computes the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

ARGUMENTS

N (input) **INTEGER**
 The order of the matrix A . $N \geq 0$.

NRHS (input)
 INTEGER
 The number of right hand sides, i.e., the number
 of columns of the matrix B . $NRHS \geq 0$.

L (input) **COMPLEX** array, dimension $(N-1)$
 On entry, the subdiagonal elements of L .

D (input) **COMPLEX** array, dimension (N)
 On entry, the diagonal elements of D .

SUBL (input)
 COMPLEX array, dimension $(N-2)$
 On entry, the second subdiagonal elements of L .

B (input/output)
 COMPLEX array, dimension $(LDB, NRHS)$
 On entry, the N -by- $NRHS$ right hand side matrix B .
 On exit, if $INFO = 0$, the N -by- $NRHS$ solution
 matrix X .

LDB (input)
 INTEGER
 The leading dimension of the array B . $LDB \geq$
 $\max(1, N)$

IPIV (output)
 INTEGER array, dimension (N)

Details of the interchanges and block pivot. If $IPIV(K) > 0$, 1 by 1 pivot, and if $IPIV(K) = K + 1$ an interchange done; If $IPIV(K) < 0$, 2 by 2 pivot, no interchange required.

INFO (output)

INTEGER
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

```

```
COMPLEX(8), DIMENSION(:) :: X, Y
```

```
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])
```

```
COMPLEX(8), DIMENSION(:) :: X, Y
```

```
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zswap(int n, doublecomplex *x, int incx, doublecomplex  
          *y, int incy);
```

```
void zswap_64(long n, doublecomplex *x, long incx, doub-
```

```
lecomplex *y, long incy);
```

PURPOSE

zswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)

On entry, INCX specifies the increment for the elements of X. Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. Unchanged on exit.

```
CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void zsycon(char uplo, int n, doublecomplex *a, int lda, int
            *ipivot, double anorm, double *rcond, int *info);

void zsycon_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipivot, double anorm, double *rcond,
               long *info);
```

PURPOSE

zsycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by ZSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U*D*U^{**T}$;
= 'L': Lower triangular, form is $A = L*D*L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is an estimate of the 1-norm of $inv(A)$ computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER :: M, N, LDA, LDB, LDC
```

```
SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],  
                  BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
```

```

COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:, :) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC

```

C INTERFACE

```

#include <sunperf.h>

void zsymm(char side, char uplo, int m, int n, doublecomplex
           *alpha, doublecomplex *a, int lda, doublecomplex
           *b, int ldb, doublecomplex *beta, doublecomplex
           *c, int ldc);
void zsymm_64(char side, char uplo, long m, long n, doublecomplex
              *alpha, doublecomplex *a, long lda,
              doublecomplex *b, long ldb, doublecomplex *beta,
              doublecomplex *c, long ldc);

```

PURPOSE

zsymm performs one of the matrix-matrix operations $C := \alpha A B + \beta C$ or $C := \alpha B A + \beta C$ where α and β are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha A B + \beta C$,

SIDE = 'R' or 'r' $C := \alpha B A + \beta C$,

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, n). Before

entry, the leading m by n part of the array B must contain the matrix B . Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar β . When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C , except when β is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)  
INTEGER N, K, LDA, LDB, LDC
```

```
SUBROUTINE ZSYR2K_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,  
                     C, LDC)
```

```
CHARACTER * 1 UPLO, TRANSA  
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)  
INTEGER*8 N, K, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYR2K(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],  
                BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA  
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:, :) :: A, B, C  
INTEGER :: N, K, LDA, LDB, LDC
```

```
SUBROUTINE SYR2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,  
                    [LDB], BETA, C, [LDC])
```

```

CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:, :) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC

```

C INTERFACE

```

#include <sunperf.h>

void zsyr2k(char uplo, char transa, int n, int k, doublecom-
    plex *alpha, doublecomplex *a, int lda, doublecom-
    plex *b, int ldb, doublecomplex *beta, doublecom-
    plex *c, int ldc);
void zsyr2k_64(char uplo, char transa, long n, long k, doub-
    lecomplex *alpha, doublecomplex *a, long lda,
    doublecomplex *b, long ldb, doublecomplex *beta,
    doublecomplex *c, long ldc);

```

PURPOSE

zsyr2k performs one of the symmetric rank 2k operations $C := \alpha A^*B' + \alpha B^*A' + \beta C$ or $C := \alpha A^*B + \alpha B^*A' + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A^*B' + \alpha B^*A' + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^*B + \alpha B^*A' + \beta C$.

$\alpha * B' * A + \beta * C.$

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta.
Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

    *ipivot, doublecomplex *b, long ldb, doublecomplex
    *x, long ldx, double *ferr, double *berr, long
    *info);

```

PURPOSE

zsyrfbs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular

part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

AF (input)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSYTRF.

LDAF (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

B (input) The right hand side matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

X (input/output)

On entry, the solution matrix X, as computed by ZSYTRS. On exit, the improved solution matrix X.

LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zsyrrk(char uplo, char transa, int n, int k, doublecomplex *alpha, doublecomplex *a, int lda, doublecomplex *beta, doublecomplex *c, int ldc);
```

```
void zsyrrk_64(char uplo, char transa, long n, long k, doublecomplex *alpha, doublecomplex *a, long lda, doublecomplex *beta, doublecomplex *c, long ldc);
```

PURPOSE

zsyrrk performs one of the symmetric rank k operations $C := \alpha A A^T + \beta C$ or $C := \alpha A^T A + \beta C$ where α and β are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha A A^T + \beta C$.

TRANSA = 'T' or 't' $C := \alpha A^T A + \beta C$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwrit-

ten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

```
#include <sunperf.h>
```

```
void zsysv(char uplo, int n, int nrhs, doublecomplex *a, int
           lda, int *ipivot, doublecomplex *b, int ldb, int
           *info);
void zsysv_64(char uplo, long n, long nrhs, doublecomplex
              *a, long lda, long *ipivot, doublecomplex *b, long
              ldb, long *info);
```

PURPOSE

zsysv computes the solution to a complex system of linear equations

$A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$A = U * D * U^{*T}$, if UPLO = 'U', or

$A = L * D * L^{*T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A is stored;

= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSYTRF.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D, as determined by ZSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of WORK. $LWORK \geq 1$, and for best performance $LWORK \geq N*NB$, where NB is the optimal blocksize for ZSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

void zsysvx(char fact, char uplo, int n, int nrhs, doublecomplex *a, int lda, doublecomplex *af, int ldaf, int *ipivot, doublecomplex *b, int ldb, doublecomplex *x, int ldx, double *rcond, double *ferr, double *berr, int *info);

void zsysvx_64(char fact, char uplo, long n, long nrhs, doublecomplex *a, long lda, doublecomplex *af, long ldaf, long *ipivot, doublecomplex *b, long ldb, doublecomplex *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

```

PURPOSE

zsysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A.

The form of the factorization is

$A = U * D * U^{**T}$, if UPLO = 'U', or

$A = L * D * L^{**T}$, if UPLO = 'L',

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices, and D is symmetric and block diagonal with

- 1-by-1 and 2-by-2 diagonal blocks.
2. If some $D(i,i)=0$, so that D is exactly singular, then the routine
returns with $INFO = i$. Otherwise, the factored form of A
is used
to estimate the condition number of the matrix A . If the
reciprocal of the condition number is less than machine
precision,
 $INFO = N+1$ is returned as a warning, but the routine
still goes on
to solve for X and compute error bounds as described
below.
3. The system of equations is solved for X using the fac-
tored form
of A .
4. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

ARGUMENTS

FACT (input)

Specifies whether or not the factored form of A
has been supplied on entry. = 'F': On entry, AF
and $IPIVOT$ contain the factored form of A . A , AF
and $IPIVOT$ will not be modified. = 'N': The
matrix A will be copied to AF and factored.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
the matrix A . $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number
of columns of the matrices B and X . $NRHS \geq 0$.

A (input) The symmetric matrix A . If $UPLO = 'U'$, the lead-
ing N -by- N upper triangular part of A contains the
upper triangular part of the matrix A , and the
strictly lower triangular part of A is not refer-
enced. If $UPLO = 'L'$, the leading N -by- N lower
triangular part of A contains the lower triangular
part of the matrix A , and the strictly upper tri-
angular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

AF (input or output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by ZSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$.

LDAF (input)
The leading dimension of the array AF. LDAF \geq max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by ZSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by ZSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine

precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

FERR (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $XTRUE$ is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of $WORK$. $LDWORK \geq 2*N$, and for best performance $LDWORK \geq N*NB$, where NB is the optimal blocksize for $ZSYTRF$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value
> 0: if $INFO = i$, and i is
<= N : $D(i,i)$ is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. $RCOND = 0$ is returned.
= $N+1$: D is nonsingular, but $RCOND$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $RCOND$ would suggest.

```

C INTERFACE

```

#include <sunperf.h>

void zsytf2(char uplo, int n, doublecomplex *a, int lda, int
            *ipiv, int *info);

void zsytf2_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipiv, long *info);

```

PURPOSE

zsytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
 Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
 = 'U': Upper triangular
 = 'L': Lower triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

IPIV (output)

Details of the interchanges and the block structure of D. If IPIV(k) > 0 , then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0 , then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0 , then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit
 < 0 : if INFO = -k, the k-th argument had an illegal value
 > 0 : if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services Company

If UPLO = 'U', then $A = U * D * U'$, where

$U = P(n) * U(n) * \dots * P(k) * U(k) * \dots$,

i.e., U is a product of terms $P(k) * U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \\ & k-s & s & n-k \end{pmatrix}$$

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-

1,k). If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIV(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

C INTERFACE

```

#include <sunperf.h>

void zsytrf(char uplo, int n, doublecomplex *a, int lda, int
            *ipivot, int *info);

void zsytrf_64(char uplo, long n, doublecomplex *a, long
               lda, long *ipivot, long *info);

```

PURPOSE

zsytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U^* D U^{**T} \quad \text{or} \quad A = L^* D L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (output)

Details of the interchanges and the block structure of D. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

WORK (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

LDWORK (input)

The length of WORK. $LDWORK \geq 1$. For best performance $LDWORK \geq N \cdot NB$, where NB is the block size returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LDWORK$ is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value
> 0: if $INFO = i$, $D(i, i)$ is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If $UPLO = 'U'$, then $A = U^* D^* U$, where

$U = P(n) \cdot U(n) \cdot \dots \cdot P(k) \cdot U(k) \cdot \dots$,

i.e., U is a product of terms $P(k) \cdot U(k)$, where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $U(k)$ is a unit upper triangular matrix, such that if the diagonal

block $D(k)$ is of order s ($s = 1$ or 2), then

$$U(k) = \begin{pmatrix} I & v & 0 & \\ 0 & I & 0 & \\ 0 & 0 & I & \end{pmatrix} \begin{matrix} k-s \\ s \\ n-k \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(1:k-1,k)$. If $s = 2$, the upper triangle of $D(k)$ overwrites $A(k-1,k-1)$, $A(k-1,k)$, and $A(k,k)$, and v overwrites $A(1:k-2,k-1:k)$.

If $UPLO = 'L'$, then $A = L*D*L'$, where

$L = P(1)*L(1)* \dots *P(k)*L(k)* \dots$,
i.e., L is a product of terms $P(k)*L(k)$, where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks $D(k)$. $P(k)$ is a permutation matrix as defined by $IPIVOT(k)$, and $L(k)$ is a unit lower triangular matrix, such that if the diagonal block $D(k)$ is of order s ($s = 1$ or 2), then

$$L(k) = \begin{pmatrix} I & 0 & 0 & \\ 0 & I & 0 & \\ 0 & v & I & \end{pmatrix} \begin{matrix} k-1 \\ s \\ n-k-s+1 \end{matrix}$$

If $s = 1$, $D(k)$ overwrites $A(k,k)$, and v overwrites $A(k+1:n,k)$. If $s = 2$, the lower triangle of $D(k)$ overwrites $A(k,k)$, $A(k+1,k)$, and $A(k+1,k+1)$, and v overwrites $A(k+2:n,k:k+1)$.

```

```
void zsytri_64(char uplo, long n, doublecomplex *a, long
              lda, long *ipivot, long *info);
```

PURPOSE

zsytri computes the inverse of a complex symmetric indefinite matrix A using the factorization $A = U^*D U^{**T}$ or $A = L^*D L^{**T}$ computed by ZSYTRF.

ARGUMENTS

UPLO (input)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
 = 'U': Upper triangular, form is $A = U^*D U^{**T}$;
 = 'L': Lower triangular, form is $A = L^*D L^{**T}$.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

IPIVOT (input)

Details of the interchanges and the block structure of D as determined by ZSYTRF.

WORK (workspace)

dimension(2*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

void zsytrs(char uplo, int n, int nrhs, doublecomplex *a,
            int lda, int *ipivot, doublecomplex *b, int ldb,
            int *info);

void zsytrs_64(char uplo, long n, long nrhs, doublecomplex
               *a, long lda, long *ipivot, doublecomplex *b, long
               ldb, long *info);
```

PURPOSE

zsytrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by ZSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is $A = U \cdot D \cdot U^{**T}$;
= 'L': Lower triangular, form is $A = L \cdot D \cdot L^{**T}$.

N (input) The order of the matrix A . $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSYTRF.

LDA (input)
The leading dimension of the array A . $LDA \geq \max(1, N)$.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by ZSYTRF.

B (input/output)
On entry, the right hand side matrix B . On exit, the solution matrix X .

LDB (input)
The leading dimension of the array B . $LDB \geq \max(1, N)$.

INFO (output)

- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value

```

```

REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND,
    [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, KD, LDA, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2

```

C INTERFACE

```

#include <sunperf.h>
void ztbcon(char norm, char uplo, char diag, int n, int kd,
    doublecomplex *a, int lda, double *rcond, int
    *info);

void ztbcon_64(char norm, char uplo, char diag, long n, long
    kd, doublecomplex *a, long lda, double *rcond,
    long *info);

```

PURPOSE

ztbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)
 Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. $LDA \geq KD+1$.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)
dimension($2*N$)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if $INFO = -i$, the i -th argument had an illegal value

NAME

ztbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE ZTBMV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(LDA,*), Y(*)  
INTEGER N, K, LDA, INCY
```

```
SUBROUTINE ZTBMV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(LDA,*), Y(*)  
INTEGER*8 N, K, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, K, LDA, INCY
```

```
SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,  
[INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, K, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ztbmv(char uplo, char transa, char diag, int n, int k,
           doublecomplex *a, int lda, doublecomplex *y, int
           incy);

void ztbmv_64(char uplo, char transa, char diag, long n,
              long k, doublecomplex *a, long lda, doublecomplex
              *y, long incy);
```

PURPOSE

ztbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A)*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. $K \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading ($k + 1$) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row ($k + 1$) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading ($k + 1$) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full

matrix storage to band storage:

```
      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

#include <sunperf.h>
```

```

void ztbrfs(char uplo, char transa, char diag, int n, int
            kd, int nrhs, doublecomplex *a, int lda, doublecomplex *b,
            int ldb, doublecomplex *x, int ldx, double *ferr, double *berr,
            int *info);

```

```

void ztbrfs_64(char uplo, char transa, char diag, long n,
               long kd, long nrhs, doublecomplex *a, long lda,
               doublecomplex *b, long ldb, doublecomplex *x, long
               ldx, double *ferr, double *berr, long *info);

```

PURPOSE

ztbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by ZTBTRS or some other means before entering this routine. ZTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)

```

= 'U': A is upper triangular;
= 'L': A is lower triangular.

```

TRANSA (input)

```

Specifies the form of the system of equations:
= 'N': A * X = B      (No transpose)
= 'T': A**T * X = B   (Transpose)
= 'C': A**H * X = B   (Conjugate transpose)

```

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)
 The number of superdiagonals or subdiagonals of
 the triangular band matrix A. $KD \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number
 of columns of the matrices B and X. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A,
 stored in the first $kd+1$ rows of the array. The
 j-th column of A is stored in the j-th column of
 the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-$
 $j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO =$
 $'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.
 If $DIAG = 'U'$, the diagonal elements of A are not
 referenced and are assumed to be 1.

LDA (input)
 The leading dimension of the array A. $LDA \geq$
 $KD+1$.

B (input) The right hand side matrix B.

LDB (input)
 The leading dimension of the array B. $LDB \geq$
 $\max(1,N)$.

X (input) The solution matrix X.

LDX (input)
 The leading dimension of the array X. $LDX \geq$
 $\max(1,N)$.

FERR (output)
 The estimated forward error bound for each solu-
 tion vector $X(j)$ (the j-th column of the solution
 matrix X). If $XTRUE$ is the true solution
 corresponding to $X(j)$, $FERR(j)$ is an estimated
 upper bound for the magnitude of the largest ele-
 ment in $(X(j) - XTRUE)$ divided by the magnitude of
 the largest element in $X(j)$. The estimate is as
 reliable as the estimate for $RCOND$, and is almost
 always a slight overestimate of the true error.

BERR (output)
 The componentwise relative backward error of each
 solution vector $X(j)$ (i.e., the smallest relative

change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void ztbsv(char uplo, char transa, char diag, int n, int k,
           doublecomplex *a, int lda, doublecomplex *y, int
           incy);

void ztbsv_64(char uplo, char transa, char diag, long n,
              long k, doublecomplex *a, long lda, doublecomplex
              *y, long incy);
```

PURPOSE

ztbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A')*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N \geq 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K \geq 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        M = K + 1 - J
        DO 10, I = MAX( 1, J - K ), J
          A( M + I, J ) = matrix( I, J )
10      CONTINUE
20      CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position

1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```

      DO 20, J = 1, N
        M = 1 - J
        DO 10, I = J, MIN( N, J + K )
          A( M + I, J ) = matrix( I, J )
10    CONTINUE
20    CONTINUE

```

Note that when $DIAG = 'U'$ or $'u'$ the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

INCY (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:, :) :: A, B  
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ztbtrs(char uplo, char transa, char diag, int n, int
            kd, int nrhs, doublecomplex *a, int lda, doublecomplex *b, int ldb, int *info);

void ztbtrs_64(char uplo, char transa, char diag, long n,
               long kd, long nrhs, doublecomplex *a, long lda,
               doublecomplex *b, long ldb, long *info);
```

PURPOSE

ztbtrs solves a triangular system of the form

$A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
= 'N': $A * X = B$ (No transpose)
= 'T': $A^{**T} * X = B$ (Transpose)
= 'C': $A^{**H} * X = B$ (Conjugate transpose)

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

KD (input)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $KD \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L',

$A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$. If
 DIAG = 'U', the diagonal elements of A are not
 referenced and are assumed to be 1.

LDA (input)
 The leading dimension of the array A. LDA \geq
 KD+1.

B (input/output)
 On entry, the right hand side matrix B. On exit,
 if INFO = 0, the solution matrix X.

LDB (input)
 The leading dimension of the array B. LDB \geq
 max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-
 gal value
 > 0: if INFO = i, the i-th diagonal element of A
 is zero, indicating that the matrix is singular
 and the solutions X have not been computed.

    doublecomplex *a, long lda, doublecomplex *b, long
    ldb, doublecomplex *vl, long ldvl, doublecomplex
    *vr, long ldvr, long mm, long *m, long *info);

```

PURPOSE

ztgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{*H} * (A - wB) = 0$$

where y^{*H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B , a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input unitary matrices. If (A,B) was obtained from the generalized Schur factorization of an original pair of matrices

$$(A0,B0) = (Q*A*Z^{*H}, Q*B*Z^{*H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvec-

tors of A.

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)

= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors,
and backtransform them using the input matrices
supplied in VR and/or VL; = 'S': compute selected
right and/or left eigenvectors, specified by the
logical array SELECT.

SELECT (input)

If HOWMNY='S', SELECT specifies the eigenvectors
to be computed. If HOWMNY='A' or 'B', SELECT is
not referenced. To select the eigenvector
corresponding to the j-th eigenvalue, SELECT(j)
must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)

The leading dimension of array A. LDA >=
max(1,N).

B (input) The upper triangular matrix B. B must have real
diagonal elements.

LDB (input)

The leading dimension of array B. LDB >=
max(1,N).

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B',
VL must contain an N-by-N matrix Q (usually the
unitary matrix Q of left Schur vectors returned by
CHGEQZ). On exit, if SIDE = 'L' or 'B', VL con-
tains: if HOWMNY = 'A', the matrix Y of left
eigenvectors of (A,B); if HOWMNY = 'B', the matrix
Q*Y; if HOWMNY = 'S', the left eigenvectors of
(A,B) specified by SELECT, stored consecutively in
the columns of VL, in the same order as their
eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

C INTERFACE

```

#include <sunperf.h>

void ztgexc(int wantq, int wantz, int n, doublecomplex *a,
            int lda, doublecomplex *b, int ldb, doublecomplex
            *q, int ldq, doublecomplex *z, int ldz, int *ifst,
            int *ilst, int *info);

void ztgexc_64(long wantq, long wantz, long n, doublecomplex
               *a, long lda, doublecomplex *b, long ldb, doub-
               lecomplex *q, long ldq, doublecomplex *z, long
               ldz, long *ifst, long *ilst, long *info);

```

PURPOSE

ztgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$\begin{aligned}
 Q(\text{in}) * A(\text{in}) * Z(\text{in})' &= Q(\text{out}) * A(\text{out}) * Z(\text{out})' \\
 Q(\text{in}) * B(\text{in}) * Z(\text{in})' &= Q(\text{out}) * B(\text{out}) * Z(\text{out})'
 \end{aligned}$$

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

B (input/output)
 On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

LDB (input)
 The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
 On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
 The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
 On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
 The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

IFST (input/output)
 Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

ILST (input/output)
 See the description of IFST.

INFO (output)
 =0: Successful exit.
 <0: if INFO = -i, the i-th argument had an illegal value.
 =1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

```

PURPOSE

ztgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right

eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ZTGSEN also computes the generalized eigenvalues

$$w(j) = \text{ALPHA}(j) / \text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are `Difu[(A11,B11), (A22,B22)]` and `Difl[(A11,B11), (A22,B22)]`, i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

=0: Only reorder w.r.t. SELECT. No extras.

=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate

(DIF(1:2)).

=3: Estimate of Difu and Difl. 1-norm-based estimate

(DIF(1:2)). About 5 times as expensive as IJOB =

2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue $w(j)$, `SELECT(j)` must be set to

N (input) The order of the matrices A and B. $N \geq 0$.

A (input/output)

On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input/output)
On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

ALPHA (output)
The diagonal elements of A and B, respectively, when the pair (A,B) has been reduced to generalized Schur form. ALPHA(i)/BETA(i) $i=1,\dots,N$ are the generalized eigenvalues.

BETA (output)
See the description of ALPHA.

Q (input/output)
On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ \geq 1. If WANTQ = .TRUE., LDQ \geq N.

Z (input/output)
On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ \geq 1. If WANTZ = .TRUE., LDZ \geq N.

M (output)
The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) $0 \leq M \leq N$.

PL (output)

IF IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.
 $0 < PL, PR \leq 1$. If $M = 0$ or $M = N$, $PL = PR = 1$.
 If IJOB = 0, 2, or 3 PL, PR are not referenced.

PR (output)

See the description of PL.

DIF (output)

If IJOB ≥ 2 , DIF(1:2) store the estimates of Difu and Difl.
 If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
 Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If $M = 0$ or N , DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK ≥ 1 If IJOB = 1, 2 or 4, LWORK $\geq 2*M*(N-M)$ If IJOB = 3 or 5, LWORK $\geq 4*M*(N-M)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. LIWORK ≥ 1 . If IJOB = 1, 2 or 4, LIWORK $\geq N+2$; If IJOB = 3 or 5, LIWORK $\geq \max(N+2, 2*M*(N-M))$;

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

=0: Successful exit.
 <0: If INFO = -i, the i-th argument had an illegal

value.

=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

ZTGSEN first collects the selected eigenvalues by computing unitary U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in

$$U'*(A, B)*W = \begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix} \begin{pmatrix} B_{11} & B_{12} \\ 0 & B_{22} \end{pmatrix} \begin{matrix} n_1 \\ n_2 \end{matrix}$$

where $N = n_1 + n_2$ and U' means the conjugate transpose of U. The first n_1 columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair $(C, D) = Q*(A, B)*Z'$, then the reordered generalized Schur form of (C, D) is given by

$$(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',$$

and the first n_1 columns of $Q*U$ and $Z*W$ span the corresponding deflating subspaces of (C, D) (Q and Z store $Q*U$ and $Z*W$, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first n_1 columns of U and W (or $Q*U$ and $Z*W$) may be returned in DIF(1:2), corresponding to Difu and Difl, resp.

The Difu and Difl are defined as:

$\text{ifu}[(A_{11}, B_{11}), (A_{22}, B_{22})] = \text{sigma-min}(Z_u)$
and

where $\text{sigma-min}(Z_u)$ is the smallest singular value of the $(2*n_1*n_2)\text{-by-}(2*n_1*n_2)$ matrix

$$u = \begin{bmatrix} \text{kron}(In_2, A_{11}) & -\text{kron}(A_{22}', In_1) \\ \text{kron}(In_2, B_{11}) & -\text{kron}(B_{22}', In_1) \end{bmatrix}.$$

Here, In_x is the identity matrix of size n_x and A_{22}' is the transpose of A_{22} . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

When $DIF(2)$ is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is $PS * \text{norm}((A, B)) / DIF(2)$,

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with (A_{11}, B_{11}) may be returned in PL and PR . They are computed as follows. First we compute L and R so that $P*(A, B)*Q$ is block diagonal, where

$$= \begin{pmatrix} I & -L \\ 0 & I \end{pmatrix} \begin{matrix} n_1 \\ n_2 \end{matrix} \quad \text{and} \quad Q = \begin{pmatrix} I & R \\ 0 & I \end{pmatrix} \begin{matrix} n_1 \\ n_2 \end{matrix}$$

and (L, R) is the solution to the generalized Sylvester equation $11*R - L*A_{22} = -A_{12}$

Then $PL = (F\text{-norm}(L)**2+1)**(-1/2)$ and $PR = (F\text{-norm}(R)**2+1)**(-1/2)$. An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is $EPS * \text{norm}((A, B)) / PL$.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest $F\text{-norm}(E, F)$ for which an eigenvalue of (A_{11}, B_{11}) may move and coalesce with an eigenvalue of (A_{22}, B_{22}) under perturbation (E, F) , (i.e. $(A + E, B + F)$), is

$$x = \min(Difu, Difl) / ((1/(PL*PL) + 1/(PR*PR))**(1/2) + 2*\max(1/PL, 1/PR)).$$

An approximate bound on x can be computed from $DIF(1:2)$, PL and PR .

If $y = (F\text{-norm}(E, F) / x) \leq 1$, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the $(1,1)$ -blocks can be bounded as

$$\begin{aligned} \max\text{-angle}(L, L') &\leq \arctan(y * PL / (1 - y * (1 - PL * PL)**(1/2))) \\ \max\text{-angle}(R, R') &\leq \arctan(y * PR / (1 - y * (1 - PR * PR)**(1/2))) \end{aligned}$$

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm-based estimate DIF is not wanted (see `CLATDF`), then the parameter `IDIFJB` (see below) should be changed from 3 to 4 (routine `CLATDF` (`IJOB = 2` will be used)). See `ZTGSYL` for more details.

```

PURPOSE

ztgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{array}{rcccl}
 & & N-K-L & K & L \\
 A = & & K & (\begin{array}{cc} 0 & A12 \\ L & 0 \end{array} & \begin{array}{c} A13 \\ A23 \end{array}) \text{ if } M-K-L \geq 0; \\
 & & M-K-L & (\begin{array}{cc} 0 & 0 \end{array} & 0)
 \end{array}$$

$$\begin{aligned}
 & \begin{array}{ccccc} & & N-K-L & K & L \\ A = & K & (& 0 & A12 & A13 &) \text{ if } M-K-L < 0; \\ & M-K & (& 0 & 0 & A23 &) \end{array} \\
 & \begin{array}{ccccc} & & N-K-L & K & L \\ B = & L & (& 0 & 0 & B13 &) \\ & P-L & (& 0 & 0 & 0 &) \end{array}
 \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. On exit,

$$U' * A * Q = D1 * (\begin{array}{cc} 0 & R \end{array}), \quad V' * B * Q = D2 * (\begin{array}{cc} 0 & R \end{array}),$$

where U, V and Q are unitary matrices, Z' denotes the conjugate transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:

If M-K-L >= 0,

$$\begin{aligned}
 D1 &= \begin{array}{ccccc} & & K & L & \\ & K & (& I & 0 &) \\ & & L & (& 0 & C &) \\ & M-K-L & (& 0 & 0 &) \end{array} \\
 D2 &= \begin{array}{ccccc} & & K & L & \\ L & & (& 0 & S &) \\ & P-L & (& 0 & 0 &) \end{array} \\
 (\begin{array}{cc} 0 & R \end{array}) &= \begin{array}{ccccc} & & N-K-L & K & L \\ K & (& 0 & R11 & R12 &) K \\ & L & (& 0 & 0 & R22 &) L \end{array}
 \end{aligned}$$

where

$$\begin{aligned}
 C &= \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)), \\
 S &= \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)), \\
 C^{**2} + S^{**2} &= I.
 \end{aligned}$$

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

$$\begin{aligned}
 D1 &= \begin{array}{ccccc} & & K & M-K & K+L-M \\ K & (& I & 0 & 0 &) \\ M-K & (& 0 & C & 0 &) \end{array} \\
 D2 &= \begin{array}{ccccc} & & K & M-K & K+L-M \\ M-K & (& 0 & S & 0 &) \\ K+L-M & (& 0 & 0 & I &) \\ P-L & (& 0 & 0 & 0 &) \end{array} \\
 & \begin{array}{ccccc} & & N-K-L & K & M-K & K+L-M \end{array}
 \end{aligned}$$

$$\begin{array}{cccc} \text{M-K} & (& 0 & 0 & \text{R22} & \text{R23} &) \\ \text{K+L-M} & (& 0 & 0 & 0 & \text{R33} &) \end{array}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M))$,

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M))$,

$C^{**2} + S^{**2} = I$.

$R = \begin{pmatrix} R11 & R12 & R13 \end{pmatrix}$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored

$\begin{pmatrix} 0 & R22 & R23 \end{pmatrix}$

in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1$, $V1$, or $Q1$.

ZTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$U1' A13 Q1 = C1 R1$; $V1' B13 Q1 = S1 R1$,

where $U1$, $V1$ and $Q1$ are unitary matrix, and Z' is the conjugate transpose of Z . $C1$ and $S1$ are diagonal matrices satisfying

$C1^{**2} + S1^{**2} = I$,

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

JOBV (input)

= 'U': U must contain a unitary matrix $U1$ on entry, and the product $U1*U$ is returned; = 'I': U is initialized to the unit matrix, and the unitary matrix U is returned; = 'N': U is not computed.

JOBV (input)

= 'V': V must contain a unitary matrix $V1$ on entry, and the product $V1*V$ is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ (input)

= 'Q': Q must contain a unitary matrix $Q1$ on entry, and the product $Q1*Q$ is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A . $M \geq 0$.

P (input) The number of rows of the matrix B . $P \geq 0$.

N (input) The number of columns of the matrices A and B . N

≥ 0 .

K (input) K and L specify the subblocks in the input matrices A and B:
 $A23 = A(K+1:\min(K+L,M), N-L+1:N)$ and $B13 = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by ZTGSJA. See the Further Details section below.

L (input) See the description of K.

A (input/output)
 On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1,M)$.

B (input/output)
 On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

LDB (input)
 The leading dimension of the array B. $LDB \geq \max(1,P)$.

TOLA (input)
 TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$.

TOLB (input)
 See the description of TOLA.

ALPHA (output)
 On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $\text{ALPHA}(1:K) = 1$, $\text{BETA}(1:K) = 0$, and if $M-K-L \geq 0$, $\text{ALPHA}(K+1:K+L) = \text{diag}(C)$,
 $\text{BETA}(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $\text{ALPHA}(K+1:M) = C$, $\text{ALPHA}(M+1:K+L) = 0$
 $\text{BETA}(K+1:M) = S$, $\text{BETA}(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $\text{ALPHA}(K+L+1:N) = 0$
 $\text{BETA}(K+L+1:N) = 0$.

BETA (output)
 See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain a matrix U1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBU = 'I', U contains the

unitary matrix U; if JOBU = 'U', U contains the product $U1*U$. If JOBU = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. $LDU \geq \max(1,M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

V (input) On entry, if JOBV = 'V', V must contain a matrix V1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBV = 'I', V contains the unitary matrix V; if JOBV = 'V', V contains the product $V1*V$. If JOBV = 'N', V is not referenced.

LDV (input)

The leading dimension of the array V. $LDV \geq \max(1,P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBQ = 'I', Q contains the unitary matrix Q; if JOBQ = 'Q', Q contains the product $Q1*Q$. If JOBQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq \max(1,N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

WORK (workspace)

dimension($2*N$)

NCYCLE (output)

The number of cycles required for convergence.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

= 1: the procedure does not converge after MAXIT cycles.

```

PURPOSE

ztgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
 = 'E': for eigenvalues only (S);
 = 'V': for eigenvectors only (DIF);

= 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNT (input)

= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)

If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper triangular matrix A in the pair (A,B).

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A, B).

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

VL (input)

If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by ZTGEVC. If JOB = 'V', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL >= 1; and If JOB = 'E' or 'B', LDVL >= N.

VR (input)

If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by ZTGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq 1;
 If JOB = 'E' or 'B', LDVR \geq N.

S (output)
 If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF (output)
 If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM (input)
 The number of elements in the arrays S and DIF. MM \geq M.

M (output)
 The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
 If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK \geq 1. If JOB = 'V' or 'B', LWORK \geq 2*N*N.

IWORK (workspace)
 dimension(N+2) If JOB = 'E', IWORK is not referenced.

INFO (output)
 = 0: Successful exit
 < 0: If INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of the i-th generalized eigenvalue $w = (a, b)$ is defined as

$$S(I) = (|v' Au|^{**2} + |v' Bu|^{**2})^{**(1/2)} / (\text{norm}(u) * \text{norm}(v))$$

where u and v are the right and left eigenvectors of (A, B) corresponding to w ; $|z|$ denotes the absolute value of the complex number, and $\text{norm}(u)$ denotes the 2-norm of the vector u . The pair (a, b) corresponds to an eigenvalue $w = a/b (= v' Au / v' Bu)$ of the matrix pair (A, B) . If both a and b equal zero, then (A, B) is singular and $S(I) = -1$ is returned.

An approximate error bound on the chordal distance between the i -th computed generalized eigenvalue w and the corresponding exact eigenvalue λ is

$$\text{chord}(w, \lambda) \leq \text{EPS} * \text{norm}(A, B) / S(I),$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows. Suppose

$$(A, B) = \begin{pmatrix} a & * \\ 0 & A_{22} \end{pmatrix}, \begin{pmatrix} b & * \\ 0 & B_{22} \end{pmatrix} \begin{matrix} 1 \\ n-1 \end{matrix}$$

Then the reciprocal condition number $\text{DIF}(I)$ is

$$\text{Difl}[(a, b), (A_{22}, B_{22})] = \text{sigma-min}(Z_1)$$

where $\text{sigma-min}(Z_1)$ denotes the smallest singular value of

$$Z_1 = \begin{bmatrix} \text{kron}(a, I_{n-1}) & -\text{kron}(1, A_{22}) \\ \text{kron}(b, I_{n-1}) & -\text{kron}(1, B_{22}) \end{bmatrix}.$$

Here I_{n-1} is the identity matrix of size $n-1$ and X' is the conjugate transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

We approximate the smallest singular value of Z_1 with an upper bound. This is done by ZLATDF .

An approximate error bound for a computed eigenvector $\text{VL}(i)$ or $\text{VR}(i)$ is given by

$$\text{EPS} * \text{norm}(A, B) / \text{DIF}(i).$$

See ref. [2-3] for more details and further references.

```

PURPOSE

ztgsyl solves the generalized Sylvester equation:

$$\begin{aligned}
 A * R - L * B &= \text{scale} * C \\
 D * R - L * E &= \text{scale} * F
 \end{aligned}
 \tag{1}$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} * b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix},
 \tag{2}$$

Here I_x is the identity matrix of size x and X' is the conjugate transpose of X. $\text{Kron}(X, Y)$ is the Kronecker product

between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system $Z'y = \text{scale} * b$ is solved for, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * -F \end{aligned} \quad (3)$$

This case (TRANS = 'C') is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If IJOB >= 1, ZTGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

ARGUMENTS

TRANS (input)
= 'N': solve the generalized sylvester equation (1).
= 'C': solve the "conjugate transposed" system (3).

IJOB (input)
Specifies what kind of functionality to be performed. =0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (look ahead strategy is used). =4: Only an estimate of $\text{Dif}[(A,D), (B,E)]$ is computed. (CGECON on sub-systems is used). Not referenced if TRANS = 'C'.

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1, M).

B (input) The upper triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

C (input/output)
 On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)
 The leading dimension of the array C. LDC >= max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
 The leading dimension of the array D. LDD >= max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
 The leading dimension of the array E. LDE >= max(1, N).

F (input/output)
 On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)
 The leading dimension of the array F. LDF >= max(1, M).

SCALE (output)
 On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

DIF (output)
 On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma_{\min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

WORK (workspace)
 If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO=0 then WORK(1) returns the optimal LWORK.

LWORK (input)
 The dimension of the array WORK. LWORK >= 1. If

IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)

If IJOB = 0, IWORK is not referenced.

INFO (output)

=0: successful exit

<0: If INFO = -i, the i-th argument had an illegal value.

>0: (A, D) and (B, E) have common or very close eigenvalues.

DOUBLE COMPLEX A(*), WORK(*)  
INTEGER*8 N, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],  
[INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: A, WORK  
INTEGER :: N, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE TPCON_64(NORM, UPLO, DIAG, [N], A, RCOND, [WORK], [WORK2],
```

[INFO])

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void ztpcon(char norm, char uplo, char diag, int n, doublecomplex *a, double *rcond, int *info);
void ztpcon_64(char norm, char uplo, char diag, long n, doublecomplex *a, double *rcond, long *info);
```

PURPOSE

ztpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO =

'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if
 UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for
 $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of
 A are not referenced and are assumed to be 1.

RCOND (output)

The reciprocal of the condition number of the
 matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

COMPLEX*16 array, dimension(2*N)

WORK2 (workspace)

DOUBLE PRECISION array, dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

ztpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE ZTPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(*), Y(*)  
INTEGER N, INCY
```

```
SUBROUTINE ZTPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(*), Y(*)  
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A, Y  
INTEGER :: N, INCY
```

```
SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A, Y  
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ztpmv(char uplo, char transa, char diag, int n, doublecomplex *a, doublecomplex *y, int incy);

void ztpmv_64(char uplo, char transa, char diag, long n, doublecomplex *a, doublecomplex *y, long incy);

```

PURPOSE

ztpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A.
N \geq 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

            nrhs, doublecomplex *a, doublecomplex *b, int ldb,
            doublecomplex *x, int ldx, double *ferr, double
            *berr, int *info);

void ztprfs_64(char uplo, char transa, char diag, long n,
               long nrhs, doublecomplex *a, doublecomplex *b,
               long ldb, doublecomplex *x, long ldx, double
               *ferr, double *berr, long *info);

```

PURPOSE

ztprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by ZTPTRS or some other means before entering this routine. ZTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number

of columns of the matrices B and X. NRHS >= 0.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$
The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B (input) COMPLEX*16 array, dimension (LDB,NRHS)
The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input) COMPLEX*16 array, dimension (LDX,NRHS)
The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output) DOUBLE PRECISION array, dimension (NRHS)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output) DOUBLE PRECISION array, dimension (NRHS)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
COMPLEX*16 array, dimension(2*N)

WORK2 (workspace)
DOUBLE PRECISION array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

ztpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE ZTPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(*), Y(*)  
INTEGER N, INCY
```

```
SUBROUTINE ZTPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(*), Y(*)  
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A, Y  
INTEGER :: N, INCY
```

```
SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A, Y  
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ztpsv(char uplo, char transa, char diag, int n, doublecomplex *a, doublecomplex *y, int incy);

void ztpsv_64(char uplo, char transa, char diag, long n, doublecomplex *a, doublecomplex *y, long incy);

```

PURPOSE

ztpsv solves one of the systems of equations $Ax = b$, or $A^H x = b$, or $\text{conjg}(A^H)x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $Ax = b$.

TRANSA = 'T' or 't' $A^H x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A^H)x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

(($n*(n+1)/2$)). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

($1 + (n-1)*abs(INCY)$). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

ztptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE ZTPTRI(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
DOUBLE COMPLEX A(*)  
INTEGER N, INFO
```

```
SUBROUTINE ZTPTRI_64(UPLO, DIAG, N, A, INFO)
```

```
CHARACTER * 1 UPLO, DIAG  
DOUBLE COMPLEX A(*)  
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: A  
INTEGER :: N, INFO
```

```
SUBROUTINE TPTRI_64(UPLO, DIAG, [N], A, [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: A  
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ztptri(char uplo, char diag, int n, doublecomplex *a,
            int *info);

void ztptri_64(char uplo, char diag, long n, doublecomplex
               *a, long *info);
```

PURPOSE

ztptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input/output) COMPLEX*16 array, dimension $(N*(N+1)/2)$
 On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value
 > 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = 1, J
          A(JC+I-1) = A(I,J)
A(I,J)
1      CONTINUE
      JC = JC + J
1
2 CONTINUE

```

UPLO = 'L':

```

      JC = 1
      DO 2 J = 1, N
        DO 1 I = J, N
          A(JC+I-J) =
1      CONTINUE
      JC = JC + N - J +
2 CONTINUE

```

COMPLEX(8), DIMENSION(:, :) :: B  
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE TPTRS_64(UPLO, [TRANSA], DIAG, [N], [NRHS], A, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: A  
COMPLEX(8), DIMENSION(:, :) :: B  
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztptrs(char uplo, char transa, char diag, int n, int  
            nrhs, doublecomplex *a, doublecomplex *b, int ldb,  
            int *info);
```

```
void ztptrs_64(char uplo, char transa, char diag, long n,
               long nrhs, doublecomplex *a, doublecomplex *b,
               long ldb, long *info);
```

PURPOSE

ztptrs solves a triangular system of the form
 $A * X = B$, $A^{*T} * X = B$, or $A^{*H} * X = B$

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)

Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{*T} * X = B$ (Transpose)
 = 'C': $A^{*H} * X = B$ (Conjugate transpose)

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) COMPLEX*16 array, dimension $(N*(N+1)/2)$

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

B (input/output) COMPLEX*16 array, dimension (LDB,NRHS)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

ztrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE ZTRANS(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
DOUBLE COMPLEX SCALE  
DOUBLE COMPLEX SOURCE(*), DEST(*)  
INTEGER M, N
```

```
SUBROUTINE ZTRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)
```

```
CHARACTER * 1 PLACE  
DOUBLE COMPLEX SCALE  
DOUBLE COMPLEX SOURCE(*), DEST(*)  
INTEGER*8 M, N
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
COMPLEX(8) :: SCALE  
COMPLEX(8), DIMENSION(:) :: SOURCE, DEST  
INTEGER :: M, N
```

```
SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])
```

```
CHARACTER(LEN=1) :: PLACE  
COMPLEX(8) :: SCALE  
COMPLEX(8), DIMENSION(:) :: SOURCE, DEST  
INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>

void ztrans(char place, doublecomplex *scale, doublecomplex
            *source, int m, int n, doublecomplex *dest);

void ztrans_64(char place, doublecomplex *scale, doublecom-
               plex *source, long m, long n, doublecomplex
               *dest);
```

PURPOSE

ztrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)
Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)
Scale factor on the SOURCE matrix.

SOURCE (input/output)
on input. Array of (N, M) on output if in-place transpose.

M (input)
Number of rows in the SOURCE matrix on input.

N (input)
Number of columns in the SOURCE matrix on input.

DEST (output)
Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

                     INFO)
```

```
CHARACTER * 1 NORM, UPLO, DIAG  
DOUBLE COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, LDA, INFO  
DOUBLE PRECISION RCOND  
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK], [WORK2],  
                [INFO])
```

```
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX(8), DIMENSION(:) :: WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL(8) :: RCOND  
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE TRCON_64(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
                   [WORK2], [INFO])
```

```

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2

```

C INTERFACE

```

#include <sunperf.h>
void ztrcon(char norm, char uplo, char diag, int n, doublecomplex *a, int lda, double *rcond, int *info);

void ztrcon_64(char norm, char uplo, char diag, long n, doublecomplex *a, long lda, double *rcond, long *info);

```

PURPOSE

ztrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

NORM (input)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
 = '1' or 'O': 1-norm;
 = 'I': Infinity-norm.

UPLO (input)

= 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)

= 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower

triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)

The leading dimension of the array A. LDA \geq max(1,N).

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

```

SUBROUTINE TREVC_64(SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL],
    VR, [LDVR], MM, M, [WORK], [RWORK], [INFO])

CHARACTER(LEN=1) :: SIDE, HOWMNY
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: T, VL, VR
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL(8), DIMENSION(:) :: RWORK

```

C INTERFACE

```

#include <sunperf.h>
void ztrevc(char side, char howmny, int *select, int n,
    doublecomplex *t, int ldt, doublecomplex *vl, int
    ldvl, doublecomplex *vr, int ldvr, int mm, int *m,
    int *info);

void ztrevc_64(char side, char howmny, long *select, long n,
    doublecomplex *t, long ldt, doublecomplex *vl,
    long ldvl, doublecomplex *vr, long ldvr, long mm,
    long *m, long *info);

```

PURPOSE

ztrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y'*T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary matrix. If T was obtained from the Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

```

SIDE (input)
    = 'R': compute right eigenvectors only;
    = 'L': compute left eigenvectors only;
    = 'B': compute both right and left eigenvectors.

```

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)
If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)
The upper triangular matrix T. T is modified, but restored on exit.

LDT (input)
The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q^*Y ; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. $LDVL \geq \max(1, N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-

th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR. MM \geq M.

M (output)

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)

dimension(2*N)

RWORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be $|x| + |y|$.

```

```
SUBROUTINE ZTREXC_64(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
```

```
CHARACTER * 1 COMPQ  
DOUBLE COMPLEX T(LDT,*), Q(LDQ,*)  
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
COMPLEX(8), DIMENSION(:, :) :: T, Q  
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE TREXC_64(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ  
COMPLEX(8), DIMENSION(:, :) :: T, Q  
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrexc(char compq, int n, doublecomplex *t, int ldt,
```

```

doublecomplex *q, int ldq, int ifst, int ilst, int
*info);

void ztrexc_64(char compq, long n, doublecomplex *t, long
ldt, doublecomplex *q, long ldq, long ifst, long
ilst, long *info);

```

PURPOSE

ztrexc reorders the Schur factorization of a complex matrix $A = Q^*TQ^{**H}$, so that the diagonal element of T with row index IFST is moved to row ILST. The Schur form T is reordered by a unitary similarity transformation $Z^{**H}T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

ARGUMENTS

COMPQ (input)
 = 'V': update the matrix Q of Schur vectors;
 = 'N': do not update Q .

N (input) The order of the matrix T . $N \geq 0$.

T (input/output)
 On entry, the upper triangular matrix T . On exit, the reordered upper triangular matrix.

LDT (input)
 The leading dimension of the array T . $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix Z which reorders T . If COMPQ = 'N', Q is not referenced.

LDQ (input)
 The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

IFST (input)
 Specify the reordering of the diagonal elements of T : The element with row index IFST is moved to row ILST by a sequence of transpositions between adjacent elements. $1 \leq \text{IFST} \leq N$; $1 \leq \text{ILST} \leq N$.

ILST (input)
 See the description of IFST.

```
INFO (output)
    = 0:  successful exit
    < 0:  if INFO = -i, the i-th argument had an
          illegal value

```
SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,  
                  [LDA], B, [LDB])
```

```

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER(8) :: M, N, LDA, LDB

```

C INTERFACE

```

#include <sunperf.h>

void ztrmm(char side, char uplo, char transa, char diag, int
           m, int n, doublecomplex *alpha, doublecomplex *a,
           int lda, doublecomplex *b, int ldb);
void ztrmm_64(char side, char uplo, char transa, char diag,
              long m, long n, doublecomplex *alpha, doublecom-
              plex *a, long lda, doublecomplex *b, long ldb);

```

PURPOSE

ztrmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to

be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = conjg(A').

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M \geq 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N \geq 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal

elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

B (input/output)

COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least $\max(1, M)$. Unchanged on exit.

```

```
SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrmv(char uplo, char transa, char diag, int n, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztrmv_64(char uplo, char transa, char diag, long n, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

ztrmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A)*x$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

Y (input/output)

$(1 + (n - 1) * \text{abs}(\text{ INCY }))$. Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. $\text{ INCY } \neq 0$. Unchanged on exit.

void ztrrfs(char uplo, char transa, char diag, int n, int
            nrhs, doublecomplex *a, int lda, doublecomplex *b,
            int ldb, doublecomplex *x, int ldx, double *ferr,
            double *berr, int *info);

void ztrrfs_64(char uplo, char transa, char diag, long n,
               long nrhs, doublecomplex *a, long lda, doublecom-
               plex *b, long ldb, doublecomplex *x, long ldx,
               double *ferr, double *berr, long *info);

```

PURPOSE

ztrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by ZTRTRS or some other means before entering this routine. ZTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA \geq max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB \geq max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX \geq max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

ztrsen reorders the Schur factorization of a complex matrix $A = Q^*TQ^*H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

= 'N': none;

= 'E': for eigenvalues only (S);

= 'V': for invariant subspace only (SEP);
= 'B': for both eigenvalues and invariant subspace
(S and SEP).

COMPQ (input)

= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

SELECT (input)

SELECT specifies the eigenvalues in the selected cluster. To select the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. $N \geq 0$.

T (input/output)

On entry, the upper triangular matrix T. On exit, T is overwritten by the reordered matrix T, with the selected eigenvalues as the leading diagonal elements.

LDT (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ (input)

The leading dimension of the array Q. $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

W (output)

The reordered eigenvalues of T, in the same order as they appear on the diagonal of T.

M (output)

The dimension of the specified invariant subspace.
 $0 \leq M \leq N$.

S (output)

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If $M = 0$ or N , $S = 1$. If JOB = 'N' or 'V', S is not referenced.

SEP (output)

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK (workspace)

If JOB = 'N', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If JOB = 'N', LWORK >= 1; if JOB = 'E', LWORK = M*(N-M); if JOB = 'V' or 'B', LWORK >= 2*M*(N-M).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

ZTRSEN first collects the selected eigenvalues by computing a unitary transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

$$\begin{array}{rcl} Z'^*T*Z = & \begin{pmatrix} T_{11} & T_{12} \\ 0 & T_{22} \end{pmatrix} & \begin{matrix} n_1 \\ n_2 \end{matrix} \end{array}$$

where N = n1+n2 and Z' means the conjugate transpose of Z. The first n1 columns of Z span the specified invariant subspace of T.

If T has been obtained from the Schur factorization of a matrix A = Q*T*Q', then the reordered Schur factorization of A is given by A = (Q*Z)*(Z'*T*Z)*(Q*Z)', and the first n1 columns of Q*Z span the corresponding invariant subspace of A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

$$P = \begin{pmatrix} I & R \end{pmatrix} \begin{matrix} n_1 \end{matrix}$$

$$\begin{pmatrix} 0 & 0 \\ n1 & n2 \end{pmatrix}$$

is the projector on the invariant subspace associated with T_{11} . R is the solution of the Sylvester equation:

$$T_{11} * R - R * T_{22} = T_{12}.$$

Let $F\text{-norm}(M)$ denote the Frobenius-norm of M and $2\text{-norm}(M)$ denote the two-norm of M . Then S is computed as the lower bound

$$(1 + F\text{-norm}(R)^2)^{-1/2}$$

on the reciprocal of $2\text{-norm}(P)$, the true reciprocal condition number. S cannot underestimate $1 / 2\text{-norm}(P)$ by more than a factor of \sqrt{N} .

An approximate error bound for the computed average of the eigenvalues of T_{11} is

$$EPS * \text{norm}(T) / S$$

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first $n1$ columns of Z (or of $Q * Z$) is returned in SEP . SEP is defined as the separation of T_{11} and T_{22} :

$$\text{sep}(T_{11}, T_{22}) = \sigma\text{-min}(C)$$

where $\sigma\text{-min}(C)$ is the smallest singular value of the $n1 * n2$ -by- $n1 * n2$ matrix

$$C = \text{kprod}(I(n2), T_{11}) - \text{kprod}(\text{transpose}(T_{22}), I(n1))$$

$I(m)$ is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate $\sigma\text{-min}(C)$ by the reciprocal of an estimate of the 1-norm of $\text{inverse}(C)$. The true reciprocal 1-norm of $\text{inverse}(C)$ cannot differ from $\sigma\text{-min}(C)$ by more than a factor of $\sqrt{n1 * n2}$.

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

$$EPS * \text{norm}(T) / SEP$$

NAME

ztrsm - solve one of the matrix equations $\text{op}(A)X = \alpha B$, or $X\text{op}(A) = \alpha B$

SYNOPSIS

```
SUBROUTINE ZTRSM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
                LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB
```

```
SUBROUTINE ZTRSM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
                   LDB)
```

```
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRSM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
                B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:, :) :: A, B
INTEGER :: M, N, LDA, LDB
```

```
SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
                   [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
```

```
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>

void ztrsm(char side, char uplo, char transa, char diag, int
           m, int n, doublecomplex *alpha, doublecomplex *a,
           int lda, doublecomplex *b, int ldb);

void ztrsm_64(char side, char uplo, char transa, char diag,
              long m, long n, doublecomplex *alpha,
              doublecomplex *a, long lda, doublecomplex *b, long
              ldb);
```

PURPOSE

ztrsm solves one of the matrix equations $\text{op}(A)X = \alpha B$, or $X\text{op}(A) = \alpha B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$.

The matrix X is overwritten on B .

ARGUMENTS

SIDE (input)

On entry, SIDE specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A)X = \alpha B$.

SIDE = 'R' or 'r' $X\text{op}(A) = \alpha B$.

Unchanged on exit.

UPLO (input)

On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = conjg(A').
Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, k),
where k is m when SIDE = 'L' or 'l' and is n
when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

enced.

Note that when `DIAG = 'U' or 'u'`, the diagonal elements of `A` are not referenced either, but are assumed to be unity.

Unchanged on exit.

`LDA (input)`

On entry, `LDA` specifies the first dimension of `A` as declared in the calling (sub) program. When `SIDE = 'L' or 'l'` then `LDA >= max(1,M)`, when `SIDE = 'R' or 'r'` then `LDA >= max(1,N)`. Unchanged on exit.

`B (input/output)`

`COMPLEX*16` array of `DIMENSION (LDB, n)`. Before entry, the leading `M` by `N` part of the array `B` must contain the right-hand side matrix `B`, and on exit is overwritten by the solution matrix `X`.

`LDB (input)`

On entry, `LDB` specifies the first dimension of `B` as declared in the calling subprogram. `LDB >= max(1,M)`. Unchanged on exit.

    *s, double *sep, long mm, long *m, long ldwork, long *info);

```

PURPOSE

ztrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q^*TQ^{**H} with Q unitary).

ARGUMENTS

JOB (input)
 Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):
 = 'E': for eigenvalues only (S);
 = 'V': for eigenvectors only (SEP);
 = 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
 = 'A': compute condition numbers for all eigenpairs;
 = 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
 If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. $N \geq 0$.

T (input) The upper triangular matrix T.

LDT (input)
 The leading dimension of the array T. $LDT \geq \max(1, N)$.

VL (input)
 If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q^*TQ^{**H} with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by ZHSEIN or ZTREVC. If JOB = 'V', VL is not referenced.

LDVL (input)
 The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

VR (input)
 If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q^*TQ^{**H} with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by ZHSEIN or ZTREVC. If JOB = 'V', VR is not referenced.

LDVR (input)
 The leading dimension of the array VR. $LDVR \geq 1$; and if JOB = 'E' or 'B', $LDVR \geq N$.

S (output)
 If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)
 If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If

JOB = 'E', SEP is not referenced.

MM (input)
 The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)
 The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)
 dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)
 The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)
 dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue λ is defined as

$$S(\lambda) = |v'^*u| / (\text{norm}(u)*\text{norm}(v))$$

where u and v are the right and left eigenvectors of T corresponding to λ ; v' denotes the conjugate transpose of v , and $\text{norm}(u)$ denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If $n = 1$, $S(\lambda)$ is defined to be 1.

An approximate error bound for a computed eigenvalue $W(i)$ is given by

$$\text{EPS} * \text{norm}(T) / S(i)$$

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to λ is defined as follows. Suppose

$$T = \begin{pmatrix} \text{lambda} & c \\ 0 & T22 \end{pmatrix}$$

Then the reciprocal condition number is

$$\text{SEP}(\text{lambda}, T22) = \text{sigma-min}(T22 - \text{lambda} * I)$$

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of $T22 - \text{lambda} * I$. If $n = 1$, $\text{SEP}(1)$ is defined to be $\text{abs}(T(1,1))$.

An approximate error bound for a computed right eigenvector $\text{VR}(i)$ is given by

$$\text{EPS} * \text{norm}(T) / \text{SEP}(i)$$

NAME

ztrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE ZTRSV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(LDA,*), Y(*)  
INTEGER N, LDA, INCY
```

```
SUBROUTINE ZTRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(LDA,*), Y(*)  
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:) :: Y  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrsv(char uplo, char transa, char diag, int n, doublecomplex *a, int lda, doublecomplex *y, int incy);
```

```
void ztrsv_64(char uplo, char transa, char diag, long n, doublecomplex *a, long lda, doublecomplex *y, long incy);
```

PURPOSE

ztrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A')*x = b$.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N \geq 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

```
SUBROUTINE TRSYL_64(TRANA, TRANB, ISGN, [M], [N], A, [LDA], B, [LDB],  
                   C, [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB  
COMPLEX(8), DIMENSION(:,:) :: A, B, C
```

```

INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE

```

C INTERFACE

```

#include <sunperf.h>

void ztrsyl(char trana, char tranb, int isgn, int m, int n,
            doublecomplex *a, int lda, doublecomplex *b, int
            ldb, doublecomplex *c, int ldc, double *scale, int
            *info);

void ztrsyl_64(char trana, char tranb, long isgn, long m,
               long n, doublecomplex *a, long lda, doublecomplex
               *b, long ldb, doublecomplex *c, long ldc, double
               *scale, long *info);

```

PURPOSE

ztrsyl solves the complex Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**H} , and A and B are both upper triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

ARGUMENTS

TRANA (input)
 Specifies the option $\text{op}(A)$:
 = 'N': $\text{op}(A) = A$ (No transpose)
 = 'C': $\text{op}(A) = A^{**H}$ (Conjugate transpose)

TRANB (input)
 Specifies the option $\text{op}(B)$:
 = 'N': $\text{op}(B) = B$ (No transpose)
 = 'C': $\text{op}(B) = B^{**H}$ (Conjugate transpose)

ISGN (input)
 Specifies the sign in the equation:
 = +1: solve $\text{op}(A)*X + X*\text{op}(B) = \text{scale}*C$
 = -1: solve $\text{op}(A)*X - X*\text{op}(B) = \text{scale}*C$

M (input) The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

N (input) The order of the matrix B , and the number of

columns in the matrices X and C. $N \geq 0$.

A (input) The upper triangular matrix A.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

B (input) The upper triangular matrix B.

LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

C (input/output)

On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$

SCALE (output)

The scale factor, scale, set ≤ 1 to avoid overflow in X.

INFO (output)

= 0: successful exit

< 0: if $INFO = -i$, the i-th argument had an illegal value

= 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

INTEGER :: N, LDA, INFO
```

```
SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO, DIAG  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ztrti2(char uplo, char diag, int n, doublecomplex *a,
            int lda, int *info);

void ztrti2_64(char uplo, char diag, long n, doublecomplex
               *a, long lda, long *info);

```

PURPOSE

ztrti2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
 Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
 = 'L': Lower triangular

DIAG (input)
 Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
 = 'U': Unit triangular

N (input) The order of the matrix A. $N \geq 0$.

A (input/output)
 On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
 The leading dimension of the array A. $LDA \geq \max(1, N)$.

```
INFO (output)
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an ille-
      gal value
```

void ztrtri_64(char uplo, char diag, long n, doublecomplex
               *a, long lda, long *info);

```

PURPOSE

ztrtri computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input/output)
 On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
 The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, A(i,i) is exactly zero. The
triangular matrix is singular and its inverse can
not be computed.

INFO)
```

```
CHARACTER * 1 UPLO, TRANSA, DIAG  
DOUBLE COMPLEX A(LDA,*), B(LDB,*)  
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTRS(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:,:) :: A, B  
INTEGER :: N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE TRTRS_64(UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B, [LDB],  
[INFO])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG  
COMPLEX(8), DIMENSION(:,:) :: A, B  
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrtrs(char uplo, char transa, char diag, int n, int
```

```

        nrhs, doublecomplex *a, int lda, doublecomplex *b,
        int ldb, int *info);

void ztrtrs_64(char uplo, char transa, char diag, long n,
        long nrhs, doublecomplex *a, long lda, doublecom-
        plex *b, long ldb, long *info);

```

PURPOSE

ztrtrs solves a triangular system of the form
 $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)
 = 'U': A is upper triangular;
 = 'L': A is lower triangular.

TRANSA (input)
 Specifies the form of the system of equations:
 = 'N': $A * X = B$ (No transpose)
 = 'T': $A^{**T} * X = B$ (Transpose)
 = 'C': $A^{**H} * X = B$ (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
 = 'N': A is non-unit triangular;
 = 'U': A is unit triangular.

N (input) The order of the matrix A. $N \geq 0$.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
 The leading dimension of the array A. $LDA \geq$

```

        max(1,N).
B (input/output)
    On entry, the right hand side matrix B.  On exit,
    if INFO = 0, the solution matrix X.

LDB (input)
    The leading dimension of the array B.  LDB >=
    max(1,N).

INFO (output)
    = 0: successful exit
    < 0: if INFO = -i, the i-th argument had an ille-
    gal value
    > 0: if INFO = i, the i-th diagonal element of A
    is zero, indicating that the matrix is singular
    and the solutions X have not been computed.

NAME

ztzrqf - routine is deprecated and has been replaced by routine CTZRZF

SYNOPSIS

```
SUBROUTINE ZTZRQF(M, N, A, LDA, TAU, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), TAU(*)  
INTEGER M, N, LDA, INFO
```

```
SUBROUTINE ZTZRQF_64(M, N, A, LDA, TAU, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), TAU(*)  
INTEGER*8 M, N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRQF([M], [N], A, [LDA], TAU, [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, INFO
```

```
SUBROUTINE TZRQF_64([M], [N], A, [LDA], TAU, [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void ztzrqf(int m, int n, doublecomplex *a, int lda, doublecomplex *tau, int *info);

void ztzrqf_64(long m, long n, doublecomplex *a, long lda, doublecomplex *tau, long *info);

```

PURPOSE

ztzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq M$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The k th transformation matrix, $Z(k)$, whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ th row of A , is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the k th row of X .

The scalar τ is returned in the k th element of TAU and the vector $u(k)$ in the k th row of A , such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A .

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

INTEGER*8 M, N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRF([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: M, N, LDA, LWORK, INFO
```

```
SUBROUTINE TZRF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztzrzf(int m, int n, doublecomplex *a, int lda, doub-
```

```

        lecomplex *tau, int *info);

void ztzrzf_64(long m, long n, doublecomplex *a, long lda,
        doublecomplex *tau, long *info);

```

PURPOSE

ztzrzf reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. $M \geq 0$.

N (input) The number of columns of the matrix A. $N \geq 0$.

A (input/output)

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

TAU (output)

The scalar factors of the elementary reflectors.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
 = 0: successful exit
 < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, $Z(k)$, which is used to introduce zeros into the $(m - k + 1)$ th row of A, is given in the form

$$Z(k) = \begin{pmatrix} I & 0 \\ 0 & T(k) \end{pmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{pmatrix} 1 \\ 0 \\ z(k) \end{pmatrix},$$

τ is a scalar and $z(k)$ is an $(n - m)$ element vector. τ and $z(k)$ are chosen to annihilate the elements of the kth row of X.

The scalar τ is returned in the kth element of TAU and the vector $u(k)$ in the kth row of A, such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of A.

Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

PURPOSE

zung2l L generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \dots H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA (input)

The first dimension of the array A. LDA >= max(1,M).

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK (workspace)

dimension(N)

INFO (output)

= 0: successful exit
 < 0: if INFO = -i, the i-th argument has an illegal value

                   [INFO])
```

```
CHARACTER(LEN=1) :: VECT  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A
```

```
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zungbr(char vect, int m, int n, int k, doublecomplex  
            *a, int lda, doublecomplex *tau, int *info);
```

```
void zungbr_64(char vect, long m, long n, long k, doublecom-  
               plex *a, long lda, doublecomplex *tau, long  
               *info);
```

PURPOSE

zungbr generates one of the complex unitary matrices Q or $P^{*}H$ determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P^{*}H$. Q and $P^{*}H$ are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and ZUNGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and ZUNGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and $P^{*}H$ is of order N :

if $k < n$, $P^{*}H = G(k) \dots G(2) G(1)$ and ZUNGBR returns the first m rows of $P^{*}H$, where $n \geq m \geq k$;

if $k \geq n$, $P^{*}H = G(n-1) \dots G(2) G(1)$ and ZUNGBR returns $P^{*}H$ as an N -by- N matrix.

ARGUMENTS

VECT (input)

Specifies whether the matrix Q or the matrix $P^{*}H$ is required, as defined in the transformation applied by CGEBRD:

= 'Q': generate Q ;

= 'P': generate $P^{*}H$.

M (input) The number of rows of the matrix Q or $P^{*}H$ to be returned. $M \geq 0$.

N (input) The number of columns of the matrix Q or $P^{*}H$ to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M, K)$; if $VECT = 'P'$, $N \geq M \geq \min(N, K)$.

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by CGEBRD. $K \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M-by-N matrix Q or P^*H .

LDA (input)

The leading dimension of the array A. $LDA \geq M$.

TAU (input)

($\min(M,K)$) if VECT = 'Q' ($\min(N,K)$) if VECT = 'P'
TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P^*H , as returned by CGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, \min(M,N))$. For optimum performance $LWORK \geq \min(M,N) \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

zunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

SYNOPSIS

```
SUBROUTINE ZUNGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
```

```
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE UNGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],  
[INFO])
```

```
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunghr(int n, int ilo, int ihi, doublecomplex *a, int  
lda, doublecomplex *tau, int *info);
```

```
void zunghr_64(long n, long ilo, long ihi, doublecomplex *a,
               long lda, doublecomplex *tau, long *info);
```

PURPOSE

zunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by CGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

N (input) The order of the matrix Q . $N \geq 0$.

ILO (input)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

IHI (input)

See the description of IHI.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N -by- N unitary matrix Q .

LDA (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

TAU (input)

$\text{TAU}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEHRD.

WORK (workspace)

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK .

LWORK (input)

The dimension of the array WORK . $\text{LWORK} \geq \text{IHI} - \text{ILO}$. For optimum performance $\text{LWORK} \geq (\text{IHI} - \text{ILO}) * \text{NB}$, where NB is the optimal blocksize.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

doublecomplex *tau, int *info);

void zungl2_64(long m, long n, long k, doublecomplex *a,
              long lda, doublecomplex *tau, long *info);

```

PURPOSE

zungl2 generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

A (input/output)

On entry, the i-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the m by n matrix Q.

LDA (input)

The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGELQF.

WORK (workspace)

dimension(M)

doublecomplex *tau, int *info);
```

```
void zunglq_64(long m, long n, long k, doublecomplex *a,
              long lda, doublecomplex *tau, long *info);
```

PURPOSE

zunglq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $N \geq M$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

A (input/output)

On entry, the i-th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)

The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGELQF.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

doublecomplex *tau, int *info);
```

```
void zungql_64(long m, long n, long k, doublecomplex *a,
               long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \dots H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $M \geq N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

A (input/output)

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)

The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEQLF.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, N)$. For optimum performance $LWORK \geq N \cdot NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

```

```

void zungqr(int m, int n, int k, doublecomplex *a, int lda,
            doublecomplex *tau, int *info);

void zungqr_64(long m, long n, long k, doublecomplex *a,
               long lda, doublecomplex *tau, long *info);

```

PURPOSE

zungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF.

ARGUMENTS

M (input) The number of rows of the matrix Q. $M \geq 0$.

N (input) The number of columns of the matrix Q. $M \geq N \geq 0$.

K (input) The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

A (input/output)

On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)

The first dimension of the array A. $LDA \geq \max(1, M)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)

The dimension of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N \cdot NB$, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

NAME

zungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

SYNOPSIS

```
SUBROUTINE ZUNGTR(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER N, LDA, LWORK, INFO
```

```
SUBROUTINE ZUNGTR_64(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
```

```
CHARACTER * 1 UPLO  
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)  
INTEGER*8 N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGTR(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER :: N, LDA, LWORK, INFO
```

```
SUBROUTINE UNGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO  
COMPLEX(8), DIMENSION(:) :: TAU, WORK  
COMPLEX(8), DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```

void zungtr(char uplo, int n, doublecomplex *a, int lda,
            doublecomplex *tau, int *info);

void zungtr_64(char uplo, long n, doublecomplex *a, long
               lda, doublecomplex *tau, long *info);

```

PURPOSE

zungtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by CHETRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)

= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

N (input) The order of the matrix Q . $N \geq 0$.

A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N -by- N unitary matrix Q .

LDA (input)

The leading dimension of the array A . $LDA \geq N$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHETRD.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. $LWORK \geq N-1$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message

related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               *info);
```

PURPOSE

zunmbr VECT = 'Q', ZUNMBR overwrites the general complex M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'	TRANS = 'N':	
Q * C	C * Q	TRANS = 'C':	Q**H * C	C *
Q**H				

If VECT = 'P', ZUNMBR overwrites the general complex M-by-N matrix C with

	SIDE = 'L'	SIDE = 'R'
TRANS = 'N':	P * C	C * P
TRANS = 'C':	P**H * C	C * P**H

Here Q and P**H are the unitary matrices determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P^{*H}$. Q and P**H are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P**H that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix:

```
if nq >= k, Q = H(1) H(2) . . . H(k);  
if nq < k, Q = H(1) H(2) . . . H(nq-1).
```

If VECT = 'P', A is assumed to have been a K-by-NQ matrix:

```
if k < nq, P = G(1) G(2) . . . G(k);  
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

VECT (input)
= 'Q': apply Q or Q**H;

```

= 'P': apply P or P**H.

SIDE (input)
= 'L': apply Q, Q**H, P or P**H from the Left;
= 'R': apply Q, Q**H, P or P**H from the Right.

TRANS (input)
= 'N': No transpose, apply Q or P;
= 'C': Conjugate transpose, apply Q**H or P**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the original
matrix reduced by CGEBRD. If VECT = 'P', the
number of rows in the original matrix reduced by
CGEBRD. K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q' (LDA,nq) if
VECT = 'P' The vectors which define the elementary
reflectors H(i) and G(i), whose products determine
the matrices Q and P, as returned by CGEBRD.

LDA (input)
The leading dimension of the array A. If VECT =
'Q', LDA >= max(1,nq); if VECT = 'P', LDA >=
max(1,min(nq,K)).

TAU (input)
TAU(i) must contain the scalar factor of the elementary
reflector H(i) or G(i) which determines Q
or P, as returned by CGEBRD in the array argument
TAUQ or TAUP.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is
overwritten by Q*C or Q**H*C or C*Q**H or C*Q or
P*C or P**H*C or C*P or C*P**H.

LDC (input)
The leading dimension of the array C. LDC >=
max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal
LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L',
LWORK >= max(1,N); if SIDE = 'R', LWORK >=
max(1,M). For optimum performance LWORK >= N*NB

```

if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R',
where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-
gal value

               lecomplex *tau, doublecomplex *c, long ldc, long  
               *info);
```

PURPOSE

zunmhr overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of IHI-ILO elementary reflectors, as returned by
CGEHRD:

$$Q = H(\text{ilo}) H(\text{ilo}+1) \dots H(\text{ihi}-1).$$

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)

= 'N': apply Q (No transpose)
= 'C': apply Q^{*H} (Conjugate transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

ILO (input)

ILO and IHI must have the same values as in the
previous call of CGEHRD. Q is equal to the unit
matrix except in the submatrix
 $Q(\text{ilo}+1:\text{ihi}, \text{ilo}+1:\text{ihi})$. If SIDE = 'L', then $1 \leq$
 $\text{ILO} \leq \text{IHI} \leq \text{M}$, if M > 0, and ILO = 1 and IHI =
0, if M = 0; if SIDE = 'R', then $1 \leq \text{ILO} \leq \text{IHI}$

$\leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

IHI (input)

See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

TAU (input)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**H}C$ or CQ^{**H} or CQ .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1,M)$.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1,N)$; if SIDE = 'R', $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N*NB$ if SIDE = 'L', and $LWORK \geq M*NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

zunml2 overwrites the general complex m-by-n matrix C with

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q' from the Left
 = 'R': apply Q or Q' from the Right

TRANS (input)
 = 'N': apply Q (No transpose)
 = 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGELQF in the first k rows of its

array argument A. A is modified by the routine but restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

C (input/output)

On entry, the m-by-n matrix C. On exit, C is overwritten by Q^*C or Q'^*C or C^*Q' or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

(N) if SIDE = 'L', (M) if SIDE = 'R'

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               k, doublecomplex *a, long lda, doublecomplex *tau,
               doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmlq overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C \quad C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by CGELQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as
returned by CGELQF in the first k rows of its
array argument A. A is modified by the routine
but restored on exit.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

PURPOSE

zunmql overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C \quad C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by CGEQLF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit

PURPOSE

zunmqr overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C \quad C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) The i-th column must contain the vector which
defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k
columns of its array argument A. A is modified by
the routine but restored on exit.

LDA (input)
The leading dimension of the array A. If SIDE = 'L', LDA \geq max(1,M); if SIDE = 'R', LDA \geq max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)
The leading dimension of the array C. LDC \geq max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK \geq max(1,N); if SIDE = 'R', LWORK \geq max(1,M). For optimum performance LWORK \geq N*NB if SIDE = 'L', and LWORK \geq M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

zunmr2 overwrites the general complex m-by-n matrix C with

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
 = 'L': apply Q or Q' from the Left
 = 'R': apply Q or Q' from the Right

TRANS (input)
 = 'N': apply Q (No transpose)
 = 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array

argument A. A is modified by the routine but restored on exit.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

C (input/output)

On entry, the m-by-n matrix C. On exit, C is overwritten by Q^*C or Q'^*C or C^*Q' or C^*Q .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

(N) if SIDE = 'L', (M) if SIDE = 'R'

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

               k, doublecomplex *a, long lda, doublecomplex *tau,
               doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunmrq overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C \quad C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The
i-th row must contain the vector which defines the
elementary reflector H(i), for $i = 1, 2, \dots, k$, as
returned by CGERQF in the last k rows of its array
argument A. A is modified by the routine but
restored on exit.

LDA (input)
The leading dimension of the array A. $LDA \geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)
The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if SIDE = 'L', and $LWORK \geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

zunmrz overwrites the general complex M-by-N matrix C with
 $\text{TRANS} = \text{'C'}: \quad Q^{*H} * C \quad C * Q^{*H}$

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$;
if SIDE = 'R', $N \geq K \geq 0$.

L (input) The number of columns of the matrix A containing
the meaningful part of the Householder reflectors.
If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L$

≥ 0 .

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. LDA $\geq \max(1, K)$.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or Q^*H^*C or C^*Q^*H or C^*Q .

LDC (input)
The leading dimension of the array C. LDC $\geq \max(1, M)$.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK $\geq \max(1, N)$; if SIDE = 'R', LWORK $\geq \max(1, M)$. For optimum performance LWORK $\geq N \cdot NB$ if SIDE = 'L', and LWORK $\geq M \cdot NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

zunmtr overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by
CHETRD:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

UPLO (input)

= 'U': Upper triangle of A contains elementary
reflectors from CHETRD; = 'L': Lower triangle of A
contains elementary reflectors from CHETRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. $M \geq 0$.

N (input) The number of columns of the matrix C. $N \geq 0$.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The

vectors which define the elementary reflectors, as returned by CHETRD.

LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, M)$ if $SIDE = 'L'$; $LDA \geq \max(1, N)$ if $SIDE = 'R'$.

TAU (input)

$(M-1)$ if $SIDE = 'L'$ $(N-1)$ if $SIDE = 'R'$ TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**H}C$ or CQ^{**H} or CQ .

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

On exit, if $INFO = 0$, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N \cdot NB$ if $SIDE = 'L'$, and $LWORK \geq M \cdot NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if $INFO = -i$, the i-th argument had an illegal value

void zupgtr_64(char uplo, long n, doublecomplex *ap, doublecomplex *tau, doublecomplex *q, long ldq, long *info);
```

PURPOSE

zupgtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by CHPTRD using packed storage:

if $UPLO = 'U'$, $Q = H(n-1) \dots H(2) H(1)$,

if $UPLO = 'L'$, $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

N (input) The order of the matrix Q . $N \geq 0$.

AP (input)
The vectors which define the elementary reflectors, as returned by CHPTRD.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHPTRD.

Q (output)
The N -by- N unitary matrix Q .

LDQ (input)
The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

WORK (workspace)
dimension($N-1$)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
INTEGER(8) :: M, N, LDC, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zupmtr(char side, char uplo, char trans, int m, int n,  
            doublecomplex *ap, doublecomplex *tau, doublecom-  
            plex *c, int ldc, int *info);
```

```
void zupmtr_64(char side, char uplo, char trans, long m,  
               long n, doublecomplex *ap, doublecomplex *tau,  
               doublecomplex *c, long ldc, long *info);
```

PURPOSE

zupmtr overwrites the general complex M-by-N matrix C with
TRANS = 'C': $Q^{*H} * C$ $C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m
if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product of nq-1 elementary reflectors, as returned by CHPTRD
using packed storage:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

SIDE (input)

= 'L': apply Q or Q^{*H} from the Left;
= 'R': apply Q or Q^{*H} from the Right.

UPLO (input)

= 'U': Upper triangular packed storage used in
previous call to CHPTRD; = 'L': Lower triangular
packed storage used in previous call to CHPTRD.

TRANS (input)

= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q^{*H} .

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

AP (input)

($M*(M+1)/2$) if SIDE = 'L' ($N*(N+1)/2$) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHPTRD. AP is modified by the routine but restored on exit.

TAU (input)

or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

C (input/output)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q*C$ or $Q**H*C$ or $C*Q**H$ or $C*Q$.

LDC (input)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

WORK (workspace)

(N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

DESCRIPTION

zvbrmm performs one of the matrix-matrix operations

$$C \leftarrow \alpha \operatorname{op}(A) B + \beta C$$

where alpha and beta are scalars, C and B are dense matrices, A is a sparse M by K matrix represented in the variable block sparse row format and op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').
(' indicates matrix transpose)

The number of rows in A and the number of columns in A are determined as follows

$$M = \text{RPNTR}(\text{MB}+1) - \text{RPNTR}(1), \quad K = \text{CPNTR}(\text{KB}+1) - \text{CPNTR}(1).$$

ARGUMENTS

TRANSA(input)	TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
KB(input)	On entry, integer KB specifies the number of block columns in the matrix A. Unchanged on exit.
ALPHA(input)	On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
DESCRA (input)	Descriptor argument. Five element integer array: DESCRA(1) matrix structure 0 : general 1 : symmetric (A=A')

```

2 : Hermitian (A= CONJG(A'))
3 : Triangular
4 : Skew(Anti)-Symmetric (A=-A')
5 : Diagonal
6 : Skew-Hermitian (A= -CONJG(A'))
DESCRA(2) upper/lower triangular indicator
1 : lower
2 : upper
DESCRA(3) main block diagonal type
0 : non-unit
1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
0 : C/C++ compatible
1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
0 : unknown
1 : no repeated indices

VAL(input)      On entry, scalar array VAL of length NNZ consists of the
                  block entries of A where each block entry is a dense
                  rectangular matrix stored column by column where NNZ
                  denotes the total number of point entries in all nonzero
                  block entries of a matrix A. Unchanged on exit.

INDX(input)      On entry, INDX is an integer array of length BNNZ+1 where BNNZ is
                  the number of block entries of the matrix A such that the
                  I-th element of INDX[] points to the location in VAL of
                  the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input)      On entry, BINDX is an integer array of length BNNZ consisting
                  of the block column indices of the block entries of A where
                  BNNZ is the number block entries of the matrix A. Unchanged on
                  exit.

RPNTR(input)      On entry, RPNTR is an integer array of length MB+1 such that
                  RPNTR(I)-RPNTR(1)+1 is the row index of the first point
                  row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1)
                  where M is the number of rows in the matrix A.
                  Thus, the number of point rows in the I-th block row is
                  RPNTR(I+1)-RPNTR(I). Unchanged on exit.

CPNTR(input)      On entry, CPNTR is an integer array of length KB+1 such that
                  CPNTR(J)-CPNTR(1)+1 is the column index of the first point
                  column in the J-th block column. CPNTR(KB+1) is set to
                  K+CPNTR(1) where K is the number of columns in the matrix A.
                  Thus, the number of point columns in the J-th block column
                  is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

BPNTRB(input)      On entry, BPNTRB is an integer array of length MB such that
                  BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the
                  first block entry of the I-th block row of A.
                  Unchanged on exit.

BPNTRE(input)      On entry, BPNTRE is an integer array of length MB such that
                  BPNTRE(I)-BPNTRB(1) points to location in BINDX of the
                  last block entry of the I-th block row of A.
                  Unchanged on exit.

B (input)         Array of DIMENSION ( LDB, N ).
                  Before entry with TRANSA = 0, the leading k by n
                  part of the array B must contain the matrix B, otherwise
                  the leading m by n part of the array B must contain the
                  matrix B. Unchanged on exit.

```

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N).
 Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * \text{op}(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK (is not referenced in the current version)

LWORK (is not referenced in the current version)

SEE ALSO

Libsunperf SPARSE BLAS is fully parallel and compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

The routine is designed so that it provides a possibility to use just one sparse matrix representation of a general matrix A for computing matrix-matrix multiply for another sparse matrix composed by block triangles and/or the main block diagonal of A. The full description of the feature for block entry formats is given in section NOTES/BUGS for the cbcomm manpage.

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array

BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
SUBROUTINE ZVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
*                B, LDB, BETA, C, LDC, WORK, LWORK )
```

long *cpntr, long *bpntrb, long *bpntre, doublecomplex *b,
long ldb, doublecomplex *beta, doublecomplex *c, long ldc);

```

DESCRIPTION

zvbrsm performs one of the matrix-matrix operations

```

C <- alpha op(A) B + beta C,      C <-alpha D op(A) B + beta C,
C <- alpha op(A) D B + beta C,

```

where alpha and beta are scalars, C and B are m by n dense matrices, D is a block diagonal matrix, A is a sparse m by m unit, or non-unit, upper or lower triangular matrix represented in the variable block sparse row format and op(A) is one of

```

op( A ) = inv(A) or op( A ) = inv(A') or op( A ) =inv(conjg( A' ))
(inv denotes matrix inverse, ' indicates matrix transpose).
The number of rows in A is determined as follows

```

```

m=RPNTR(MB+1)-RPNTR(1).

```

ARGUMENTS

TRANSA(input)	On entry, TRANSA indicates how to operate with the sparse matrix: 0 : operate with matrix 1 : operate with transpose matrix 2 : operate with the conjugate transpose of matrix. 2 is equivalent to 1 if matrix is real. Unchanged on exit.
MB(input)	On entry, integer MB specifies the number of block rows in the matrix A. Unchanged on exit.
N(input)	On entry, integer N specifies the number of columns in the matrix C. Unchanged on exit.
DV(input)	On entry, array DV contains the block entries of the block diagonal matrix D. The size of the J-th block is RPNTR(J+1)-RPNTR(J) and each block contains matrix

entries stored column-major. The total length of array DV is given by the formula:

sum over J from 1 to MB:

$((\text{RPNTR}(J+1) - \text{RPNTR}(J)) * (\text{RPNTR}(J+1) - \text{RPNTR}(J)))$

Unchanged on exit.

ALPHA(input) On entry, ALPHA specifies the scalar alpha.
Unchanged on exit.

DESCRA (input) Descriptor argument. Five element integer array:

DESCRA(1) matrix structure

- 0 : general
- 1 : symmetric (A=A')
- 2 : Hermitian (A= CONJG(A'))
- 3 : Triangular
- 4 : Skew(Anti)-Symmetric (A=-A')
- 5 : Diagonal
- 6 : Skew-Hermitian (A= -CONJG(A'))

Note: For the routine, DESCRA(1)=3 is only supported.

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-identity blocks on the main diagonal
- 1 : identity diagonal blocks
- 2 : diagonal blocks are dense matrices

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL(input) On entry, scalar array VAL of length NNZ consists of the block entries of A where each block entry is a dense rectangular matrix stored column by column where NNZ denotes the total number of point entries in all nonzero block entries of the matrix A. Unchanged on exit.

INDX(input) On entry, INDX is an integer array of length BNNZ+1 where BNNZ is the number of block entries of the matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry. Unchanged on exit.

BINDX(input) On entry, BINDX is an integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ is the number block entries of the matrix A. Block column indices MUST be sorted in increasing order for each block row. Unchanged on exit.

RPNTR(input) On entry, RPNTR is an integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row. RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in the matrix A. Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I). Unchanged on exit.
NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR(input) On entry, CPNTR is integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is the number of columns in the matrix A. Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J). Unchanged on exit.

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB(input) On entry, BPNTRB is an integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A. Unchanged on exit.

BPNTRE(input) On entry, BPNTRE is an integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A. Unchanged on exit.

B (input) Array of DIMENSION (LDB, N). Before entry with TRANSA = 0, the leading k by n part of the array B must contain the matrix B, otherwise the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input) On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. Unchanged on exit.

BETA (input) On entry, BETA specifies the scalar beta. Unchanged on exit.

C(input/output) Array of DIMENSION (LDC, N). Before entry with TRANSA = 0, the leading m by n part of the array C must contain the matrix C, otherwise the leading k by n part of the array C must contain the matrix C. On exit, the array C is overwritten by the matrix $(\alpha * op(A) * B + \beta * C)$.

LDC (input) On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. Unchanged on exit.

WORK(workspace) Scratch array of length LWORK. On exit, if LWORK = -1, WORK(1) returns the optimum size of LWORK.

LWORK (input) On entry, LWORK specifies the length of WORK array. LWORK should be at least $M = RPNTR(MB+1) - RPNTR(1)$. For good performance, LWORK should generally be larger. For optimum performance on multiple processors, $LWORK \geq M * N_CPUS$ where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

Libsunperf SPARSE BLAS is parallelized with the help of OPENMP and it is fully compatible with NIST FORTRAN Sparse Blas but the sources are different. Libsunperf SPARSE BLAS is free of bugs found in NIST FORTRAN Sparse Blas. Besides several new features and routines are implemented.

NIST FORTRAN Sparse Blas User's Guide available at:

<http://math.nist.gov/mcsd/Staff/KRemington/fspblas/>

Based on the standard proposed in

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

<http://www.netlib.org/utk/papers/sparse.ps>

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.
2. If `DESCRA(3)= 0` , the lower or upper triangular part of each diagonal block is used by the routine depending on `DESCRA(2)`.
3. If `DESCRA(3)=1` , the diagonal blocks in the variable block row representation of A don't need to be the identity matrices because these block entries are not used by the routine in this case.
4. If `DESCRA(3) = 2` , diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. `WORK(1)=0` on return if the factorization for all diagonal blocks has been completed successfully, otherwise `WORK(1) = - i` where `i` is the block number for which the LU factorization could not be computed.
5. The routine is designed so that it checks the validity of each sparse block entry given in the sparse blas representation. Block entries with incorrect indices are not used and no error message related to the entries is issued.

The feature also provides a possibility to use the sparse matrix representation of a general matrix A for solving triangular systems with the upper or lower block triangle of A. But `DESCRA(1)` MUST be equal to 3 even in this case.

Assume that there is the sparse matrix representation a general matrix A decomposed in the form

$$A = L + D + U$$

where L is the strictly block lower triangle of A, U is the strictly block upper triangle of A, D is the block diagonal matrix. Let's I denotes the identity matrix.

Then the correspondence between the first three values of `DESCRA` and the result matrix for the sparse representation

of A is

DESCRA(1)	DESCRA(2)	DESCRA(3)	RESULT
3	1	1	$\alpha * \text{op}(L+I) * B + \beta * C$
3	1	0	$\alpha * \text{op}(L+D) * B + \beta * C$
3	2	1	$\alpha * \text{op}(U+I) * B + \beta * C$
3	2	0	$\alpha * \text{op}(U+D) * B + \beta * C$

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
SUBROUTINE ZVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,  
*                VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),  
*                B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

zvmul - compute the scaled product of complex vectors

SYNOPSIS

```
SUBROUTINE ZVMUL(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
```

```
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX X(*), Y(*), Z(*)  
INTEGER N, INCX, INCY, INCZ
```

```
SUBROUTINE ZVMUL_64(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
```

```
DOUBLE COMPLEX ALPHA, BETA  
DOUBLE COMPLEX X(*), Y(*), Z(*)  
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
```

```
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y, Z  
INTEGER :: N, INCX, INCY, INCZ
```

```
SUBROUTINE VMUL_64([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
```

```
COMPLEX(8) :: ALPHA, BETA  
COMPLEX(8), DIMENSION(:) :: X, Y, Z  
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zvmul(int n, doublecomplex *alpha, doublecomplex *x,  
           int incx, doublecomplex *y, int incy, doublecom-
```

```

plex *beta, doublecomplex *z, int incz);

void zvmul_64(long n, doublecomplex *alpha, doublecomplex
             *x, long incx, doublecomplex *y, long incy, doublecomplex
             *beta, doublecomplex *z, long incz);

```

PURPOSE

zvmul computes the scaled product of complex vectors:

$$z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$$

for $1 \leq i \leq N$.

ARGUMENTS

N (input)
Length of the vectors. $N \geq 0$. ZVMUL will return immediately if $N = 0$.

ALPHA (input)
Scale factor on the multiplicand vectors.

X (input) dimension(*)
Multiplicand vector.

INCX (input)
Stride between elements of the multiplicand vector X.

Y (input) dimension(*)
Multiplicand vector.

INCY (input)
Stride between elements of the multiplicand vector Y.

BETA (input)
Scale factor on the product vector.

Z (input/output) dimension(*)
Product vector. On exit, $z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$.

INCZ (input)
Stride between elements of Z.
