Trademark Notice

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

License Restrictions Warranty/Consequential Damages Disclaimer

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

Warranty Disclaimer

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

Restricted Rights Notice

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

Hazardous Applications Notice

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate failsafe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Third Party Content, Products, and Services Disclaimer

This software or hardware and documentation may provide access to or information on content, products and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

Contents

Preface

Oracle's PeopleSoft CRM Advanced Configurator Preface	xxi
PeopleSoft Advanced Configurator	xxi
PeopleSoft Order Capture Applications	xxii
PeopleBooks and the PeopleSoft Online Library	xxii

Part 1

Getting Started

Chapter 1

Getting Started with PeopleSoft Advanced Configurator	3
Additional Documentation for Advanced Configurator	3
Testing and Administration Tools	3
Advanced Configurator Architecture	4
Advanced Configurator Interfaces	5
Other Sources of Information	6
Advanced Configurator Implementation	6
Implementing an Integrated Configurator Solution	6
Implementing a Standalone Configurator Solution	6

Part 2

Product Modeling with a Component Model

Chapter 2

Understanding Modeling	11
Basic Model Concepts	11
Visual Modeler	12
Visual Modeler Objects	13

Domain Members	14
Selection Points	15
Relationships Between Objects	15
Requirement Constraint	18
Dynamic Default	20
Resource Constraint	21
Summation	21
Elimination	21
Comparison	22
Effectivity Dates	25
Expressions in Relationships	26
Relationship Explanations	29
Relationship Properties	30
Default Values Within Expressions	33
Quantities in Modeling	34
Static Default Quantities	36
Dynamic Default Quantities	36
Multiple Selections on a Single Domain Member	37
Understanding Minimum and Maximum Selections and Limits	42
Domain Member Min/Max	43
Interaction between Default Quantities and Min/Max Settings at Run Time	44
Minimum Violation Explanation and Incomplete Configuration Explanation	45
Creating Parameterized Explanations	46
Optimizing Performance and Minimizing Model Maintenance	47
Using the Sample Models	48
The Modeling Process	48
Model Tester	49
Interfacing with Third-Party Tools	49
Microsoft SQL Server, Oracle Databases, and IBM DB2	50
MacroMedia DreamWeaver	50
Source Control Interfaces	50

Chapter 3

Setting Up the Modeling Environment	51
Common Elements in this Chapter	51
Connecting to Third-Party Software	52
Source Control Software	52
Database Interface Configuration	53
Configuring JNDIDBName.properties	55
Connecting to a Database from Visual Modeler	56
Specify a Database Connection	57
Specify a Default Database	57

Getting Started with Visual Modeler	58
Model Structure View	59
Components and Files View	60
Properties Editor	61
Overview Window	61
Find Window	61
Understanding Project Files	62
Creating a New Project or Workspace	64
Specifying Model Project Settings	65
Adding a Project to Source Control	67
Importing and Exporting Models	68
Exporting a Model	69
Importing a Model	69
Compiling a Model	70
Using the Model Tester	72
Internalizing Model Data	74

Chapter 4

Creating Objects for the Model	75
Creating a Class	75
Deleting a Class	77
Changing Class Structure	77
Adding Class Attributes	78
Creating Internal Domain Members	80
Creating a "None" Domain Member	80
Assigning Values to Attributes	81
Inputting Date-Type Attributes Manually	81
Setting Up Binding for External Domain Members	82
Selecting a Primary Table	82
Filtering and Manipulating Table Data	87
Storing a Dynamic Default Quantity in a Database	87
Retrieving Expression Values and Externs from a Database	88
Working with Selection Points	88
Internalizing Data	92

Chapter 5

Creating Relationships Between Model Objects	95
Prerequisites	95
Common Elements Used in this Chapter	96
Creating and Editing Expressions	97

Creating Externs	100
Creating a Relationship	102
Working with Relationships	106
Editing Compatibility Constraints	109
Editing Requirement Constraints	109
Editing Dynamic Defaults	110
Editing Resource Constraints	111
Editing Summation Relationships	112
Editing Elimination Constraints	113
Editing Comparison Constraints	115
Creating Relationships Outside the Model with SQL Queries	115

Chapter 6

Specifying Quantities on Selection Points	119
Understanding Quantity Setup	119
Specifying the Number of Allowed Selections and Optional or Required Status	120
Specifying Single- or Multi-Select Controls	121
Setting Quantity Limits on Domain Members	122
Setting Default Selections and Quantities	124
Setting Explicit Default Choices and Quantities	126
Getting Default Selections and Quantities at Runtime Through Attributes	128
Defining a Dynamic Default Quantity for a Selection	128
Attaching Metadata to Selection Points	130

Part 3

Product Modeling with Compound Models

Chapter 7

Understanding Compound Modeling	135
Applications for Compound Models	135
Compound Model Structure Types	135
Architecture	138
Relationships in a Compound Model	139
Modeling Strategy	140

Chapter 8

Working with Compound Models	143
Getting Started with Compound Models	143
Creating a Compound Modeling Project	145
Editing Project Settings	146
Creating a Configurable Component	147
Deleting a Configurable Component	150
Rearranging Component Models in the Compound Model	150
Adding and Removing a Component Model from the Project	150
Editing Default Values	153
Creating and Deleting Relationships Between Configurable Components	154
Displaying a Compound Model Relationship	158
Specifying Required Relationships	159
Editing Component Model Versions	161
Compiling, Running, and Testing a Compound Model	163
Managing Simultaneous Model Development Among Team Members	163

Chapter 9

Standardizing Compound ModelBuilding	165
Creating and Editing Configurable Component Types	165
Creating and Editing Connection Point Types	168

Part 4

Application Extensions

Chapter 10

Client Operations Processor API	173
Understanding the COP Java API	173
Choices	174
Decision Points and Domain Members	174
Application Classes	176
ClientOperations	176
Configuration	176
ControlData	177

ControlItem	177
Choice	177
DMChoice	178
EVChoice	178
ItemFilter	178
ItemIterator	178
ExternVar	179
NumericData	179
Violation	179

Chapter 11

Using the COP Java API	181
ClientOperations	181
Methods	181
Initializing the COP	182
Releasing the COP	184
Processing and Displaying a Page	184
Getting a ControlData Object	186
Specifying Delta-Pricing and Total-Pricing Requirements	189
Getting Other Display Information	189
Verifying a Configuration	190
Configuration	190
Methods	191
Saving and Restoring a Configuration	191
ControlData	192
Methods	193
Getting Display Information for a Decision Point and Its Domain Members	193
Getting the State of a Decision Point	194
Sorting and Filtering	195
Handling Deleted Domain Members	197
ControlItem	197
Methods	197
Getting Display Information for a Domain Member	198
Getting the State of a Domain Member	199
Choice	201
DMChoice	202
Methods	202
Examining a DMChoice	202
EVChoice	203
Methods	203
Examining an EVChoice	203
ItemFilter	203

Methods	204
Filtering Out Domain Members	204
ItemIterator	204
ExternVar	205
NumericData	205
Violation	205

Chapter 12

Understanding the Configurator XML Interface	207
Request-Response	207
Elements and Attributes	207
Retrieving Model Information	208
Updating a Configuration Interactively	209
Retrieving Configuration Information	209
Copying a Configuration	210
Using Batch Configuration Mode	210
Changing the Order Status of a Configuration	210
COP.dtd	210
Element-Attribute Trees	210

Chapter 13

Retrieving Model Information	213
Elements and Attributes	213
Version and Compile Version	213
Latest Version and Compile Version	213
Latest Compile Version	214
Error Messages	215
Decision Points	216
All Decision Points	216
Public Decision Points	216

Chapter 14

Updating a Configuration	219
Updating a Configuration	219
Elements and Attributes	220
Choices	220
Choices and Response	221

Chapter 15

Retrieving Configuration Information	225
Understanding Configuration Information	225
Elements and Attributes	226
Total Price	227
Choices	227
Domain Member Data	229
Every Decision Point	229
Selected Decision Points	230
Sorting Domain Members	232
Filtering Domain Members	233
Explanations	234
Attributes	237
Delta Price	241
Class	242
State and Quantity	243
Multi-Select Decision Points	244
Global Explanations	245
Global Only	245
Global and Decision Point	246
Numeric Values	247
All Values	247
Selected Values	248
Value (VL)	248

Chapter 16

Retrieving Saved Configuration Information	253
Understanding Saved Configuration Information	254
Elements and Attributes	254
The CONFIGURATION Element	255
The CONFIG_DETAILS Element	256
The DELTA_INFO Element	257
Components	257
Compounds	258

Total Price	260
Compound Violations	261
Components	261
Choices	267

Choice Violations	273
Component Violations	274
Externs	274
Numeric Values	276
External Variables	277
All Values	277
Selected Values	278
Configuration Attributes	279
Hierarchical Component Structure	280
Connections	281
Completeness Information	282
Summary of Configuration Information Elements and Attributes	283

Chapter 17

Copying a Configuration	287
Elements and Attributes	287
Copy and Response	287

Chapter 18

Using Batch Configuration Mode	289
Elements and Attributes	289
Configuring a Component	290
Configuring a Compound Configuration	290
Saving a Configuration	291
Retrieving a Configuration	291

Chapter 19

Changing the Order Status of a Configuration	293
Elements and Attributes	293
Order Change and Response	294

Part 5

PeopleSoft CRM Order Capture Integration

Chapter 20

Understanding Integration with PeopleSoft CRM Order Capture	297
Integration with PeopleSoft Order Capture Applications	297
Insurance and Financial Products	298
Service Products	298
Security	298

Chapter 21

Setting Up Integration	299
Setting Up PeopleSoft Advanced Configurator for Integration	299
Setting Up PeopleSoft CRM to Integrate with Advanced Configurator	300
Page Used to Set Up Configurator Integration with PeopleSoft CRM	301
Associating Advanced Configurator Messaging Node and Enabling Debugging	301
Creating Advanced Configurator Schemas	303
Pages Used to Create Advanced Configurator Schemas	303
Understanding Configurator Schemas	303
Creating Schemas for External Solutions	304
Creating Schemas for Internal Solutions	305
Establishing Configuration Display and Pricing Options	309
Specifying Request Details	312
Accessing the Advanced Configurator Solution from Within PeopleSoft CRM	316
Understanding How to Access Advanced Configurator	316
Page Used to Access the Advanced Configurator Solution from Within PeopleSoft CRM	317
Sample Product Configuration	317
Viewing Configuration Details	318

Part 6

Building a Custom User Interface

Chapter 22

Understanding the Runtime System	323
Deployment Framework	323
Advanced Configurator Web Components	327
Sequential Application JSP Pages	327
Deployment for a Web Application Based on a Single Component Model	328
Optimizing Performance	329
Restore Policy	329
Deployment for a Web Application Based on a Compound Model	329

Chapter 23

JSP and Page Templates	331
The Midtier Framework	331
Scope of the Servlet	333
Using JSP Processing	333
Writing JSP	334
Using Generated Java and Class Files	335

Chapter 24

Processing User Picks and Entries	337
Understanding Runtime Processing	337
Initializing the WCP	338
Processing User Picks and Entries	339
Configuration Records	339
Attribute Records	340
Making COP Calls	341

Chapter 26

Using JSP Form Control Templates	351
Understanding Form Control Templates	351
Understanding Properties, Parameters, and Attributes	352
Properties	352
Parameters	352
Attributes	352
Understanding JSP Code Templates	353
Using Configuration Form Control Templates	368
Plugging Form Controls into the Application Pages	369
Parameters in the Inclusion Set	371
Specifying the Model and Locale Properties for the Solution	374
Specifying Solution Information Properties	376
Specifying Display Properties	377
Displaying Delta Information	377
Displaying Delta Pricing	378
Application Page Example	379
Configuring a Form Control Template	380
Registering Custom Form Control Templates	382
Custom Form Control Template Example	382
Common Errors	383

Chapter 27

Using the Page Editor Extensions for Dreamweaver	385
Understanding Dreamweaver Extensions	385
Advanced Configurator Runtime Objects	386
Creating a Solution	387
Editing CalicoUI.properties	387
Inserting a Configurator Runtime Object	388
Inserting a Form	389
Inserting a Button	389
Inserting a List	390
Inserting a Group	392
Inserting a Table	395
Inserting an Image	397
Inserting Why Help	399
Inserting a Numeric Data Object	400
Editing Properties of Advanced Configurator Objects	402
Editing Forms and Buttons	403
Editing Lists, Groups, and Tables	403

Chapter 28

Compound Modeling	405
Understanding the Compound Model at Run Time	405
Runtime Capabilities	405
Architecture	406
Using Compound Model JSP Pages	407
Calling the Compound Model API	409
Creating an Application from the Sample	410
Viewing the Sample Application	410
Node-Hub-Circuit Services	411
Configurable Components	411
Relationships	412
Modeling Node-Hub-Circuit Services	413
Configuring Node-Hub-Circuit Services	413
Creating a Compound Configuration	413
Reconfiguring a Compound Configuration	414
Obtaining the Configuration Delta	414

Part 7

Advanced Configurator System Administration

Chapter 29

Understanding Advanced Configurator Administration	417
--	-----

Chapter 30

Using Administration Tools	419
Administration Console	419
Testing Solutions	422
Page Used to Test Solutions	422
Accessing the Solution Tester	427
Understanding the Output and Solution User Interface	427
Setting Configuration Solution Parameters	428
Model Tester	429

Chapter 31

Maintaining the Advanced Configurator System	431
Managing Model Versioning	431
Loading Models	432
Managing the Memory Usage of the Configurator Server	434
Compressing Configuration Data	434
Using the Explanations.properties File	435
Copying the Explanations.properties File	435
Searching for the Explanations.properties File	436
Compiling Models from the Command Line	436
Accessing and Using COPXML Servlet Statistics	436

Appendix A

Visual Modeler Expression Editor Functions	439
Numeric Operators and Functions	439
Boolean Functions	443

Date Functions	445
String Functions	447

Appendix B

Creating and Adding User-Defined Functions	451
Adding a User-Defined Function	451
Implementing the UserFunction Interface	452
Methods	452
Exceptions	453
Editing UserFunctions.xml	454
Using the Sample User-Defined Function getQuantity()	456
Understanding the getQuantity() Sample Function	456
Setting Up getQuantity()	458
Viewing getQuantity() Behavior	459

Appendix C

Advanced Configurator Form Controls	461
Single-Select Group Form Control	461
Multi-Select Group Form Control	462
Single-Select Table Form Control	462
Multi-Select List Form Control	463
Single-Select List Form Control	464
Multi-Select Table Form Control	464
Single-Select Image	465
Single-Select Image Table	466

Index	517
--------------------	------------

Oracle's PeopleSoft CRM Advanced Configurator Preface

This preface discusses:

- PeopleSoft advanced configurator.
- PeopleSoft order capture applications

PeopleSoft Advanced Configurator

The *PeopleSoft Advanced Configurator 9.1 PeopleBook* provides implementation and processing information for the Advanced Configurator application. Information is organized into these topics:

- *Getting Started* provides an overview of the application's basic concepts, capabilities, implementation phases, and tools.
- *Product Modeling with a Component Model* explains how to build the central component of a configuration implementation, the model, to represent a product or service, using PeopleSoft Visual Modeler.
- *Product Modeling with a Compound Model* explains how to represent a product or service with parts that are themselves configurable.
- *Application Extensions* describes how to build specific functionality by calling or extending Advanced Configurator Java APIs.
- *PeopleSoft Order Capture Integration* describes how to set up Advanced Configurator for configuration sessions from within the PeopleSoft Order Capture application.
- *Building a Custom User Interface* details the front-end components that allow you to build a completely custom configuration interface for hosting on an independent production environment.
- *Advanced Configurator System Administration* describes how to use the deployment and testing tools to validate and maintain configuration implementations.

In addition to the core reference sections of this PeopleBook, there are six appendixes:

- *Visual Modeler Expression Editor Functions* lists the many operators and functions available for writing expressions to describe model behavior.
- *Creating and Adding User-Defined Functions* is a tutorial for writing your own functions for use in creating expressions for a model.
- *Advanced Configurator Form Controls* provides a reference for the HTML and JSP code that renders each of the form controls available for a custom configuration interface.
- *Compound Model Properties File* provides a hard-copy reference for the compound model properties file in two versions: annotated and non-annotated.

- *Node-Circuit-Hub Service Sample Model* describes a sample complex product (communications services) offering that includes the XML representation of its compound structure definition

PeopleSoft Order Capture Applications

Additional essential information describing the setup and design of your system appears in a companion volume of documentation called *PeopleSoft CRM 9.1 Order Capture Applications PeopleBook*.

The *PeopleSoft CRM 9.1 Order Capture Applications PeopleBook* consists of topics that apply if you are integrating PeopleSoft Order Capture with Advanced Configurator.

PeopleBooks and the PeopleSoft Online Library

A companion PeopleBook called *PeopleBooks and the PeopleSoft Online Library* contains general information, including:

- Understanding the PeopleSoft online library and related documentation.
- How to send PeopleSoft documentation comments and suggestions to Oracle.
- How to access hosted PeopleBooks, downloadable HTML PeopleBooks, and downloadable PDF PeopleBooks as well as documentation updates.
- Understanding PeopleBook structure.
- Typographical conventions and visual cues used in PeopleBooks.
- ISO country codes and currency codes.
- PeopleBooks that are common across multiple applications.
- Common elements used in PeopleBooks.
- Navigating the PeopleBooks interface and searching the PeopleSoft online library.
- Displaying and printing screen shots and graphics in PeopleBooks.
- How to manage the locally installed PeopleSoft online library, including web site folders.
- Understanding documentation integration and how to integrate customized documentation into the library.
- Application abbreviations found in application fields.

You can find *PeopleBooks and the PeopleSoft Online Library* in the online PeopleBooks Library for your PeopleTools release.

Part 1

Getting Started

Chapter 1

Getting Started with PeopleSoft Advanced Configurator

Chapter 1

Getting Started with PeopleSoft Advanced Configurator

This chapter provides an overview of Advanced Configurator architecture and discusses:

- Additional documentation for Advanced Configurator.
- Testing and administration tools.
- Advanced Configurator architecture.
- Advanced Configurator interfaces.
- Other sources of information.
- Advanced Configurator implementation.

Additional Documentation for Advanced Configurator

This section lists the documentation for PeopleSoft Advanced Configurator that is available in the Configurator installation and on My Oracle Support.

See Also

PeopleSoft CRM 9.1 Installation Guide

Testing and Administration Tools

This section discusses the tools available for testing and administration.

Configurator includes two tools to help you validate your model and its associated solution. The *Solution Tester* and the *Model Tester* provide valuable troubleshooting information. Solutions require updating to reflect changes in the product or service.

Note. The *Administration Tool* can help you track and manage versions as well as service, compile, and run models remotely.

[Advanced Configurator System Administration](#)

Advanced Configurator Architecture

This section describes the basic elements of Advanced Configurator architecture:

- Application server
- Web server
- Relational databases

Application Server

The application server, such as Oracle WebLogic , has three "tiers" within it: dynamic presentation logic, business logic, and database abstraction.

- Dynamic presentation

This tier is used to process any presentation content that is determined at run time. It is conditional based upon user actions and selections, and can be personalized.

- Business logic

This tier houses the Configurator models and other product components.

- Database abstraction

This tier contains calls to the database so that designers do not need to know which specific database is being used. It also maintains connections to any databases that might be utilized.

After the dynamic content is processed by these "tiers," it is then passed to the web server for display in the browser.

Web Server

Web servers are used as the static presentation tier. A web server displays static HTML pages and images. It also displays the HTML results of the processed Java Server Pages (JSPs) after the application and database servers have compiled the dynamic information.

Relational Databases

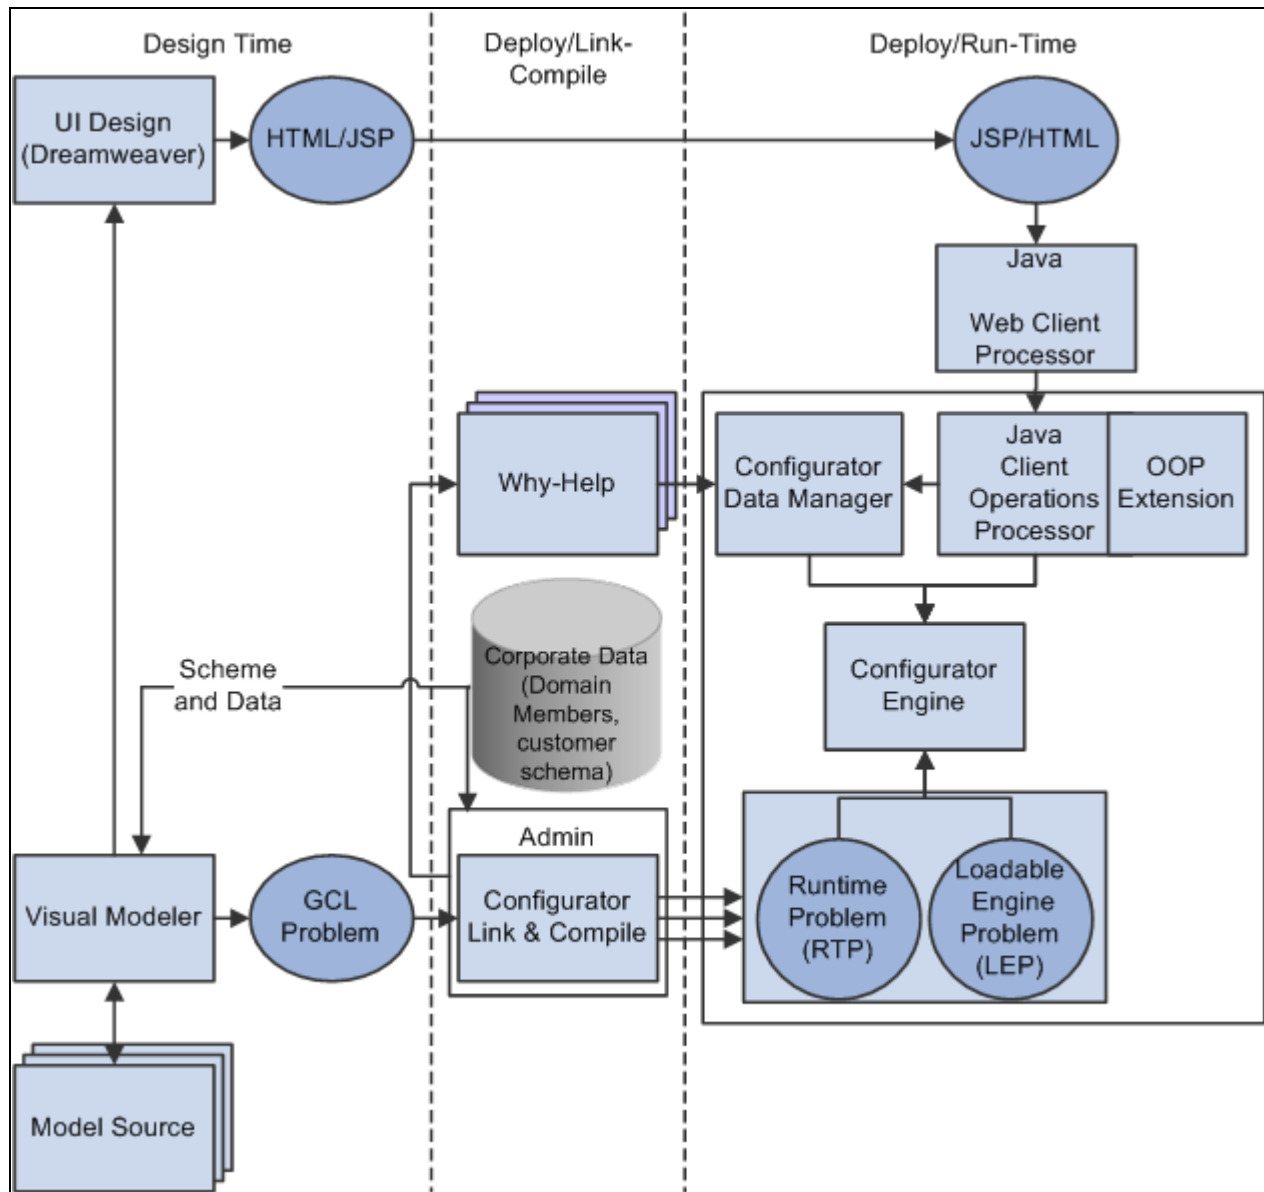

The relational databases contain any external data that you use in product models. Examples of these might be third-party product tables, catalogs, or marketing information. This data can be refreshed without requiring business logic to change. This allows for a flexible and maintainable system.

Advanced Configurator Interfaces

The PeopleSoft Advanced Configurator interacts with industry-standard applications commonly used for web development and deployment. Java 2 Enterprise Edition compliance and Oracle WebLogic® application certification combine to provide a fast, scalable, and secure configuration service.

PeopleSoft Advanced Configurator interacts within a multi-tier structure called the Lightning Architecture™ that is based on Java 2 Enterprise Edition (J2EE) technology.

The following diagram shows the architecture of Advanced Configurator.

Advanced Configurator architecture

Other Sources of Information

In the planning phase of your implementation, take advantage of all PeopleSoft sources of information, including the installation guides, table-loading sequences, data models, and business process maps. A complete list of these resources appears in the preface in the *PeopleSoft CRM 9.1 Application Fundamentals PeopleBook*, with information about where to find the most current version of each.

See Also

PeopleSoft CRM 9.1 Order Capture Applications PeopleBook

Advanced Configurator Implementation

This section discusses:

- Implementing an integrated Configurator solution.
- Implementing a standalone Configurator solution.

Implementing an Integrated Configurator Solution

If you intend for users to configure the product from within a PeopleSoft CRM application, you do not need to create a user interface (although it is still an option). PeopleSoft CRM pages can provide the user interface for you, requiring only that you specify the pages' data content. Optionally, you can create a custom user interface using JSP.

Step	Reference
Install Configurator and set it up for integration. (For integration with PeopleSoft CRM Order Capture).	<i>PeopleSoft CRM 9.1 Installation Guide</i>
Build a model of the product(s) or service(s) using the PeopleSoft Visual Modeler.	See and Product Modeling with a Component Model , and Product Modeling with Compound Models .
Deploy the solution files to the production environment using the Advanced Configurator Administration console.	See and Advanced Configurator System Administration .
Set up the solution schema.	See and PeopleSoft CRM Order Capture Integration .

Implementing a Standalone Configurator Solution

A solution that runs on PeopleSoft Advanced Configurator independent of other PeopleSoft applications requires a custom User Interface in addition to the configuration model. Advanced Configurator is also extensible, and the solution may include Java implementations of the Configurator interfaces.

Step	Reference
Build a model of the product(s) or service(s) using the PeopleSoft Visual Modeler.	See and Product Modeling with a Component Model . See and Product Modeling with Compound Models .
Build a UI. Create the JavaServer Pages for the User Interface using the provided templates and, if desired, Dreamweaver extensions.	See and Building a Custom User Interface .
Write Java extensions for any custom functions and modify the JSP pages as needed.	See and Application Extensions . Also consult the PeopleSoft Advanced Configurator API Reference Guide in your server installation root\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\calico\apidocs.
Deploy the solution files to the production environment using the Configurator Administration Console.	See and Advanced Configurator System Administration .

Part 2

Product Modeling with a Component Model

Chapter 2

Understanding Modeling

Chapter 3

Setting Up the Modeling Environment

Chapter 4

Creating Objects for the Model

Chapter 5

Creating Relationships Between Model Objects

Chapter 6

Specifying Quantities on Selection Points

Chapter 2

Understanding Modeling

This chapter discusses:

- Basic model concepts.
- Relationships between objects
- Relationship properties.
- Expressions in relationships.
- Default values within expressions.
- Quantities in Modeling.
- Creating parameterized explanations.
- Optimizing performance and minimizing model maintenance
- Using the sample models.
- The modeling process.
- Model Tester.
- Interfacing with third-party tools.

Basic Model Concepts

The PeopleSoft Visual Modeler is a graphical hierarchical modeling tool for designing complex configuration solutions. You use it to create a model of a product or a service that then serves as the "blueprint" for specifying actual instances of the product or service that are customized to a customer's needs.

Advanced Configurator models represent products and services using three concepts:

- The hierarchy—a logical structure that identifies and organizes its components.
- Relationships—how the components relate to each another and interact.
- Components—a product's parts are represented by classes, attributes, domain members, and selection points.

Visual Modeler

Advanced Configurator technology supports configuration modeling and runtime configuration processing.

Using the concepts of hierarchy, components, and relationships, Visual Modeler allows you to describe even complex products and services:

- Uses a multi-paned window to simplify model navigation and the creation of classes, attributes, and relationships.
- Uses a "no programming" paradigm.

All modeling is accomplished through drag-and-drop operations and table selections.

- Integrates easily with existing customer data.
- Provides support for team development.
- Separates the UI design from the product modeling problem.

Modelers don't need to create a UI in order to test their model logic.

Model data can be defined in the model (internal data), or obtained from a relational database.

The Configurator engine uses a compiled version of the Visual Modeler model to process user picks, ensuring a valid configuration at runtime.

In this document, a general reference to the Advanced Configurator includes both design-time and runtime components.

You can use Visual Modeler stand-alone or with the Advanced Configurator engine. The Visual Modeler interface uses common hierarchical concepts:

- A model is built from objects. An object is a functional component such as a class, attribute, relationship, or domain member.
- A class is a group or category of like things; for example, products or services.

A class defines common attributes such as color, weight, power requirements, or price.

- A class hierarchy applies a hierarchical organization to a group of classes.

Attributes are defined on a class. A new class that inherits attributes from an existing "ancestor" class is a "subclass" or "child." The nearest ancestor class is referred to as the "parent."

- A class member, or "domain member" is an instance of a class that assigns specific values to class attributes.
- A relationship, such as compatibility or incompatibility, can be defined between classes or class attributes, and between selection points.

Visual Modeler Objects

Visual Modeler employs standard object-oriented principles for class and inheritance. A model includes an automatically generated Root class, and any classes, subclasses, domain members, and relationships that you define. Inheritance moves from left to right, such that child classes and domain members inherit attributes from parent classes. Hierarchical modeling makes a large configuration task more approachable. Classes can be grouped in meaningful ways, and inheritance capabilities can greatly reduce the work of explicit value assignment.

The compiled model provides basic configuration functionality. To visually organize the display of controls at run time, use DreamWeaver with the Advanced Configurator Extensions. Using DreamWeaver reduces the need to hand-code JSP pages. Model functionality can be further extended with custom Java code that manipulates the controls and options displayed at run time.

Object Properties and Attributes

All Visual Modeler objects (classes, domain members, or relationships) have properties, also referred to as system properties. Classes can have both properties and attributes.

- Properties are part of the object definition and cannot be removed.

For example, classes, domain members, and relationships all have a Name property. You supply a string to define this property. A property setting is specific to an object.

- Attributes can be thought of as optional user-defined extensions to a class description.

Attributes can be changed or deleted at any time. Attributes are inherited by subclasses. Domain members assign values to attributes, creating an instance of a class.

Classes and Class Attributes

A class is a group of related objects—items or characteristics a user can order, specify, or require.

- The Root class is a special class defined in every model.

It behaves like any other class, except it can't be deleted and can't have domain members.

- Any number of attributes can be added to a class.

Attributes can be of type Boolean, Float, Int, String, and Date. User-defined class attributes appear on all subclasses and subsequent domain members.

- Class attributes can be assigned default values only in the class on which they are defined (class attribute values cannot be altered in subclasses).

An attribute value can be assigned on a domain member instance as well.

- The Internal flag is a class property that determines whether internal domain members will be used, or if domain members will be obtained from a database. A list of class properties follows.
- When external domain members are used, an attribute must exist for each column pulled from the database. This includes the Name. The name defined when the class was created exists internally, so it is not available if the Internal attribute is set to False. (Attribute names should begin with a letter. Attribute names starting with "_" and "\$" are reserved for use by the Advanced Configurator system.)

Visual Modeler supplies the following default properties for each class:

Name (String)	The class name specified at creation.
File Name (String)	The file name specified at creation. Although the class name you see in the Visual Modeler can be changed interactively, the corresponding file name cannot be changed.
Internal (Boolean)	Default is <i>True</i> , implying that domain members are internal (defined within the model). If this property is set to <i>False</i> , the SQL Query dialog will be displayed. A model can combine both internal and external domain member data, although not within a single class.
SQL Query	Only displayed if Internal is set to <i>False</i> . Click on the Edit button to raise the Primary Table dialog. This dialog allows you to specify the data source, the table used, and the columns accessed.

You must consider the effect of inheritance principles as you build a model. Click anywhere in the Model Structure View to ensure focus on the modeling area.

See and [Chapter 4, "Creating Objects for the Model," Creating a Class, page 75.](#)

Domain Members

A domain member is an instance of a class that describes a particular item, service, or decision. Domain members assign values to class attributes. A class can have either internal or external domain members, but the Internal flag determines the source of the domain members used in the model.

Internal Domain Members

If a domain member is internal, values are assigned as part of the domain member definition. An internal domain member has only one property: its name. A domain member can instantiate attributes from the parent class.

See and [Chapter 4, "Creating Objects for the Model," Creating Internal Domain Members, page 80.](#)

External Domain Members

External domain members populate the model based on the SQL Query defined for the class. Values extracted from a database are assigned to a corresponding class attribute. External domain members can be internalized using the menu command Project, Internalize Model. This tool is primarily for use when you need to package a model with its data, such as for transfer and setup at an off-line location for support and testing.

See and [Chapter 4, "Creating Objects for the Model," Setting Up Binding for External Domain Members, page 82.](#)

Selection Points

A selection point is an object in the model that will be exposed at run time. A class or a class attribute can become a selection point (sometimes referred to as a decision point). Only selection points shown in the model structure view are available for display at run time.

In addition, a selection point:

- May or may not be visible and selectable at run time.
- May or may not be required to satisfy the runtime completeness check.

By default, a selection point is created for every leaf class that participates in a relationship.

It also participates in all relationships that refer to the original parent class. If a relationship is made directly between a selection point and another object, that relationship is confined to the selection point.

Relationships Between Objects

The relationships you can define between objects in Visual Modeler are:

- Compatibility constraints
- Requirement constraints
- Dynamic defaults
- Resource constraints
- Summation
- Elimination
- Comparison

Compatibility

A non-directional compatibility constraint explicitly identifies all *valid* combinations and eliminates all other possibilities. Consider the example of an eyeglass product in which Sport frames are compatible with plasticShatterproof lenses. Thus, a pick on either Sport or plasticShatterproof eliminates all other choices. The single remaining choice will be computer-selected if the control is not optional.

Note. Any options not explicitly marked as compatible are assumed to be incompatible. There is no neutral state in a compatibility constraint.

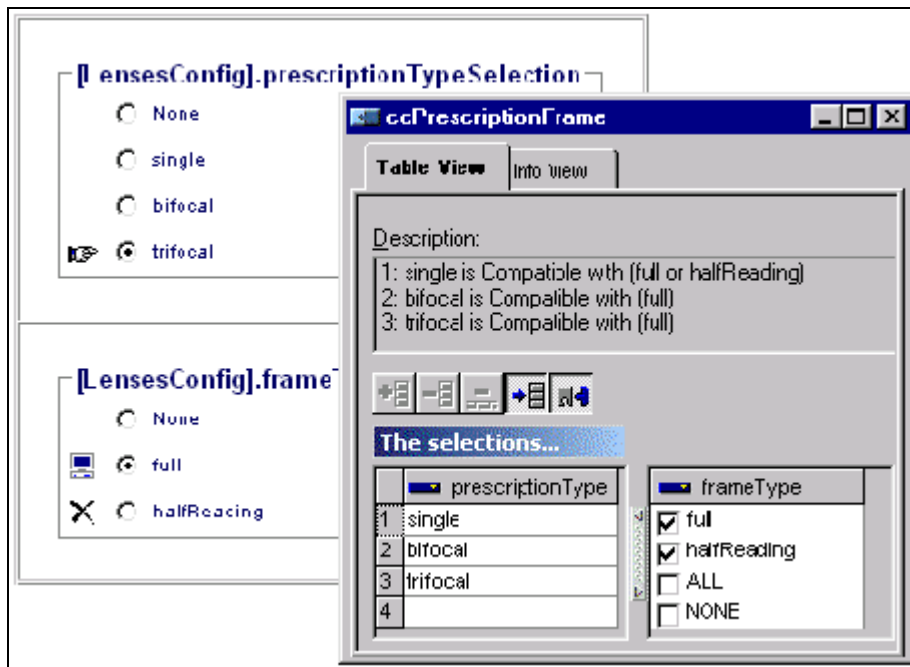

Directional Compatibility

A directional compatibility constraint has a left-hand side (LHS) and a right-hand side (RHS). It identifies compatible combinations, and eliminates all other selections. In the relationship editor, the constraint is expressed in a table with a directional bar separating the LHS arguments from the RHS arguments. The bar indicates that the combined LHS selections are compatible with one of the RHS items; the RHS items are considered separate and unrelated.

- At run time, the constraint can't eliminate all incompatible items until a pick or a computer selection is made on all but one of the controls. In other words, given N columns in the constraint, the constraint is not "bound" until a user or computer pick is made on $N-1$ controls. Then the remaining pick is calculated and all incompatible items are eliminated.
- If a RHS object is optional, elimination will occur but a computer selection cannot be made. If the RHS object is required and there is only one valid selection on the RHS, it will be computer-selected.
- Do not use directional compatibility if any RHS object is multi-select. A directional compatibility cannot eliminate items from a multi-select control. Since nothing is eliminated, nothing is computer-selected so the constraint has no effect. If a RHS argument is set to multi-select, you will see the following message at compile time:

```
multi-select decision point <nameSelection> in RHS of directional compatibility=>
constraint <constraintName> will be ignored
```

The following figure shows an example of relationship dialog settings and the HTML result of a directional compatibility:

Directional compatibility

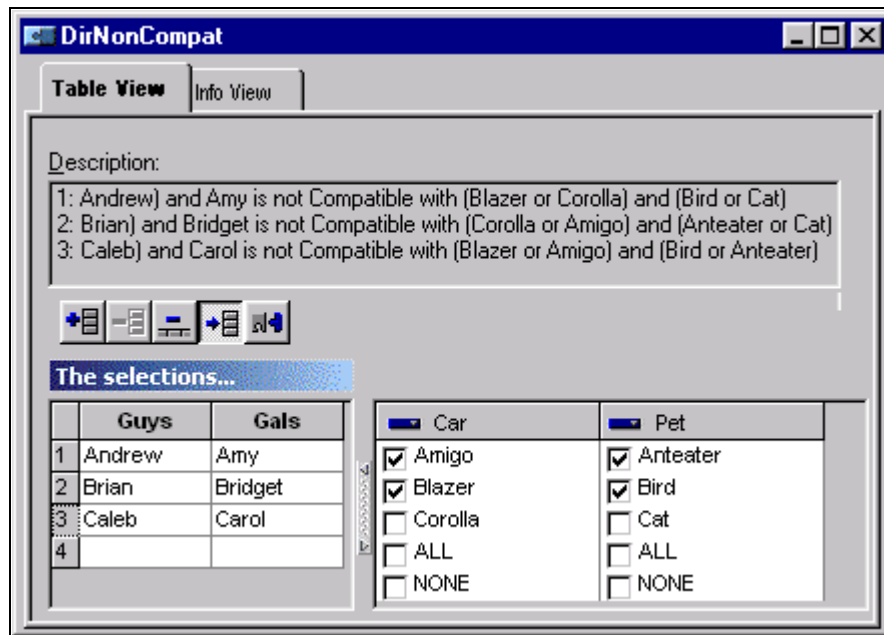

Non-Compatibility

A non-compatible constraint enumerates all invalid combinations. If any member of an invalid combination is selected, all members are eliminated. This is true for both single- and multiple-select controls.

- If a control is not optional and only one option remains, that option will be computer-selected.
- Generally, in a non-compatibility constraint, when there are more than two arguments in a constraint (that is, more than two columns in a relationship editor table), the full set of eliminations will not appear unless there is a user pick or a computer-selection for all but one selection. In other words, given N columns in the constraint, the constraint is not "bound" until a user or computer pick is made on $N-1$ controls. Then the remaining pick is calculated and all incompatible items are eliminated. In some cases, however, it's possible for fewer than $N-1$ selections to cause eliminations to appear. For example, in a three-column, non-compatibility constraint, if a value from the first column along with a value from the second column are incompatible with every value from the third remaining column (and that column is a required selection), then selecting the value from the first column will eliminate the corresponding value from the second column (since the additional selection of the value from the second column would eliminate all selections for the third column).

Directional Non-Compatibility

A directional, non-compatible constraint evaluates a pick and then eliminates all the incompatible items. In the relationship editor, the constraint is expressed in a table with a directional bar separating the LHS arguments from the RHS arguments. Row by row, the combined LHS selections are incompatible with one of the RHS items. The RHS items are separate and unrelated as shown in the figure.

Relationship dialog for a non-directional compatibility

Because RHS items are unrelated, a directional non-compatibility is equivalent to many constraints. For example, row 3 equates to:

- Caleb and Carol are incompatible with Amigo.
- Caleb and Carol are incompatible with Blazer.
- Caleb and Carol are incompatible with Anteater.
- Caleb and Carol are incompatible with Bird.

Expressions in the Left-Hand Side of the Relationship

Using expressions in the LHS of the relationship lets you to constrain against values that aren't known until run time. Since expressions name variables whose values are input at run time through user- or database input, by using expressions you can describe a condition or set of conditions that result in a desired default selection or quantity on a selection, or both.

For example, a model for financial services product offers differing plans based on the customer's marital status and the spouse's age. You can use an expressions on the LHS for a requirement constraint to determines whether the customer or their spouse is older and thus which partner is considered the principal applicant. The selection "Main applicant" is computer-selected if the customer is older than the spouse.

Description:

- 1: Married and (fxAge > fxSpouseAge) Default (Main Applicant)
- 2: Married and (fxAge == fxSpouseAge) Default (Same Age)
- 3: Divorced and (fxAge < fxSpouseAge) Default (Spouse)
- 4: Single and (fxAge >=) Default ()

The selections...

	Marital Status		fxAge	
1	Married	>	f(x)	fxSpouseAge
2	Married	==	f(x)	fxSpouseAge
3	Divorced	<	f(x)	fxSpouseAge
4	Single	>=	const	
5				

Will default the selections.

Who is Older

- ☒ Main Applicant
- ☐ Not Applicable
- ☐ Same Age
- ☐ Spouse
- ☐ ANY
- ☐ NONE

Requirement constraint: If "Married" is selected, and the result of the expression fxAge is greater than fxSpouseAge, then "Main Applicant" is selected.

The example illustrates the two capabilities that using expressions in the LHS of a relationship allow you:

- Eliminate items (in the case of a compatibility constraint) and require items (in the case of a requirement constraint),
- Define a range of values that default a selection.
- Describe conditions that default a selection that can't be known at design time, especially in the case of external data.

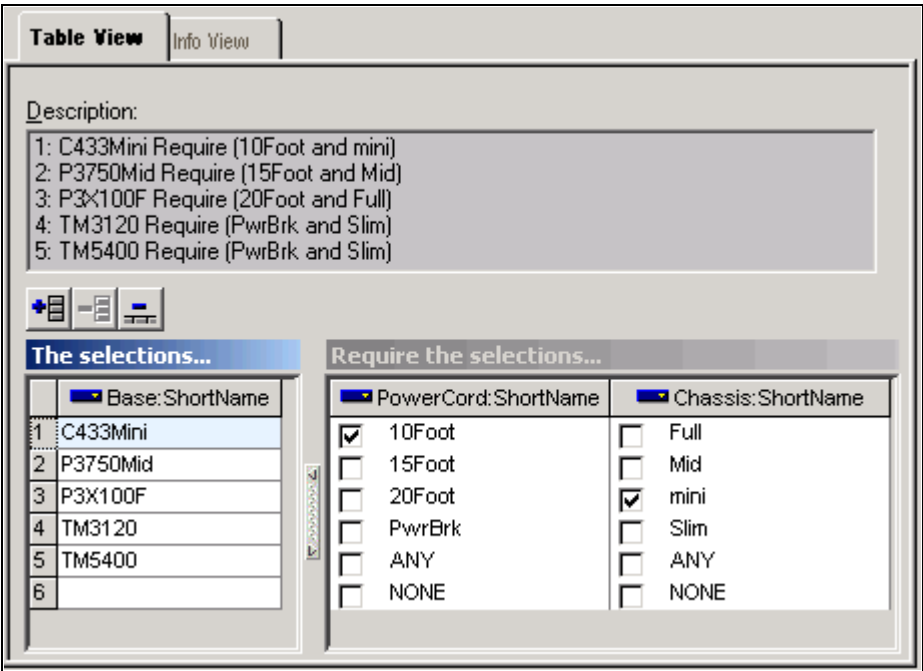

In defining a range of values, you can describe the lower limit, the upper limit, or both. In addition, you can use more than one expression to define the default conditions.

Requirement Constraint

A requirement constraint makes a computer selection on items that meet the LHS criteria. The figure below shows a simple Requirement, where selecting "photogray" causes "glass" to be computer-selected.

Requirement constraints have these characteristics:

- Requirement constraint behavior is unaffected by optional/required status on a selection point.
- If an RHS control is single-select, the selection is made and the rest of the items are eliminated. In the multi-select case, the computer selections on the RHS are made, but no eliminations occur.
- Given the constraint shown in the figure, if the RHS item "glass" is eliminated (by a different constraint), then the LHS item "photogray" will also be eliminated.
- Externs can be used on the LHS and the RHS of a requirement constraint.

Requirement constraint

When the Requirement is written on a Selection Point, you can define default quantities on the selections. If the Selection Point has Quantity property set to True, settings appear in the column.

Requirement constraint with quantity settings

See [Chapter 5, "Creating Relationships Between Model Objects," Editing Requirement Constraints, page 109.](#)

Dynamic Default

As mentioned earlier, a Dynamic Default is not a true constraint because it is not considered in the model verification process. There are some similar traits, however. A Dynamic Default is directional. When the LHS criteria is met, a computer-select occurs on the item on the RHS, provided it is available and selecting it will not cause a violation. The RHS can have multiple arguments (multiple columns in the relationship table), in which case a default pick can be made on each control.

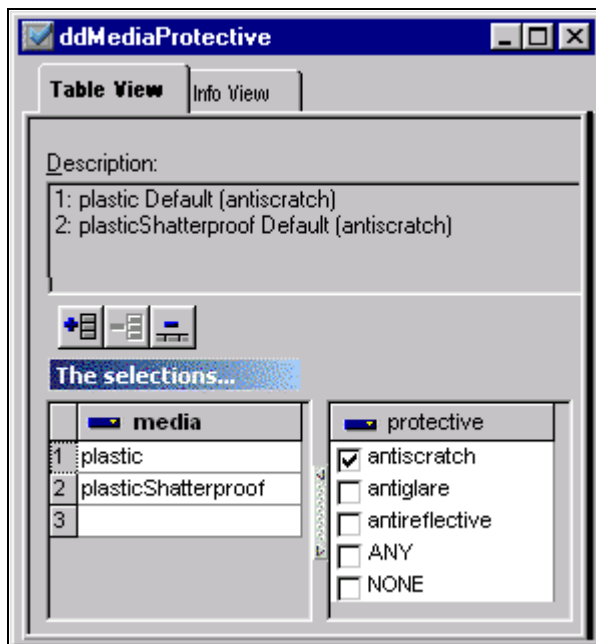

See [Chapter 5, "Creating Relationships Between Model Objects," Editing Dynamic Defaults, page 110.](#)

A dynamic default has these characteristics:

- If a default item has been eliminated, nothing is done.
- Once the default pick exists, any constraint reference to the item can eliminate it. There is no violation when a Dynamic Default is superseded.

The following figure shows a simple default with two rows. Each LHS argument has a different pick on the RHS. "Plastic" picks "anti-scratch," and "plasticShatterproof" picks "anti-reflective."

- As with Requirement constraints, when the default is written on a selection point, you can define quantities for the selection. If the selection point flag Quantity is set to True, settings appear in the column.

Dynamic default relationship

Media		protective	
1	plastic	Max of	2 antiscratch
2	plasticShatterproo	Min of	0 antiglare
3		Min of	0 antireflective
		Min of	0 ANY
		Min of	0 NONE

Dynamic default with quantity settings

Resource Constraint

A Resource constraint evaluates numeric attribute values. A constraint designates one or more provider attributes and one or more consumer attributes. If the sum of the consumers exceeds the sum of the providers, a conflict occurs and an explanation, if defined, is displayed at the page level. This behavior can also be achieved with a numeric Comparison.

See and [Chapter 5, "Creating Relationships Between Model Objects," Editing Resource Constraints, page 111.](#)

Summation

The summation relationship adds the value of numeric attributes. The sum can be displayed at run time. The summation relationship does not affect model verification.

See and [Chapter 5, "Creating Relationships Between Model Objects," Editing Summation Relationships, page 112.](#)

Elimination

An elimination compares a specific attribute value on a selection point with the value of a numeric, boolean, string, or date expression. The following figure shows an elimination where domain members of the selection point "HardDriveSelection" are eliminated if the value of the selected hard drive's Watts attribute exceeds the value passed in by externExpression. An explanation appears at the page level when the constraint is violated.

to the constant:

Elimination of numeric types

See [and Chapter 5, "Creating Relationships Between Model Objects," Editing Elimination Constraints, page 113.](#)

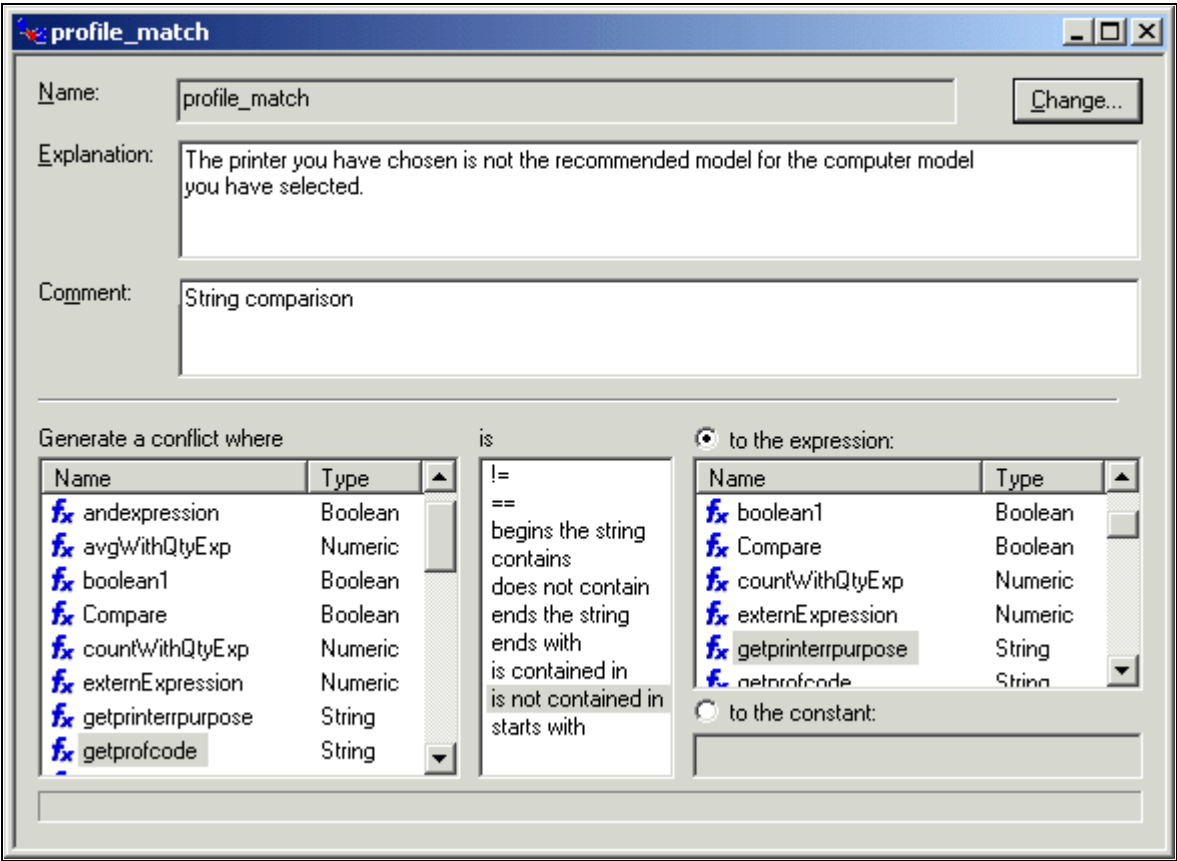

Comparison

Advanced Configurator supports comparison relationships for the four data types string, numeric, boolean, and date. If the comparison is False, a conflict occurs, and an explanation, if defined, appears at the page level. Because comparisons operate on expressions, it does not pick or eliminate domain members.

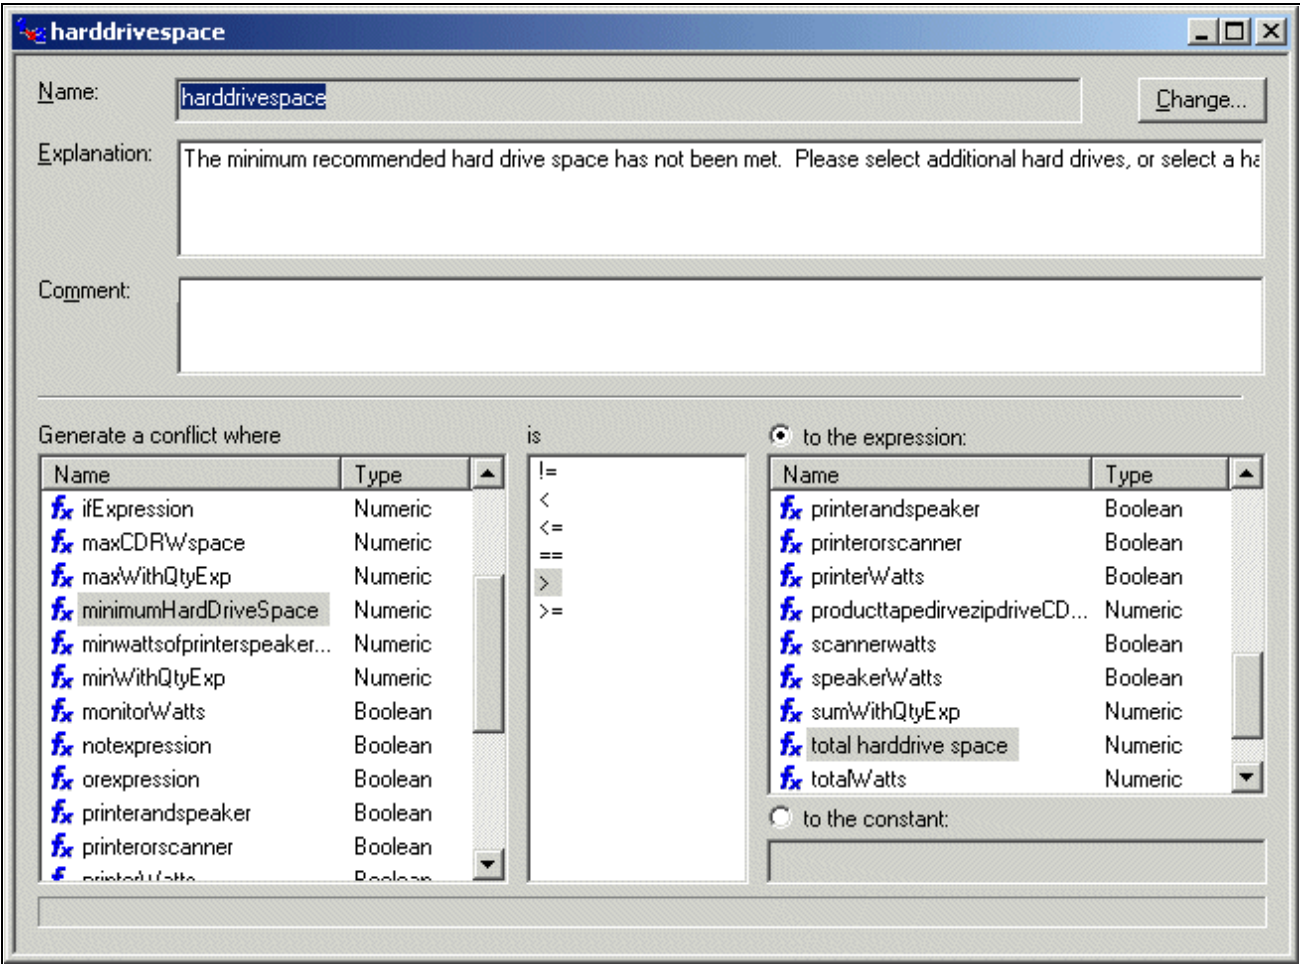

A numeric comparison compares the value of one numeric expression with the value of another; a boolean comparison compares boolean values; a string comparison, strings; and a date comparison, dates. Or, you can compare the value of an expression with a constant rather than an expression with the "to the constant" option.

The figures illustrate examples of a string, numeric, and boolean comparison.

Boolean comparison relationship

Effectivity Dates

Relationships and comparisons have optional date of effectivity ranges to indicate when they are to be considered active and thus used in a configuration session. With effectivity dates, you can define constraints and defaults that apply only during special sale periods, holiday periods, or other times when the valid or suggested configuration is slightly different.

In contrast, expressions and summations do not have effectivity dates because their results may be used in other, active relationships and expressions, and may be displayed on the UI. You can set effectivity dates on compatibility and incompatibility constraints, dynamic defaults, resource and requirement constraints, comparisons, and eliminations.

Effectivity dates are set in the relationship's table editor using the Effectivity dialog. Click the Edit button to open the dialog.

Effectivity in the property editor and in its dialog

You can enter multiple date ranges by clicking the Add button.

At run time, the server's system date or a specific solve date is compared to the date ranges specified on each of the relationships in the model. If it falls within any date range specified on a relationship, then that relationship will be included in the configuration session. As soon as the Configurator engine detects at least one valid range on a relationship, it will cease further comparison against any remaining date range rows and the relationship will be enabled. If the date entered at run time does not fall within any date range specified on a relationship, then that relationship is disabled. Relationships that have no date ranges specified are considered to always be enabled.

Active relationships will be executed and propagated, and their results returned to the end-user UI. Disabled relationships will not be executed or participate in propagation, nor will they interact in any way with the configuration.

Any date can be entered at run time, however, if no date value is entered, the current date will be used.

To facilitate model testing, Visual Modeler allows you to specify a date to use as the solve date, so that when the model is run, the engine will use that date rather than the system date or a specified date. The model test solve date is set in the Projects Settings dialog. In addition, the Model Tester itself lets you change the solve date without recompiling the model.

Setting the compile effectivity date for testing in the Projects Settings dialog

Expressions in Relationships

Note that every expression you create appears at the bottom of the Model Tester with its current value. This will help you determine what is happening when you test your model.

Expressions will evaluate without selections or user entries. If a referenced object does not have a user selection or user-entered value, the default value for the object will be used. If you don't want the expression to evaluate, you can use the "bnd()" function around the participating objects.

Note. The model will still verify as true when expression values are missing or incomplete. Because an unbound constraint is never evaluated, no conflict is generated. Use the "bnd()" function with any objects that you want to remain optional.

A pick can be a user pick, *None* on a single-select, default picks, or computer-selections. This is a limiting factor if you want to use multi-selects or if you want items to be optional. This example shows a workaround for the multi-select case, where an extra domain member *No Thanks* has been added and is selected by default.

This figure also demonstrates explanations for relationships that use expressions. The total exceeds the budget amount specified, so a message is displayed at the top and the configuration evaluates to false.

Violations
You are over budget! This is only a warning.

<p>Total: 70.0</p>	<p>RecipientAgeNumeric: 11.0</p>

Expression behavior and display at run time

Note. Advanced Configurator doesn't support date constants in expressions. Rather than using a constant, use the function `date`, `toDate`, or `intToDate` to generate the date.

For example, instead of

```
dateToInt ( 2002-10-24 )
```

use one of these:

```
dateToInt ( intToDate ( 20021024 ) )
```

```
dateToInt ( toDate ( "2002-10-24" ) )
```

```
dateToInt ( date ( 2002, 10, 24 ) )
```

Relationship Explanations

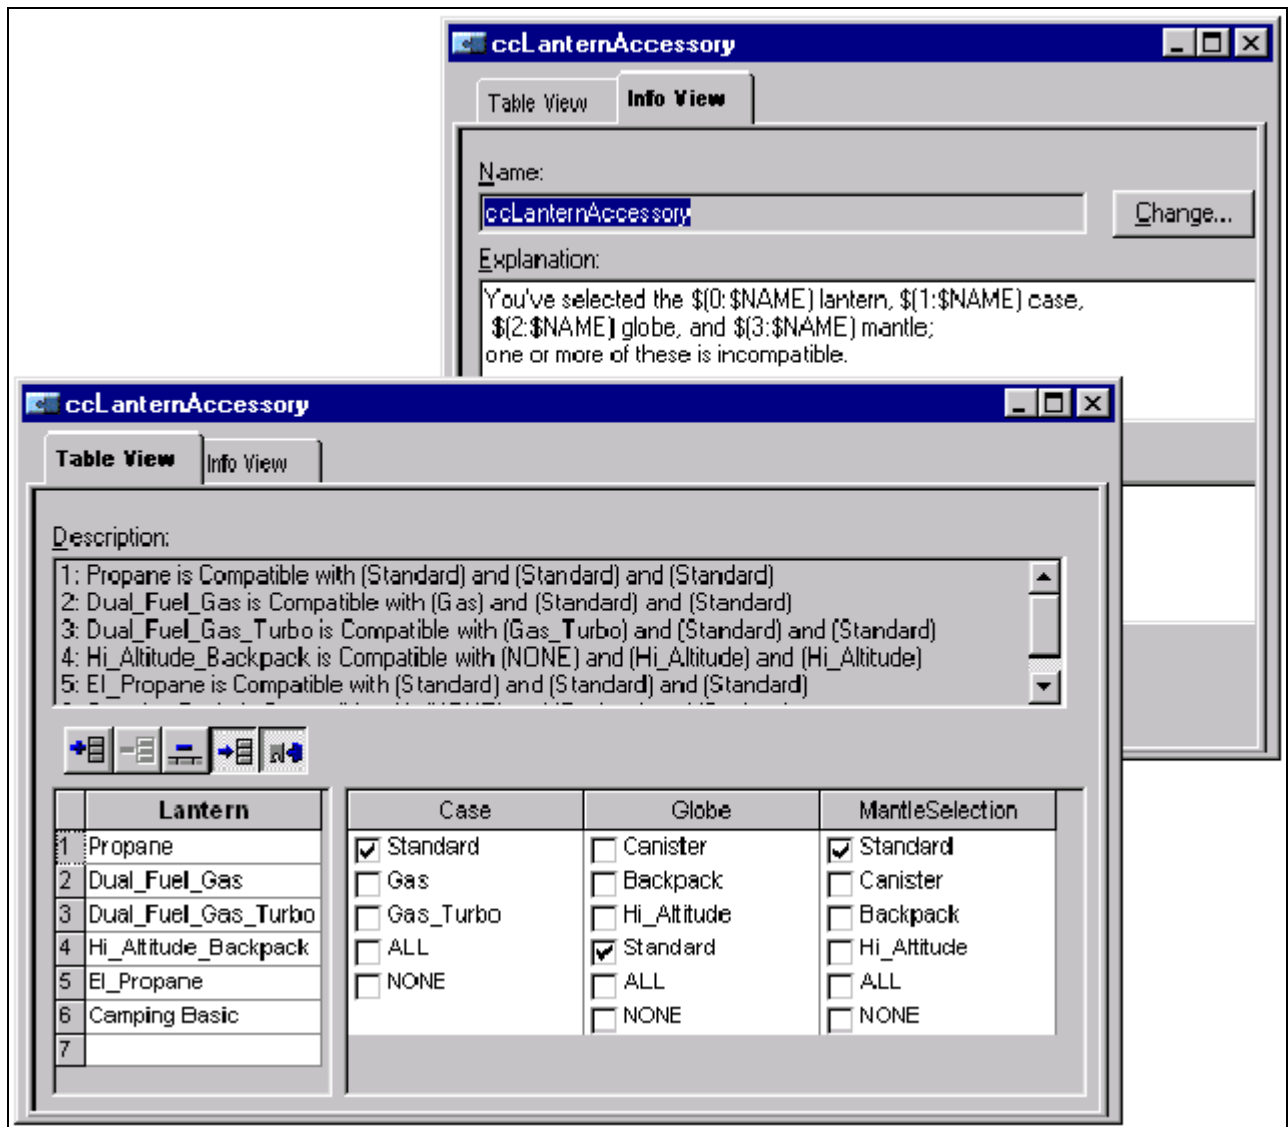

The relationship editors for constraints have a field named Explanations. For Compatibility and Requirement constraints, it appears on the Info View tab. For all others it is at the top of the form.

The Explanations field allows you to specify a message for display at run time. The explanation will only be displayed if the constraint is violated. (Text entered in the Explanations field is passed to the "Why Help" control if one is implemented for the page.)

- If the constraint is a Compatibility or Requirement constraint, the explanation will appear on all control(s) participating in the constraint and also at the page level.
- If the constraint is a Resource constraint, Elimination, or Comparison, the message appears at the page level only. In the Model Tester, this is at the top of the model.
- A parameter can be used to display the name of the pick as part of the explanation. The parameter format is `$(N:$NAME)`. You can also show other values besides the name by replacing `$NAME` with an attribute value or one of a list of provided parameters. If the domain members are external, you must refer to the database column name instead of an attribute name.

N is a number corresponding to a column in the relationship table. The left-most column is 0 and the number increments as you count to the right.

See and [Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.](#)

Explanation field with parameters

Relationship Properties

Depending on their type, relationships can have these properties:

- Enabled
- Exclusive
- Format
- Effectivity Date
- Levels

Enabled

All relationships have the Enabled property. When Enabled is True (the default) the relationship is included in the model at compile time. If Enabled is False, the relationship is ignored. This setting is useful for testing relationships.

Exclusive

The Requirement constraint has a special field named Exclusive. Setting Exclusive to True means that a control will be reserved for the RHS element in a Requirement constraint. You must define a separate constraint for each selection point that requires a reserved RHS selection. At compile time, the selection point for the RHS argument will be "cloned" for each constraint that requires it. In this manner, a selection on the RHS can make a pick on the reserved control without eliminating that option for other constraints.

Name	Type	Value
Name	String	rqt150
Filename	String	C:\Program Files\Peop
Enabled	Bool	True
Format	String	Internal
Effectivity	Editor	Edit...
Levels	Editor	Edit...
Exclusive	Bool	False

True
False

Requirement constraint exclusive property

Format

Constraints can be stored in three formats. The format can be selected as shown in the figure.

Name	Type	Value
Name	String	BaseComponentsReq
Filename	String	C:\Program Files\Peop
Enabled	Bool	True
Format	String	Internal
Effectivity	Editor	Internal
Levels	Editor	DB Table
Exclusive	Bool	SQL Query

Internal
DB Table
SQL Query

Possible format options

Internal

In the Internal format, the constraint is stored in the .cms file specified when it was created.

SQL Query

Structured Query Language (SQL) query constraints offer an alternative to constraint relationships built and maintained within the model.

For example, the standard approach to defining a compatibility constraint between a Chassis and a Drive type is to manually enter and match the Chassis types with their compatible (or incompatible) Drive types. If compatibilities change, the relationship must be edited.

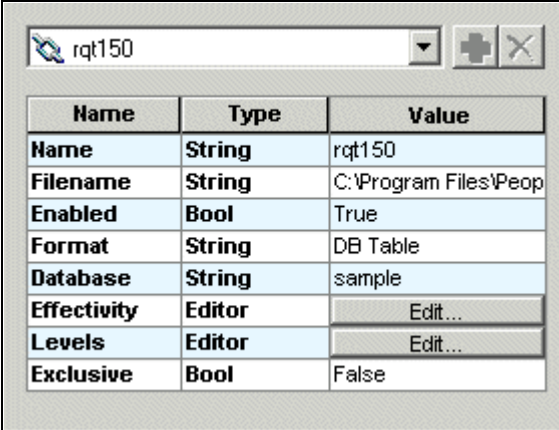

This approach, although easy to use, can prove difficult to maintain if relationships change often.

For example, if a manufacturing change causes a formerly incompatible Desktop Chassis to be compatible with the 40G Drive, you would need to edit the constraint to reflect this new relationship. For products that change often, you can use the SQL query feature, which removes the constraint definition from the model altogether and places it in a database.

See [Chapter 5, "Creating Relationships Between Model Objects,"](#) [Creating Relationships Outside the Model with SQL Queries, page 115.](#)

DB Table

When you select the DB Table option, the constraint information is saved to a table. The DB Table option can be used only for a constraint that operates on external data only; it will not work if any of the participating classes are using internally defined data. By default, a table with the same name as the constraint is stored in the current database. An additional Database row appears in the properties editor. You can specify a different database provided you have the proper ODBC driver set up for it.

Name	Type	Value
Name	String	rqt150
Filename	String	C:\Program Files\Peop
Enabled	Bool	True
Format	String	DB Table
Database	String	sample
Effectivity	Editor	Edit...
Levels	Editor	Edit...
Exclusive	Bool	False

Requirement constraint exclusive property

Effectivity Date

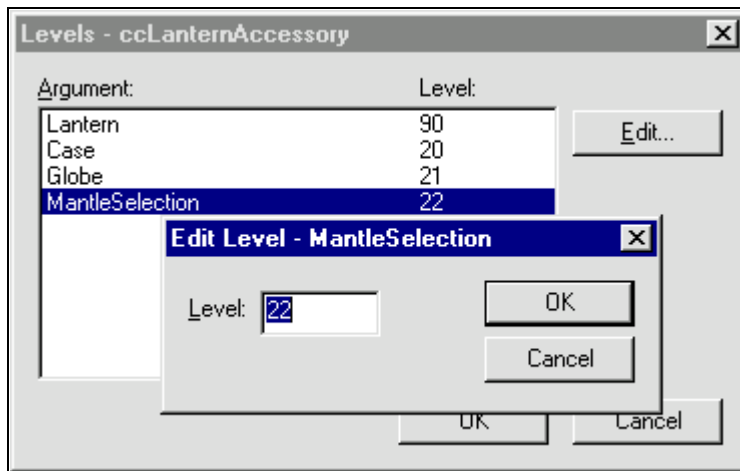

Relationships and comparisons can be set to participate in a configuration session only during one or more specified time periods. The Effectivity property allows you to enter one or more "From" and "To" date ranges. If the configuration session's "solve date," taken from the end-user's system, falls within one of the specified ranges, the relationship or comparison is made available for the session.

By default, relationships and comparisons have a single effective date with the range *1/1/1900 to 12/31/2099*.

Levels

A constraint can have an arbitrary level number assigned to each argument. The level number is only returned when an item is eliminated, including when it is in violation. JSP page designers can use the level number to decide when to suppress display of certain selections.

To set a level, click the its Edit button in the Relationship properties editor to raise the Levels dialog. Select an argument, then click the dialog Edit button to change the level.

Levels dialog

In the Model Tester, if the Show Elimination Level option is checked, the lowest level number for an eliminated item will be displayed. If no elimination level was defined for a selection, the Model Tester automatically returns 1.

Default Values Within Expressions

At run time, expressions are not evaluated until all the arguments used in the expression are bound. For selection points, binding occurs when a selection has been made; for an extern, when a value has been applied. However, preferred behavior is that expressions are evaluated all of the time unless there is a specific reason to delay evaluation until all arguments are bound.

In order to enable testing when there are unbound arguments, expressions use the defined default value for unbound arguments.

Default values allow an expression to evaluate regardless of whether all of the arguments are bound. However, if you don't want the expression to evaluate unless particular arguments are bound, use the `bnd()` function within the expression. The `bnd()` function returns the value of the first bound argument or a "not bound" status if none of the arguments are bound. If `bnd()` is used within an expression and it returns the "not bound" status, the expression will not evaluate.

Example: The following expression always evaluates and returns a result even if the selection points don't yet have selections:

```
SP1:attr1 + SP2:attr2
```

To cause the expression not to evaluate unless arguments are bound, use the `bnd()` function within it:

```
SP1:attr1 + bnd(SP2:attr2)
```

You can also use the `bnd()` function in cases where a different, non-bound value is required:

```
SP1:attr1 / bnd(SP2:attr2, 1)
```

In this case, the `bnd()` function is used to return the value "1" for the numeric attribute of SP2, if SP2 is not yet bound.

Quantities in Modeling

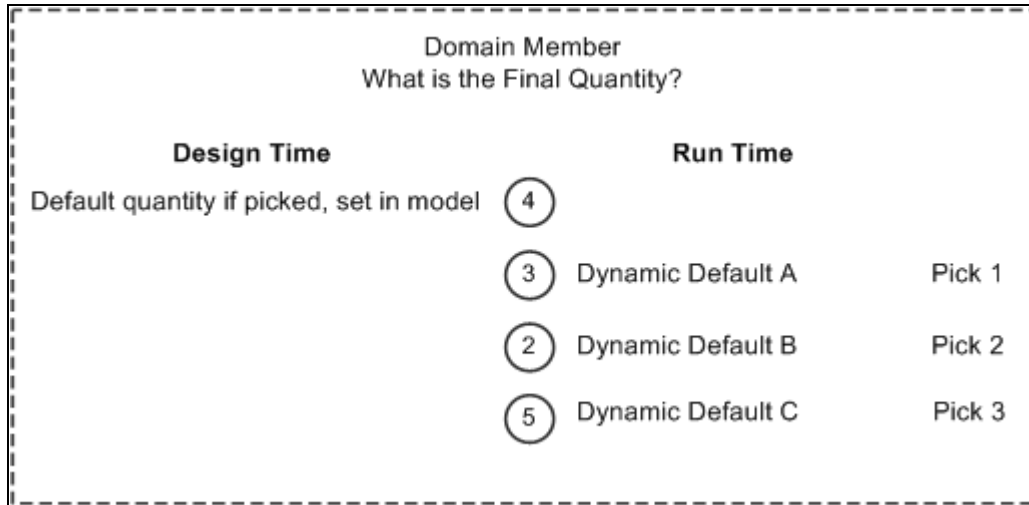

In a model, you can define quantities on a selection point and quantities for a selected domain member that allow you to implement a wide variety of quantity-dependent business logic.

Advanced Configurator quantity functionality lets you:

- Control how many different items on a control can be selected (single- and multi-select). The user or computer can select either ItemA1 or ItemA2, but not both. Or, the user can select any number of items in the control, up to the number displayed.
- Control the quantity of the domain members themselves. The user or the computer can select one or more of ItemA1.
- Do both of the above in combination:
 - One or more of ItemA1 and ItemA2.
 - One or more of ItemA1 and just one of ItemA2.
 - One of ItemA1.
 - One or more of ItemA2.
- Specify default selections based on quantities—if the user selects three of ItemA1, then select ItemB1 (or 3 of ItemB1, if desired).
- Specify default quantities based on selections—if ItemA1 is selected, then select three of ItemB2 (and ItemB3 and ItemC1, if desired).
- Limit or specify the number of items a user can select within a selection point. For example, the user can select up to three of ItemA3, and no more than one of ItemA4.

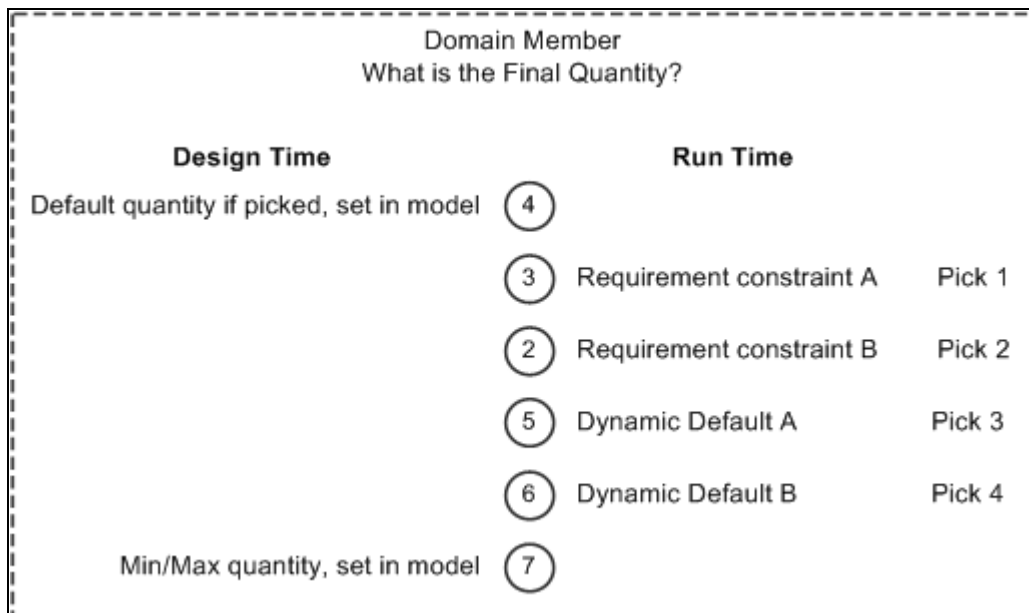

- Set up minimum default quantities to ensure that enough of ItemA3 is ordered when it is selected.
- Ensure that enough of ItemA3 is ordered when the user selects ItemB2 in another selection point, which requires a specific quantity of ItemA3.
- Use an expression to calculate the required quantity of an item that is dependent on user input.
- Determine item quantities based on domain member values.

Advanced Configurator default quantity definitions allow you to build flexibility into quantity determination for domain members that takes into account both predetermined quantity requirements and their interaction with runtime conditions. The following illustrates the problem:

Quantity determination in response to runtime events

Advanced Configurator lets you set limits on the final quantities, whatever quantity choices the end-user makes:

Dynamic process of determining the final quantity of a selected domain member

You must be able to set limits on the quantity of each domain member, yet allow for quantities that result from runtime processes, such as constraints and user entries. In addition, you may need to take into account quantities defined for its selection point.

Defining quantities in models depends on these basic concepts:

- Quantity defaults for individual domain members control how many of the selected item is chosen—2 of ItemA, or 0 of ItemB.
- A quantity defined for an entire control—in the model represented by the selection point—determines how many of the control's items can be selected. If the quantity is one, it is a single-select control; more than one, a multi-select control.
- You can set default quantities at design time whose default values do not change during run time, acting as absolute values for calculating a final quantity that takes into account quantities generated by run time events such as user picks and constraints.

Static Default Quantities

The quantity of the selection DomainMemberX can be affected by static default quantities—the default value you assign to it during modeling. An example is the quantities assigned automatically when a domain member is selected.

For example, in a network model, NodeY always requires at least two Routers, more if certain other components are selected in combinations determined by various constraints. By setting a static default of 2 on the NodeY domain member, and giving it a Quantity Policy of MIN, you can ensure that if it is selected, it will be ordered in a quantity of at least 2. Static default information for a selection point is applied whenever a dynamic default or Requirement constraint selects any domain member of that selection point, provided there are no user selections.

In addition, if the other nodes in the Node selection point—NodeX and NodeZ—have the same MIN(2) requirement, you can set the *Use Quantity Policy for all Domain Members* option as a "blanket" default.

See Also

Chapter 2, "Understanding Modeling," Interaction between Default Quantities and Min/Max Settings at Run Time, page 44

Dynamic Default Quantities

The value of dynamic default quantities is determined at run time in response to expressions or dynamic default constraints. Expressions can be included in a quantity policy—*Overridable $f(x)$* , *Min of $f(x)$* , *Max of $f(x)$* , and *Sum $f(x)$* .

The Requirement constraint and Dynamic Default relationships select domain members in response to user or computer picks during run time. Quantity for the default-selected domain member is 1, unless you specify a new quantity and a new quantity policy. Quantities are defined on the table editor for the relationship.

A dynamic quantity definition would be needed in the case of a computer model. The model specifies by a dynamic default that when BoardA is selected, the Advanced Configurator should select FanA as well. Thus, a computer-select occurs for FanA, with a quantity of *1*. (This computer-select occurs unless the selection causes a conflict with another selection that is either required or user-selected.) However, BoardB requires 2 of a different fan, FanB, so quantity must be added to the default definition of the BoardB/FanB requirement. In the relationship editor, the constraint's RHS for BoardB would be *Min of 2* for FanB.

Only selection points with Quantity = *True* are settable.

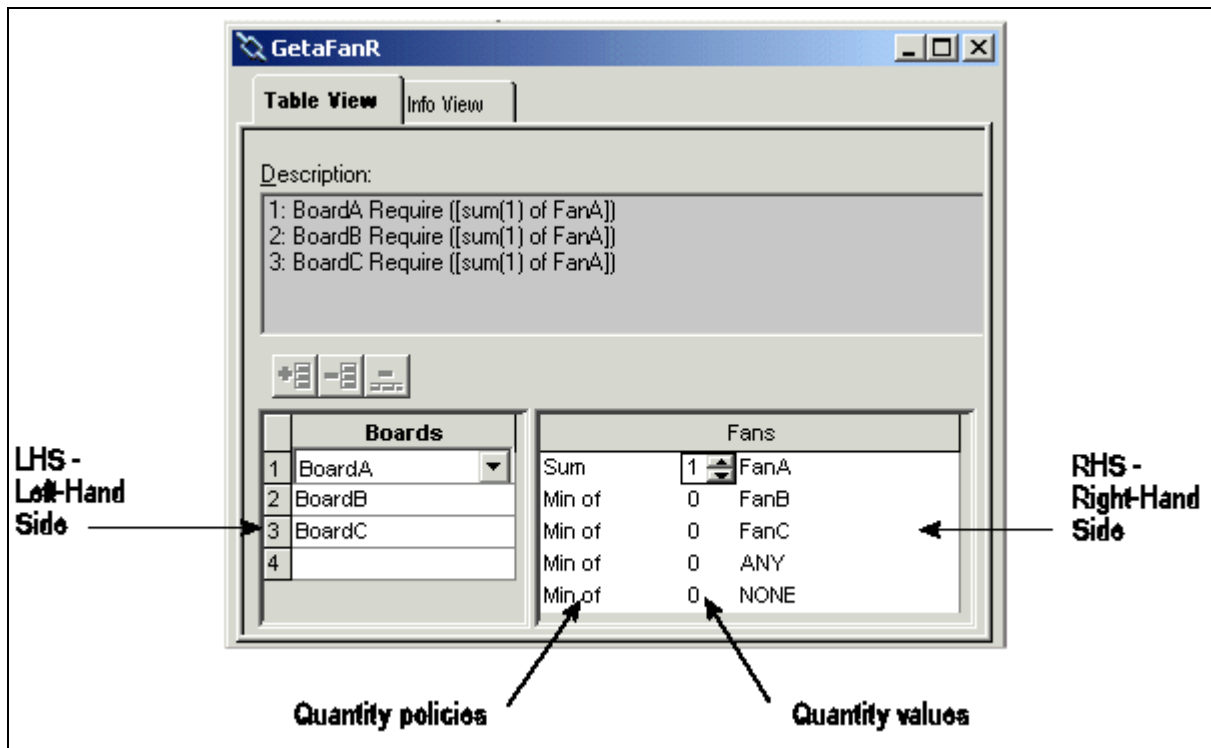

Multiple Selections on a Single Domain Member

When there is the potential for multiple default selections on the same domain member, you must set up contingent definitions at design time that correctly calculate the final quantity no matter what or how many of the domain members are selected in response to runtime criteria. An example is a network model that contains server boxes requiring chassis. The chassis type (domain member) and quantity depend on the number of slots the server requires, as one chassis provides two slots and the other chassis provides four. When the user selects the desired server boxes, the proper chassis type(s), in the required number, are default-selected. In such a case, the quantity of chassis' can be the largest of the default quantities (minimum value), it can be summed, or it can be a combination of the two.

Order of Evaluation

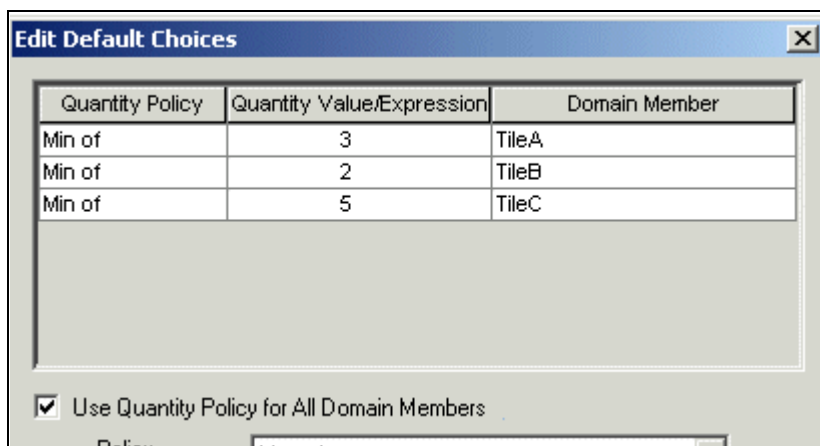

When a domain member has multiple default quantities, the Advanced Configurator evaluates the selections in a predetermined order.

Step 1—Default quantities for the domain members are evaluated first to arrive at a single value according to the policy: the least value (*Min of*); the greatest (*Max of*), and total (*Sum*). These are specified in the relationship editor:

Relationship editor showing quantity settings for BoardA

Step 2—The domain member's static Min/Max setting, if any, is applied: adjust up to the minimum value (*Min of*), adjust down to the maximum value (*Max of*), total (*Sum*). If *Overridable* is the policy, this step is not performed. Policies are specified in the Defaults editor:

Default editor and static default settings

Step 3—If *Use Base Quantity Policy for All Domain Members* is specified, it is applied against the result of Step 2 in the same way as the domain member's static policy.

☒ Use Quantity Policy for All Domain Members

Policy: Max of

Quantity: 5

OK Cancel

Default editor and dynamic default settings

Step 4—Step 3 yields the final calculated value. If a user enters a value, it overrides this value.

Example 1: Taking the largest quantity of the selected domain members

At Design Time

If you need to define default quantities for domain member A on a selection point so that the final quantity after runtime selections was at least n, the settings in the defaults editor are:

$$A_{\text{Default}} = \text{MIN}(2)$$

(The default minimum quantity for domain member A when a runtime selection is NOT made, or when a selection IS made but is less than n. Static default.)

$$A_{\text{User}} = \text{MIN}(x)$$

(The default minimum quantity for domain member A when the user selects A and enters a quantity for it (using a control with quantity). It differs from $A_{\text{Default}} = \text{MIN}(n)$ in that the default quantity is left to the user.)

$$A_{\text{DynamicDefault}(B)} = \text{MIN}(3)$$

$$A_{\text{DynamicDefault}(C)} = \text{MIN}(5)$$

(The default minimum quantity for A when domain member B or C is picked by an expression or constraint triggered during run time.)

Steps in calculating the final quantity:

- Selections are made.
- The runtime quantities for each A selection are compared and the largest is applied against the static default $A_{\text{Default}} = \text{MIN}(2)$.
- If it is equal to or greater than 2, the runtime value will be A's final quantity; if not, $A_{\text{Default}} = \text{MIN}(2)$ is applied, and A's final quantity is 2.

At Run Time:

If the user picks *none*, then $A = 2$.

If the user picks *B*, then $A = 3$.

If the user picks *C*, then $A = 5$.

If the user picks *B* and *C*, then $A = 5$.

If the user picks *A [4]* and *B*, then $A = 4$.

If the user picks *A [4]* and *C*, then $A = 5$.

Example 2: Taking the sum of the selected item(s)*At Design Time*

Using the SUM policy, you can specify that the final quantity of a selected item is the sum of its default-selected quantities. As in the previous example, you can ensure that if no items are selected during run time, A will nonetheless be assigned a quantity value (ADefault).

$$A_{\text{Default}} = \text{MIN}(2)$$

(The default minimum quantity for domain member A when a runtime selection is NOT made, or when a selection IS made but is less than n. Static default.)

$$A_{\text{User}} = \text{MIN}(x)$$

(The default minimum quantity for domain member A when the user selects A and enters a quantity for it (using a control with quantity). It differs from ADefault = MIN(n) in that the default quantity is left to the user.)

$$A_{\text{DynamicDefault}}(B) = \text{MIN}(3)$$

$$A_{\text{DynamicDefault}}(C) = \text{MIN}(5)$$

(The default minimum quantity for A when domain member B or C is picked by an expression or constraint triggered during run time.)

Steps in calculating the final quantity:

- Selections are made.
- The quantities of each A selection are totaled.
- The total is applied against the static default ADefault = MIN(2).
- If it satisfies static default policy, the runtime sum is A's final quantity; if not, ADefault = MIN(2) is applied.

At Run Time:

If the user picks *none*, then $A = 2$.

If the user picks *A*, then $A = 2$.

If the user picks *B*, then $A = 3$.

If the user picks *C*, then $A = 5$.

If the user picks *B* and *C*, then $A = 8$.

If the user picks *A* and *B*, then $A = 3$.

If the user picks *A* [4] and *B*, then $A = 4$.

If the user picks *A* [1] and *C*, then $A = 5$.

Example 3: Figuring quantities using attribute values and expressions*At Design Time*

A's final quantity can be based on an attribute value or one derived from an expression. For example, using attributes to define Min/Max limits allows you to specify quantity limits on a per-domain member basis for external data. Expressions in defaults allow you to determine the quantity to default dynamically based on an external parameter, such as a value entered via an extern or an equation. Similarly, expressions in Min/Max limits enforce dynamic quantity limits.

The following example's definitions includes a dynamic default on domain member A that is the sum of all the values of the *A_Needed* attribute of the B domain members selected.

$A_{\text{Default}} = \text{MIN}(2)$

(The default minimum quantity for domain member A when a runtime selection is NOT made, or when a selection IS made but is less than n. Static default.)

$A_{\text{User}} = \text{MIN}(x)$

(The default minimum quantity for domain member A when the user selects A and enters a quantity for it (using a control with quantity). It differs from $A_{\text{Default}} = \text{MIN}(n)$ in that the default quantity is left to the user.)

$A_{\text{DynamicDefault}}(B) = \text{SUM}(B:A_{\text{Needed}})$

(The default quantity for A when domain member B is picked during run time. The quantity is the value of B's attribute *A_Needed*. The SUM policy indicates that the value is to be added to any other default value for A in calculating A's final quantity.)

$A_{\text{DynamicDefault}}(C) = \text{SUM}(5)$

(As above, with the value predetermined at design time to be 5.)

$A_{\text{DynamicDefault}}(D) = \text{MIN}(\text{exp_name})$

(The default quantity for A when domain member D is picked during run time. The quantity is the value of an expression defined in the Expression editor. The MIN policy indicates that the final value must be equal to or larger than the value given by the expression.)

$(\text{exp_name}) = 3$

$B1, A_{\text{Needed}} = 1$

(An instance of B where the attribute *A_Needed* has a specific value.)

$B2, A_{\text{Needed}} = 2$

$B3, A_{\text{Needed}} = 3$

$B4, A_{\text{Needed}} = 4$

Steps in calculating the final quantity:

- Selections are made.
- Add the values for ItemA's SUM policy selections.
- Take any values with MAX policies and compare them against the specified MIN values, including the static default $A_{\text{Default}} = \text{MIN}(2)$ to check that the runtime value satisfies the minimum quantity requirements.
- If the MIN requirements are met, apply the calculated runtime quantity. If MIN requirements are not met, apply the quantities specified for the MIN defaults.

Example 3: Figuring quantities using attribute values and expressions

At Run Time:

If the user picks *B1*, then $A = 1$.

If the user picks *B2*, then $A = 2$.

If the user picks *B1* and *C*, then $A = 6$.

If the user picks *B4* and *C*, then $A = 9$.

If the user picks *A[4]* and *B3*, then $A = 4$.

If the user picks *A[3]* and *B4*, then $A = 4$.

If the user picks *A* and *D*, then $A = 3$.

If the user picks *B1* and *D*, then $A = 3$.

If the user picks *B2* and *C* and *D*, then $A = 7$.

Understanding Minimum and Maximum Selections and Limits

Advanced Configurator allows you to set constraints based on the minimum and maximum quantity entered for domain members and on the minimum and maximum number of selections made within a selection point.

Min/Max limits can be specified on these Visual Modeler objects:

- Selection points
- Domain members

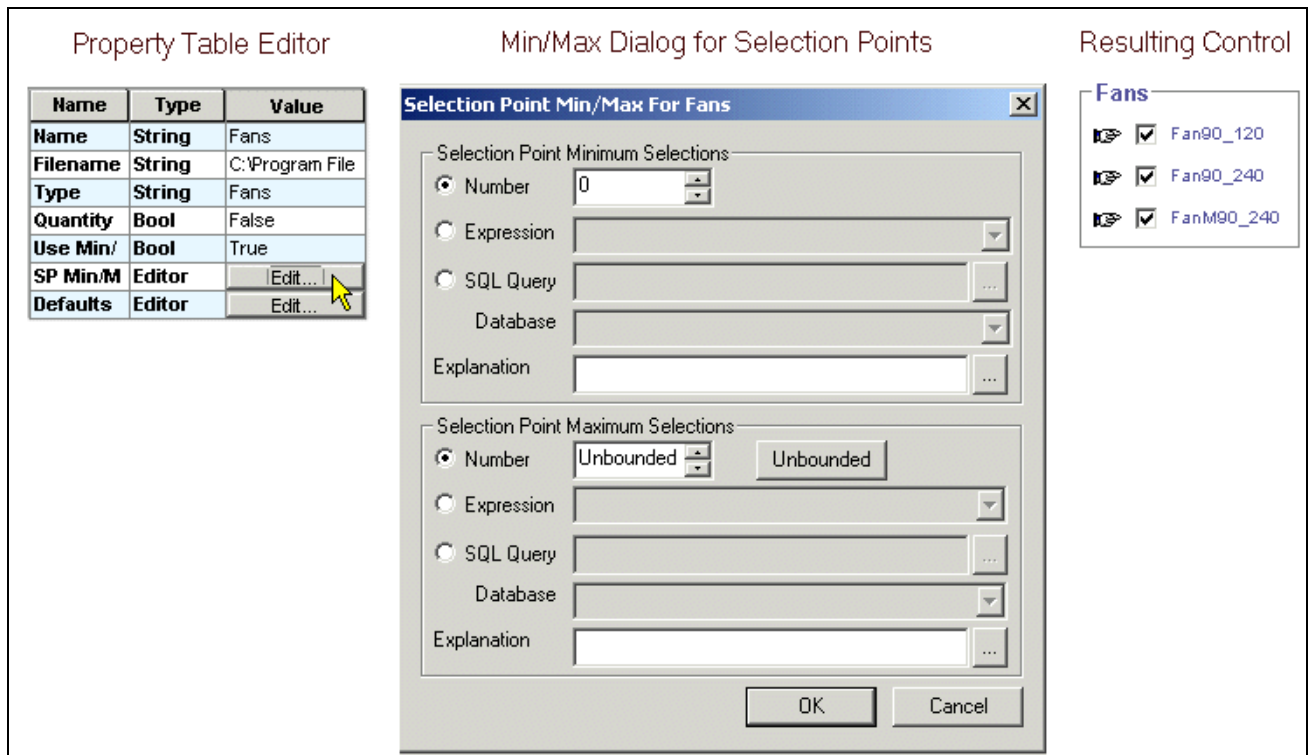

Selection Point Min/Max

Min/Max limits on a selection point determines whether its control is single-select or multi-select, and if multi-select, how many of the domain members can be selected.

You can use any of the following to input min/max limits:

- An absolute number (for a static, known check).
- A database reference.
- A reference to an expression defined elsewhere in the model.

Note. With dynamic inputs such as the result from a database query or an expression, it is possible for a single-select control to be re-specified a multi-select control during a configuration session when the SP Max changes from 1 to >1. When the Max limit is specified in this way, the control will behave like a multi-select that is limited to a single selection, versus a true single-select. Limitations that apply to multi-select selection points will apply even when the maximum number of selections is one. For instance, multi-selects do not allow violation explanation substitutions, and there are limitations on how they can be used in constraints.

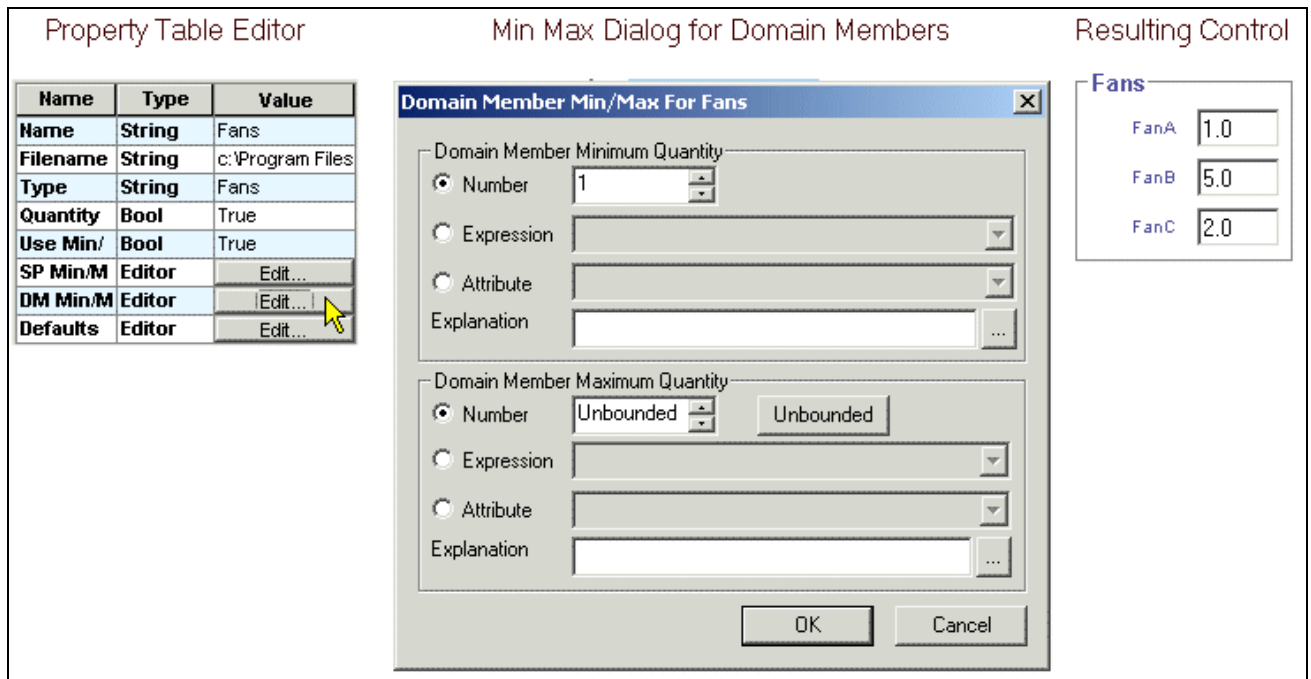

Selection point Min/Max

Domain Member Min/Max

Min and Max limits on domain members determine how many of each domain member can be ordered if selected.

Values for domain member Min and Max limits are input from:

- An absolute number entered by the modeler.
- A reference to an expression.
- A domain member attribute whose type is Int or Float.

Domain member Min/Max

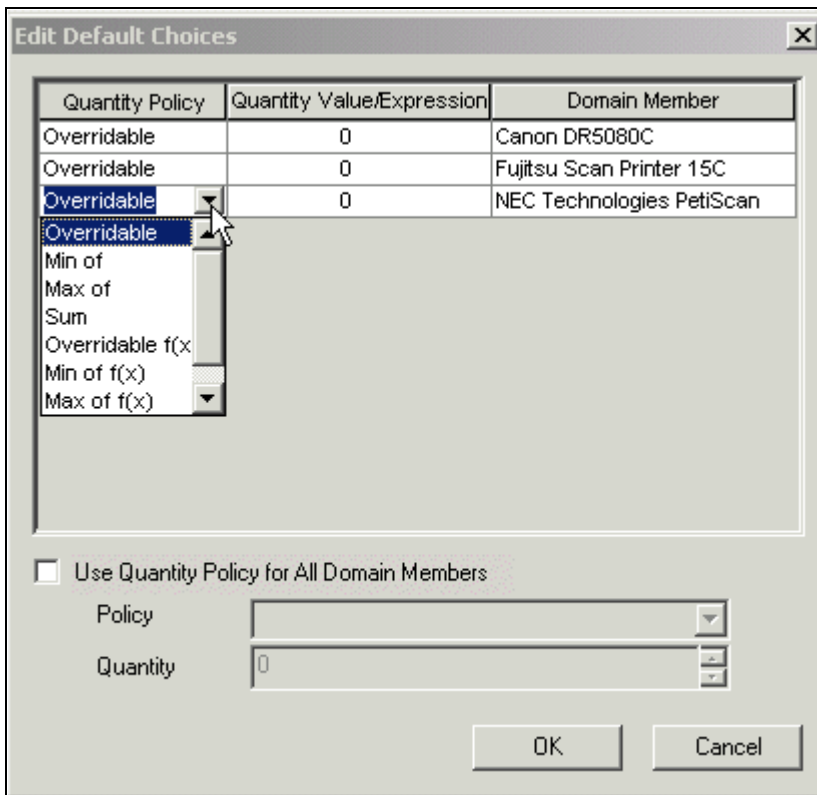

Note. The Min/Max function applies to the number of selections on a selection point that can be specified at the selection point level or the quantity that can be entered for a selected domain member at the domain member level, or both. It is a separate function from the Min of and Max of quantity policies of the Default Quantity functionality described in the previous section.

Interaction between Default Quantities and Min/Max Settings at Run Time

Min/Max settings add another aspect to the runtime process of determining final quantities on selected domain members.

When a selection point has both default quantity properties and Min/Max properties defined on it, specific runtime behaviors apply.

The Quantity policy—the manner in which to apply the default value—for a static default can be either Overridable, MIN, MAX, or SUM. If MIN, MAX or SUM is specified, then the static default is used in conjunction with any dynamic defaults and requirement constraints that select the same domain member. By default, the Quantity Policy for a static default is Overridable (meaning, "do not apply the value if run time selections assign a quantity").

The quantity policy applied to the domain members of a selection point

Static default information for a selection point is applied whenever a dynamic default or a requirement constraint selects any domain member of that selection point and there are no user-selects. A static default on a specific domain member applies only to that domain member.

Default quantities, whether static or dynamic, are not applied if they would cause any constraint to be in violation.

Ultimately, a user-specified quantity overrides any quantities specified by static defaults, or assigned by dynamic defaults during run time. Advanced Configurator allows the user to enter a quantity even if it violates a constraint, a quantity default, or min/max settings. However, the appropriate violation explanation will be displayed.

Note. When you use the Model Tester, you may observe that when you attempt to undo or back out of a configuration pick sequence, all picks on the control disappear rather than just the expected last pick. This occurs because the Configuration Engine is stateless; it receives all picks at one time, at each submission, and doesn't know which was the last pick. By turning off Auto-Submit when you test the selection point on the Model Tester, you can observe true runtime behavior.

Minimum Violation Explanation and Incomplete Configuration Explanation

Advanced Configurator distinguishes between two very similar violation circumstances involving quantities on a selection point.

The project setting "Incomplete Configuration Explanation" is similar to the Min/Max violation explanation in that it alerts the user of a non-valid configuration condition.

These two explanations differ in the circumstances in which they are presented.

If a completeness check operation is requested, the Incomplete Configuration Explanation is shown when no selections have been made on a required selection point.

If selections have been made on the selection point, but the number of selections doesn't satisfy the minimum value specified, the selection point Minimum Selection Explanation will be shown rather than the Incomplete Configuration Explanation.

See Also

[Chapter 3, "Setting Up the Modeling Environment," Specifying Model Project Settings, page 65](#)

Creating Parameterized Explanations

Advanced Configurator allows you to offer specific information to users when their picks violate a constraint based on a numeric relationship. Using the parameters representing objects such as maximum quantity allowed, you can write a violation explanation that describes the violation more specifically than does a generic text message.

You can include parameters in the Explanation fields of all constraint editors, and in the SP and DM Min/Max editor dialogs.

You can also represent external objects.

If the control is single-select, you can parameterize an explanation specific to the domain members in violation. Parameter substitution can not resolve the domain members in multi-select controls, so use on multi-select controls is limited to the selection point level Min and Max Value, selection point Name, or an expression value.

General syntax is:

```
$(replacement_specification)
```

`replacement_specification` is either

`n:attribute_identifier` or `expr:expression_identifier`.

`n` is the positional identifier for the class within the relationship ($0 - n$ left to right in the relationship).

Note. Use $n = 0$ for SP Min/Max and DP Min/Max explanations.

`attribute_identifier` is a class attribute name or one of the reserved names from the list in the table below. If the objects are external, you must refer to the database column name instead of an attribute name.

`expression_identifier` is an expression name.

The following table describes the reserved parameters and indicates whether each is available for single- and multi-select controls.

Note. Please observe letter case as shown in the syntax column for each variable (expression and attribute names are lower case; all others are upper case).

Parameter name	Syntax	Single-select control	Multi-select control
Selection point name	\$(n:\$DPNAME)	yes	yes
Selection point Min Value	\$(n:\$MINCHOICES)	yes	yes
Selection point Max Value	\$(n:\$MAXCHOICES)	yes	yes
Domain member name	\$(n:\$NAME)	yes	no
Current number of selections made in the Selection Point	\$(n:\$CHOICES)	yes	no
Selected domain member Min Value	\$(n:\$MINQTY)	yes	no
Selected domain member Max Value	\$(n:\$MAXQTY)	yes	no
Selected domain member quantity	\$(n:\$QTY)	yes	no
Domain member attribute value	\$(n:attributename)	yes	no
Expression value	\$(expr:exprname)	yes	yes

For example, in a requirement constraint, messages are:

Explanation syntax The selected base requires the \$(1:Description) power cord and \$(2:Description) chassis.

Run-time display The selected base requires the Z40-15 power cord and the 8R_KU chassis.

In another example, in a DP Min, messages are:

Explanation syntax The value of \$(0:\$DPNAME) must be between \$(expr:refract_min) and \$(expr:refract_max).

Run-time display The value of LensRefraction must be between 1.0 and 4.0.

Optimizing Performance and Minimizing Model Maintenance

To improve performance and minimize effort expended on maintaining a model, consider these tips:

- Plan your model hierarchy so that you can use attributes efficiently.

- Stabilize attribute names, class names, and selection point names before creating constraints or expressions.
- If a model uses numerous multi-select controls, it is possible for constraints against the same control to conflict with other constraints to the point that all items on a control are eliminated. The following practices can reduce the occurrence of this problem:
 - Articulate the class hierarchy to a greater degree. If a multi-select control contains many domain members that are known to conflict, create subclasses and group the domain members in compatible sets. Alternatively, separate single-select and multi-select items.
 - Write more constraints. Instead of writing a single large constraint with many columns and rows, write more specific classes and constraints.
- Do not use a directional compatibility constraint if a multi-select is on the right-hand side. A directional compatibility with a multi-select on the RHS is ignored because every combination is considered valid. If a multi-select is required on the RHS, write the constraint as a directional non-compatibility constraint or a Requirement constraint.
- If possible, use a Requirement constraint instead of a Compatibility constraint. Because a Requirement constraint does not eliminate, there is less chance of conflicts between constraints.
- For all directional constraints (compatible, non-compatible, requirement, and dynamic default), if there are multiple arguments on the RHS, there is no explicit relationship between them. So, instead of writing multiple constraints against a single class, it is more convenient to write a single constraint with multiple arguments on the RHS.

Using the Sample Models

Visual Modeler is shipped with these example models:

- A component model called Sample, which you can load by choosing the Sample button in the Visual Modeler launch screen.
- A telecommunications compound model called TelcoSampleCompoundModel, containing three component models TelcoComp, TelcoCompCircuit, and TelcoCompHub.

The Modeling Process

Defining a robust model of a product or service requires some or all of these steps:

1. Use Visual Modeler to:
 - Build a class structure that represents data relationships in a configuration problem.
 - Define class attributes, create domain members, and provide attribute values in the model, or bring in domain members and attribute values from an external source, such as a database or the user.
 - Write relationships between classes and class attributes on a component model.
 - Specify quantities for default selections and define quantity behaviors that calculate a quantity at run time.
 - If supported version control software is available and connected in the Visual Modeler, you can interact with the version control software at any time during model development.
 - If you are building a compound model, create configurable components and associate each with a component model, then create the relationships between the component models.
2. Connect to the Configurator engine to compile the model and launch the Model Tester.
3. In the Model Tester, verify that relationships work properly on runtime controls.
4. Using model information from the Visual Modeler source, use PeopleSoft Extensions for DreamWeaver to develop JSP pages or use those provided with PeopleSoft Order Capture.

Model Tester

Included with the Visual Modeler install is a web-based test tool that renders the selection points in a pre-formatted form when you compile and run the model. Using it, you can test most facets of model behavior without building your own test UI. The Model Tester lets you verify the validity and behavior of relationships, data input and handling, error recognition, and control behavior.

See [Chapter 3, "Setting Up the Modeling Environment," Using the Model Tester, page 72.](#)

Interfacing with Third-Party Tools

This section lists Advanced Configurator interfaces with industry-standard applications.

Microsoft SQL Server, Oracle Databases, and IBM DB2

Visual Modeler can query tables in Microsoft® SQL Server™, Oracle™, or IBM® DB2® databases. In addition to obtaining domain members from a database, you can write model constraint information to a database table, or read constraint information from a database.

MacroMedia DreamWeaver

Visual Modeler creates an XML file that contains information about the model that can be used to lay out controls at run time. Advanced Configurator provides extensions to MacroMedia® DreamWeaver® so that you can use this information to create JSP pages.

See and [Chapter 27, "Using the Page Editor Extensions for Dreamweaver," page 385.](#)

Source Control Interfaces

The Visual Modeler uses a standard Microsoft interface to access compatible configuration management software. Microsoft® Visual SourceSafe™, Rational ClearCase®, and Merant™ PVCS are verified as being compatible.

See and [Chapter 3, "Setting Up the Modeling Environment," Source Control Software, page 52.](#)

Chapter 3

Setting Up the Modeling Environment

This chapter discusses:

- Connecting to third-party software.
- Connecting to a database from Visual Modeler.
- Getting started with Visual Modeler.
- Understanding project files.
- Importing and exporting models.
- Compiling a model.
- Using the Model Tester.
- Interfacing with third-party tools.

Common Elements in this Chapter

Open the Overview Window.

Save and compile the model.

Compile and run the model.

Open the Viewer dialog, which contains the Find tab, where objects are listed.

Standard Windows "show and hide" indicator buttons. Appear in the model structure view to control display of hierarchy items. Also indicate that the domain members of the node are internal.

In the model structure view, this icon appears next to external domain members. Internal domain members are indicated by the plus and minus symbols.

Add button for the component properties table. Adds rows—properties—to a class or subclass.

Add button for the component properties table. Adds a row—properties—for defining attributes on selection points.

Connecting to Third-Party Software

This section discusses setup procedures for:

- Source control software.
- Database interface configuration.
- Connecting to a database from Visual Modeler.

Source Control Software

The Visual Modeler supports the latest version of the Microsoft Source Control (MSC) interface. An installed source control application that complies with the correct MSC version is shown as an option in the Visual Modeler.

1. Create or obtain a user account and login for your source control tool.
2. In Visual Modeler, go to Tools, Options, then click the Source Control tab.

3. Choose a provider from the "Source Control Provider to Use" drop down. This drop down displays MSC-compatible applications installed on your system.

Optionally, select the source control options best suited to your project:

Option	Explanation
<i>Get files when opening the workspace.</i>	Automatically get the latest versions of all .cms files in this project whenever a workspace is opened.
<i>Check in files when closing the workspace</i>	If this option is checked, you must remember to save before closing the workspace. If files are saved before the workspace closes, the all files will be checked in. If unsaved files are open when the workspace is closed, the files will be checked in, but any files previously not saved will be checked out again.
<i>Prompt to add files when inserted</i>	When a .cms file is inserted into the project, prompt to add the file to source control.
<i>Perform background status updates</i>	Not all source control tools support this option. If background status updating is supported, the IDE can change the appearance of a file in the File View when a file under source control is altered by an external checkin.
<i>Use dialog for checkout</i>	Specify that a comment dialog automatically appears when a file is checked out.
<i>Add new projects to source control</i>	Automatically add new projects (.csp file) to source control.
<i>Automatically add new files to source control</i>	Automatically add new .cms files to source control.

4. Enter the source control login name in the Login field, then click OK. You will be notified that the provider change will not take effect until you restart the Visual Modeler. The changes will be available when the Visual Modeler is restarted.

Once the source control tool is selected, it is possible to set Advanced options. Select Tools, Options then click the Source Control tab. Click the Advanced button. An Options window appears. Consult your source control documentation for information on the options displayed.

Database Interface Configuration

Advanced Configurator supports Microsoft SQL Server, Oracle, IBM DB2 database connections.

Note. If your database is Oracle, you must install an Oracle client on the machine where Visual Modeler is installed. Your system will then have the Oracle ODBC Driver, which ensures compatibility with Oracle.

Before proceeding, you need certain system information:

- The database name, username/login, and password. Consult your database administrator for login and password information. At a minimum, you must have read and write permission for the database.

- The name (machine ID) of the machine that the database server resides on, and the port it uses.
- The name of the machine that WebLogic is installed on, and the port it uses. If the defaults were accepted during Advanced Configurator installation, the default port number is 7777.

The Visual Modeler relies on the ODBC Data Source Administrator for connection information. Setting up an ODBC data source allows you to view external domain members in the Visual Modeler.

See [and Chapter 3, "Setting Up the Modeling Environment," Connecting to a Database from Visual Modeler, page 56.](#)

To compile a model, Advanced Configurator uses the Java Naming and Directory Interface (JNDI) Database connection. This connection requires customizing two properties files.

See [and Chapter 3, "Setting Up the Modeling Environment," Configuring JNDIDBName.properties, page 55](#)

.

Configuring an ODBC Data Source for Microsoft SQL Server

Use the Windows data source wizard to configure an ODBC data source.

To connect Advanced Configurator to Microsoft SQL Server:

1. Open My Computer, Control Panel, Administrative Tools, and Data Sources.
2. Click the Add button.
3. Select a driver from the list, then click Finish. The data source connection dialog appears.
4. Enter the indicated information in the fields. Choose a name carefully. The name is case-sensitive, and it will be used to identify the data source both in the properties files and in the Visual Modeler database interface.
5. Click Finish. The authentication dialog appears.
6. Select an authentication option. If a password is not required, click "With Windows NT authentication of the login ID", then click Next.

If the database has a login and password, click "With SQL Server authentication using a login ID and password entered by the user," then click "Connect to SQL Server to obtain default settings for the additional configuration options." Enter the database login and password, then click Next. The remaining screens address DSN Configuration options that are not critical for the connection. Click Next, then on the last screen click Finish.

7. Configure JNDIDBName.properties.

See [and Chapter 3, "Setting Up the Modeling Environment," Configuring JNDIDBName.properties, page 55.](#)

Configuring an ODBC Data Source for Oracle

Use the Windows data source wizard to configure an ODBC data source.

To connect Advanced Configurator to an Oracle data source:

1. Open My Computer, Control Panel, Administrative Tools, and then Data Sources.

2. Click the Add button.
3. Select a driver from the list, then click Finish. The data source connection dialog appears.
4. Enter the indicated information in the fields. Choose a name carefully. The name is case-sensitive, and it will be used to identify the data source both in the properties files and in the Visual Modeler database interface. In most cases it is appropriate to accept the default settings for Database Options, Application Options, and Translation Options. Consult your database administrator. Click OK.
5. Configure JNDIDBName.properties.

See [and Chapter 3, "Setting Up the Modeling Environment," Configuring JNDIDBName.properties, page 55.](#)

Configuring an ODBC Data Source for IBM DB2

To connect Advanced Configurator to an IBM DB2 data source:

1. Launch the IBM DB2 setup tool (Programs, IBM DB2, Set-up Tools, Configuration Assistant).
2. Select Selected, Add Database Using Wizard. The wizard appears.
3. In window 1, Source, select Manually configure a connection to a database and click Next.
4. In window 2, Protocol, select your protocol.
5. In window 3, assign the appropriate values to the fields.
6. In window 4, Database, enter the database name and alias.
7. In window 5, Datasource, select Register this database for ODBC and As system data source. Enter a value for Data source name.
8. In window 6, Node Options, specify the operating system and the remote instance name.
9. In window 7, System Options, specify System name, Host name, and Operating system.
10. In window 8, Security Options, specify Use authentication in server's DBM Configuration. Click Finish. The wizard closes and the Configuration Assistant reappears with the connection listed in the pane.
11. Select Selected, Test Connection to verify the connection.

Configuring JNDIDBName.properties

By default JNDIDBName.properties is located on the Advanced Configurator Server:

```
C:\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\config
```

Note. You may not need to hand-edit this file. If you are using data from the database specified during installation the file will be updated based on the information entered with a (datasource) name of "PSCFG."

Only the portion of the file relevant to your database needs to be changed. All entries except the machine name are case-sensitive and must match your environment exactly. Substitute your information as follows:

1. Replace *sqldb*, *oracledb* or *DB2DB* with your data source name. This name is defined when the ODBC driver is configured. The "name" (the portion before the first '.') should match the name of the data source specified for the classes in the model.

See and Chapter 3, "Setting Up the Modeling Environment," Database Interface Configuration, page 53.

2. Replace username and password with the user name or login defined for your database account. The square brackets [] used to delimit the sample must be deleted.

If you specified "Windows NT authentication using the network login ID," the fields may be left blank.

3. Save a copy of the customized.properties file in a location outside the Advanced Configurator tree. The properties file will be overwritten if an upgrade is installed.
4. Bounce the server so that JNDIDBName changes can take affect.

The JNDIDBName properties file is shown below.

Begin =====

```
# example for setting up a SQL server database with the Microsoft driver
# SQL server default PortNumber is 1433
sqldb.url=jdbc:sqlserver://[ServerName]:[PortNumber];DatabaseName=[Database=>
Name];sql70=true;charset=Cp1252
sqldb.driver=com.microsoft.sqlserver.jdbc.SQLServerDriver
sqldb.username=[username]

Cp1252
PSCFG.password=satst
```

End =====

Connecting to a Database from Visual Modeler

Once the ODBC data source and the properties files have been configured, your environment is ready to support a database connection within Visual Modeler.

Database connection involves two steps:

- Specify a database connection.

- Specify a default database.

See Also

[Chapter 3, "Setting Up the Modeling Environment," Database Interface Configuration, page 53](#)

[Chapter 3, "Setting Up the Modeling Environment," Configuring JNDIDBName.properties, page 55](#)

Specify a Database Connection

To specify a database connection:

1. In the Visual Modeler, select Project, Database References. A dialog for specifying the default database appears.
2. Click Add. A dialog for specifying or modifying a database connection appears.
3. Type a name in the Alias field. This is a name of your choice for referring to the database from within this model; it will be displayed in the drop down on the SQL query dialogs.
4. Type in the Data Source Name exactly as specified in the data source configuration .
5. Type in the Login ID and password defined for the database. These fields can be left blank if the database uses the Windows NT login. Press OK to view a dialog for setting the default database. The dialog for selecting the default database reappears, now displaying the database alias you specified.
6. To add another database, repeat steps 2 through 5.

Specify a Default Database

To specify a default database:

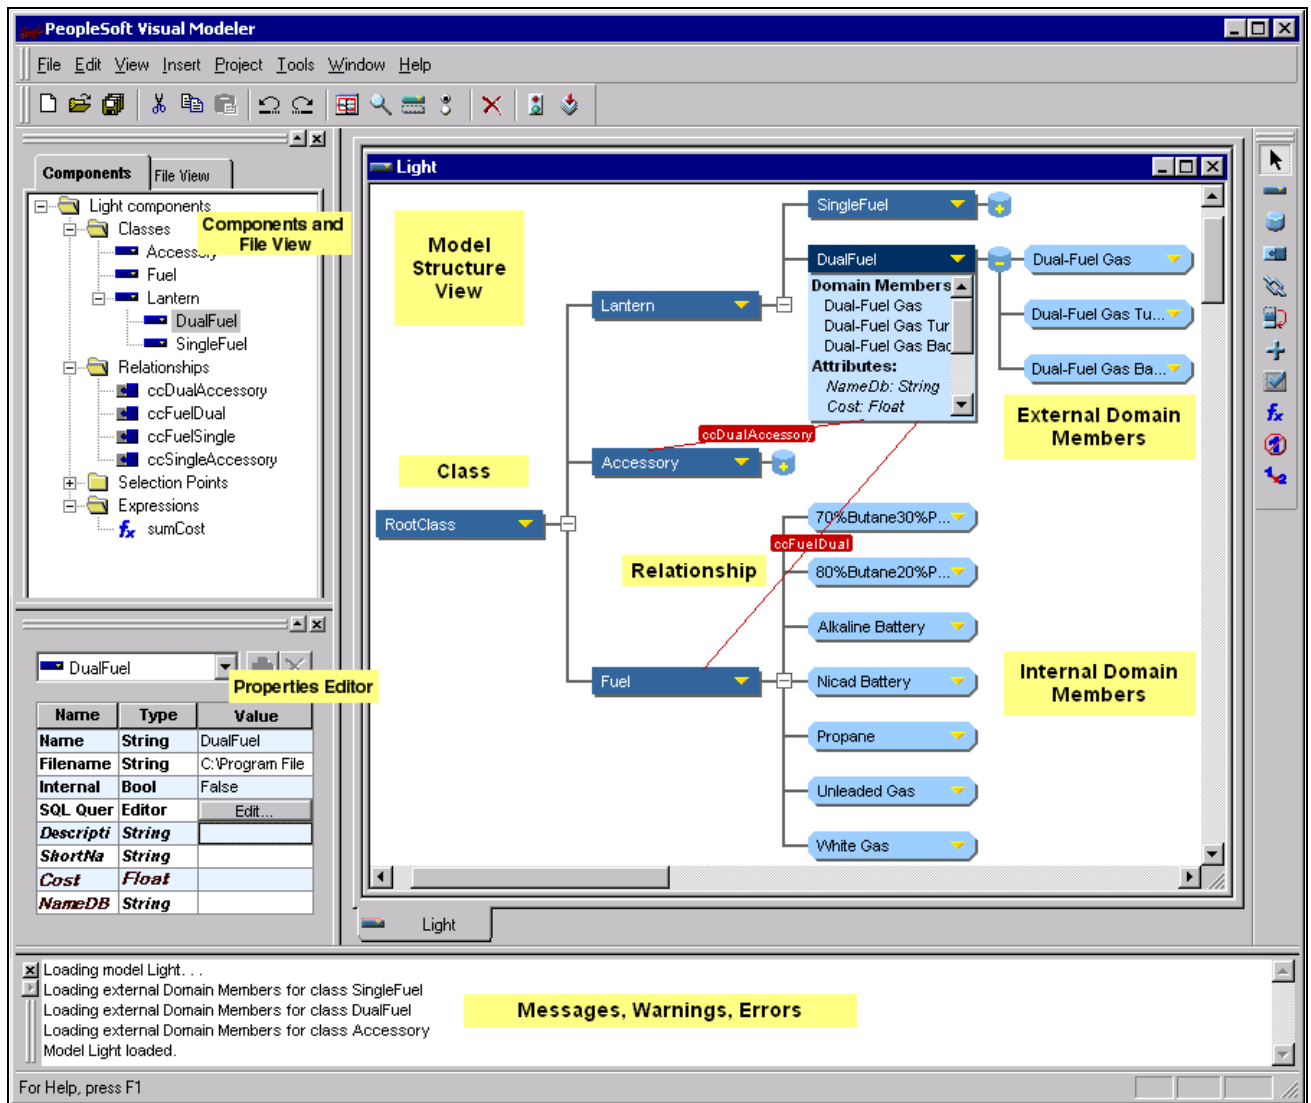

1. In Visual Modeler, select Project, Database References.
2. Select a the desired database in the database listing. The default database is the same for all database connections in the model.
3. Make sure the database name appears in the Default Database field at the bottom. Click OK.
4. Map a class to a database column.

See [Chapter 4, "Creating Objects for the Model," Selecting a Primary Table, page 82.](#)

The ability to specify a default is a convenience feature. If, at a later time, you need to query a different database, simply redefine the datasource name to refer to the new database.

Getting Started with Visual Modeler

To start Visual Modeler, select Start, Programs, PeopleSoft Applications, Visual Modeler 9.1, Visual Modeler 9.1. By default, Visual Modeler displays model information in three major windows. The largest area, the model structure view, is the modeling work area.

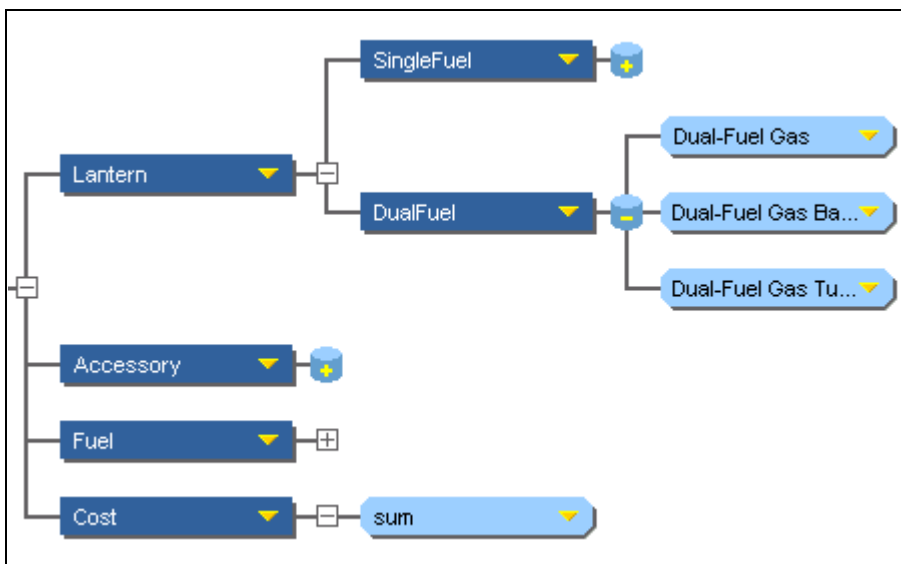

Visual Modeler window elements and model components

Model Structure View

Visual Modeler provides several tools for viewing and navigation in the Model Structure View.

The model structure view offers a standard windows "show and hide" paradigm for nodes in the class hierarchy. Click the "minus" icon to hide a hierarchy and click the "plus" icon to show all items in the hierarchy. If the node has external domain members, the database icon appears rather than the simple plus/minus icons.

Hierarchy with shown and hidden nodes

From the View menu you can Show or Hide the following:

- Selection Points
Equivalent to clicking the selection point icon.
- All Domain Members
Show/Hide all domain members in the model.
- Selected Class' Domain Members
Show/Hide the domain members for a class that is selected in the model structure view or in the Components view.
- Children
Show/Hide the class hierarchy for a class that is selected in the model structure view or in the Components view.

The View menu also offers similar options for expanding or collapsing items throughout the model.

Note. Expanding is equivalent to clicking the yellow triangle on an object.

Components and Files View

The Components tab is a navigation aid that displays the model's objects in hierarchical structure. The tab shows classes, subclasses, domain members, selection points, relationships, and expressions. Double-click on a class, domain member, or selection point to display it in the Model Structure view. Double-click on a relationship or expression and its editor appears. Properties for the selected object appear in the Properties Editor.

Properties Editor

All objects' properties appear in the property table when they are selected. Use this table-based editor to view, change, add, and delete an object's properties.

Overview Window

If the model is large, use the Modeling editor scroll bars to adjust the view. To "zoom" the model, click the Viewer icon to display the Viewer window Overview tab. A miniature view of the model is shown; the viewable area is outlined with a blue dashed line.

The overview window

To zoom the view, move the slide on the right.

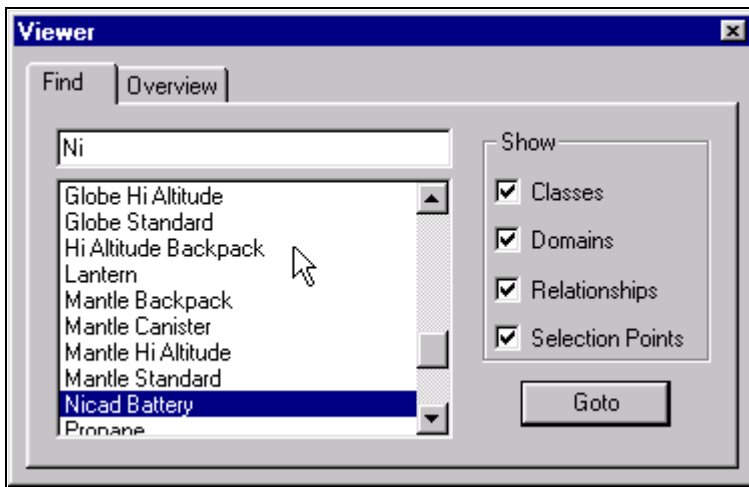

To refocus the model structure view display, click within the view outline; a hand cursor appears. Drag to reposition the view outline over the model.

Find Window

To find an object by name, click the Find icon, or select the X icon, then click the Find tab. Select or deselect the Show options to vary the objects displayed.

To find an object:

- Scroll the listing until you find its name.
- Start typing a name in the field above the listing. This field supports type-ahead, so the list will automatically jump to a partial match as you type.
- Select an item in the listing and click Go To, or type *Return* to bring the entry within the current window focus. Alternatively, double-click on an item.

Find window

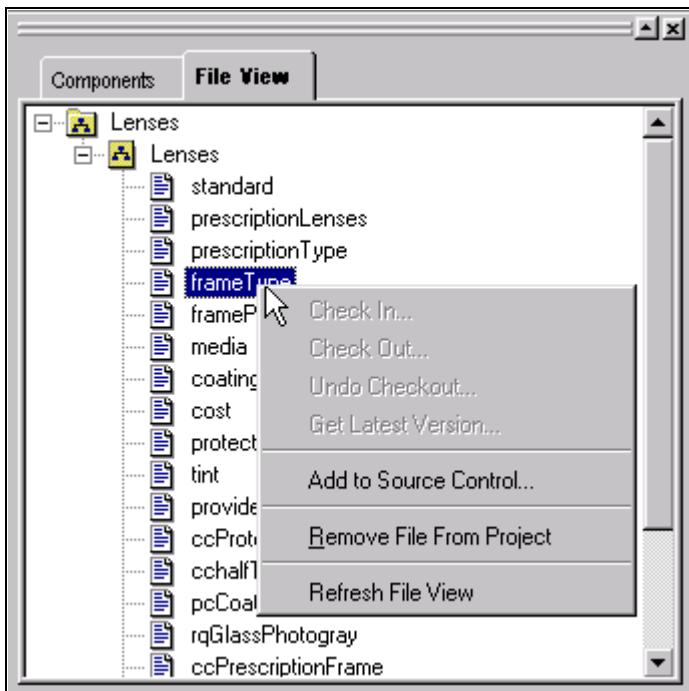

Understanding Project Files

A Visual Modeler project has three file types: a project file (.csp), a workspace (.csw), and multiple source files (.cms).

Configurator Source Project (.csp)

When a new project is created, a project file is written to the specified workspace. Typically the workspace and the project file share the same root name, but a single workspace can contain multiple projects if so desired. A Project file lists the .cms files required to describe the model, including standard.cms and any objects stored in separate .cms files.

The .csp file is maintained through Visual Modeler interaction. The File View displays the contents of the .csp file.

The File View

As you create objects, filenames are dynamically added to the .csp. Note that deleting an object in the model structure view does not remove its name from the .csp. To remove a file, right-click on a file to raise the context-sensitive menu. Removing a file from the project does not delete it from the workspace. Note that you can also perform source control operations from this menu.

See [Chapter 2, "Understanding Modeling," Source Control Interfaces, page 50.](#)

Configurator Source Workspace (.csw)

The Visual Modeler displays one workspace at a time. Each workspace contains one or more projects. When a .csw file is opened, all the projects within it are opened. To view a different workspace, select File, Open Workspace to browse for a workspace, or, select File, Recent Workspace and select a previous workspace. If the current workspace has unsaved changes, you will be given the opportunity to save.

Configurator Model Source (.cms)

Advanced Configurator model source (.cms) files contain an XML representation of one or more model objects, for example, a class or relationship that is created in and saved from Visual Modeler. There can be many .cms files in a project.

By default, Visual Modeler creates a separate file for each class, relationship, and expression. At creation time, Visual Modeler proposes a .cms file name based on the object name. You can specify an alternate new name or an existing file name. If an existing file is specified, the new object is appended to it. A file name can only be specified at creation time; it cannot be changed after the fact. This implies that although the class name is changed in the Visual Modeler, the supporting file name is not affected.

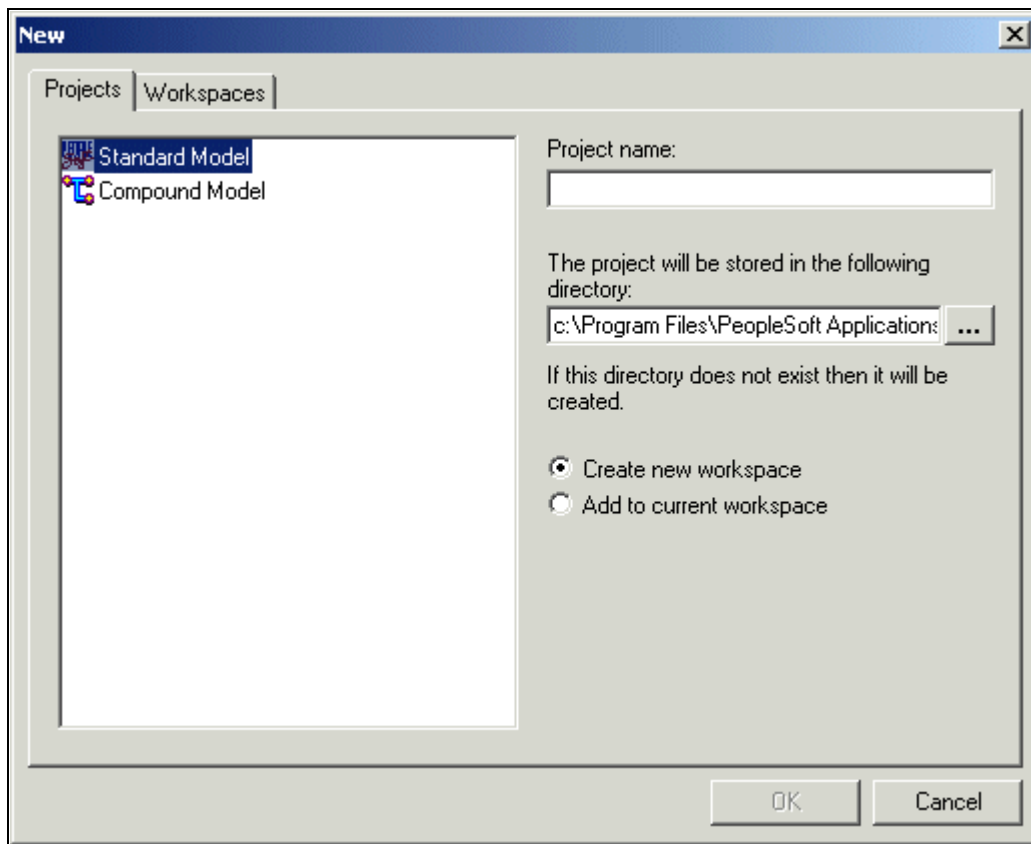

Each Standard model contains a file named standard.cms. This file is included when the project is created. standard.cms contains the root class and must be present in all projects containing standard models.

Team Modeling

The Visual Modeler file structure makes team modeling possible. Using multiple source files, a modeling team can work on the same model simultaneously. Changes can be checked in and checked out using source control. Additionally, most merge tools support the CMS format.

Creating a New Project or Workspace

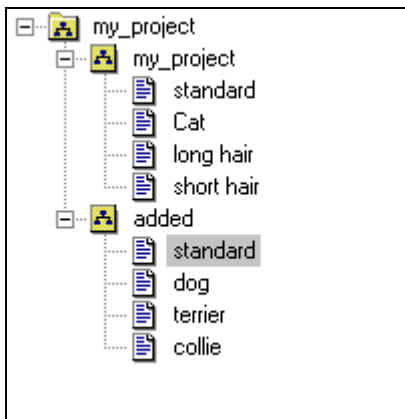

To create a new project in a new workspace, select File, New and click the Projects tab. Select the model type, standard or compound. Click Create new workspace. Browse for or type in a project directory, then type in a Project name; the name will be appended to the project directory path. Click OK.

Creating a new project

You can store multiple projects in a single workspace.

To create a new project in an existing workspace, select File, New and click the Projects tab. *Click Add to current workspace*, then browse for a project directory. Specify the Project Name, then click OK. The new project appears in the specified workspace; it has its own structure, as shown in the File view:

File view

When there are multiple projects in one workspace, you must explicitly set the active project so that Configurator system knows which project to compile. Select Project, Set Active Project to do this.

The File, Save Model As command allows you to save a copy of the model. All of the files in the project will be copied into a new destination directory and all occurrences of the original project name (model name) are replaced with the new project name. Source control status for the project and the source files will be cleared (you will need to add the new project to source control). The new project then becomes the active project.

The File, Save All option saves all model and workspace information for the current project. In addition, a model information file is created in the source workspace path. The filename format is <modelName>.modelinfo.xml. The Configurator Extensions for DreamWeaver use this file.

See and [Chapter 27, "Using the Page Editor Extensions for Dreamweaver," page 385.](#)

Visual Modeler provides a way to create (save) a description of the model to an HTML file. Select File, HTML Report.

Specifying Model Project Settings

You can specify model-level information in the Project Settings dialog.

Dialog Used to Specify Model Project Settings

Select Project, Settings. In this dialog you can specify compilation options and settings for use at compile time and run time.

Project Settings - Sample

Model Version
Current Version: 1.0
Major Version: 1 Minor Version: 0

PeopleSoft Configurator Server Location
Server: localhost
Port: 7777

Project settings for a component model

Current Version	The number of the current model version before any changes to the Major or Minor Version.
Major Version	An arbitrary model version used for model maintenance in <install directory>\ViM\models.
Minor Version	An arbitrary minor version used for model maintenance in <install directory>\ViM\models.
Server	The server on which WebLogic and Advanced Configurator are installed. For example: my_machine.peoplesoft_config.com.

Port	The port number for the WebLogic application server. It is 7777 by default.
Test UI	<p>Uses the Model Tester provided with the Advanced Configurator installation (component models only).</p> <ul style="list-style-type: none"> • <i>Auto Submit</i>—Check this box to turn on Auto Submit in the Model Tester. If Auto Submit is on, the page is refreshed with each pick. • <i>Columns</i>—The Model Tester displays runtime controls using a table form. Specify the number of columns in the output display. • <i>Extern Default</i>—The value to apply to any extern variables at model initiation. • <i>Control Type</i>—Select either of Radio Buttons or Dropdown Lists. This selection applies to all controls.
Other UI	Use your own JSP pages.
Effectivity Settings	<p>Choose test date settings to verify effectivity dates on relationships.</p> <ul style="list-style-type: none"> • <i>Use System Date</i>—Use the local system's date (usually the current date). • <i>Use This Date</i>—Enter a date in or out of an effectivity range.
Separator Settings	Specify the character you use in SQL queries for separating the Quantity and Policy values.
Incomplete Configuration Explanation	<p>Text to display to the user when a completeness check is run. You can compose the message with these parameters:</p> <ul style="list-style-type: none"> • Selection point name— <code>\$(n : \$DPNAME)</code> • Expression value— <code>\$(expr : exprname)</code> <p>If the name parameter is included within the explanation text, a separate explanation message will be generated for each required selection point that does not have a selection. Otherwise, a single explanation message will be generated for the Incomplete Configuration violation.</p>

Adding a Project to Source Control

For a description of the source control interface and instructions on configuring source control options.

See [and Chapter 2, "Understanding Modeling," Source Control Interfaces, page 50.](#)

1. To add a project to source control, select one or more components in the Visual Modeler File view.

If the Visual Modeler does not recognize files that are already in source control, check out the files and check them back into the same location. The Visual Modeler will detect the files and duplicates will not be created.

Note. Some providers will always prompt for a log in when a workspace or project file is checked in. Consequently, when adding all the files in the File view, you will be prompted to log in once for the .cms files and again for the project file. This is not an extra message. Be sure to provide the project information; do not leave the field blank. This behavior is known to occur with Visual SourceSafe.

2. Right-click in the tree view, then select Add to Source Control. You will be prompted to add a comment. To retain checked out files, check the "Keep files checked out" option.
3. Click OK to send the source control request to the provider software; at this point the source control software takes over.
4. To check out a file, select it in the File view, right-click, then select Check Out.

The source control status is visually depicted as follows:

File not in source control.

File checked in.

File checked out

Project or Workspace not in source control.

Project or Workspace checked in.

Project or Workspace checked out.

Importing and Exporting Models

Advanced Configurator provides a means to manage, update, and maintain models by importing and exporting model data. If you have model data that you would like to combine with another model—even if it is not currently an Advanced Configurator model—or if you want to update an older model by overwriting all or some of its components, you can use the export and import commands in the Projects menu.

These commands allow you to import and export all or parts of a model:

- Database references.
- Classes, with or without domain members and SQL queries.

- Selection points.
- All or selected relationship types.
- Expressions.

Importable models must be created in one of two ways:

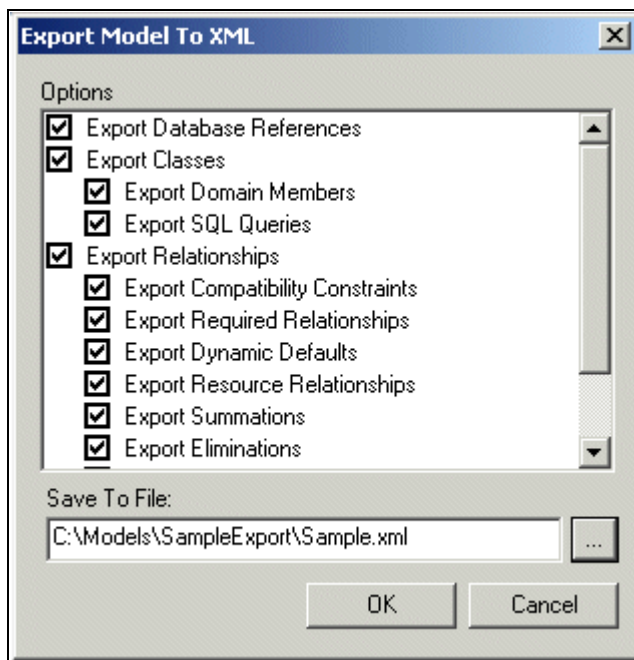

- From an Advanced Configurator model that has been exported, as this formats them in the XML defined by PeopleSoft Configurator Interchange Format (PCIF).
- From an XML file that compiles with the PCIF.dtd.

The latter method allows you to import a model, partial or complete, from an outside data source.

See [Appendix F, "PCIF," page 479](#).

Exporting a Model

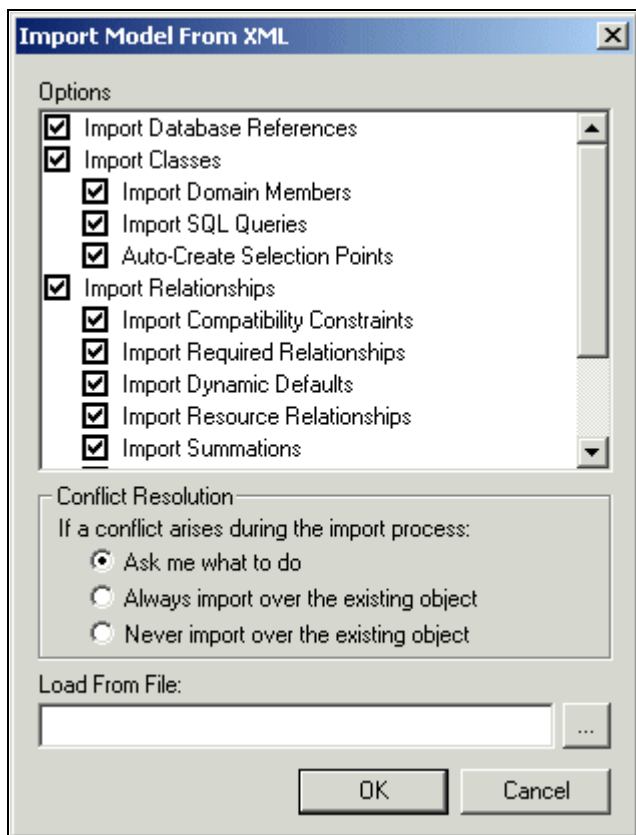

To export a model, open it in the Visual Modeler, and choose Projects, Export Model. The Export Model to XML dialog appears.

Export dialog, showing default settings with all components selected

Importing a Model

The dialog box for importing a model is very much like that for exporting a model.

Import dialog, showing default settings with all components selected

To import an Advanced Configurator model:

1. Open the target model in the Visual Modeler and select Projects, Import Model.

The Import dialog appears.

2. Uncheck any components that you don't want to appear in the target model.
3. Select the desired method for handling conflicts that result when a component being imported has the same name as an existing component.

These options let you control, on a case-by-case basis, whether components are overwritten or not.

4. Choose the desired filename for the import file (XML) and click OK.

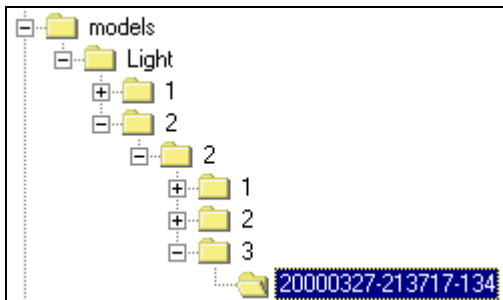

Compiling a Model

Compiling a model triggers several separate actions.

- The current model is compiled.
- At compilation, an intermediate XML file is created in the TEMP environment variable.

- If an intermediate XML file does not yet exist, a directory with the same name as the model is created on the Configurator server in
`\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\`
`Web-inf\models`
`.`

This process preserves a hierarchy of files.

A typical hierarchy of model files

In the above hierarchy,

- The directory name Light is derived from the model name.
- The Major versions, 1 and 2, were taken from settings in the Project Settings dialog, as was the Minor version (2.1).
- Any sub-minor versions (1, 2, and 3) are created automatically whenever the model structure changes or the Explanations information changes.
- Each compile is stored in its own directory identified by the compile ID. In the above sample, this is 20000327-0333825-244. The ID is extrapolated from the date and time. A sub-minor version can have many compiles.

Advanced Configurator provides a Model Tester for component models. It is a JSP page for testing model relationships. The Configurator engine must be running in order for the compile to take place.

Note. Compilation takes place for the Active Project, which may not necessarily be the project you are currently viewing in the Visual Modeler. To check the active project, select Project, Set Active Project.

Advanced Configurator provides tools for maintaining the contents of the \models directory and the temporary files in \TEMP.

See [Chapter 31, "Maintaining the Advanced Configurator System," page 431.](#)

To compile a model:

1. Start the Configurator server by either running `<WebLogic home>startConfigurator.cmd`, or selecting Start, Programs, PeopleSoft Applications, Configurator 9.1, Start Configurator Server.
2. Click the Compile and Run icon on the toolbar to compile the model and launch the Model Tester. If you would like to save before compiling, select Tool, Options, then select the Save before Run option on the General tab.

Alternatively, click the Compile icon on the toolbar to compile the file without launching the Model Tester.

3. Check the output window (below the Model Structure View by default) for compile-time messages, warnings, or errors.

At least one relationship must be specified in order to compile a model. In addition, each class that participates in a relationship must have a selection point. (Click the Selection Point icon on the toolbar to display the selection points in the Model Structure View.)

Using the Model Tester

The Model Tester displays the following information and display options.

Model Info

Model Name: Sample
Model Version: 1-0-18
Compile ID: 20030718-143415-294

Legend

Eliminated

User Selected

Conflict

Computer Selected

Options

☐ Show Elimination Level

☒ Auto Submission Of Picks

2

Number Of Controls Per Row

☐ Verify Configuration

☐ Use Select (List) Controls

Attribute To Display

☐ Sort By State

☐ Show None On Required Controls

Solve date (YYYYMMDD)

Model Tester information and display options

Model Name	The name of the model as it appears in the Visual Modeler project.
Model Version	Displays the model's version. The major and minor versions can be set in the Project Settings dialog.
Compile ID	The compile ID is based on the time the file was compiled on the application server.
Show Elimination Level	If the model contains elimination levels, display them on the Model Tester.
Verify Configuration	If Verify Configuration is checked, the Advanced Configurator checks the current set of picks for missing selections (on required controls) and violations. The model is assumed complete and valid if all required selections are made and no violations are detected.
Sort By State	Display the most recent pick at the top of the control.

Auto Submission of Picks	Refresh the page as soon as a pick is made. If Auto submission is off, make one or more picks, then click the Submit button. This value can be set from the Project Settings dialog.
Use Select (List) Controls	<p>If this box is not checked, radio button controls will be used for the entire model. If this box is checked, list control drop downs will be used. When list controls are selected, text indicators, rather than the graphics shown in the Legend box, are displayed:</p> <ul style="list-style-type: none"> • D_S—Default selected (used when None is selected by default) • C_S—Computer-selected • C_E—Computer-eliminated • U_S—User-selected • U_E—User-eliminated
Show None on Required Controls	None is added to single-select controls at runtime so that if List controls are used the control can initialize with nothing picked. You can hide these values on single-select controls.
Number of Controls Per Row	The number of columns in the Model Tester table. This value can be set from the Project Settings dialog.
Attribute to Display	Display an attribute that is defined for the domain member instead of the Name. May also display an attribute that is not defined in the model, but is part of the class. For example, a long description could be displayed even though the model knows nothing of that description.
Solve Date (YYYYMMDD)	<p>Displays the date that the Model Tester is using to test the model. If the box is initially blank, the system date is being used. If a date appears in the box initially, it is the specified Model Tester solve date for the project. (The model test solve date is set in the Projects Settings dialog.)</p> <p>You can specify a different date in the Model Tester and re-run the test under the new date by clicking the Submit button. The model is not recompiled.</p>

Note. Be aware that, in the Model Tester, four or more controls placed horizontally may not be displayed properly in Microsoft Internet Explorer.

Internalizing Model Data

Internalizing the data can be accomplished in the Configurator Administration Console or with the Visual Modeler. If you have auxiliary files that must accompany the data, use the Administration Console. Also, internalizing data in the Visual Modeler is a one-time operation that will create a model with internal data. Internalizing data with the Administration Console preserves the SQL query information in the model, yet still produces a compiled model that doesn't need the database to run. If the database data changes you can re-compile to pick up the new data.

To internalize model data using the Visual Modeler:

1. Make a copy of the model's files (in Explorer).

Note. You must internalize a copy so that there remains a database-connected model for continued maintenance. You will always make a copy of the latest version to use in creating a distributable Mobile Solution Package.

2. Open the copy of the model in the Visual Modeler.
3. Select Project, Internalize Model.
4. Select *Yes* to internalize data.

Internalization automatically converts model data into domain members and constraints. If the data is very large, this process may be lengthy.

Chapter 4

Creating Objects for the Model

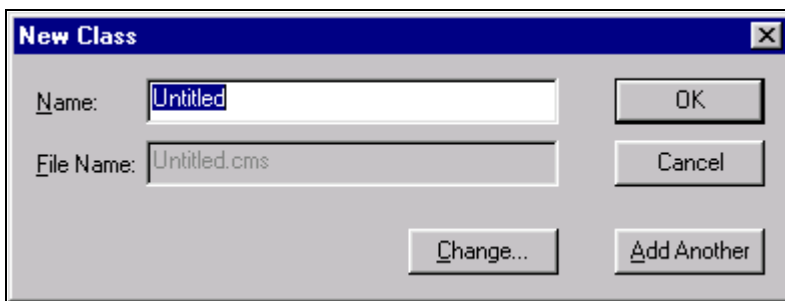

This chapter discusses how to:

- Create a class.
- Delete a class.
- Change class structure.
- Add class attributes.
- Create internal domain members.
- Create external domain members.
- Create a "None" domain member.
- Assign values to attributes.
- Inputting date-type attributes manually.
- Set up binding for external domain members.
- Filter and manipulating table data.
- Work with selection points.
- Storing a dynamic default quantity in a database.
- Internalize data.

Creating a Class

A class has the following default properties:

Inheritance principles must be considered while a model is being built. Click anywhere in the model structure view to ensure focus on the modeling area.

New Class dialog box

To create a class:

1. Click the Create Class icon in the right margin, then click the parent class, or, select a class, then select Insert, Class.

To create multiple classes, hold down the Shift key, click the Create Class icon, then click the parent class, or, select a class, then select Insert, Multiple Classes.

The New Class dialog appears.

Note. A class may have either subclasses or domain members. If a class has domain members, they must be deleted before a subclass can be added.

2. Type a name into the Name entry field of the New Class dialog. The dialog prompts with a .cms file name based on the string you enter. Before continuing be sure the name is correct according to the following:
 - Class names must be unique within a model.
 - The name cannot include \, =, <, >, :, ", (, or). The initial character cannot be dollar (\$) or underscore (_), but these characters can be included in other positions.
3. Click the Change button to specify a different file name. A class object can be saved to an existing .cms file.

Once a name is accepted, the class name can be changed within the model, but the file name cannot change.

4. If you are adding a single class, click OK to end the process, or click Add Another to continue adding classes. Or, If you are adding multiple classes, type "Return" to make another, or click the cursor arrow in the menu bar to revert to the normal Windows cursor.

When a class is created the following events occur:

- The information for the new class is displayed in the context-sensitive properties editor (if it has focus).
- The class name appears in the Class list in the Components view.
- The file name appears in the file list in the File view.
- The file name is automatically added to the model's .csp file.
- If the class is a leaf class, a corresponding selection point is automatically created.

Deleting a Class

To delete a class, select it and press the delete key.

Deleting a class:

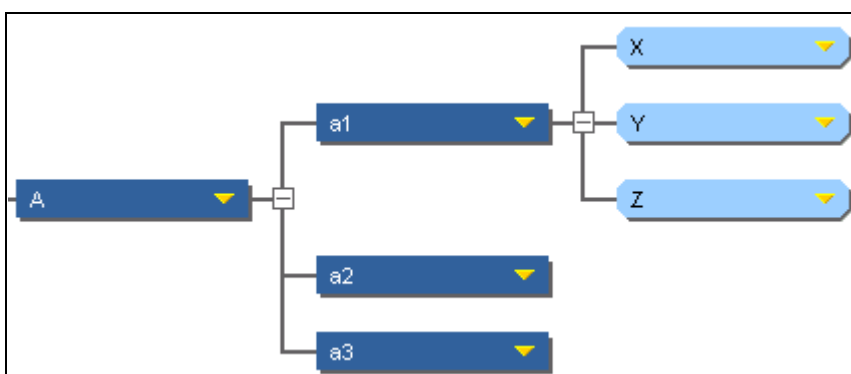

- Removes the class, any subclass(es), and any domain members.
- Removes the class from any relationships that reference it.

To remove the corresponding file from the .csp file, click the File View tab. Locate the associated class file and right-click to open the context-sensitive menu, then select *Remove File From Project*. Note that deleting a class in Visual Modeler does not remove the corresponding .cms file from the file system.

Changing Class Structure

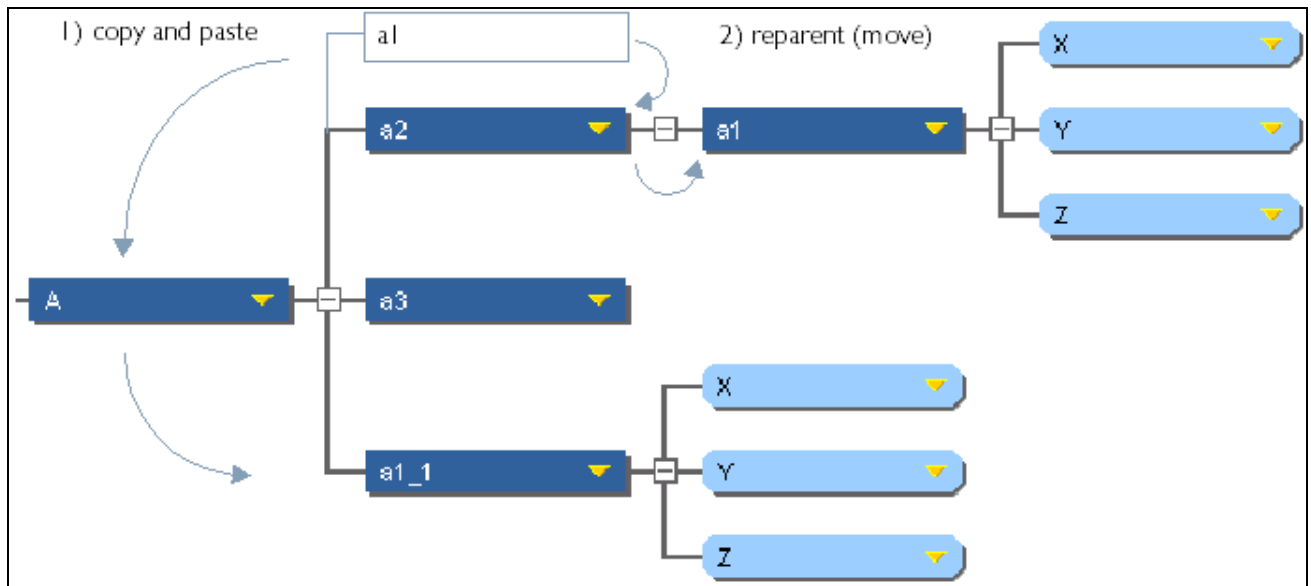

It is possible to reuse parts of a diagram with the Reparent and Copy and Paste features.

Compare the following two figures:

Original structure

- a1 is copied and dropped on the Root class. Because the new class is a sibling of a1, a new name, a1_1 is automatically created.
- The original a1 is dragged and dropped onto a2. a1 becomes a subclass of a2; there is no need for a name change.

Copy and paste, and reparent

To reparent a class:

Drag and drop it on a class that does not have domain members.

To copy and paste a class:

Copy a class and paste it on another class that does not have domain members. The original class remains unchanged in the diagram. Any domain members and relationships will be transferred along with the copied class to its new location. If the class is on the same hierarchical level (a sibling) the class will be automatically renamed to keep it unique. If the class is not a sibling, the name is unchanged.

Note. Copying and pasting a class will not copy the corresponding selection points. If the copied class is a leaf class, a selection point will be created for it; however that selection point will have the default properties, not the properties, of the original class's selection point.

Adding Class Attributes

Class, domain member, constraint, and selection point values and attributes can be specified or edited in the context-sensitive Properties editor.

Name	Type	Value
Name	String	Anytime Minutes
Filename	String	C:\bea\weblogic81\config
Internal	Bool	False
SQL Query	Editor	Edit...
Description	String	
ListPrice	Float	0.0
MonthlyPrice	Float	0.0
Short Name	String	
On Output	Bool	False

The Properties editor for a selection point

The figure shows the Properties editor for a class in which the user has defined attributes, and the Internal property is set to False, so that the attribute values will be imported from an external source.

Note. The SQL Query field is not shown unless Internal is set to False.

Name	Type	Value
Name	String	Scanners
Filename	String	C:\Program Files\Peo
Internal	Bool	False
SQL Query	Editor	Edit...
Description	String	
ShortName	String	
Watts	Float	0.0

Class or subclass properties

To add an attribute to a class:

Click the Add button at the top of the panel to open the Create a New Property dialog. You can either use the dialog to enter the name, type, and value, or click the OK button to add a blank row to the table for editing. Possible types are Boolean, float, int, String, and date.

An entry in the Value column becomes the default for child classes and for domain members. The value can be changed in the class in which it is defined, or in an internal domain member. When the SQL Query property is set to False, internal values are generally ignored, however, if a database happens to have a null value, the default value from the model will be substituted.

Creating Internal Domain Members

A domain member is an instance of a class. You can create any number of domain members. An internal domain member is one that is stored within the model rather than a database or another system file.

To create internal domain members:

1. To create a single domain member, click the domain member icon, then click the parent class.

To create multiple domain members, hold down the Shift key, and click the domain member icon, then click the parent class. Alternatively, select a class, then select Insert, Domain Member or Insert, Multiple Domain Members.
2. Click OK to complete the process, or click Add Another to continue adding domain members on the same class. The New Domain Member dialog appears.
3. Type in a name. The name cannot include \, =, <, >, :, ", (, or). The initial character cannot be dollar (\$) or underscore (_), but these characters can be included in other positions. An asterisk (*) cannot be used alone, but it can be used in combination with other characters.
4. When you are finished creating domain members for this class, select another class, or click Cancel.

Or,

To stop creating multiple domain members, click the cursor icon in the Windows menu bar to revert to the normal Windows cursor.

Creating a "None" Domain Member

When a control is single-select, an item named *None* is automatically displayed in the Model Tester when you launch it. If the selection point flag Optional is set to True, *None* is computer-selected (unless a default was set). It is important to understand that this "generated" None is not a domain member, and it has no value. As such, *None* does not participate in constraints.

When a user selects *None at run time*, it means "there is no selection made on this selection point."

None is not generated for a multi-select control.

For required single-select controls, none has no meaning, so the Model Tester has an option to hide None on required controls.

If you want an item named *None* to be selectable on a multi-select or single-select control, you must create a domain member for that purpose. It is helpful to name this domain member something other than None, such as "No Thanks" or "I don't want any" to avoid confusion with the "generated" None.

Assigning Values to Attributes

Type appropriate values in the Value column. The figure shows the attributes for an internally defined domain member. The naming restrictions for domain members also apply to attributes.

Name	Type	Value
Name	String	HardDrives
Filename	String	C:\Program Files\Peop
Internal	Bool	True
<i>Description</i>	<i>String</i>	
<i>ShortName</i>	<i>String</i>	
InterfaceType	String	IDE
StorageCapacity	Int	
Watts	Float	2.00

Domain Member Attributes

Note the use of font styles in the Properties editor:

- Items that cannot be changed are shown in black bold face. For example, the Name and File Name types cannot be changed.
- Items shown in plain text can be modified, that is, the value of the name can be changed.
- Items defined in an ancestor class—for example, the attribute price in the figure, are shown in italic font.

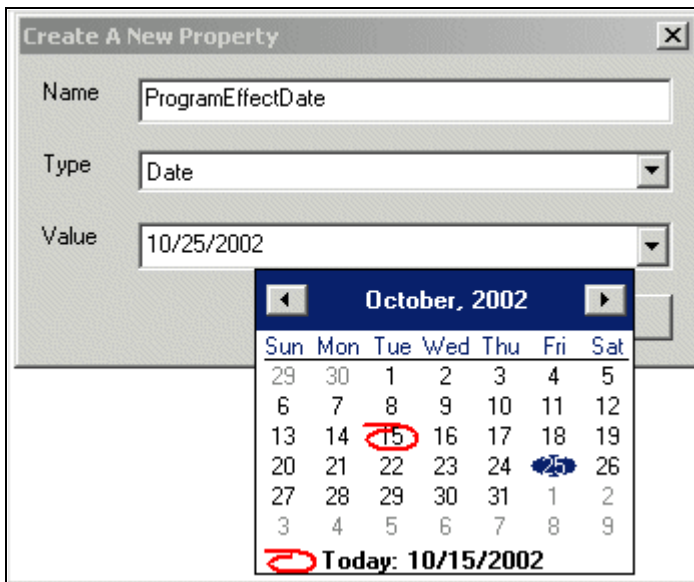

Inputting Date-Type Attributes Manually

You can input date-typed attributes on classes and domain members manually, through the Property Editor, and through an SQL query from a database. The Visual Modeler also supports date-typed data in compatibility, requirement, and dynamic default constraints.

You can express values for dates using the full ISO 8601 format. However, any time zone, hour, minute, and sub-second information will be truncated during the compilation process to yield a YYYY-MM-DD format. The validity of dates is checked during the compilation process and error messages are generated for any invalid dates detected. Advanced Configurator stores the dates as strings in their YYYY-MM-DD format since many date operations can be performed on the ISO 8601 format using string manipulation and comparison functions.

Date values loaded from a database are retrieved and converted to the YYYY-MM-DD format. Thus, you can store and retrieve date values in formats other than YYYY-MM-DD.

Note. Strings can be input directly from the user interface if they are in a parseable date format.

Editing a class property with date type

You can also use date data in expressions.

See and [Chapter 5, "Creating Relationships Between Model Objects," Creating and Editing Expressions, page 97.](#)

Setting Up Binding for External Domain Members

Relationships can be created between classes or selection points and domain members obtained from a database. Setting up the modeling environment to work with external objects requires:

- Configuring the database.

See and [Chapter 3, "Setting Up the Modeling Environment," Database Interface Configuration, page 53.](#)

- Configuring your system so that you can see external data in the model.

See and [Chapter 3, "Setting Up the Modeling Environment," Connecting to a Database from Visual Modeler, page 56.](#)

- Specifying the appropriate values for properties in the JNDIDBName.properties file so that you can compile and run a model with external data.

See and [Chapter 3, "Setting Up the Modeling Environment," Configuring JNDIDBName.properties, page 55.](#)

Selecting a Primary Table

Select a class, and in the Properties editor, set Internal to *False*. The SQL Query field appears. Click the Edit button to display the primary table dialog. (If no databases are listed in the drop down on the upper left, the Visual Modeler is not connected to a database.)

See and Chapter 3, "Setting Up the Modeling Environment," Specify a Database Connection, page 57.

Primary Table [SingleFuel]

sample Edit Database Properties...

☐ Advanced Query

Primary Table: Lantern

Where: Type = ('S')

☐ Distinct

Table Column	maps to	Class: Attribute	Domain Member Key
LanternName	NameDb (String)		<input checked="" type="checkbox"/>
Cost	Cost (Float)		<input type="checkbox"/>
Abbreviation	Abbrev (String)		<input type="checkbox"/>
Type	Type (String)		<input type="checkbox"/>
CandlePower	CandlePower (Float)		<input type="checkbox"/>
	NameDb (String)		<input type="checkbox"/>
	Cost (Float)		<input type="checkbox"/>
	Abbrev (String)		<input type="checkbox"/>
	CandlePower (Float)		<input type="checkbox"/>
	Type (String)		<input type="checkbox"/>

Secondary Tables... OK Cancel

Primary table with attribute mapping and WHERE clause

Simple Queries

Simple queries, where a database table column corresponds exactly to the model needs, do not require an advanced SQL query.

To write a simple query:

1. Type the database table name into the Primary Table field.

Note. The table name and all other names associated with the database are case-sensitive.

2. Type a Column name from your database into an empty Table Column cell. To map the values to class attributes, make a selection in the corresponding Class:Attribute drop down.
3. (Optional) Enter a Where clause. The SELECT and FROM portions of the query are derived from the dialog inputs. You need only enter the WHERE portion.
4. (Optional) Check the Distinct check box to ensure that repeated values are not displayed.

5. Click the Domain Member Key box next to the value you want displayed on the domain member. At least one row must be chosen as Domain Member Key. The Domain member key does not have to match the Primary Key in the database.

Note the following important points about queried data:

- Data queried for a Domain Member key must be unique. The Domain Member key data will be used as an identifier for domain members at run time.
- If two domain member keys are chosen, both will be displayed on the imported domain members. The topmost key will be displayed first.

If more than one domain member key is chosen, the union of all keys will be used to identify domain members at run time; the combined list cannot have duplicates.

- Queried data has the same restrictions as internal data. A query cannot return a name that includes \, =, <, >, :, ", (, or).

The initial character cannot be dollar (\$) or underscore (_), but these characters can be included in other positions. An asterisk (*) cannot be used alone, but it can be used in combination with other characters.

- *None* is displayed on single-select controls at run time. This "generated" None is not a domain member. If you want a domain member to perform this function, you must create one in the database.

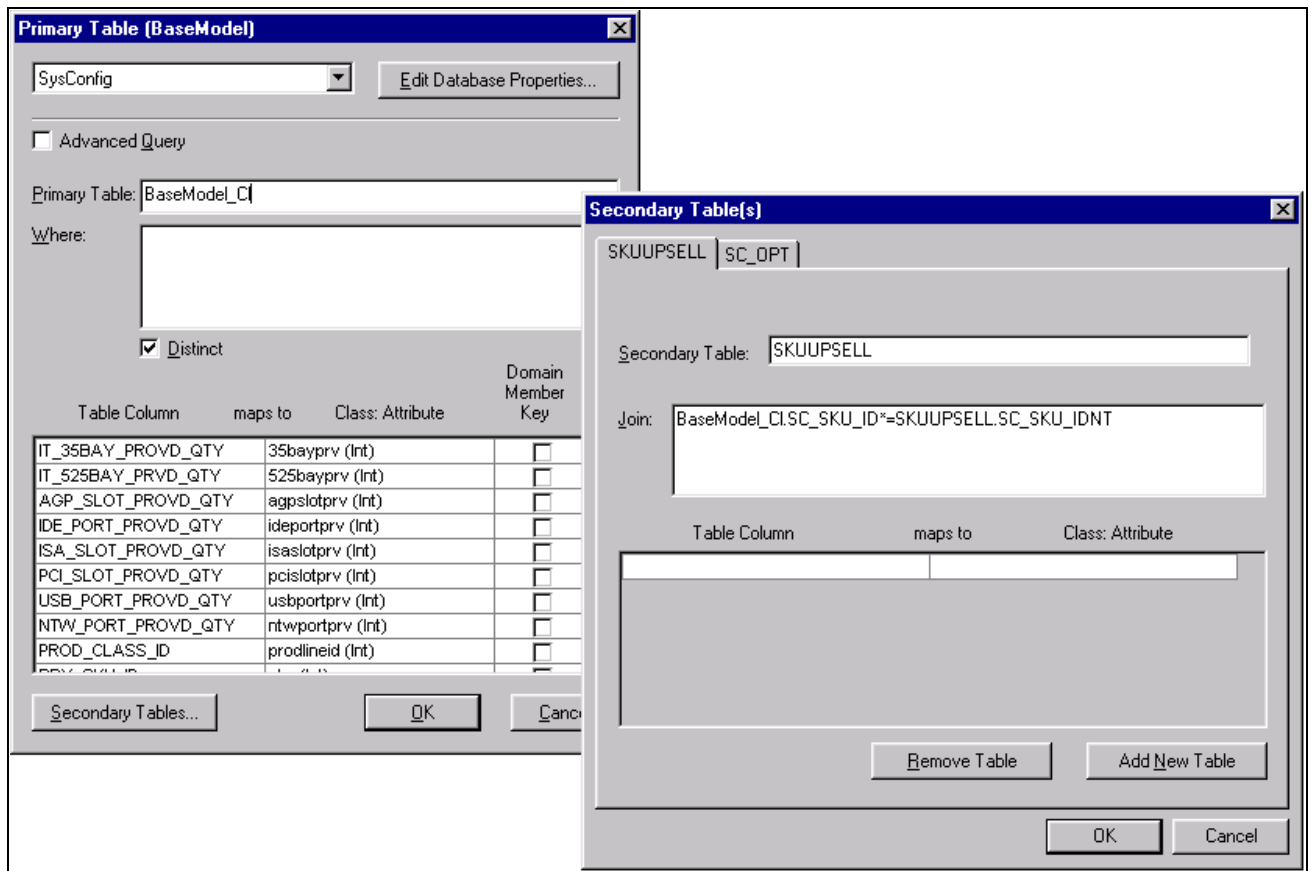

See [Chapter 4, "Creating Objects for the Model," Creating a "None" Domain Member, page 80.](#)

Secondary Table Option

To join a secondary table to a Primary table, click the Secondary Table button. Database-to-class property mapping is similar to that for the Primary window, with these exceptions:

- The SQL query is a Join clause. Typically, a secondary table is used to add an attribute from another table to an external domain member. The secondary table has at least one column in common with the primary table. The common column is used to state the join condition.
- Columns cannot be mapped to domain members in this dialog.
- Multiple secondary tables are allowed. Click Add New Table. Each table appears on a separate tab in the Secondary Table(s) window.

Note. Limit using secondary tables to situations where they are truly necessary. Secondary tables are preferred to defining advanced queries, but they slow Visual Modeler performance and increase compilation time.

Primary and Secondary Tables with SQL Queries

Advanced Queries

An Advanced Query is required if filtering must be applied to the table data and if you plan to do any data manipulation in the SQL. For example, you could calculate someone's age based on the current date and their birth date and return that value as AGE. You may also need an advanced query if you are using nested select statements or complex joins.

When you use an advanced query, the runtime system can not dynamically read additional database data as requested by run time components. Any data needed must be provided by the query specified in the Advanced Query specification.

You can not request additional attributes on the UI with advanced queries. For example, with a simple query, you don't have to map LONG_DESCRIPTION into the model, but you can still display it at run time since it is added onto the query for the class. With advanced queries, all attributes that will be displayed or otherwise referenced (for example, in pricing) must be mapped into the model.

Note. An advanced query must be written such that the first column returned is returned as "\$NAME". This should be the domain member key (or equal to the domain member key).

To enter an advanced query:

1. Click the Advanced Query check box. The Primary Table field will disappear.

2. Type an SQL Server or Oracle query into the Enter Advanced Query field to:

- Generate the domain-member name column from the key columns.
- Return it as column 1 and call it '\$NAME'.

This part of the query looks like:

```
(tbl1.keycol1 || tbl1.keycol2 || tbl2.keycol1) AS '$NAME', tbl1.col2 WHERE ...
```

Examples

SQL-Server:

(single-column key)

```
SELECT (cast( tbl1.keycol1 as nvarchar(4000))) AS '$NAME', tbl1.col2 WHERE ...
```

(multi-column key):

```
SELECT (cast( tbl1.keycol1 as nvarchar(4000)) + '_' + cast( tbl1.keycol2 as
nvarchar(4000)) + '_' + cast( tbl2.keycol1 as nvarchar(4000))) AS '$NAME', =>
tbl1.col2 WHERE ...
```

Oracle:

(single-column key):

```
SELECT (tbl1.keycol1) AS "$NAME", tbl1.col2 WHERE ...
```

(multi-column key):

```
SELECT (tbl1.keycol1 || '_' || tbl1.keycol2 || '_' || tbl2.keycol1) AS "$NAME", =>
tbl1.col2 WHERE ...
```

(You can also leave out the table prefix ("tbl1.", "tbl2.") if there is only one table being queried.)

3. Add the data call portion of the query:

In an example where a class' attributes name, *attr1*, and *attr2* are taken from tableX, and there is a need to order by *attr1*, the query (for Oracle) is similar to this:

```
select name as "$NAME", attr1, attr2 from tableX order by attr1
```

The column mappings are:

```
$NAME -> tableXID(domain member key)
attr1 -> columnA
attr2 -> columnB
```

4. Perform the remaining steps as described in the preceding instructions "Simple Queries."

Note. Do not use the Advanced query unless it is absolutely necessary. The simple query is preferred because it can be optimized at run time.

Using Table Aliases

Using a table alias helps allows you to:

- Refer to the same table/view more than once in a single query.
- Refer to a table by a sorter name in the where clause.

In particular, a table alias can help you create joins and differentiate between multiple instances of the same table. To create a table alias, follow the table/view name with a name of your choosing—the alias. When you refer to that table instance in the where clause, prefix the column name with the prefix. The SQL below is what the system actually generates at run time. Note the prefix names used in the WHERE section—you can see them defined in the FROM section.

```
SELECT DISTINCT ( CAST(kit.PROD_COMPONENT_ID AS NVARCHAR(4000))) AS '$NAME'
FROM PS_PRODKIT_COMPS kit, PS_EOEP_PRICE_LIST list, PS_EOEP_PRICE_LIST recur, PS_⇒
PROD_ITEM prod
WHERE kit.SETID = 'COM01'
    and kit.PRODUCT_ID = 'TEL200002'
    AND list.RECURRING_FLG = 'N'
    and list.PRICE_LIST_ID = 'COM_PRICE'
    and list.SETID = kit.SETID
    and list.PRODUCT_ID = kit.PROD_COMPONENT_ID
    AND recur.RECURRING_FLG = 'Y'
    and recur.PRICE_LIST_ID = 'COM_PRICE'
    and recur.SETID = kit.SETID
    and recur.PRODUCT_ID = kit.PROD_COMPONENT_ID
    AND prod.SETID = kit.SETID
    and prod.PRODUCT_ID = kit.PROD_COMPONENT_ID
```

Filtering and Manipulating Table Data

An Advanced Query is required if filtering must be applied to the table data and if you plan to do any data manipulation in the SQL. For example, you could calculate someone's age based on the current date and their birth date and return that value as AGE. You may also need an advanced query if you are using nested select statements or complex joins.

Storing a Dynamic Default Quantity in a Database

A special character is used to separate the quantity values and policy from the constraint value. For instance, if you want to default four fans with a SUM policy, the string "FANA~4~SUM" might appear in the database to denote that default. The format for a value stored in a database can be one of the following:

```
<value>
<value><delimiter><quantity-or-expression>
<value><delimiter><quantity-or-expression><delimiter><policy>
```

The <value> token is the value to be used by the constraint. In the prior example, this would be the symbol FanA. The <delimiter> token is the special separation character. In the example, this was the character '~'. You can specify the delimiter character in the Project, Settings dialog.

The <quantity-or-expression> token is either a numeric quantity or the name of an expression. The <policy> token is SUM, MIN OF, or MAX OF.

Retrieving Expression Values and Externs from a Database

You can populate LHS expressions and RHS extern values from stored data. Visual Modeler and the compiler recognize data output from the database in specific format and will populate the rows of constraints with that data.

The format for LHS expressions is:

```
<comparator><space><"const" or "f(x)"><space><value or expression name>
```

Examples: `<= const 2` and `> f(x) expSum`

Format for RHS externs is `< "true" or "false">` to indicate whether it is required (true) or optional (false).

You should have one column in the database for each expression or extern in the constraint.

Working with Selection Points

The selection point is the model component that communicates directly with the HTML control in the UI. By default, a selection point is created for every leaf class that participates in a relationship.

A selection point has these properties, which are displayed and editable in the properties table:

Name	Type String. By default, the name of the selection point is the class name with Selection appended. This name can be changed. If you change the name, all constraints or expression that use it must be updated.
Filename	Type String. Filename and path to this object.
Type	Type String. The name of the original class.
Quantity	Type Boolean. Determines default quantities for selections. <i>False</i> indicates that domain members, when selected, have a quantity of 1. <i>True</i> indicates that domain members, when selected, have the quantity of 1 or greater, as set in the Defaults editor (explanation follows), which replaces the Def Choice property.
Use Min/Max	Type boolean. Settings for minimum and maximum number of choices allowed for the control, and for minimum and maximum quantity of each domain member allowed. Determines single- and multi-select control type. When set to <i>False</i> (default), the control is optional, and only one domain member can be selected (single-select). (You can also specify single-selection with the property Multi Sel = <i>False</i> .) When Use Min/Max is set to <i>True</i> , the Defaults editor replaces the Def Choice property

Defaults

The default quantity policies and values for each domain member in the selection point. Click Edit to open the Edit Default Choices dialog. This quantity is compared to the quantity that is assigned to the domain member during run time when it is selected by a dynamic default constraint. It is applied if the dynamic default quantity does not meet the requirement indicated by the policy.

See and [Chapter 2, "Understanding Modeling." Quantities in Modeling, page 34.](#)

Quantity Policy column—One of four ways to apply the static quantity value in the Quantity Value/Expression column to each domain member:

- *Overridable, Overridable $f(x)$*

Assign the quantity to the domain member only in the absence of a dynamic default quantity on the domain member.
- *Min of, Min of $f(x)$*

Check that the largest of the dynamic quantities assigned to the domain member (assuming it was selected more than once) is the specified static quantity or greater. If it is not, assign the static quantity value.
- *Max of, Max of $f(x)$*

Check that the largest of the dynamic quantities assigned to the domain member (assuming it was selected more than once) is the specified quantity or less. If it is not, assign the static quantity value.
- *Sum, Sum $f(x)$*

Check that the specified quantity equals the sum of the dynamic quantities assigned to the domain member (should it be selected multiple times), otherwise assign the static quantity.

Quantity Value/Expression column—Static quantity. Click on the cell to display the selector arrows and set the static quantity value, or a predefined expression, of a domain member. If you use an expression, the value resulting from the expression will be used.

A value of 0 indicates that there is no minimum, maximum, or summed quantity requirement on the domain member. 1 - n is the quantity to be compared to the dynamic quantity, to be applied to the domain member if the policy requirement is not met.

Domain Member column—(not editable) Name of the domain member in the selection point.

Use Quantity Policy for All Domain Members—Specifies whether and how to apply a default quantity to all the domain members. Policy and Quantity fields specify the same entries as the Quantity Policy and Quantity Value cells for individual domain members described above.

Multi-Sel

Type Boolean. Determines whether a selection point is single- or multi-select.

False indicates that only one selection can be made on the selection point. Be sure to choose *Def Choice* if desired (explanation follows). In this sense, the Quantity property duplicates the Multi-Sel property (explanation follows).

True indicates that multiple selections can be made on the selection point. When *True* is selected, the input row Defaults appears in place of the Def Choice property, and the Defaults Editor is made available for setting the default choices, their default quantities and policies.

SP Min/Max

Click the SP Min/Max Edit button to open a dialog to specify:

- Selection point Minimum Number:

0 indicates that the selection point is optional.

1 – n indicates that the selection point is required and must have at least 1 or n selections.

- Selection point Maximum Number:

Unbounded indicates that there is no limit to the number of discrete domain members the user can choose (up to all members available). For efficient model maintenance, use this setting when the number of domain members is expected to vary over the life of the model or during run time.

1 – n indicates a static limit; *0* has no meaning.

- Expression—the minimum and maximum are determined by an expression. Choose the expression from the drop down.
- SQL Query—the minimum and maximum are determined by query of the indicated database. Click the ellipsis button to open an edit window in which to create the query. Be sure to indicate the database to query.

Note. The Configurator system looks for the selection value in the first column of the first row of the data returned by the SQL query. Be sure to create a query that returns only one column and one row.

- Explanation—Message that you want to appear when the min/max limits are violated, advising the user when not enough choices are made, or too many. Explanations can be parameterized to indicate the objects involved.

See and Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.

DM Min/Max

Minimum and maximum limits on the quantity of each domain member that may be selected.

- Domain member Minimum quantity: The least quantity that can be specified of a domain member when selected.
- Domain member Maximum quantity: Unbounded indicates that there is no limit to a domain member's allowable quantity.
- Expression—If you want the minimum or maximum quantity to be determined at run time by an expression, select Expression and then select the desired expression (already defined) from the drop down list.
- SQL Query—the minimum and maximum are determined by query of the indicated database. Click the ellipsis button to open an edit window in which to create the query. Be sure to indicate the database to query. row.

Note. The Configurator system looks for the selection value in the first column of the first row of the data returned by the SQL query. Be sure to create a query that returns only one column and one.

- Explanation—Message that you want to appear when the min/max limits are violated, advising the user when too few or too many of a domain member are selected. Explanations can be parameterized to indicate the objects involved.

See and [Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.](#)

Optional

Type Boolean. Default is *False* (required). If *False* is set, the user must make a selection on the control before the configuration can be verified.

Note. The same condition applies if Use Min/Max is *True* and Minimum Number is not 0.) If Optional is *True* and Multi Sel is *False*, the item *None* will be automatically added to the control at compile time.

Def Choice

Type String. Optional. The item in the control that is pre-selected. Can be a domain member name or *None*, which means "none of these domain members". If Optional (described below) is *True*, the <None> option is computer-selected. If Optional is *False* (the control is required), *None* has no meaning. This property is not available if either Quantity or Multi Sel is *True*, as these properties indicate that quantities greater than 1 are to be specified.

See and [Chapter 4, "Creating Objects for the Model," Creating a "None" Domain Member, page 80.](#)

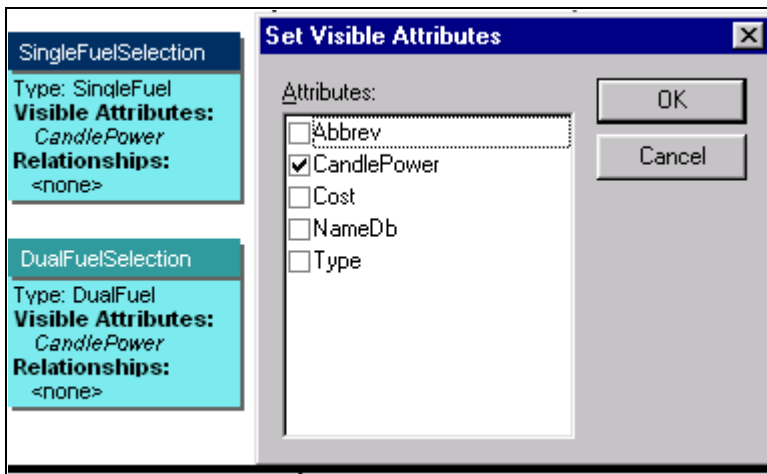

To view a model's selection points, select View, Show, Selection Points or click the selection point icon in the toolbar. The selection points are displayed on the left side of the model structure view.

A selection point participates in all relationships that refer to the original parent class. If a relationship is made directly between a selection point and another object, that relationship is confined to the selection point. To add a selection point, drag a class from the components view into the selection point area, or drag a class from the Model Structure View into the selection point area.

To delete a selection point, select it in the Model Structure View, then press the Delete key. Once created, a selection point can participate in relationships with classes or class attributes members in the modeling editor.

Note the Properties Editor entries for selection points. Because selection points interface with the UI, settings made here determine how controls behave at run time. A selection point can be designated as multi-select (the user can select more than one of its items), and/or optional. If a control is optional, the user does not have to make a selection on the control. If a selection point is required, the model will not be considered valid until a selection is made. Selection point properties (Table Editor) New selection points appear at the bottom of the selection points area, and at the end of the selection points listing in the component view.

A class can have many attributes, but if attribute values are to be selectable at run time, they must be made visible from the selection point. To do this, right-click on a selection point that has attributes, select Set Visible Attributes, and check any attributes that you want to display at runtime. When an attribute is made visible, it will be shown on all the selection points for a class. The display of an attribute cannot be confined to certain controls.

Set visible attributes on selection points

Internalizing Data

External data can be extracted from the database and automatically inserted and defined in the model as for manually entered data.

This is a necessary step if the model is to be deployed in an another environment where configuration will take place locally on a standalone version of Advanced Configurator. The Configurator Administration Console has a more comprehensive internalization function than does Visual Modeler. It can internalize data stored in files other than those in a database.

Internalizing data is a "one time" operation. Once it is performed, changes to the data in the database will no longer be reflected in the model. To internalize data on an ongoing basis, use the option available with the compile command on the Server's Administration page.

To internalize external data using the Visual Modeler, use the Project, Internalize Model command.

Chapter 30, "Using Administration Tools," Administration Console, page 419

Chapter 5

Creating Relationships Between Model Objects

This chapter lists prerequisites and common elements and discusses how to:

- Create and edit expressions.
- Create externs.
- Create a relationship.
- Work with relationships.
- Create relationships outside the model with SQL queries.

Prerequisites

Visual Modeler provides graphical ways to express common configuration relationships. You can create relationships between classes, class attributes, selection points, and selection point attributes.

Before you create relationships, verify these setup requirements:

- To create a relationship by using internal domain members, the Internal flag must be set to *True* on the parent class.
- To create a relationship by using external data, the Internal flag must be set to *False* and you must have a valid database connection.

See [Chapter 3, "Setting Up the Modeling Environment," Connecting to a Database from Visual Modeler, page 56.](#)

- The Elimination and Comparison constraints and relationships operate on expressions; therefore, expressions of the proper type—numeric, Boolean, string, and date—must be defined before they can be created.

Common Elements Used in this Chapter

Click the Compatibility Constraint button to create a constraint that identifies all *valid* combinations and eliminates all other possibilities. Click the button, move the cursor to the first object in the desired relationship, and then click and drag to the second object. You can set up compatibility constraints between two classes and between a class and a selection point. However, you can't set up a relationship between a selection point and a class.

Click the Requirement Constraint button to create a constraint that causes a default quantity to be selected or a default selection to be made. Click the button, move the cursor to the first object in the desired relationship, and then click and drag to the second object. You can set up requirement constraints between two classes and between a class and a selection point. However, you can't set up a relationship between a selection point and a class.

Click the Resource Constraint button to create a constraint based on the required quantities for particular selection. Click the button, move the cursor to the first object in the desired relationship, and then click and drag to the second object. You can define a resource constraint between two classes, two selection points, and between a class and a selection point. However, you can't set up a relationship between a selection point and a class.

Click the Summation Constraint button to create a constraint based on the sums of the values of class attributes. Click the button, move the cursor to the first object in the desired relationship, and then click and drag to the second object. You can set up summation constraints between two classes, two selection points, and between a class and a selection point. However, you can't set up a relationship between a selection point and a class.

Click the Dynamic Default Constraint button to create a constraint based on values determined at run time. Click the button, move the cursor to the first object in the desired relationship, and then click and drag to the second object. You can set up dynamic default constraints between two classes, two selection points, and between a class and a selection point. However, you can't set up a relationship between a selection point and a class.

Click the Expression button to open a dialog box to create a new expression.

Click the Elimination Relationship button to create a relationship that eliminates specified domain members when another domain member is selected.

Click the Comparison Relationship button to create a relationship that is executed when two values are compared. Output is either of numeric or Boolean type.

Click the Selection Points button in the Insertable Objects window of the expression editor, to insert a selection point object in the expression.

In the Insertable Objects window of the expression editor, signifies a domain member object that holds the value of the specified attribute from an extern.

In the Insertable Objects window of the expression editor, signifies an extern variable.

In the Insertable Objects window of the expression editor, signifies an expression that returns a date.

In the Insertable Objects window of the expression editor, signifies an expression that returns a numeric value.

In the Insertable Objects window of the expression editor, signifies an expression that returns a Boolean value.

Creating and Editing Expressions

An expression defines a variable. It associates a numeric, Boolean, date, or string value with a name. All relationships use expressions except summations and resource constraints.

An expression can contain:

- A literal value (to act as a constant).
- Selection point attribute values.
- A value that a user enters at runtime.
- Functions that operate on other expressions.

When you create an expression:

- The name appears in the Relationships or Expressions folder.
- The file name appears in the file list in the File view.
- The file name is automatically added to the project's .csp file.

There are a few points to remember while using the expression editor. When you create an expression, the numeric, Boolean, date, or string value within it is assigned to the expression name. Data for use in expressions can come from constants, class attributes, and other expressions.

Expressions have their own editor, which opens when you click the Expression editor button on the toolbar. The expression editor has these elements:

Return Type	Select the expression type to return values of types: <i>Numeric</i> , <i>Boolean</i> , <i>Date</i> , or <i>String</i> .
Expression	<p>Displays the expression. Insert an attribute or expression name into this window, select a name in the Insertable Objects list, and drag it, or double-click it. Large or complex expressions can be formatted in a text editor and then pasted into this area. Edit carefully. There is no error checking on expressions until the model is compiled.</p> <hr/> <p>Note. You should stabilize selection point and attribute names before writing expressions. When an object name changes, Visual Modeler updates listings, selection points, and other places that the name is displayed; however, an existing expression can't be updated because it is text. An obsolete attribute or expression name will not be found at compile time.</p> <hr/>
Name	Displays the expression name as defined.
Change Name	Opens a dialog box to change the expression name. Like other .cms objects, an expression is given a file name at the time of creation. This file name does not change when you edit the description name. The project manages the expression by the original file name.
Function Category	Select the general type of function to restrict the list of available functions in the Function Name list box to those that are appropriate for the expression type—Boolean, date, numeric, string, and user-defined. Or, click All to display the entire list of functions.
Function Name	Select the function by scrolling and selecting, or by clicking in the list box and typing the name of the function. The list box auto-scrolls to the function as you type its name. To narrow the list of functions to those that are available to its data type, click a function type in the Function Category list box.
Insertable Objects	<p>Lists all selection points and their attributes. It also lists all expressions that have been created thus far.</p> <hr/> <p>Note. The selection point name is shown for reference. Expressions operate on attributes only. To insert an attribute or expression into the Expression window, double-click its name.</p> <hr/>
Find	<p>Enter text to search the Insertable Objects list from top to bottom. This field performs a character match as you type.</p> <hr/> <p>Note. This feature isn't active until the list is long enough to scroll.</p> <hr/>

Refresh Functions From Server

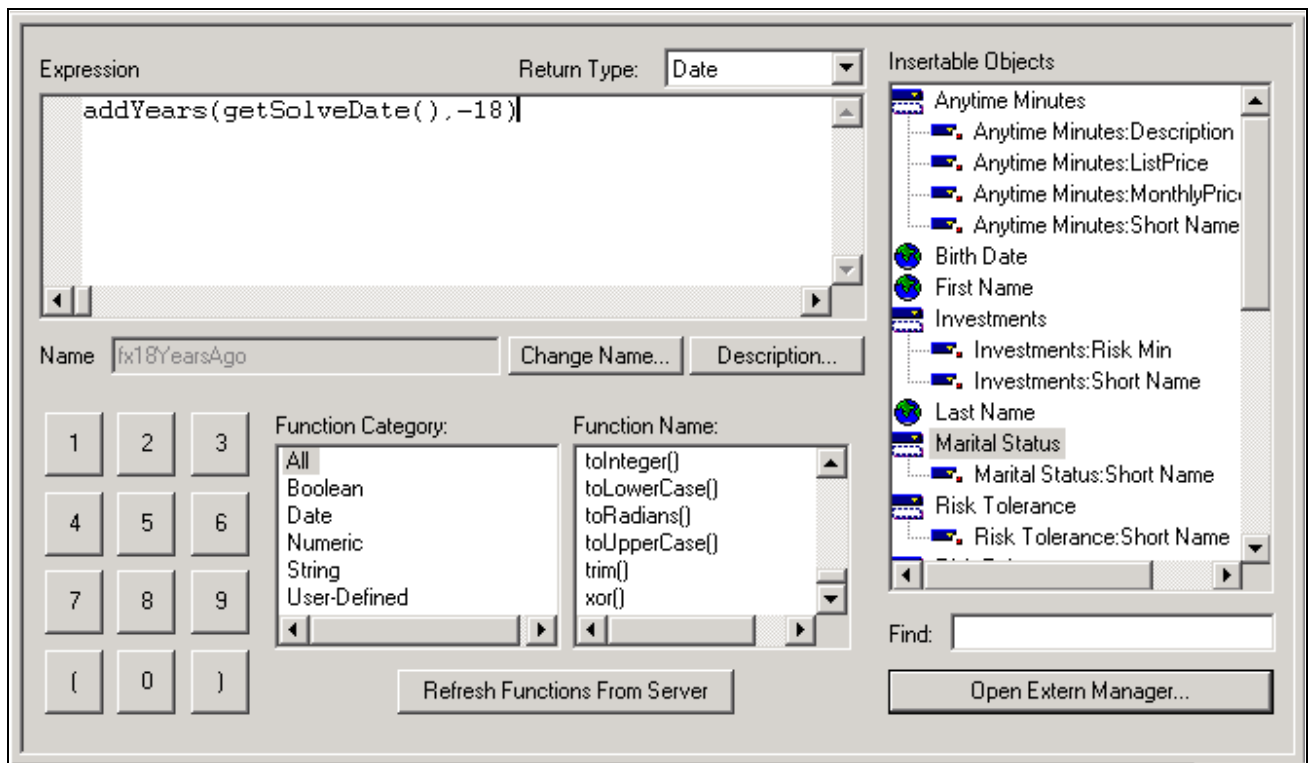

Click to retrieve user-defined functions (if any were defined) from the Configurator server. The Configurator server that the system accesses is specified in the Project Settings dialog box.

See [Chapter 3, "Setting Up the Modeling Environment," Specifying Model Project Settings, page 65.](#)

Open Extern Manager

Click to open the Extern Manager and add new extern variables to the Insertable Object list.

The following figure shows the expression editor window.

Expression editor

To create an expression:

1. Click the Expression editor button.

A name dialog box appears in which you name the new expression.

2. Click OK; the editor opens.
3. Write the expression in the Expression field by double-clicking the functions and insertable objects.

Enter additional information as necessary. Indicate the data type of the result in the Return Type drop-down list box.

Warning! Limit attribute values to 10 characters or fewer. Otherwise, the model will not compile.

See and [Appendix A, "Visual Modeler Expression Editor Functions," page 439.](#)

To delete a relationship or expression, select its name in the Components view and press the Del key, or right-click the name and select Delete.

Static Variables

A static variable is an expression that performs no operations and always returns a constant value.

To create a static variable, create an expression, set the return type, enter a value, and then close the window. (You cannot make an explicit assignment, such as *SalesTax*=9.5, inside the expression editor.) For example, to create an expression named *Airport Tax*, set the return type to *Numeric* and enter the value *12* in the Expression window.

External Variables

Use the external variable to retrieve a value—float, numeric, string, Boolean, or date—from the user or a database at runtime.

You cannot assign a value to a variable and operate on it in the same expression. Any calculated value must be assigned to its own expression name. Expressions can be built by using many other expressions.

User-Defined Functions

If you do not find a function that is appropriate to your specific needs, you can create one that is. To create your own function, you must create a description of the function in XML and write a Java class that implements the interface of Advanced Configurator. Sample code and sample files are provided.

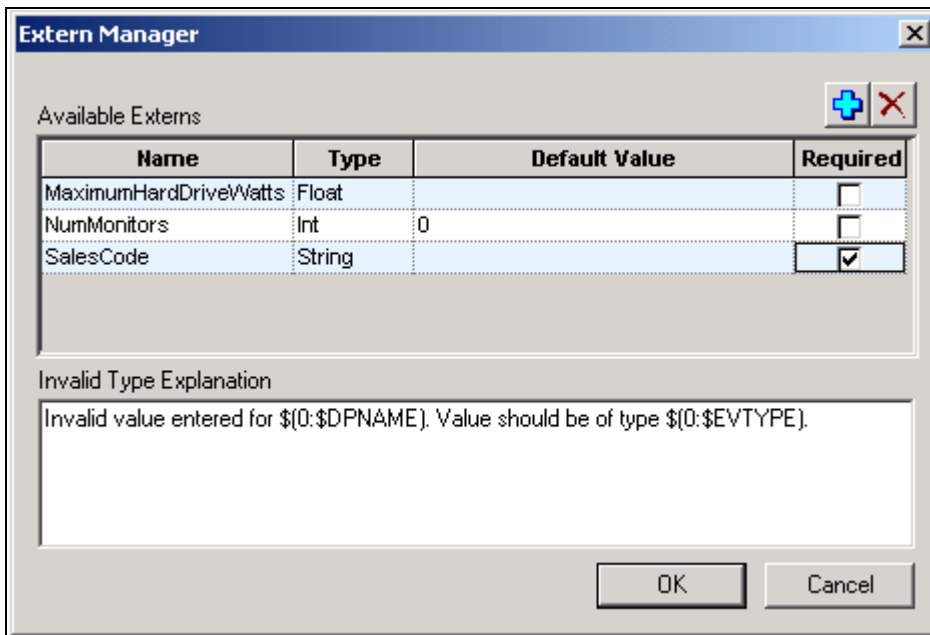

See and [Appendix B, "Creating and Adding User-Defined Functions," page 451.](#)

To display the user-defined functions in the function list of the Expression editor, click the Refresh Functions from Server button and compile the model.

Creating Externs

You can direct the model to pull data at runtime from outside sources such as the enterprise database. Externs can have the following types: float, integer, date, string, and Boolean. The modeler can specify a default value for each extern and specify whether the passed-in value is required. Defaults can be overridden by end-user input on the user interface (UI).

You can declare externs in the Extern Manager dialog box. The Extern Manager lists all externally referenced data for the component model:

Extern Manager dialog box

Externs participate in the right-hand side of requirement constraints. Each extern has a Required check box in the cells of its column, which, when selected, makes the extern required if the left-hand side conditions are satisfied. The Required check box is the only setting that is available for the constraint-level use of externs.

Extern-based controls display violations and Control Why Help when the extern is declared as an argument or as part of an expression that serves as an argument. The arguments can be in a variety of relationships, including eliminations, comparisons, requirements, and compatibility constraints. Externs that are marked *required* at the object level in the Extern Manager display violations and Control Why Help only when running the completeness check.

At runtime, the system checks each type of extern for accuracy, but only date externs are also checked for formatting errors. If the value is not of the right type or format, an error message is displayed to the end user.

Because the requirement of an extern doesn't affect propagation, the requirement of externs is determined after static and dynamic default selections are applied.

To declare an extern:

1. Select Project, Extern Manager to open the Extern Manager dialog box.
2. Click the Add button to add a new row to the table.

3. Specify the properties of each:

Type	Select <i>Boolean</i> , <i>Date</i> , <i>Float</i> , <i>Int</i> , or <i>String</i> .
Default Value	Enter a default value to appear in the UI when the configuration session begins or when it is reset.
Required	Select this check box if you want the extern to be required on a model-global basis. To make an extern required when constraint conditions are met, do not select the Required option in the Extern Manager, but rather in the constraint itself by inserting the extern as a column in the right-hand side of the relationship and selecting the Required check box in the cells.
Invalid Type Explanation	Enter the message that you want to appear to the user when the type of the data does not match that specified for the extern variable. You can define parameters for explanations to indicate the objects involved. See and Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.

4. Click OK.

The externs now appear in lists of objects for building requirement constraints.

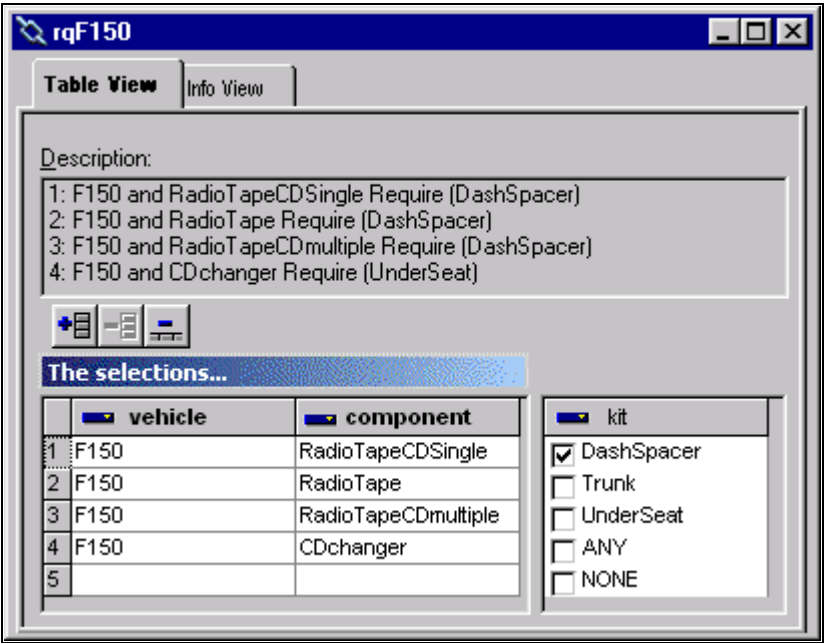

Creating a Relationship

You can start a relationship from either the Insert menu or the relationship palette of icons on the right margin of the application window. Depending on the type of relationship, one of two editors appears:

- The table-based editor, for compatibility and requirement constraints, and for dynamic defaults.
- The participant-list editor, for resource constraints and summation relationships.

The dialog boxes for compatibility constraints, requirement constraints, and dynamic defaults provide an opportunity to name the relationship and select the class or domain member attributes to constrain against. These relationships are created by using a table interface.

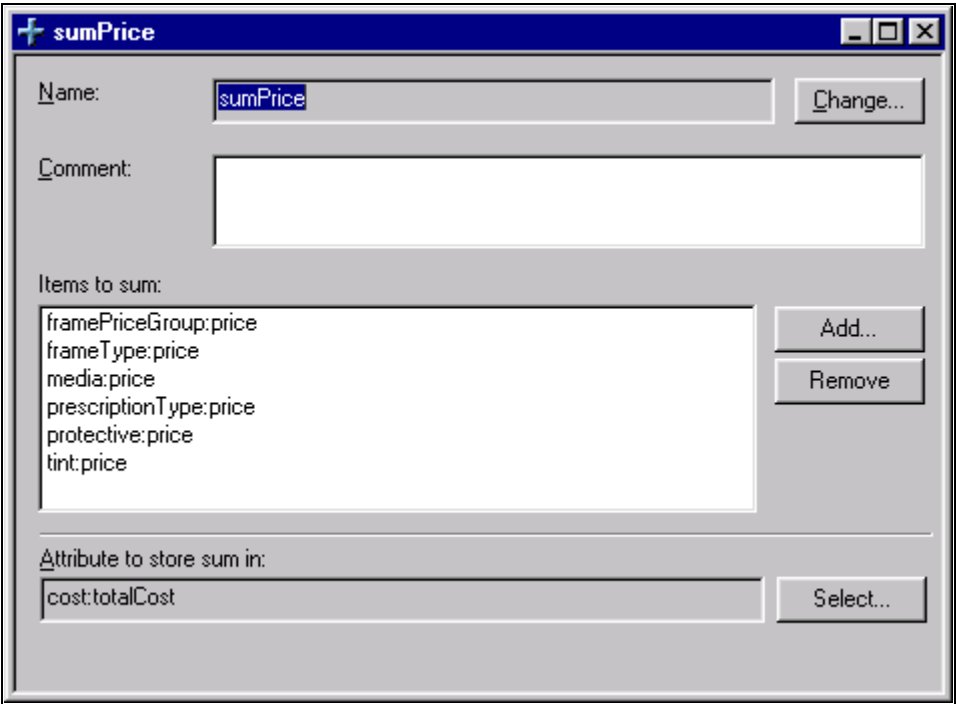

See and [Chapter 2, "Understanding Modeling," Relationships Between Objects, page 15.](#)

Requirement dialog box

The dialog boxes for resource constraint and summation relationships differ slightly because each participating object takes a specific role in the constraint. These constraints are created by using a simple list of participants.

See [Chapter 2, "Understanding Modeling," Relationships Between Objects, page 15.](#)

The dialog box for a summation

To launch the relationship editor:

1. From the Insert menu, select a relationship.

Alternatively, click a relationship icon on the palette.

If the relationship is an elimination or a comparison, the relationship editor appears immediately.

For all other relationships, you can draw a line to indicate the relationship after the relationship icon is selected. Position the cursor over a class; the class is highlighted. Click and drag to draw a line to another class; when the target class is highlighted, release the button. You can also draw a line from a class to a selection point.

2. Provide a name for the relationship.

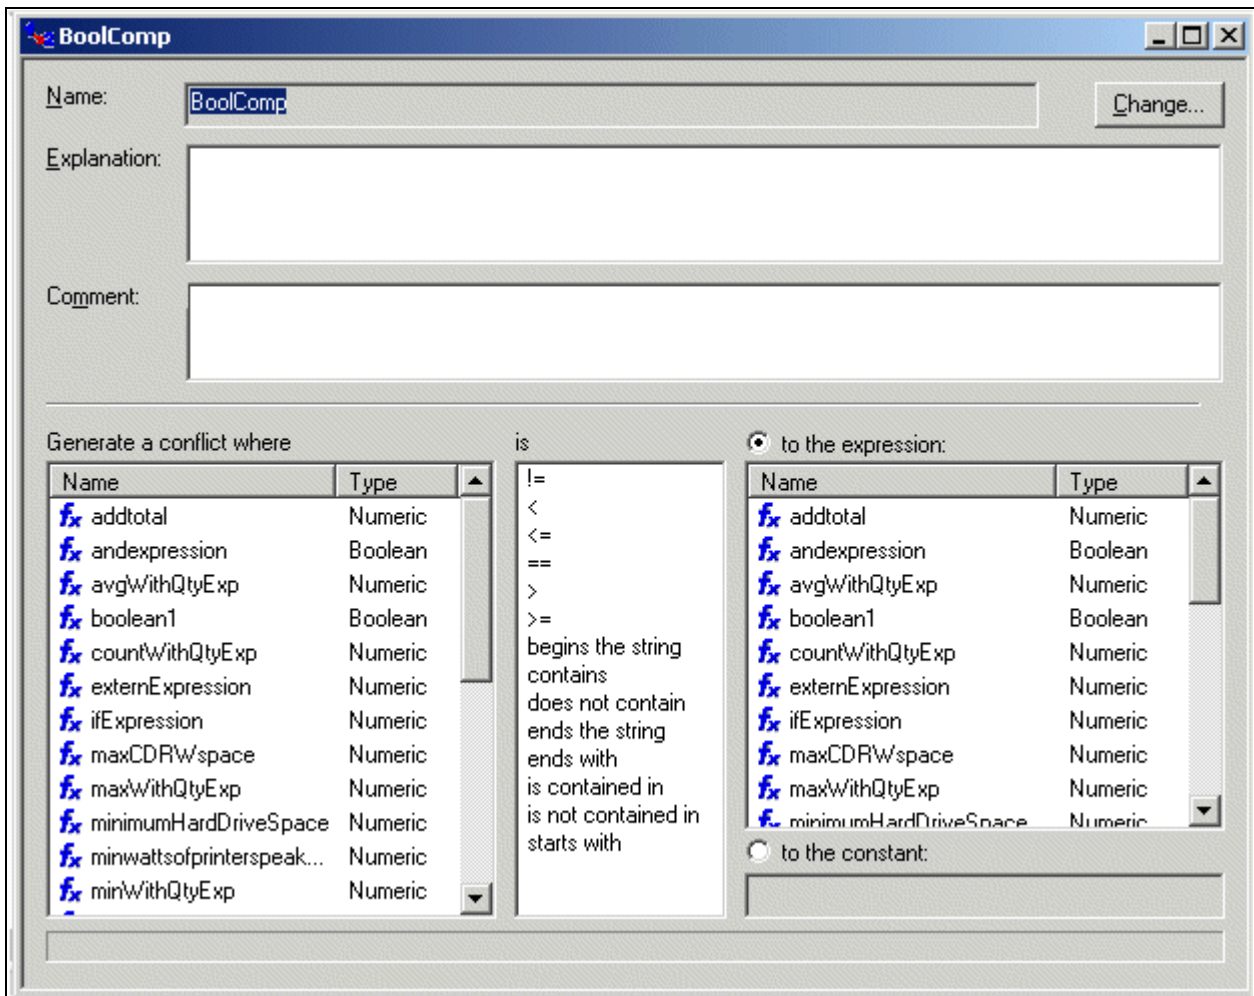

Note that the relationship name is assigned to a corresponding .cms file. To change a relationship name, click the Change button.

The dialog boxes for compatibility constraints, requirement constraints, and dynamic defaults provide an opportunity to name the relationship and select the class or domain member attributes to constrain against. These relationships are created by using a table similar to that shown in the example that follows.

See and [Chapter 2, "Understanding Modeling," Relationships Between Objects, page 15.](#)

Creating Relationships that Have Expressions

All relationships use expressions, with the exception of summations and resource relationships. The figures below show a numeric elimination, numeric comparison, and Boolean comparisons, respectively. To create a comparison or elimination relationship, click its icon on the palette. The comparison editor lists operators and available expressions; the elimination editor lists operators, selection points, and expressions. From these lists you can build an elimination or comparison expression that determines when a conflict will occur. If you have no expressions of a given type, the corresponding editor field is empty.

Comparison editor before expressions are selected

To include an expression in either the left- or right-hand side of the relationship:

1. Click the heading of the column to the right of where you want to insert the expression.
2. Click the Add Column button.

The Object Selection window displays, listing the available objects.

3. Scroll to the expressions, which are at the end of the list, and double-click the one that you want.

It is inserted into the new column.

4. If the relationship is a requirement constraint, dynamic default, or a compatibility constraint, define the relationship for each domain member:
 - a. Click in the cell of a domain member column to open a drop-down list box that contains the allowed domain member options.

For instance, rows of the selection point columns contain lists of domain members; expression columns contain subcolumns for operators, expression type (function or constant), and value.

- b. In the same row as the domain member, click the cells of the expression subcolumns.

The first subcolumn, beginning left to right, contains a list of the allowable operators for the expression. The second subcolumn is the argument type, constant or function $f(x)$, of the value that is operated on. The third column is the value. If you chose the constant type in the preceding subcolumn, type the value. Be sure that it is the correct data type for the expression. If you chose the function argument type, use the cell drop-down list box to insert the expression.

Note. The allowed choices for comparison operators depend on the return type of the expression argument. Similarly, allowed choices for the constant values depend on the expression argument's return type. Selecting an operator with the function symbol $f(x)$ narrows the allowed choices in the values subcolumn to a list of expressions that are compatible with the column's expression type.

- c. Repeat these steps for each domain member.
5. On the other side of the relationship, select the argument for the relationship from the list for the domain member or selection point.

Note. You can't add expressions to the right-hand side (RHS) of a compatibility, requirement, or dynamic default constraint.

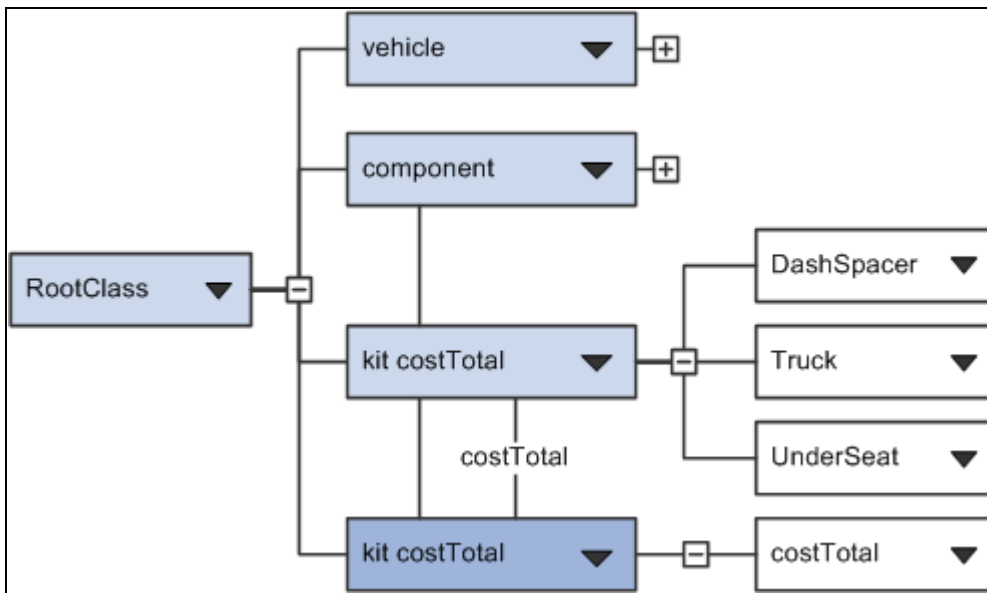

Working with Relationships

When a relationship is created:

- The name appears in the Relationships folder.
- The file name appears in the file list in the File view.
- The file name is automatically added to the project's .csp file.

To delete a relationship or expression, select its name in the Components view and press the Del key, or right-click the name and select Delete. The constraint is removed from its .cms file. If the .cms file is then empty, you can delete it and manually remove the file name from the .csp file from the File view.

To display relationships in the Model Structure view, click a participating object, such as a class. Red lines appear, connecting all participants. The relationship name appears on the connecting lines. Double-clicking the name opens the relationship editor.

The costTotal relationship between subclasses cost and kit and subclasses cost and component

When an object is selected, the Attributes tab shows the relationship or expression name and the path to the file containing the relationship.

To reopen an editor, double-click its name in the Components tab.

Relationships Displayed as a Table

Compatibility, requirement, and dynamic default relationships are created by using a table-based editor.

The Relationship Editor toolbar appears directly above the table. The buttons are:

Add Column button. Add a column to the right of the current selection.

Add Row button. Add a row below the current selection.

Delete Column button. Click to delete the selected column.

Delete Row button. Click to delete the selected row.

Direction button. Toggle the directional bar in the current editor.

Toggle Compatibility button . Click to toggle the compatibility direction of the expression.

Clear LHS button. Clear all selected items on the left-hand side.

When inserting columns in a directional constraint, click to the right or left of the bar before clicking the Add Column button.

To resize columns, position the cursor over a header's vertical border and then drag left or right.

To move a column, position the cursor over its name, then drag the column to a new position; a red vertical line appears when a possible location is reached.

Note. The column of check boxes cannot be moved.

Table View | Info View

Description:

- 1: Married and (fxAge > fxSpouseAge) Default (Main Applicant)
- 2: Married and (fxAge == fxSpouseAge) Default (Same Age)
- 3: Divorced and (fxAge < fxSpouseAge) Default (Spouse)
- 4: Single and (fxAge >=) Default ()
- 5: <Missing Value> and (fxAge) Default ()

The selections...

	Marital Status		fx fxAge
1	Married	>	f(x) fxSpouseAge
2	Married	==	f(x) fxSpouseAge
3	Divorced	<	f(x) fxSpouseAge
4	Single	>=	const
5			const
6			const
7			

Will default the selections.

Who is Older

- ☒ Main Applicant
- ☐ Not Applicable
- ☐ Same Age
- ☐ Spouse
- ☐ ANY
- ☐ NONE

Dynamic default example using an expression on the left-hand side

In the preceding example of an expression, if the value of Married is greater than the value of SpouseAge, then the default selection is Main Applicant.

Table-based relationships have the Format property, which enables you to define them within a database table.

See and [Chapter 5, "Creating Relationships Between Model Objects," Creating Externs, page 100.](#)

Expressions (Boolean, numeric, string, and date expressions) can participate as arguments (that is, columns) only on the left-hand side (LHS) of the expression; only the dynamic default can have expressions in both the left-hand and right-hand sides of table-based relationships. Each row of the expression column comprises two subcolumns—the comparison operator subcolumn followed by the values subcolumn. The allowed choices for the comparison operators depend on the return type of the expression argument. In turn, input validation for the constant values depends on the expression argument's return type. To reference other expressions in the values subcolumn, the term $f(x)$ is attached to copies of the allowed comparison operators. If the relationship is on the RHS and you choose a $f(x)$ version of the operators, you narrow the allowed choices in the values subcolumn to a list of other expressions that are compatible with the column's expression type.

Relationships Displayed with Participant Lists

For the resource constraint and summation relationship, the relationship editor displays a list of the attributes that are involved. They differ somewhat from table-based relationships in that each participating object takes a specific role in the constraint.

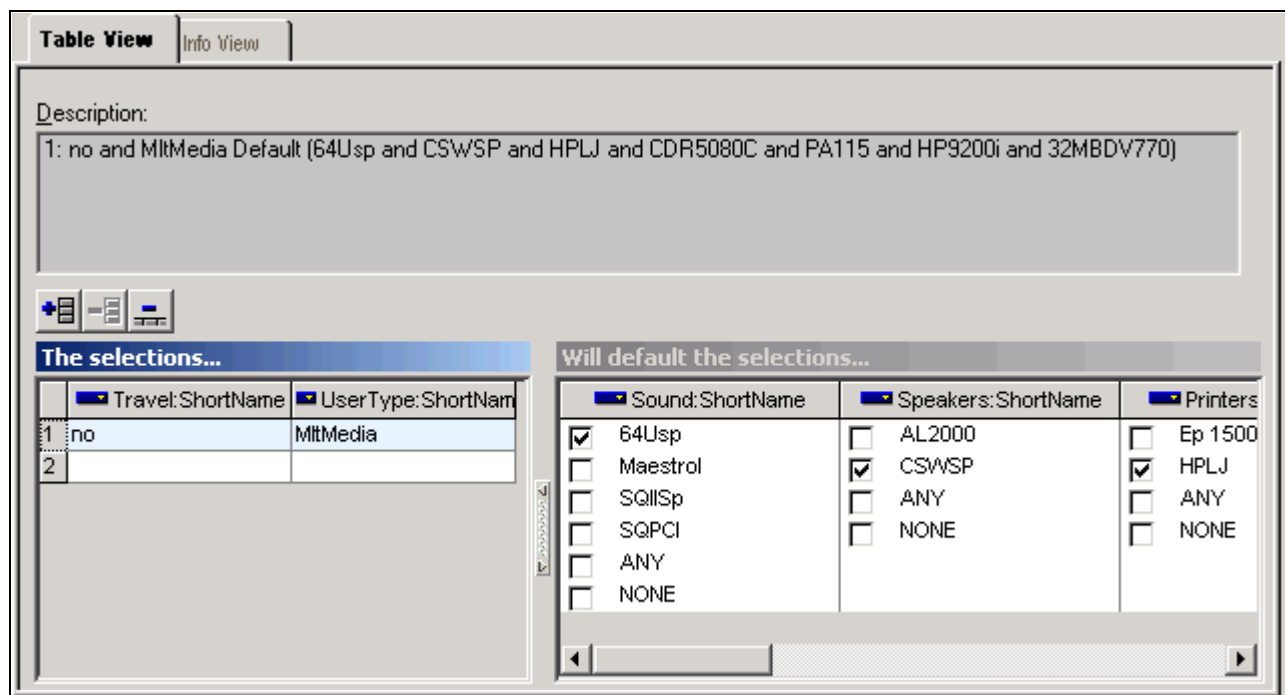

Editing Compatibility Constraints

In a compatibility constraint, the constraint type can be toggled from *Compatible* to *Not Compatible*. Typically, the majority of domain members are compatible. Check the Description window to verify that you have the expected setting.

ANY and ALL

The selection option ANY can appear in each row and column where internal data is used. ALL appears where external data is used.

Note. ALL does not exist in the database; it is merely a shorthand representation that Visual Modeler displays so that you can select all queried domain members. ALL implies that any queried value is acceptable.

Compatibility constraint

Editing Requirement Constraints

The requirement constraint is displayed in a table similar to the compatibility constraint. ANY and ALL behave as they do in compatibility constraints.

Table View | Info View

Description:

1: C433Mini Require (10Foot and mini)
 2: P3750Mid Require (15Foot and Mid)
 3: P3X100F Require (20Foot and Full)
 4: TM3120 Require (PwrBrk and Slim)
 5: TM5400 Require (PwrBrk and Slim)

The selections...

	Base:ShortName
1	C433Mini
2	P3750Mid

<input type="checkbox"/>	PwrBrk	<input type="checkbox"/> Slim
<input type="checkbox"/>	ANY	<input type="checkbox"/> ANY
<input type="checkbox"/>	NONE	<input type="checkbox"/> NONE

Requirement constraint

See Also

[Chapter 2, "Understanding Modeling," Requirement Constraint, page 18](#)

Editing Dynamic Defaults

A dynamic default is a way to specify that a particular item will be preselected in response to a runtime event, such as a user selection. An end user can override a dynamic default without violating a constraint. (If a user overrides a constraint, a violation occurs, which can prevent a user from completing a valid configuration unless the selections are altered.) Regardless of the default, if all but one choice is constrained away, the remaining choice will be computer-selected. This behavior occurs automatically; no programming is required.

The dynamic default relationship table is similar to that of the compatibility or requirement constraints. ANY has the same significance. Dynamic defaults include the option NONE for every row. Selecting NONE means that there are no defaults for that combination of domain members, or that every combination of class and domain member properties is to be ignored. NONE allows you to work with queried values without knowing the specific domain members.

Dynamic Default

Note. Do not confuse the relationship editor NONE option with the None that is displayed at runtime.

See [Chapter 4, "Creating Objects for the Model," Creating a "None" Domain Member, page 80.](#)

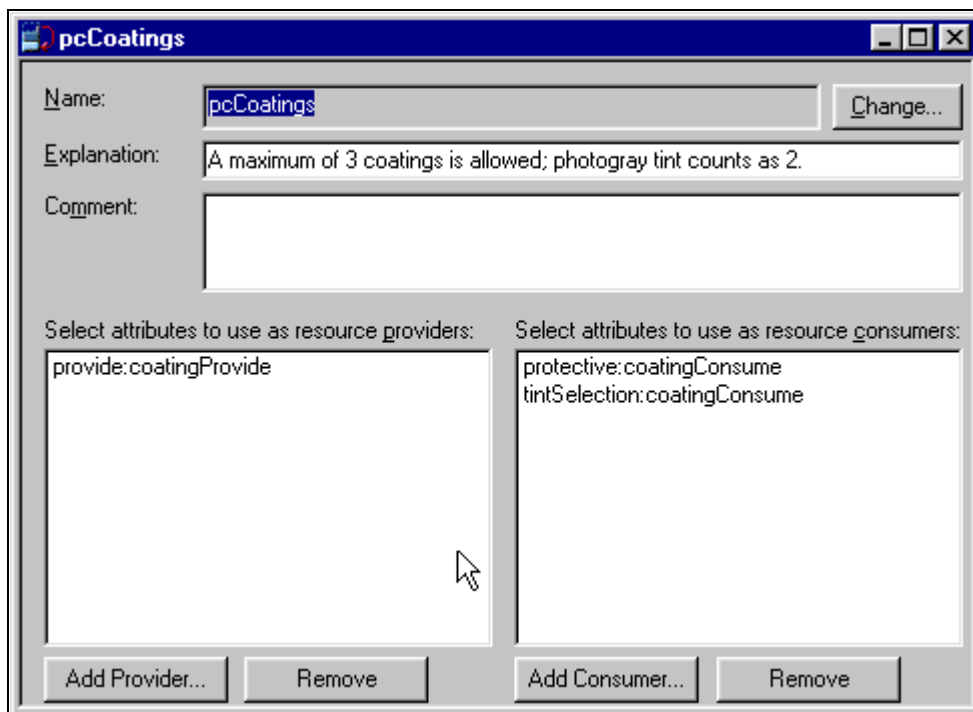

By default, the Comment area displays an equation for each selected combination.

Editing Resource Constraints

For the resource constraint, the relationship editor initially displays the classes or attributes that were selected or defined when the constraint was created. However, the system allows multiple providers and consumers. Clicking the Add Provider, Add Consumer, or Remove button displays a list of all attributes in the model.

Note. For the constraint to work correctly at runtime, the provider must be a selection point. The Model Tester automatically supplies controls for the provider and consumer so that you can monitor resources as choices are made.

The following figure shows an example in which a lens is arbitrarily assigned as a resource that can contain no more than three coatings. The coatings might take the form of a tint or other coating type, such as an anti-reflective coating.

Lens resource and coating consumer

Editing Summation Relationships

Attribute summation uses a dialog box similar to that of the resource provider relationship. It simply lists all of the classes that contain the attribute that you want to sum. The total is placed in a domain member attribute on the class specified in the Attribute to store sum in field. The sum automatically appears in the Model Tester.

Note. The attribute that is used to store the sum must be different from the attribute that is totaled, or it must be a child of a class that is not participating in the summation relationship.

A summation constraint cannot calculate quantity. Instead, you must use an expression that uses `sumWithQty()`. An expression can use `sum()` or the `+` operator to accomplish the same task as this relationship. An expression has the additional capability to sum external variables.

Editing Elimination Constraints

An elimination compares a specific attribute value on a selection point with the value of a numeric, Boolean, string, or date expression. For example, you might create an elimination constraint so that domain members of the selection point `HardDriveSelection` are eliminated if the value of the selected hard drive's `Watts` attribute exceeds the value passed in by `externExpression`.

The layout of the options in the elimination editor allows you to build a constraint in logical order. The following table details each of the editor's options:

Explanation	Enter the message that the user sees when the conditions that are defined in the elimination are met.
Comment	Enter internal notations.

Allow	<p>Specify which members of a selection point are eliminated. Values in the Allow list vary depending on the type of attribute that is specified.</p> <p><i>All Of:</i> The domain members that did not satisfy the condition are eliminated. Supported by all attribute types.</p> <p><i>None Of:</i> The domain members that did satisfy the condition are eliminated. Supported by all attribute types.</p> <p><i>The First Of:</i> All domain members are eliminated except the first domain member that satisfies the condition. Supported by Boolean and string types.</p> <p><i>The Last Of:</i> All domain members are eliminated except the last domain member that satisfies the condition. Supported by Boolean and string types.</p> <p><i>The Least Of:</i> All domain members are eliminated except the domain members that contain the smallest numeric value out of all domain members that satisfy the condition. For example, if A1, A3, A7, and A9 satisfy the condition with attribute values of 3, 7, 3, and 9, then every domain member except A1 and A7 is eliminated. Supported by the numeric type only.</p> <p><i>The Greatest Of:</i> All domain members are eliminated except the domain members that contain the largest numeric value out of all domain members that satisfy the condition. For example, if A1, A3, A7, and A9 satisfy the condition with attribute values of 3, 7, 3, and 9, then every domain member except A9 is eliminated. Supported by the numeric type only.</p> <p><i>The Earliest Of:</i> Analogous to <i>The Least of</i>. Supported by the date type only.</p> <p><i>The Latest Of:</i> Analogous to <i>The Greatest of</i>. Supported by the date type only.</p>
the members of	Select model selection points.
where	Select from a list of all domain members for the selection point that is selected in <i>the members of</i> column.
is	Select an operator. The list of available values varies with the domain member type.
to the expression	Select the expression option to specify the constraint's determining value at runtime.
to the constant	Select the constant option to set a known, static value. Use this option to test the constraint.

To create a definition, select:

1. A selection point from the members of column.
2. An attribute from the where column.
3. A comparison operator from the is column.
4. Either the to the expression or to the constant option.

5. A selection from the Allow column.

Repeat selections 2 through 4 for each attribute of the selection point class.

Note. The attribute type must match the expression or constant type.

During runtime, the system uses the comparison operator in the is column to compare the domain attribute value to the value that is supplied by the specified expression or by the constant.

If the comparison evaluates to true, the system adds the domain member to a list of domain members that satisfy the condition of the elimination.

Editing Comparison Constraints

The comparison editor, like the elimination editor, is designed so that you can build and view the constraint in logical sequence.

Like the elimination editor, the comparison relationship editor allows you to enter an arbitrary constant for comparison. You can use this constant instead of creating an expression to represent the value.

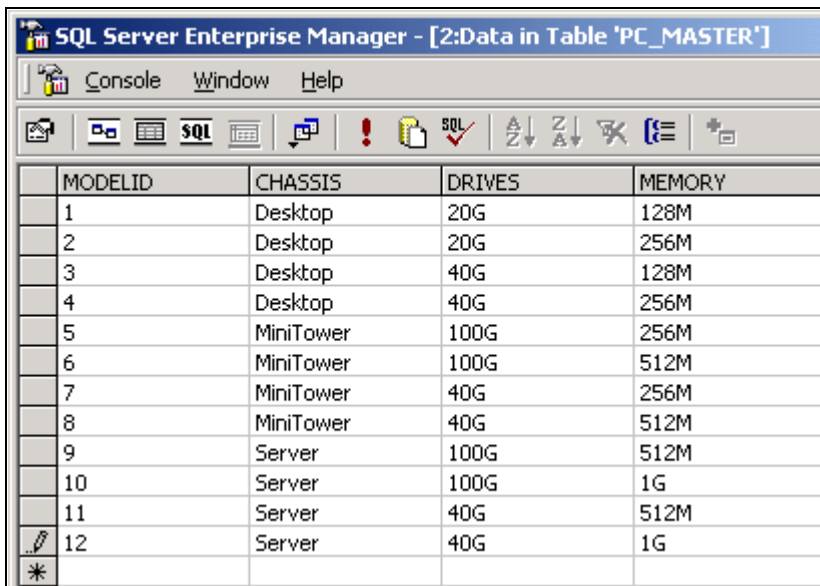

To create a comparison, select one item from each of the columns. Operators presented in the is column depend on the type of expression that is selected in the Generate a conflict where column.

Note. Attribute types for the expressions (and constant if used) must match.

Creating Relationships Outside the Model with SQL Queries

You can use the SQL query feature to define constraints. This feature removes the constraint definition from the model altogether and places it in a database.

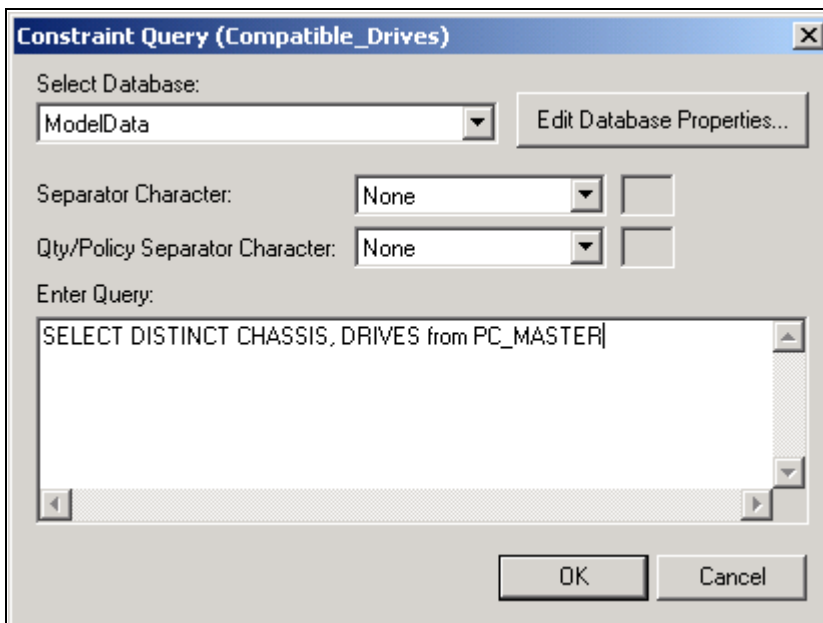

The SQL query uses a SELECT DISTINCT statement to dynamically retrieve the domain member combinations that are compatible. To update compatibilities, you edit the database entries rather than the constraint definition in the model, eliminating the need to recompile the model. Thus, SQL query constraints allow you to store the compatibility of product options in a SQL table and drive product logic dynamically from within a database.

MODELID	CHASSIS	DRIVES	MEMORY
1	Desktop	20G	128M
2	Desktop	20G	256M
3	Desktop	40G	128M
4	Desktop	40G	256M
5	MiniTower	100G	256M
6	MiniTower	100G	512M
7	MiniTower	40G	256M
8	MiniTower	40G	512M
9	Server	100G	512M
10	Server	100G	1G
11	Server	40G	512M
12	Server	40G	1G

Constraint Query dialog box showing a sample query

Changing the directionality of the constraint

Assigning the SQL Query property in the relationship properties panel

To create a SQL query constraint:

1. Set up the classes by associating each column in the table with an attribute in the class.

Note. Don't use the system-defined attribute Name as a constraint item. You must add your own attribute. In the example, an attribute was created called *chassis*, and then the value in the attribute that corresponds to the distinct values in the table was added. For example, the Desktop Chassis domain member has an attribute called chassis, and its value is Desktop. (Optional step) Set up a SQL Query for the domain members as well. The SQL statement for the class retrieves its data from the Chassis column in the table. Then, using a DISTINCT clause in the SQL statement, it retrieves all of the possible values for the domain member list. This step saves having to add these values manually.

2. Define the constraint:

- a. Create the constraint by using the compatibility constraint editor.

The New Compatibility Constraint dialog box appears first, in which you select the attributes.

Warning! In the New Compatibility Constraint dialog box, be sure to select the correct attribute for the constraint arguments, as this is critical for the constraint to work properly. The constraint will not work if you use the default constraint argument.

- b. Make the constraint nondirectional by clicking the button on the editor toolbar.
- c. Change the format in the Properties panel to *SQL Query*.

The Constraint Query dialog box appears.

Note. Table and column names are case-sensitive.

- d. Specify a standard SQL query for each column in the constraint, separating the queries with a comma.

Make sure that the RHS columns and LHS columns of the constraint are present on the attribute that it is being mapped to, rather than just the selection point name. You can specify that a space or another separator be used in the query output to allow for current data formatting.

- e. Click OK.

The constraint is populated with values.

If a dynamic default contains default quantities, you can specify the quantities in the database if the column refers to a selection point with quantity. Do so by separating the policy, quantity, and value using a user-definable quantity and policy separator. For example, if @ is the separator, an entry in the database would be MIN@4@Tires. The policy can be MIN OF, MAX OF, or SUM, and the quantity must be a number.

Note. The quantity cannot be an expression reference.

Chapter 6

Specifying Quantities on Selection Points

This chapter provides an overview of quantity setup and discusses how to:

- Specify the number of allowed selections and optional or required status.
- Specify single- or multi-select controls.
- Set quantity limits on domain members.
- Set default quantities and selections.
- Define a dynamic default quantity for a selection.
- Attach metadata to selection points.

Understanding Quantity Setup

After you have set up the model's classes and objects and defined their relationships, you are ready to define the properties on their selection points, including the model's quantities. Use the selection point's property table to define its quantities.

To view a model's selection points, select View, Show, Selection Points or click the View Selection Point button in the toolbar. Click the selection point to update the property table with its current property values.

Alternatively, you can click the selection point's name on the Components tab.

Setting up quantities involves these general steps:

Step	Reference
Specify whether a selection must be made from the selection point, and how many selections can or must be made.	See and Chapter 6, "Specifying Quantities on Selection Points," Specifying the Number of Allowed Selections and Optional or Required Status, page 120.
Decide how many selections the user can make.	See and Chapter 6, "Specifying Quantities on Selection Points," Specifying Single- or Multi-Select Controls, page 121.
(Optional) Set ranges for allowable domain member quantities.	See and Chapter 6, "Specifying Quantities on Selection Points," Setting Quantity Limits on Domain Members, page 122.

Step	Reference
If you want one or more items to be preselected, specify which domain members you want to appear and in what quantity.	See Chapter 6, "Specifying Quantities on Selection Points," Setting Default Selections and Quantities, page 124.
Define quantity application behavior for dynamic defaults and requirement constraints.	See Chapter 6, "Specifying Quantities on Selection Points," Defining a Dynamic Default Quantity for a Selection, page 128.

Specifying the Number of Allowed Selections and Optional or Required Status

This section describes how to specify how many different items (domain members) within the selection point—not the quantity of each selected item—that the end user can make in the control that is associated with the selection point. In the process, you also specify its optional or required status.

For example, in a selection point that contains items A, B, C, and D, a minimum of 2 means that the end-user *must* choose at least two items, such as B and C or A, C, and D. Note that a minimum greater than 1 designates the selection point as multi-select. If minimum = 0, the end user isn't required to choose any of the items—the selection point is considered optional.

Note. This section also describes how to specify single- and multi-select controls, and whether the end user is required to select at least one of its items. As described elsewhere in this chapter, you can use the Multi Sel and Optional properties to accomplish the same purpose. However, the Multi Sel and Optional properties do not allow you to specify a quantity; using the min/max quantity properties as described here gives you the full scope of the default quantity and min/max functionalities.

To specify the number of allowed selections, in the selection point's property table, select *Use Min/Max = True*.

Name	Type	Value
Name	String	Size_1
Filename	String	c:\Program Files
Type	String	Size
Quantity	Bool	False
Use Min/	Bool	True
SP Min/M	Editor	Edit...
Defaults	Editor	Edit...

Properties table for a selection point

Note. If you are not interested in defining minimum and maximum limits on the selection point, you can use the Optional property to specify the selection point type. (Optional = False specifies a required selection; Optional = True specifies an optional selection.)

Click the Edit button for SP Min/Max. The Selection Point Min/Max dialog box for the selection point appears:

Selection Point Min/Max For BaseSelection

Selection Point Minimum Selections

☒ Number

☐ Expression

☐ SQL Query

Database

Explanation

Selection Point Maximum Selections

☒ Number

☐ Expression

☐ SQL Query

Database

Explanation

Selection Point Min/Max dialog box for the selection point

Specify a minimum number of selections in one of three ways:

- *Static:* Enter in the Number list box either 0 (the user is not required to select from this selection point), or a quantity of 1 or greater, not to exceed the number of different items in the selection point.
- *Runtime, by expression:* If you want the number of selections to be determined at runtime by an expression, select Expression and select the expression that was created earlier from the drop-down list box.
- *Runtime, by SQL Query:* If you want the number of selections to be determined by stored data, select SQL Query, write the query in the entry box, and specify the database by name.

Note. Advanced Configurator looks for the selection value in question in the first column of the first row of the data returned by the SQL query. Thus, you should create a query that returns only one column and one row.

In the Explanation field, enter a message to be displayed to the user when the minimum and maximum quantities are not satisfied during runtime.

See [Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.](#)

Specifying Single- or Multi-Select Controls

You can designate a selection point's single- or multi-select property in two ways:

- Set a minimum of 2 or more, as in the previous section.

You may, in fact, have already specified it.

- Set a maximum of 2 or more, as described in this section.

Note. If you do not intend to define quantities on the selection point, you can use the Multi Sel property to specify selection point type. (Multi Sel = False specifies a single-select selection point; Multi Sel = True specifies a multi-select selection point.)

When Use Min/Max is changed from False to True, the selection point's properties provide the default values for the SP Min/Max and DM Min/Max dialog boxes. For example, if the selection point is Multi Sel=True, Optional=False, and Quantity=True, then changing Use Min/Max from False to True gives settings of SP Min = 1, SP Max = Unbounded, DM Min = 0, and DM Max = Unbounded.

To specify single- or multi-select, as you did for the selection point minimum, specify values for the maximum limit:

- Single-select: Number = 1.
- Multi-select: Number = 2 or greater, or *Unbounded*.

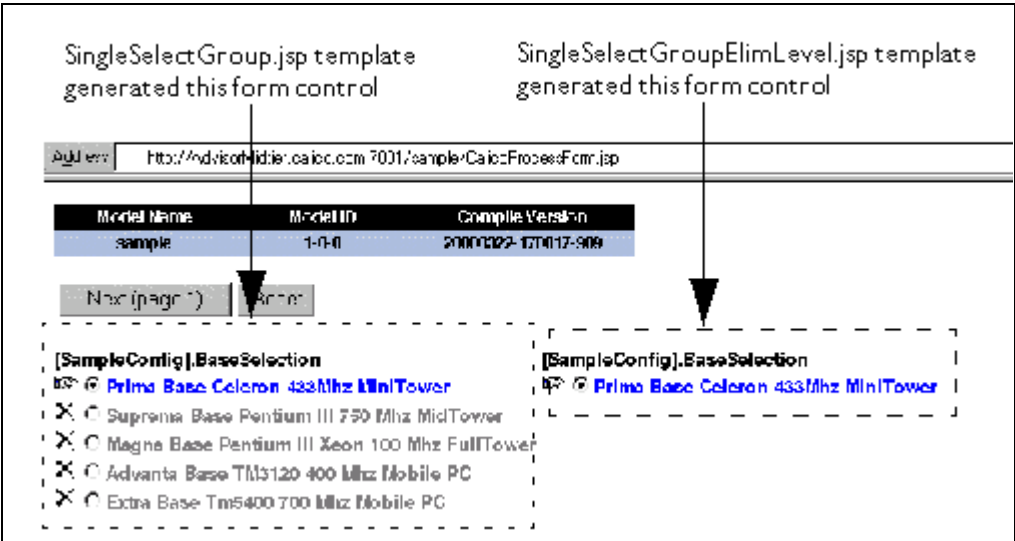

For multi-select controls, *Unbounded* allows the number of selections to be any number of domain members in the selection point. Using *Unbounded* makes model maintenance easier in cases where all domain members can be selected and the number of domain members may change over time.

In the Explanation field, write a message to be displayed to the user when the maximum number of selections is exceeded during runtime.

See and [Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.](#)

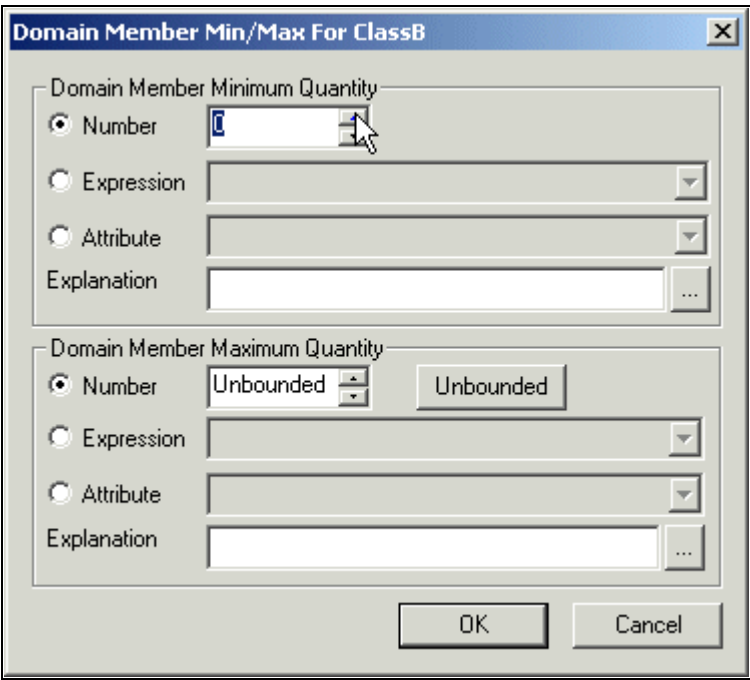

Setting Quantity Limits on Domain Members

Use domain member limits to place a minimum or a maximum limit or both on the number of the selected domain member. These limits apply to all domain members in the selection point. You can set quantity limits on the domain members of both single- and multi-select selection points. In the following example, the end user can choose no more than three of any one item (it is a single-select control):

Example of single-select control

The following example shows the domain member for the Min/Max dialog box for the selection point ClassB:

Min/Max dialog box

Number Enter a numeral to be used as an absolute number.

Expression If you want the minimum quantity to be determined at runtime by an expression, select this option and then select the expression from the drop-down list box.

Attribute	If you want the minimum number to be determined by an attribute value, select this option and select the attribute from the drop-down list box.
Explanation	Enter a message to be displayed to the user when the minimum and maximum quantities are not satisfied during runtime. See and Chapter 2, "Understanding Modeling," Creating Parameterized Explanations, page 46.
Unbounded	Click this button to Indicate that there is no upper limit.

To set minimum and maximum limits on domain members:

1. On the selection point's property table, set Quantity to *True*.
2. Set Use Min/Max to *True*.
3. Click the Edit button for DM Min/Max to access the Domain Member for Min/Max dialog box.
4. Select either *Number*, *Expression*, or *Attribute* to indicate the source of the value for the minimum quantity.
5. In the Explanation field, enter a message to be displayed to the user when the minimum and maximum quantities are not satisfied during runtime.

An example message is: "Please enter a quantity of at least 3 racks." Be sure that the message is specific enough to be helpful but that it makes sense for all domain members in the selection point.

6. Enter settings for the maximum quantity as you did for the minimum quantity.

Use the Unbounded button to indicate that there is no upper limit on the quantity.

Setting Default Selections and Quantities

You can set the selection point to display one or more default selections with quantities, to be displayed when the end user starts the configuration. The source for these quantities can be:

- **Explicit:** The modeler specifies the default value in the model.
- **Attribute:** The modeler specifies an attribute of the domain member from which to retrieve the value at runtime.

Edit Default Choices

Get default quantities from an attribute

Quantity Policy:

Overridable

Attribute:

Specify default quantities explicitly

Quantity Policy	Quantity Value/Expression	Domain Member
Overridable	0	64 Voice w/ Speakers
Overridable	0	Maestro Integrated Sound
Overridable	0	Super Quad II w/ Speakers
Overridable	0	Super Quad PC1 Card

Use Quantity Policy for All Domain Members

Policy

Quantity

0

OK

Cancel

Edit Default Choices dialog box

Quantity Policy

Specify the quantity-choosing behavior to apply when constraints derive quantity values of their own in response to runtime input.

Overridable, Overridable $f(x)$: The quantity applied by the dynamic default or requirement constraint will be the final configuration quantity for that domain member.

See and [Chapter 2, "Understanding Modeling," Interaction between Default Quantities and Min/Max Settings at Run Time, page 44.](#)

Min of, Min of $f(x)$: Apply the quantity value or expression result as a minimum quantity that will be selected as a default for the domain member.

Max of, Max of $f(x)$: Apply the quantity value or expression result as the upper limit of the quantity that will be applied to the domain member.

Sum, Sum $f(x)$: Add the quantity of each default selection of the domain member with the dynamic defaults and requirement constraints.

For instance, if ItemA has a default of 2 and a dynamic default that specifies the quantity 2, then the runtime quantity of the domain member is 4.

Quantity Value/Expression

Click in the cell of the desired domain member and select or enter a numeral (0 to n), or an expression that depends on the quantity policy that is selected. If you select an expression, the value resulting from the expression is used. 0 indicates that the domain member is not selected by default.

Domain Member

This field displays the name of the domain member in the selection point. This field is display-only.

Use Quantity Policy for All Domain Members

Specifies whether and how to apply a default quantity to all the domain members.

Policy and Quantity fields specify the same entries as the Quantity Policy and Quantity Value cells for individual domain members described above.

Setting Explicit Default Choices and Quantities

To set up default selections and their quantities:

1. On the selection point's property table, set Quantity to *True*.

The table adds the property Use Min/Max.

2. Click the Edit button for Defaults to display the Defaults editor.
3. Enter the desired quantity (1 to n) in the appropriate Quantity Value/Expression cell for the domain member.

0 indicates that the domain member is not selected by default.

4. In the selection point's property table, set Use Min/Max to *True*.

5. Click the Defaults Edit button to open the Defaults editor dialog box again.
6. If you want the default quantity to be determined by an expression, select the $f(x)$ version of the displayed quantity policy in that cell's drop-down list box.

Return to the Quantity Value/Expression column and select the expression from the drop-down list box. (Expressions are defined in the Expression editor).

7. If there are dynamic default constraints or requirement constraints that could select a domain member during runtime, consider whether you want the default quantity entered in the table cell to remain in effect if one (or more) of the dynamic defaults and requirement constraints picks the domain member.

If not, leave the policy at Overridable, the default. The quantity applied by the dynamic default or requirement constraint will be the final configuration quantity for that domain member.

See [Chapter 2, "Understanding Modeling," Interaction between Default Quantities and Min/Max Settings at Run Time, page 44.](#)

8. If you want the entered (static) quantity to be evaluated against the runtime quantities, designate a new quantity policy:
 - Min of,Min of $f(x)$: Apply the quantity value or expression result as a minimum quantity that will be selected by default for the domain member.
 - Max of,Max of $f(x)$: Apply the quantity value or expression result as the upper limit of the quantity that will be applied to the domain member.
 - Sum,Sum $f(x)$: Add the quantity of each default selection of the domain member with the dynamic defaults and requirement constraints.

For instance, if ItemA has a default of 2 and a dynamic default that specifies the quantity 2, then the runtime quantity of the domain member is 4.

9. Click the quantity policy of the domain member whose quantities you want to edit, and select the policy to apply with the quantity.
10. If you want to set up default quantities that apply for all domain members as a group, select Use Quantity Policy for All Domain Members and enter the policy or quantity.

Setting the policy and quantity at the selection point level offers these advantages:

- It simplifies model maintenance if domain members do not require different quantity settings.
- If there are no default choices at the domain member level, it allows you to apply static quantities for those domain members that are not defaulted (quantity = 0).
- If there are default choices at the domain member level, you can set a baseline quantity for all domain members that satisfies a quantity check at the selection point level.

Similarly, click the value in the Quantity Value/Expression cell for the domain members) and enter the quantity or select the expression that supplies the quantity for the domain member if it's selected.

Getting Default Selections and Quantities at Runtime Through Attributes

You can specify a static default quantity on each domain member by creating an attribute on its parent class and assigning each of the domain members a value for the attribute. One useful application of this feature is to automate the populating of a bill of materials by using a domain member attribute to set a flag on selected items.

To specify runtime defaults:

1. In the Model Structure view, select the class that contains the domain members for which to set defaults.
2. In the properties table, click the Add Property button to add a new row to the table.
3. In the pop-up dialog box, enter a name and data type.

If you want the domain members to have a default value, enter it in the Value field. Click OK.

4. If you want an external source to supply values for the attribute, change the Internal property to *False*.

The SQL property appears. Write the SQL statement to retrieve the desired values.

Warning! Limit attribute values to 10 characters or fewer. Otherwise, the model will not compile.

See [Chapter 4, "Creating Objects for the Model," Setting Up Binding for External Domain Members, page 82.](#)

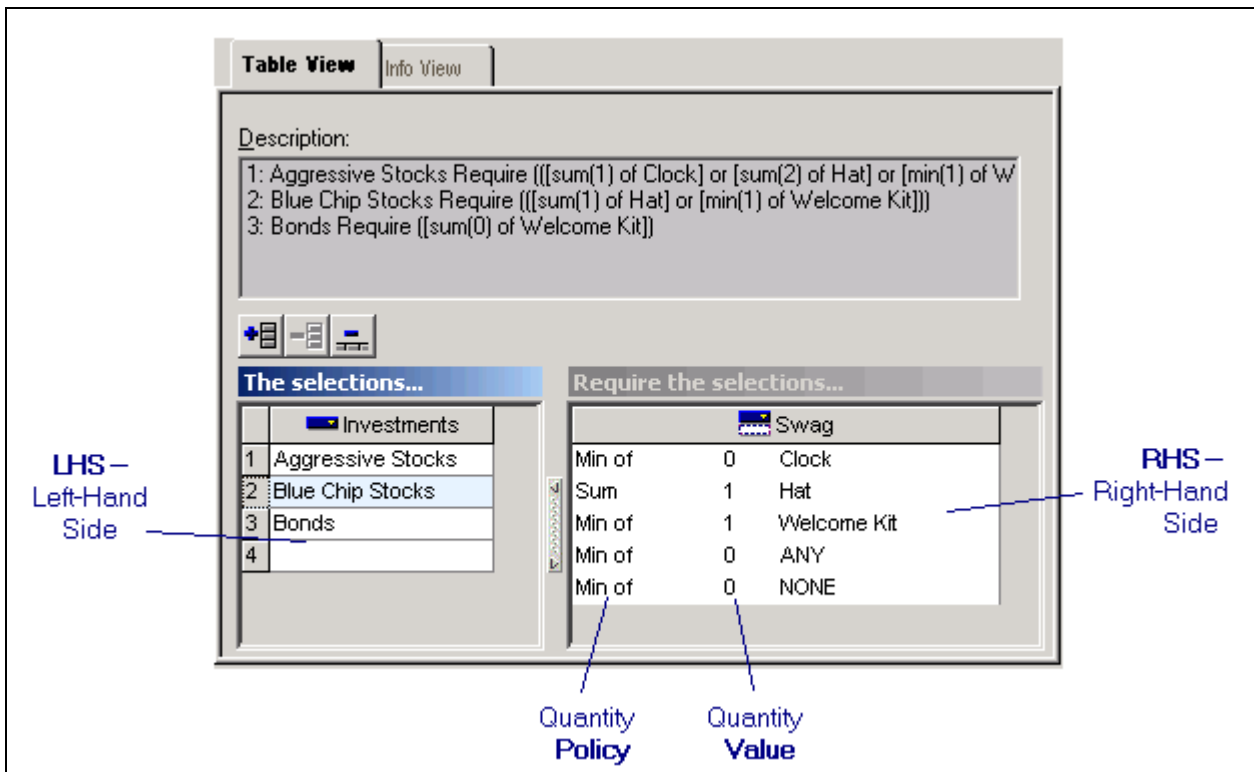

5. If you want to assign static values, select each of the domain members in turn and enter the value in the Value column of the attribute that you just created.

Be sure that the value does not exceed 10 characters.

Defining a Dynamic Default Quantity for a Selection

Another way to set up default quantities that are determined at runtime is to write dynamic default relationships with quantities. If you have dynamic default relationships that select by default one or more domain members, you may need to define the quantities in those relationships.

The following example shows default settings that indicate how many of which free gifts to give to a customer based on the investment attribute:

Default settings

Quantity policy settings are:

Quantity Policy	Quantity Values	Resulting Behavior
Min of	0	Default; no selection will be made by the left-hand side (LHS) members.
Min of Min of f(x)	1 - n exp_name	No matter how many times the domain member is selected by default by this relationship or another, the dynamic quantity for the domain member will be <i>at least</i> 1 or n.
Max of Max of f(x)	1 - n exp_name	No matter how many times the domain member is selected by default by this relationship or another, the dynamic quantity for the domain member will be <i>no more than</i> 1 or n.
Sum Sum f(x)	n exp_name	The dynamic quantity for this domain member is the sum of all default selections for this domain member in the session.

To define quantity selection behavior for a dynamic default relationship:

1. Open the relationship editor by double-clicking the name of the relationship on the Components tab.

Look for the Quantity Policy and Quantity Value columns in the right-hand side (RHS) of the editor. There should be one of each of these for each selection point in the right-hand side of the relationship. If these columns are not present, then the selection point is not set up for quantity definitions. To enable quantity definition on the relationship, close or minimize the relationship editor. Display the selection point properties on the table editor and set the quantity to *True*. Then reopen the relationship. If you still do not see the quantity columns, check that the relationship binds a class and a selection point rather than a class and a class.

2. If a default selection requires one or more of the selected domain member(s):
 - a. Click on the appropriate LHS row to display the relationship.
 - b. Click the policy of the domain member.
 - c. Select the policy from the drop-down list box.
 - d. Enter the quantity in the value column.

As with other quantity definitions, you can obtain the value from an expression as well.

The resulting dynamic quantity is then subjected to further evaluation against any static default quantities that you may have set in the preceding steps. The result is the final quantity, which is returned for display in the control.

Note. If configuration conditions are such that a default quantity (static or dynamic) would cause a violation, it will not be applied.

Attaching Metadata to Selection Points

To attach metadata to a selection point, you must place an attribute on the selection point. This attribute serves as the source of static default quantities for each domain member in the selection point. The stored metadata can be retrieved by the front end to perform ancillary operations. At runtime, selection point attributes are read-only. Advanced Configurator uses the default value for a selection point attribute if a value is not specified for a selection point attribute.

Float, integer, string, date, and Boolean data types are supported. Selection point attributes can be inherited by subclasses.

Attributes on selection points can be inherited by subclasses but not by domain members; they can't participate in constraints, and they can't be filled from external data using a SQL query.

The selection point attribute is the *On Output* property in the property table.

Note. A selection point attribute and domain member attribute within a class cannot have the same name.

Warning! Limit attribute values to 10 characters or fewer. Otherwise, the model will not compile, generating the following error:

ERROR: Compilation of model <modelname> failed: On GCL class "<classname>", domain member "<domain member name>" has a value for attribute "<attribute name>" of "<value>" which cannot be converted to type _Integer.

The following example shows the property table for the class HardDrives, with the selection point attribute AvailDate:

HardDrives

	Name	Type	Value
	Name	String	HardDrives
	Filename	String	C:\Program Files\Peopl
	Internal	Bool	True
	Descriptio	String	
	ShortNam	String	
	InterfaceTy	String	IDE
	StorageCap	Int	
	Watts	Float	2.00
	AvailDate	Date	5 /12/2004

Properties table

To attach metadata to selection points:

1. In the Model Structure view, select the class.
2. In the properties table, add a new row.

Click the Selection Point Attribute button to add a row in the properties table for the selection point attribute.

3. If you want to provide a default value for all domain members in the selection point, enter it in the Value column.

Otherwise, the system uses the value from the input source that you have assigned for the attribute.

4. If you want the default to be different for one or all other selection points of the class, create a separate selection point for each domain member.

Select one of the new selection points in the Model Structure view. The attribute appears in its property table. Enter the desired value in the Value column. Repeat for each selection point for the class.

5. If your application is integrated with Order Capture and you want the attribute's value to be output, enter the selection point attributes on the Output tab of the Schema page the same way as for regular attributes.

Chapter 9

Standardizing Compound ModelBuilding

Chapter 7

Understanding Compound Modeling

This chapter discusses:

- Applications for compound models.
- Compound model structure styles.
- Architecture.
- Relationships in a compound model.
- Modeling strategy.

Applications for Compound Models

Compound modeling enables you to:

- Create a component model for each configurable component of your product or service offering.
Selection points in each component can receive values from connected components, and can use them in constraints, creating cross-constrained models.
- Specify which configurable components to include in your offering, and how they connect to one another.
- Using PeopleSoft Advanced Configurator APIs and JavaServer Pages, build an interface that lets your user dynamically create, configure, and connect instances of your configurable components.

Compound Model Structure Types

PeopleSoft Advanced Configurator enables a variety of compound model styles as illustrated by the telecommunications scenario of the sample compound model. In the following examples, *CC* indicates a configurable component, and *Cn* indicates a connection.

Note. The sample application illustrates how to create an application that lets a user configure communication services rather than network hardware.

The following diagrams illustrates possible compound model structures, showing configurable components and their relationships (connections):

Configurable component

Single configurable component and connection

Multiple configurable components and connections

You can template connections by defining them as Connection Types, as CnB is a connection type suitable for joining CC1 and CC2.

The Configurator provides you the flexibility to structure your compound model in several ways:

Tree

Network

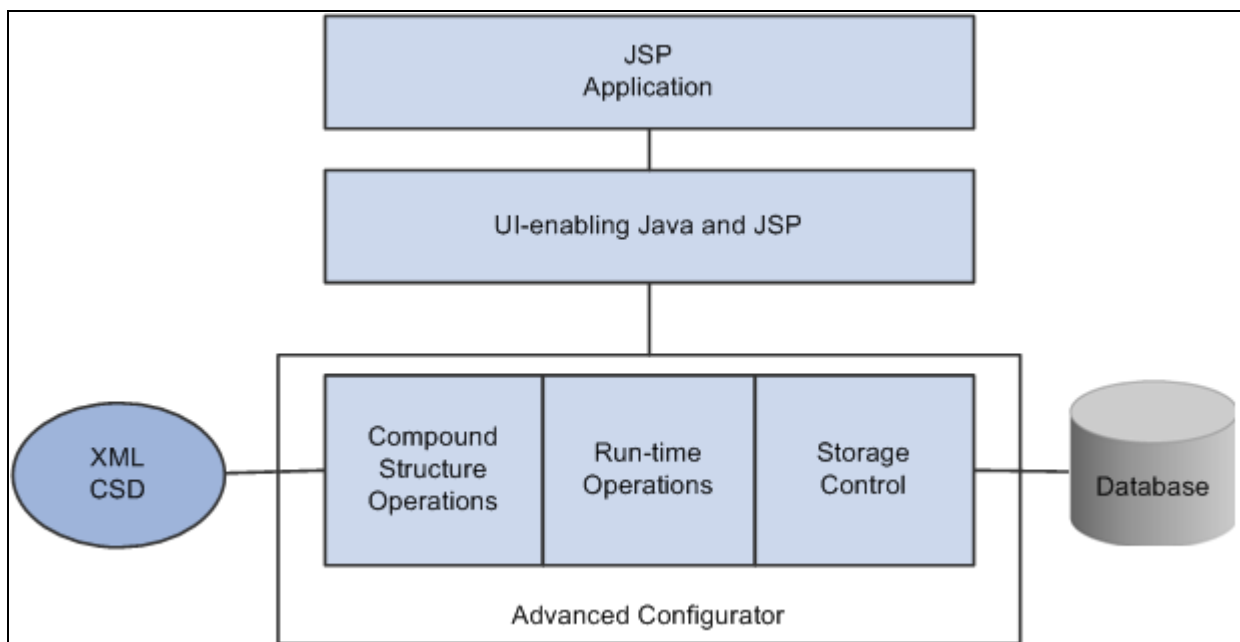

Mesh

Arbitrary

Architecture

Compound structure components extend the Configurator, which runs on the WebLogic application service. The compound structure extensions include Java classes and JavaServer Pages:

Compound model component hierarchy

Some Compound Structure Java classes work behind the scenes to enable you to:

- Create multiple instances of models and configure them.
- Constrain the selection point of one model against the selection point of another.

Other Compound Structure Java classes give you a public API that enables you to create JavaServer Pages that let your user dynamically create, configure, and verify a configuration based on a compound model.

See Also

[Building a Custom User Interface](#)

Relationships in a Compound Model

Compound models extend the basic precepts of component model objects, and relationships help you define the interaction of the component models. Interactions are defined in the compound model's Configurable Components.

In a component model, relationships define the behavior of objects at the class and domain-member level. In a compound model, relationships determine how the component models interact. Compound model relationships define connections between components—which components are connected, how many connections are allowed, and what configuration information is sent from one component to others. Using compound model relationships, you can:

- Specify the structure of the compound model—which components must connect with which, and how many.
- Set up conditions for generating valid compound configurations.
- Specify what selection points in components are sources of information, and which are targets for that information.
- Send data from one model to be acted upon by constraints within another model.

Note. The Visual Modeler lets you define relationships; it does not create them so that they are implemented in JSP pages. This must be done by the site developer. By defining compound relationships in Visual Modeler, you provide the validation logic so that an appropriate error message can be generated for the end-user when required relationships are not met.

Compound model relationships address the two central aspects of multiple-model configuration:

- Connected components
- Connection points

Connected Components

Connected components define the structure of the compound model—which and how many component models (components) connect to each other. Minimum and maximum attributes on the relationship specify how many of the specified component. In the Sample compound model, structural relationships establish that Node and Hub components can be connected to Circuit components; Circuit can be connected to Hubs and Nodes; and Hubs and Nodes can't be connected directly to each other.

Connection Points

Connection points define which data is to be communicated, if any, along the connection. Each connection point defines a specific data element that is to be transferred, and what direction the data flows. This data element can be a user pick or a collection of numeric data across components, or the output of an expression. Important:

Important! The Visual Modeler enables you to define relationships; it does not create them so that they are implemented in JSP pages. This must be done by the site developer. By defining compound relationships in Visual Modeler, you provide the validation logic so that an appropriate error message can be generated for the end-user when required relationships are not met.

Modeling Strategy

PeopleSoft Advanced Configurator provides three approaches to structuring compound models:

- Reference to template component
- Master component type
- Component type with reference

Reference to Template Component

Create a "template" configurable component and use the reference function to create all others. For example:

Template Configurable Component = *ModelPhoneCC*, Min1, Max2

Standard phone component = *StdPhoneCC_refModelPhoneCC*, Min1, Max2

Speaker phone component = *SpkPhoneCC_refModelPhoneCC*, Min1, Max2

...

Master Component Type

Create a component type and base all components on it. For example:

Component Type = *ModelPhoneCT*, Min1, Max2

Standard phone component = *StdPhoneCC_ModelPhoneCT*, Min1, Max2

Speaker phone component = *SpkPhoneCC_ModelPhoneCT*, Min1, Max2

...

Component Type with Reference

Create one component based on a component type, use the Reference function to base others on the original component. For example:

Component Type = *ModelPhoneCT*, Min1, Max2

CC1 = Standard phone component = *StdPhoneCC_ModelPhoneCT*, Min1, Max2

CC2 = Speaker phone component = *SpkPhoneCC_refStdPhoneCC_ModelPhoneCT*, Min1, Max2

...

Chapter 8

Working with Compound Models

This chapter discusses how to:

- Get started with compound models.
- Create a compound model project.
- Edit project settings.
- Create a configurable component.
- Delete a configurable component.
- Rearrange component models in the compound model.
- Add and remove a component model from the project.
- Edit default values.
- Create and delete relationships between configurable components.
- Display a compound model relationship.
- Specify required relationships.
- Edit component model versions.
- Compile, run, and test a model.
- Managing simultaneous model development among team members.

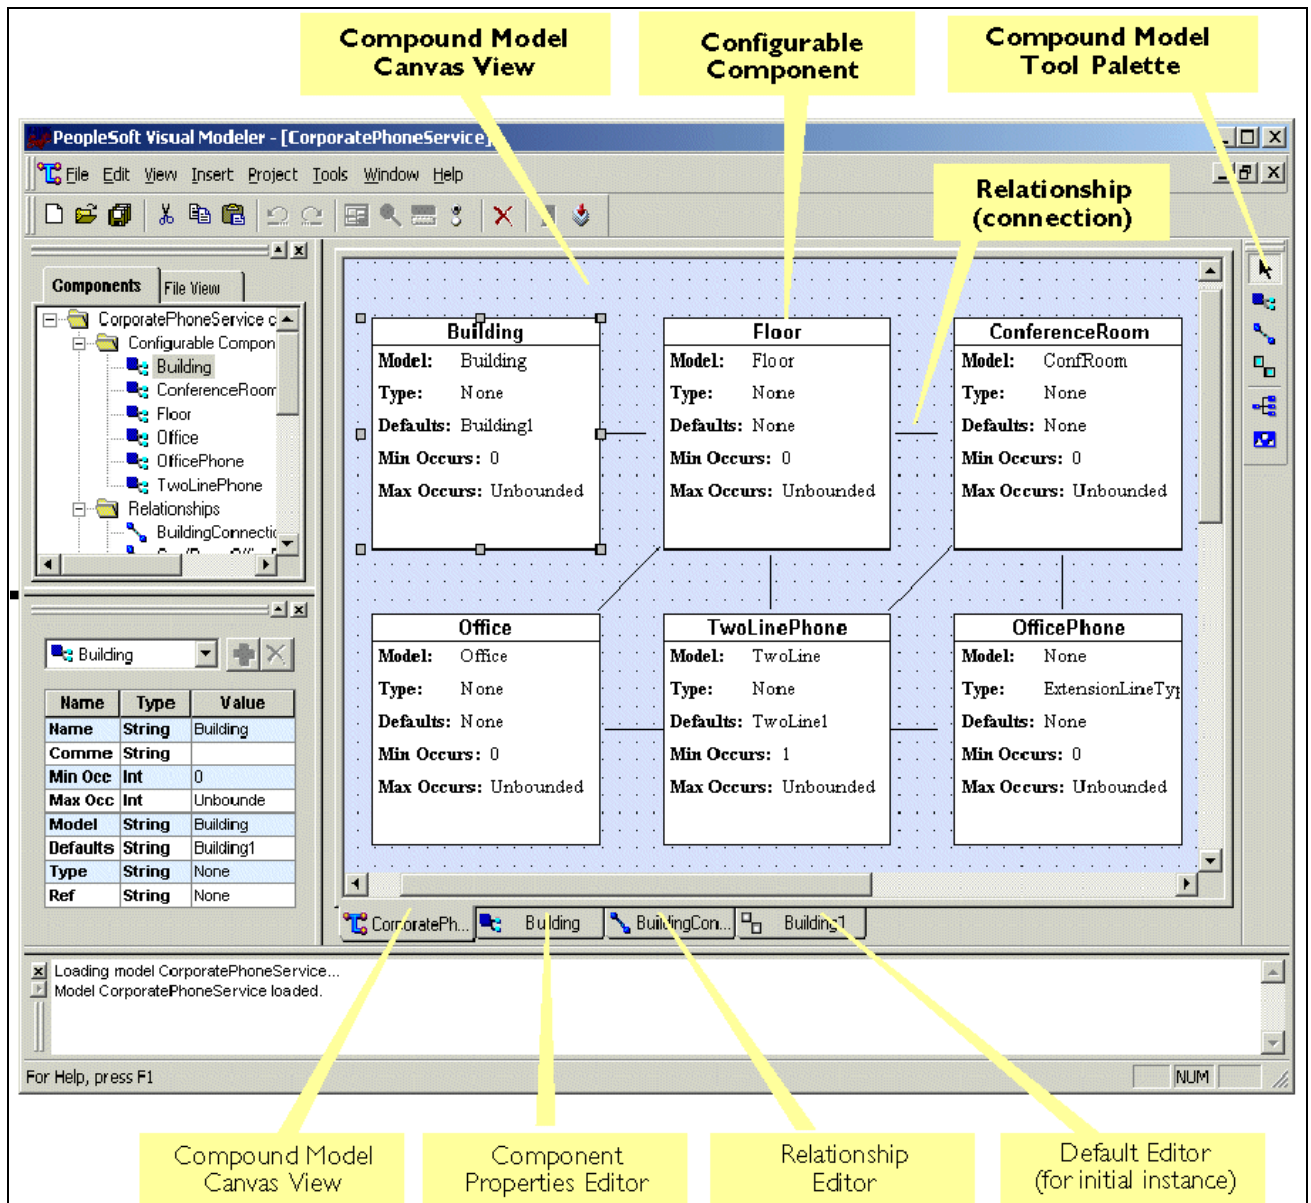

Getting Started with Compound Models

The recommended steps for creating a compound model are:

1. Create the component models that represent the configurable parts of the product.
2. Compile and test the new component models.
3. Create a new compound model in the Visual Modeler workspace, either a new workspace or an existing one (set it as the active project).
4. Insert the configurable components that represent the jump-off points for the separate configurations, and associate each with a component model.
5. Create the relationships between the configurable components.

6. Set the required relationships for each configuration component.
7. Create any defaults for the initial instance of each configuration component.
8. Specify project settings (server name and port).
9. Compile the project and run it on test JavaServer Pages (compound models do not have a Model Tester as component models do).

When you launch a compound model, the Visual Modeler displays the Compound Model Canvas, a UML-style layout grid for constructing and displaying the Compound Model.

Compound model workspace, showing the configurable components of the model CorporatePhoneService

Adds a component to the current project.

Creating a Compound Modeling Project

You can create a new project from the base project template or modify an existing project.

To create a new project from the base project template:

1. Select File, New to display the New dialog box, then click the Projects tab.

2. Specify a project name, storage location, and whether to add the project to a current or new workspace.

When you click OK, a template project tree appears in the Components tab.

3. Add models and files to the project as needed.

When you need to build a new compound model from an existing one, you can import its structure, relationships, and defaults from its .xml file.

To create a project from an existing one:

1. Create a new compound model Project.
2. Select Project, Import Existing Schema.

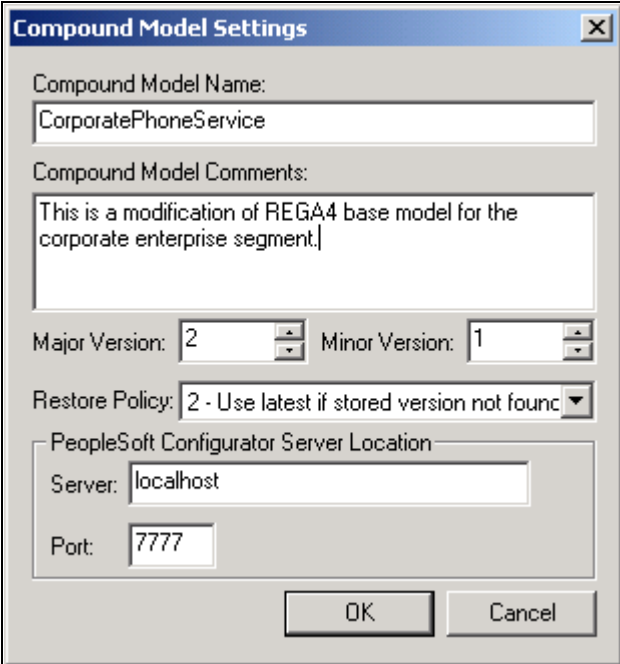

A browse dialog box appears.

3. Locate and select the appropriate .XML file.

The imported structure appears in the Components Tab view with the Compound Model canvas.

Editing Project Settings

Properties associated with the compound model are located in the Compound Model Settings dialog box:

The image shows a Windows-style dialog box titled "Compound Model Settings". It contains several input fields and a dropdown menu. The "Compound Model Name" field is filled with "CorporatePhoneService". The "Compound Model Comments" text area contains the text "This is a modification of REGA4 base model for the corporate enterprise segment.". The "Major Version" spinner is set to 2 and the "Minor Version" spinner is set to 1. The "Restore Policy" dropdown menu is set to "2 - Use latest if stored version not found". The "PeopleSoft Configurator Server Location" section has a "Server" field with "localhost" and a "Port" field with "7777". At the bottom are "OK" and "Cancel" buttons.

Compound Model Settings

Compound Model Name:
CorporatePhoneService

Compound Model Comments:
This is a modification of REGA4 base model for the corporate enterprise segment.

Major Version: 2 Minor Version: 1

Restore Policy: 2 - Use latest if stored version not found

PeopleSoft Configurator Server Location
Server: localhost
Port: 7777

OK Cancel

Compound Model Settings dialog box

Major Version and Minor Version

Compound model version containing two levels, major and minor, used for model maintenance. It is not to be confused with component model versions.

PeopleSoft Configurator	Server: The server on which WebLogic and the Configurator are installed.
Server Location	Port: The port number for the WebLogic application server. The default is 7777.

Creating a Configurable Component

A configurable component is based on a existing component model. Thus, you must create and test each component model before proceeding with this step.

See [and Product Modeling with a Component Model](#).

Use the component editor to create a configurable component:

CHOOSE A VEHICLE
- LTD ▾

CLEAR

COMPONENTS

Component editor

Name	Identifies the Configurable component whose instance is being acted upon. The name cannot include \, =, <, >, :, ", (, or). The initial character cannot be dollar (\$) or underscore (_), but these characters can be included in other positions. An asterisk (*) cannot be used alone, but it can be used in combination with other characters
Model	Name of the component model to associate the component to. This model must contain the decision point(s) required by the configurable component. Each configurable component references one model. (However, one model can reference more than one configurable component.)
Type	(Optional) The component can be based on a ConfigurableComponentType. The type definition will be used for any data values not specified within the element definition. Specify either <i>reference</i> or <i>type</i> , but not both. <div>Note. If there is a component model associated with the referenced component, it will be overridden by the component model specified for this component.</div>
Reference	(Optional) The component can be based on another configurable component. The referenced component will be used for any data values not specified within the element definition. Either <i>reference</i> or <i>type</i> can be specified, never both. <div>Note. If there is a component model associated with the referenced component, it will be overridden by the component model specified for this component.</div>

Restore Policy

Version of model to use when a stored configuration is requested by an end user.

- *None*: The Configurator will use the most recent model version on the Configurator server.

- *1*: Fail if stored version not found.

The Configurator will display an error message.

- *2*: Use latest if stored version not found.

The Configurator will look for the version of the model that created the configuration. If it is not available, it will use the most recent model version on the Configurator server.

- *3*: Always use latest model.

The Configurator will use the most recent model version on the Configurator server. If that version is not found, it will fail and display an error message.

- *4*: Ask if multiple versions.

If more than one version of the model is found, the Configurator will display a choice dialog box requesting that the end user specify which version to use.

- *5*: Always use structure version.

Use the version specified in the model's Project Settings.

Max Occurs

A non-negative integer or the term unbounded. Specifies the maximum number of instances that can be created from the component in a single configuration of the compound model.

For example, for a telecommunications product being configured for a moderate-sized business customer, the number of OfficePhones is limited by the number of office setups ordered. You can limit the number of phones the end user can configure by specifying that the Max Occurs value be taken from the OfficeSetup quantity.

Note. PeopleSoft Advanced Configurator does not automatically create components or limit deletion of components based on this number—but it will report that the configuration is invalid if the limit is not met.

- Default = Unbounded
- Minimum value = 1
- Maximum value = Unbounded

Min Occurs

A non-negative integer. Specifies the minimum number of instances that must be created in order to satisfy the requirements of the product model. For instance, if the end user creates an configurable instance of an OfficeSetup, they must also configure at least one OfficePhone for that OfficeSetup. The value of Min Occurs would be 1. A value of 0 would indicate that an OfficePhone is optional.

Note. Advanced Configurator does not automatically create components or limit deletion of components based on this number—but it will report that the configuration is invalid if the limit is not met.

- Default = 0
- Minimum value = 0
- Maximum value is less than Max Occurs

Required Relationships

Any relationship that must be satisfied for the component in order for the configuration to be valid. Important:

Important! This property does not actually implement the relationship; that must be done by the web application developer. It does, however, verify that such a relationship is satisfied.

Setting required relationships for the component here sets up a validation function that, when violated (the end user has not added a necessary component, for instance), an error message is generated for the end user.

See [Chapter 8, "Working with Compound Models," Creating and Deleting Relationships Between Configurable Components, page 154.](#)

Note. "Inherit" check boxes appear when the configurable component has a type or reference specified.

Repeat these steps for each configurable component desired.

To create a configurable component:

1. Make sure that the Compound Model Canvas is displayed, and that the desired project is selected (if the workspace contains more than one project).
2. Do one of the following:
 - Click the icon at the taskbar on the right of the window.
 - Or,
 - Select Insert, Configurable Component.
3. Move the cursor onto the blue grid where you want the configurable component to appear in the model structure.
4. Click once to create the component.

You can drag-and-drop to reposition it.

5. Double-click the component to display its component editor
6. Enter the appropriate values for the elements.

Values for Type, Defaults, and Required Relationships may not be available, as they must be created separately. These can be added later.

7. Repeat these steps for each configurable component desired.

Deleting a Configurable Component

To delete a configurable component in the Compound Model canvas, right-click the desired component and select Delete "<component name>".

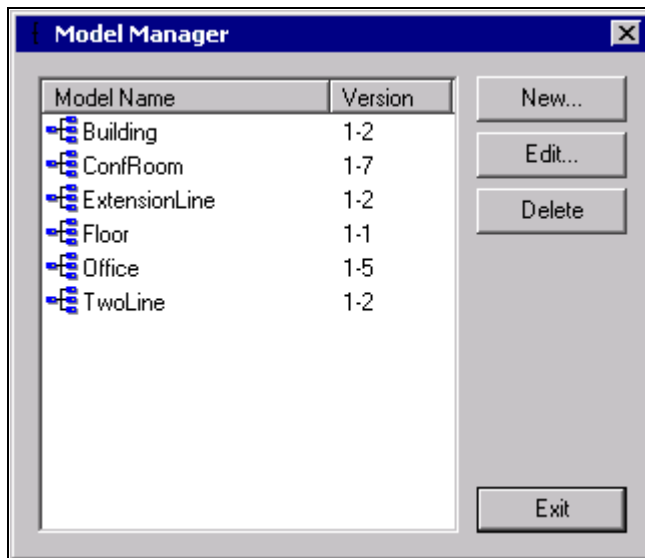

To delete a configurable component in the Components Tab view, right-click the desired component and select Delete from the menu.

Rearranging Component Models in the Compound Model

Whenever you are using the Compound Model Canvas to create and link components, you can use the View, Layout Canvas command to efficiently reposition the components in the window.

Adding and Removing a Component Model from the Project

Adding a component model adds a component model to the project. Once added, the model name makes it available for connection, by means of various selection lists, to other component models. Adding a model to the project does not connect it in the compound model. This is done when you create configurable components.

Model Manager dialog box

New Configurator Model Link dialog box

Launches the Model Manager dialog box.

To add a component model:

1. Do one of the following to display the Model Manager:
Select View, Model Manager.
Or,
Click the Model Manager icon in the tool palette.
2. In the Model Manager dialog box, click the New button to open the New Configurator Model Link dialog box.
3. Enter the model name in the Name field, for example, *ConfRoom* or *Hub*. (The Configurator looks for models at the specified Configurator server location.)

See [Chapter 8, "Working with Compound Models," Editing Project Settings, page 146.](#)

4. Set the Version preferences and click OK.

Default for each version level is *Use Latest*, which means the latest version of the model found in the model directory will be used for compiling. You can instead specify a specific model version down to the micro level, or you can specify only certain levels. To specify the version number, clear the check box to enable the version selector.

Examples:

For any version 1.2.1 – 1.2.10,

If you specify	Configurator uses
1-2-5	1.2.5
1-2	1.2.10 (the latest)
1	1.2.10 (the latest)

For any version 1.1.0 – .1.59,

If you specify	Configurator uses
1-1	1.1.59 (the latest)

Removing a component model is more accurately described as removing the link to the component model that exists in the compound model.

Note. Removing a component model from the compound model is not the same operation as deleting a configurable component.

To remove a component model:

1. Do one of the following to display the Model Manager:

Select View, Model Manager.

Or,

Click the Model Manager icon in the tool palette.

2. In the Model Manager, select the component model that you want to remove from the compound model and click the Delete button.

You will be notified if there are any components that are dependent on the one being removed. Note the dependencies and click OK to the message. You will need to make provision for the removed component model.

3. Click OK to close the dialog box.

The component will be removed from component windows during the next compile.

Editing Default Values

Defaults are the values that appear on instances of configurable components when they are created from the component models of a compound model. By definition, they are the same as defaults for a component model. But because the initial instance is created within the context of the compound model, with potential dependencies on other component models, their defaults may not be the same as they would be if an instance was created from the model in its standalone state.

Defaults are listed with Configurable Components and Relationships in the Components View tab.

Attributes

	Attribute Name	Attribute Value
1	Multiple	4
2	Branch	DbY

Choices

	Selection Point	Domain Member	Quantity
1			0

External Choices

	Selection Point
+	

Defaults tab

Attributes

Attribute Name: The name of the attribute in a component model to which to assign the Attribute Value.

Attribute Value: The value that you want the attribute to have when the configurable component is initialized.

Leave these blank if you do not need attribute defaults.

Choices

A specific value. A domain member of a particular selection point within the associated component model.

If applicable, enter a quantity of the item.

You can leave this value blank. Use this value when you have a specific selection point in a specific component model to specify.

External Choices

A value provided by a source outside the component model that is only known at runtime, such as user-entered text, numbers, Boolean values, and dates. In the component model, this will be an extern.

Leave these blank if you do not need attribute defaults.

Opens the Defaults window for new defaults specifications.

Adds rows to the table so that you can edit additional attributes, choices, and external choices.

On the External Choice element, adds rows so that you can add additional Values to the parent Selection Point.

Deletes the selected row.

To specify or edit default values:

1. For a new default, open a new Default window in *one* of three ways:

To change an existing default double-click its name in the Components View tab.

- Double-click *Defaults* in the Components tab.
- From the Configurable Components window, select Insert, Defaults.
- Click the Defaults icon in the tools palette

2. Specify or edit the desired defaults.

3. In each of the tables in the Default window, use the Add button to add a new attribute, choice, or external choice default.

Creating and Deleting Relationships Between Configurable Components

Relationships in a compound model define interactions between components (component models). By contrast, relationships within component models define interaction between classes and domain members.

Name

Relationship1

Comment

Target

X

None

Connected Components

Connection Points

Relationship1

Relationship editor

Target

Name of the component model to which data is to be passed.

Connected Components

Component: The component that can be connected to the target component. Click the field to activate the drop-down list box. There can be more than one. Use the Add (+) button to add more components. This relationship property establishes the structure of the compound model and is the basis for required relationship validations. The default is *none*.
See and Chapter 7, "Understanding Compound Modeling," Modeling Strategy, page 140.

Min Occurs: The minimum number of components (instances) that must be connected to the target component for the configuration to be valid.

- A value of 0 means that if the component is created, its connection to the target component is optional (and thus it would not be a Required Relationship).
- A value of 1 indicates that there must be at least one instance of the component connected to the target component.

Max Occurs: The maximum number of components that can be connected to the target component in the configuration. The default value is *unbounded*.

A value of 0 is meaningless. A value of 1 to 99 indicates the upper limit of allowable connections of this component to the target component. *Unbounded* indicates that there is no limit to the number of this component's connections to the target.

Adds a new connection point.

Opens the properties dialog box for the connected component displayed. Located above the Connection Point Table.

Opens the Relationship editor. Located on the Tools taskbar at the right of the window.

Adds a row (connection point instance) to the Connection Point table.

	Name	Type	Operation	Source	Target
	ConnectionPt_CP1	None	Choice		
	Instance	Target	Numeric Data		

An instance of the connection point named Connection PT_CP1

To create a compound model relationship:

1. Do one of the following:

From the main menu, select Insert, Relationship.

Or,

From the Tools taskbar at the right of the window, click the Relationship icon.

The Relationship Editor appears.

2. Enter the appropriate values.
3. To add or view the properties of the connected components, click the Properties button above the Connection Point Table.
4. Set the Connection Point information.

A Connection Point is a data element that is to be passed along the connection represented by the relationship. There can be 0, 1, or more than 1 Connection Points.

5. Click the Add button to add a new Connection Point.
6. Enter Connection Point values.

Type

If you want to assign a Connection Point type, click the field to activate the drop-down list box for selection. Depending on the type you select, the operation and source or Target properties will be provided and will appear in italics (italics indicate properties inherited from types).

If you don't want to assign a Connection Point type, leave the default value of *None* and assign the values Operation and either Source or Target.

Operation

Describes the origin of the data to gather. It can be:

Choice: Indicates the data is a value from a particular selection point domain member or attribute. If *Choice* is selected, you must provide the Target selection point in the Connect Components table (following). Target Variable and Numeric Data do not apply to Choice operations.

Collection: Indicates the data is a set of values taken from all the sources that have a particular attribute in common. If you select the Collection operation, you also must specify Target Variable and Numeric Data (following).

None: Default value; used when an inherited value will provide the value.

Source

Identifies the selection point that provides the data to be communicated over the connection. You may need to open the component model with Visual Modeler (in another window is easier) to obtain the correct name of the selection point.

Target

The name of the object in which to store the collected values of a Collection operation. Not required for Choice operations. This information is located in the component model that is to receive the information (connected component).

7. Configure the instances of the Connection Point by first expanding the row with the Add Instance button.

8. If there is only the header for the instance row as in the image above, click the button to add an instance.

If the Connection Point has a type, an instance will already be created and any inherited properties will be entered in the fields. If not, enter these values:

Instance	<p>Specifies how the instances of the Connection Point are to handle the data received. Entries are All, 0, 1, 2, n.</p> <p><i>All</i> indicates that all instances of the Connection Point handle the data as specified in the Target DP or Numeric Data columns.</p> <p><i>1....n</i> indicates order of creation of the instances of the Connection Point at run time.</p>
Target DP	<p>If the operation is <i>Choice</i>, you must specify which selection point (DP) in the source is to receive the data. In this example, the first instance of Ext_voicemailLimitSet will receive the data from the Source DP.</p>
Numeric Data	<p>If the operation is <i>Collection</i>, you must specify the name of the variable that will contain the data. Because this is a set of numerals, it is called Numeric Data. In this example, all instances of the Source DP will contribute data, which, once all data is collected, will be sent to the object lines.</p>

9. If there are additional Targets to receive source data, click the Add Instance button again to add another row.
10. To add or view documentation about the values, click the Properties button above the Connection Point Table.
11. Click OK to create the new Connection Point.

For the example below, the first instance of <ConnectionPt>_CP1, Instance 1, will send the data to a Target DP called LineA. Instance 2, however, sends its data to LineB; Instance All represents data from both LineA and LineB that the component model sums, placing the result in Target DP LineSum.

Displaying a Compound Model Relationship

To open a previously unopened Relationship Editor window, double-click the desired relationship in the Components tab.

Opening an existing relationship in the Components tab

If the relationship is already displayed but is not the active window, click its tab. Relationship windows are indicated by the Relationships icons:

Opening an existing relationship from its tab

Specifying Required Relationships

Required relationships are those that must be satisfied before a configuration is considered valid. Your product's business logic determines what relationships are required. For example, a telecom service product includes a limit on the number of voicemail accounts on certain phones. The limit applies to phones to be installed in conference rooms and offices. The components ConferenceRoom and Office can then be said to be connected to the target component OfficePhone with a voicemail limit relationship (VML):

The required relationship VML must connect OfficePhone with ConfRoom or Office

This relationship is represented in the Visual Modeler in the Relationship editor as illustrated below:

OfficePhoneVMailLimit

Name

OfficePhoneVMailLimit

Comment

Phones in offices and conference rooms can have no more than one voicemail account.

Target

OfficePhone

Connected Components

	Component	Min Occurs	Max Occurs
1	ConferenceRoom	1	1
2	Office	1	1

Connection Points

	Name	Type	Operation	Source	Target
<div></div>	VoiceMailLimit	VoiceMailLimitCPT	Choice	VoiceMailLimitSel	
	Instance	Target			
	1	Ext_VoiceMail			

Example of a required relationship specification

When a ConferenceRoom is not connected to an OfficePhone (perhaps another phone model is desired), the relationship does not apply. To indicate that the OfficePhoneVMailLimit is required, you must specify it in the target component's properties editor as described in this section.

The component editor showing required relationships

Displays a list of relations for the project.

Click the Add All Of button to insert a blank All Of clause in the Required Relationships panel at the location of the selected clause or relationship name.

Click the Add Any Of button to insert a blank Any Of clause in the Required Relationships panel at the location of the selected clause or relationship name.

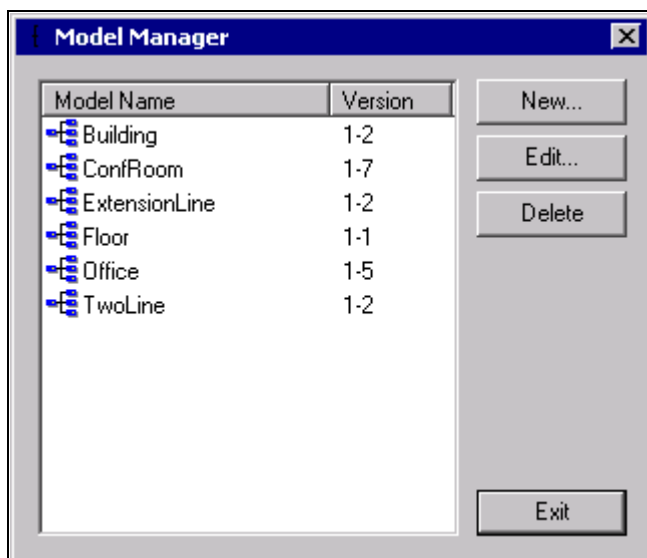

Click the Add Exactly One Of button to insert a blank Exactly One Of clause in the Required Relationships panel at the location of the selected clause or relationship name.

Editing Component Model Versions

At runtime, a compound model communicates with component models (its designated component models), which are located separately. The compound model contains only a link to its component models. Since component models are independently built and maintained, provision for version specification is included in the Compound Model.

Component model versions are specified in the Model Manager dialog box. The default version is 1-0-0 (Major-Minor-Subminor).

The Model Manager dialog box

Editing the compound model version

The figure shows the version of the component model ConfRoom is specified to the Minor level; the Micro level is always the latest. So, at run time, the model accessed will be ConfRoom version 1-7-<latest available>.

To edit a component model version:

1. Do one of the following to access the Model Manager:

Select View, Model Manager.

Or,

Click the Model Manager icon in the tool palette.

The Model Manager appears. Note the version settings for each model.

2. Select the desired component model and click the Edit button.

3. Designate the desired level or select the Use Latest check box.
4. Click OK.

The default for each version level is Use Latest, which means that the latest version of the model found in the model directory will be used for compiling. You can instead specify a specific model version down to the subminor level, or you can specify only certain levels. To specify the version number, clear the check box to enable the version selector.

Compiling, Running, and Testing a Compound Model

A Compound model must be tested on test JSP pages since there is no Model Tester as there is for a component model.

To test a compound model:

1. Compile and run each component model separately in component model mode.

Make sure that each runs to your satisfaction.

2. Select Project, Compile Only to compile the Compound model.

The compound structure definition document (.XML) will be created and placed on the server specified in the compound model settings. You can also launch the Configurator Administration Tool (from the Start/Program menu) to view the .XML file.

See [and Advanced Configurator System Administration](#).

3. Create JSP pages appropriate to test the connections and constraints between the component models.

JSP pages for the sample compound model are available for modification.

See [and Building a Custom User Interface](#).

4. Use the JSP pages to create a test web application and deploy it in a test environment.

Warning! Make sure that your browser is cookie-enabled; compound models require the use of cookies to function properly at run time.

Managing Simultaneous Model Development Among Team Members

Not only does Visual Modeler permit simultaneous development of the files of a single model, but team members can work on the different component models simultaneously. Updating a compound model with new versions of component models is managed in the Model Manager, which enables modelers to specify the model version to include in the compound model at compile time. Modelers can specify stable versions of the component models against which to test their updated model, thus controlling their test environment.

Chapter 9

Standardizing Compound ModelBuilding

This chapter discusses how to:

- Create and edit configurable component types.
- Create and edit connection point types.

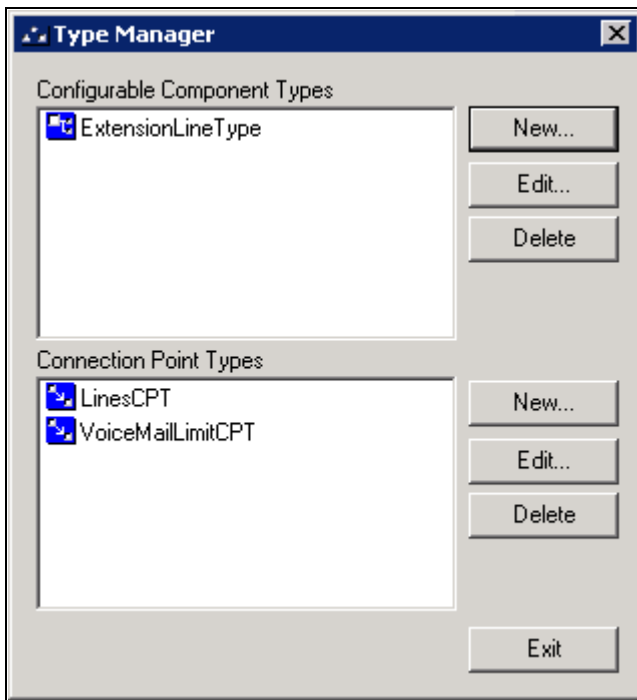

Creating and Editing Configurable Component Types

You can specify the properties of each Configurable Component one-by-one, or, if components share elements, you can create Configurable Component types to use as component templates. Then, when you create a Configurable Component, you can assign it a component type, thereby automatically associating it with a component model, providing it with default values, restore policy, and occurrence limits.

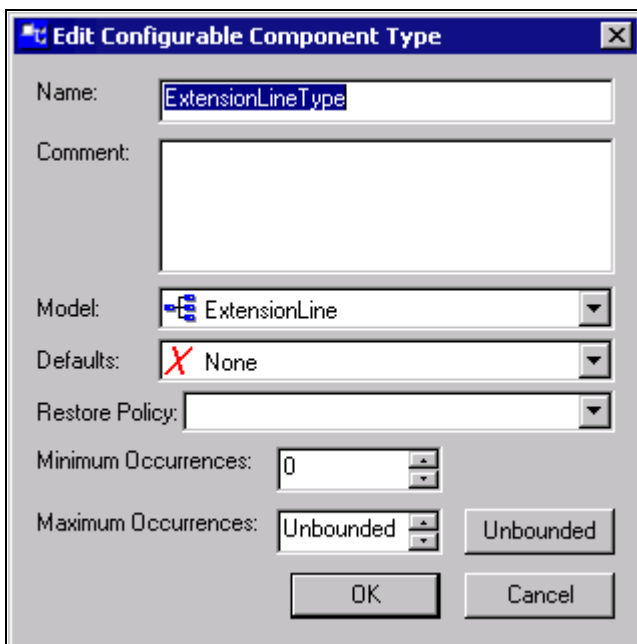

Configurable Component types are assigned in the component editor; you can assign it to a relationship in its properties editor.

See [and Chapter 8, "Working with Compound Models," Creating a Configurable Component, page 147.](#)

Any Configurable Component assigned a component type inherits the type's properties. In the editor, properties inherited from a type are indicated by italics.

Type Manager dialog

Defining a component type

Name

Identifies the Configurable Component type. The name cannot include \, =, <, >, :, ", (, or). The initial character cannot be dollar (\$) or underscore (_), but these characters can be included in other positions. An asterisk (*) cannot be used alone, but it can be used in combination with other characters.

Model	The component model with which to associate the component.
Defaults	<p>Identifies the default element that specifies the values of the attributes and the domain members when an instance of that configurable component is first created. Defaults will not be available until you describe them.</p> <p>See Chapter 8, "Working with Compound Models," Editing Default Values, page 153.</p> <hr/> <p>Note. Compound model defaults override the static defaults set in the component model itself.</p> <hr/>
Restore Policy	<p>Version of model to use when a stored configuration is requested by an end user.</p> <p><i>None:</i> The Configurator will use the most recent model version on the Configurator server.</p> <p><i>1 - Fail if stored version not found:</i> The Configurator will display an error message.</p> <p><i>2 - Use latest if stored version not found:</i> The Configurator will look for the version of the model that created the configuration. If it is not available, it will use the most recent model version on the Configurator server.</p> <p><i>3 - Always use latest model:</i> The Configurator will use the most recent model version on the Configurator server. If that version is not found, it will fail and display an error message.</p> <p><i>4 - Ask if multiple versions:</i> If more than one version of the model is found, the Configurator will display a choice dialog requesting that the end-user specify which version to use.</p> <p><i>5 - Always use structure version:</i> Use the version specified in the model's Project Settings.</p>
Minimum Occurrences	<p>A non-negative integer. Specifies the minimum number of instances that must be created in order to satisfy the requirements of the product model. For instance, if the end-user creates an configurable instance of an OfficeSetup, they must also configure at least one OfficePhone for that OfficeSetup. The value of Min Occurs would be <i>1</i>. A value of <i>0</i> would indicate that an OfficePhone is optional.</p> <p>Default = 0</p> <p>Minimum value = 0</p> <p>Maximum value is less than Max Occurs</p> <hr/> <p>Note. PeopleSoft Advanced Configurator does not automatically create components or limit deletion of components based on this number—but it will report that the configuration is invalid if the limit is not met.</p> <hr/>

Maximum Occurrences

A non-negative integer or the term unbounded. Specifies the maximum number of instances that can be created from the component in a single configuration of the compound model.

For example, for a telecommunications product being configured for a moderate-sized business customer, the number of OfficePhones is limited by the number of office setups ordered. You can limit the number of phones the end-user can configure by specifying that the OfficeSetup quantity value be passed to Max Occurs.

Default = *Unbounded*

Minimum value = *1*

Maximum value = *Unbounded*

Note. PeopleSoft Advanced Configurator does not automatically create components or limit deletion of components based on this number—but it will report that the configuration is invalid if the limit is not met.

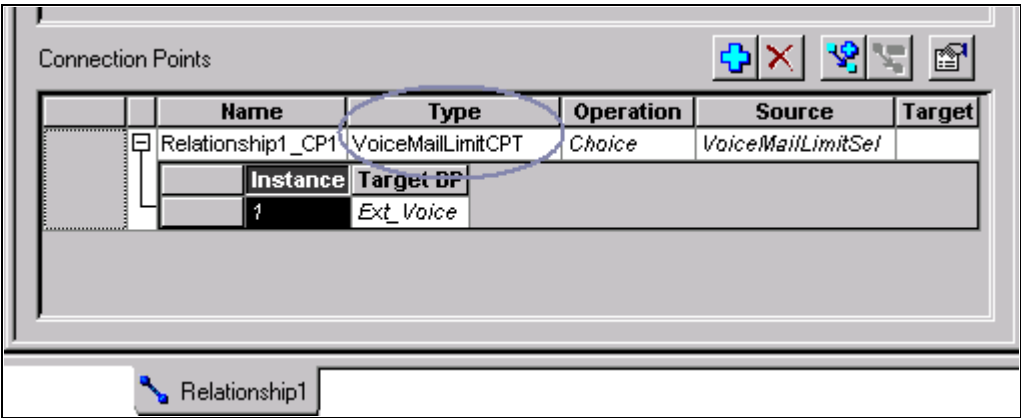

Creating and Editing Connection Point Types

You can specify the properties of each connection between components one-by-one, or, if certain types of connections have common properties, you can create connection point types to use as templates. Then, when you create a compound model relationship, you can assign it a connection point type, thereby automatically providing it with the source object, the data element, and the components that will receive the data.

Once you have created a connection point type, you can assign it to a relationship in its properties editor.

See [Chapter 8, "Working with Compound Models," Creating and Deleting Relationships Between Configurable Components](#), page 154.

Note. Any connection point assigned a connection point type (when creating a relationship) will inherit the type's properties. Properties inherited from a type are indicated by italics. This example relationship illustrates how the inherited properties appear in the Connection Points table:

Inherited properties from type VoiceMailLimitCPT are Choice, VoiceMailLimitSel, and Ext_Voice

Edit Connection Point Type

Name:VoiceMailLimitCPT

Comment:Apply the voice mail limit to a phone from either an office or a conference room

Operation:Choice

Source DP:VoiceMailLimitSel

Target Variable:

Connected Components

	Instance	Target
1	1	Ext_VoiceMailLimitSel

OK

Cancel

Editing a connection point type

- Operation

Describes the origin of the data to gather. It can be:

Choice: Indicates the data is a value entered by a user. If *Choice* is selected, you must provide the target selection point in the Connect Components table. Leave Target Variable (following) blank, as it does not apply to Choice operations.

Collection: Indicates the data is a set of values taken from all the sources that have a particular attribute in common. If you choose the Collection operation, you also must specify the target variable and numeric data (following).

None: Default value. Use this value when you want the value set for the connection point itself to be the valid value. Otherwise, the Type operation (*Choice* or *Collection*) will override it.
- Source

Identifies the selection point that provides the data to be communicated over the connection. You may need to open the component model in Visual Modeler (in another window is easier) to obtain the correct name of the selection point. For Choice operations only.
- Target Variable

The name of the object in which to store the collected values of a Collection operation. Not required for Choice operations. This information is located in the component model that is to receive the information (connected component).
- 

Associates a new connected component to the connection point type.

Removes a connected component from the connection point type.

To create a connection point type:

1. Select View, Type Manager.

The Type Manager for both configurable components and connection points appears, listing existing types (if any).

2. If you are creating a new connection point type, click the New button next to its panel.

If you are editing an existing type, select it and click the corresponding Edit button.

The Connection Point Type Editor appears for either case.

3. Enter or edit the values in the editor as desired.
4. Specify connected components by first determining which components are to receive data from the source (source selection point).

If you need to refer to a component model, open it in a separate window of the Visual Modeler.

5. Click the Add button to add a new row (connected component).
6. Enter these values:

Instance

Identifies and specifies which instances of the target DP are to receive data from the source DP. Entries are *All, 0, 1, 2, ..., n*.

All indicates that all instances of connected target (description follows) receive the data.

1...n indicates the order in which the target instances were created at run time. For example, the first instance of target, instance 1, will receive the data from the source selection point. You can designate other instances as well.

Target

If the operation is *Choice*, you must specify which selection point in the source is to receive the data. In an example in which Instance = *1* and Target = *Ext_voicemailLimitSet*, the first instance of *Ext_voicemailLimitSet* will receive the data from the Source selection point.

Numeric Data

If the operation is *Collection*, you must specify the name of the variable that will contain the data. Because this is always a set of numerals, it is called numeric data. In an example where Instance = *All* and Numeric Data = *lines*, all instances of the source selection point will contribute data, which, once all data is collected, will be sent to the object lines.

7. If there are additional targets to receive source data, click the button again to add another row.
8. Click OK to create the new type.

New connection point types will hereafter appear for selection in controls in the properties editor of the component.

Client Operations Processor API

This chapter discusses the PeopleSoft Configurator Client Operations Processor (COP) Java API and its application classes.

Understanding the COP Java API

The COP Client Operations Processor provides, through its Java API, the public interface to the Configurator. Your User Interface (UI), or other application, calls the COP Java API to communicate with the Configurator Engine and its associated modules.

In many cases, developers designing a UI to use with the PeopleSoft Configurator will not have to make COP Java API calls (or write any code) themselves. Instead, they can use the Configurator Control Templates, which allow them to use standard Configurator controls to present their interface. The Control Templates are used within JavaServer Pages. The Control Templates themselves make COP Java API calls to implement the behavior of the standard controls.

However, in some cases, you may want to have controls whose behavior or appearance is different from any of the existing Configurator controls. In these cases you will have to modify the code in the JavaServer Pages (JSP), or write your own from scratch. Alternatively, you may need to create a UI that uses something other than JSP or standard Web technologies in general.

In that case, these chapters are the reference you need. They describe how to understand, modify, and write Java code that communicates with the Configurator by making COP API calls.

You can use the COP API to:

- Connect to a particular model.
- Create objects that represent user choices.
- Submit these choices to the Configurator Engine, and get back the results.
- Get user-readable display information, such as domain member attributes and text descriptions of violations.
- Get delta-pricing information.
- Get configuration delta information.
- Verify a configuration.
- Save and restore a configuration.

Choices

Choices are inputs to the model that specify values. Usually they are user inputs (set through a UI), but they can also be programatically generated. The Configurator has two kinds of choices: extern variables and domain members.

Extern variables (also called simply "externs") are named variables whose values are of types int, double, string, boolean, and date. The UI may restrict what a user can enter so that, for example, the extern variable only contains a single floating-point number. Extern variables are frequently used in expressions.

Domain members are individual, discrete choices. They are arranged into groups, each group associated with a decision point (or selection point). A domain member usually has a number of attribute values—such as its description, size, or color—that the Advanced Configurator can access and use in various ways.

Decision Points and Domain Members

Two modeling concepts—decision points and domain members—are very important in understanding how to use the COP Java API. This section describes these concepts and how they relate to the UI.

The UI is a visual representation of your model (or, at least, a portion of the model). The model contains decision points and domain members, some of which will be displayed in the UI.

The figure shows a sample UI for a "Sandwich Model," in which the user can order a sandwich by choosing the filling, bread, condiments, extras, and temperature.

The image shows a graphical user interface for a sandwich model. At the top, there are two buttons: "Submit" and "Reset Model". Below these are four distinct sections, each representing a decision point for building a sandwich:

- Filling:** Contains four radio button options: Roast Beef, Tuna (selected), Chicken, and Veggie.
- Bread:** Contains five radio button options: White, Rye, Croissant, French Roll, and Wheat (selected).
- Condiments:** Contains six checkbox options: Cranberry Relish, Horseradish, Mayonnaise, Mustard, Pepper (checked), and Salt.
- Temperature:** Contains two radio button options: Hot and Cold (selected).

Sandwich model UI

A decision point is a collection of associated options that the user (or, through software, the application) can choose from. The options in a decision point are usually alternatives, although they need not be mutually exclusive. The individual options themselves are called domain members of that decision point. For example, in the Sandwich Model, the area labeled "Filling" represents a decision point—the user can select a sandwich meat from this collection. Each of the possible choices—Roast Beef, Turkey, Chicken, Tuna—represents a domain member of this decision point.

The COP Java API does not directly define or use decision point objects or domain member objects. Instead it encapsulates them in objects of type `ControlData` (for decision points) and `ControlItem` (for domain members). Frequently, in discussing the COP Java API, these distinctions will be blurred when there's no chance of ambiguity.

A decision point has certain properties—such as a name or a "multiselect" property—that can be obtained (through Java COP API calls) from the corresponding `ControlData` object. Likewise, a domain member has properties that can be obtained from the corresponding `ControlItem` object. But `ControlData` and `ControlItem` objects can also contain additional information, often representing current or developer-determined conditions. (For example, the `ControlItem` objects belonging to a `ControlData` object may have a sort-ordering established by the software when it created the `ControlData` object. This ordering is not a part of the corresponding decision point and its domain members.)

See Also

[Chapter 11, "Using the COP Java API," ControlData, page 192](#)

[Chapter 11, "Using the COP Java API," ControlItem, page 197](#)

Application Classes

This section lists the COP Java API classes and the primary uses of each.

ClientOperations

ClientOperations is the principal class you will be using. Its methods include:

- Initializing the session (connecting to a model).
- Creating objects that represent user choices (user selections, user eliminations, and extern variables).
- Submitting the user choices to the Configurator Engine that is retrieving the results (ControlData objects, delta-pricing information, numeric data, violations).
- Retrieving the names and values of extern variables.
- Restoring a configuration, getting the current configuration.
- Other actions.

getControlData is arguably the most important method in the ClientOperations class. It creates a ControlData object representing a decision point, which in turn contains an array of ControlItem objects representing the decision point's domain members. The UI obtains most of the information it needs from these objects.

Configuration

The Configuration class represents a configuration of choices (which may be user, computer, default choices, and extern variables), together with the configuration attributes and the model's name, version, and compileID. The ClientOperations class has methods to create a Configuration object that represents the current configuration, and to restore a configuration represented by a Configuration object.

The Configuration class includes methods for:

- Writing a representation of itself in XML format.
- Reading configuration data that has been written in XML format.
- Getting the Configuration object's data (choices, configuration attributes, model information).
- Setting the Configuration object's data (choices, configuration attributes, model information) directly.

ControlData

The `ControlData` class represents a decision point, and contains display information for the decision point and its domain members (`ControlItem` objects). `ControlData` objects are created by the `ClientOperations` method `getControlData`. The `ControlData` class includes methods for:

- Getting all `ControlItem` objects in this `ControlData` object.
- Getting iterators that sort and filter the `ControlItem` objects in specified ways.
- Getting current configuration values of the decision point (state, choices, quantity, and violations).
- Getting properties of the associated decision point (name, multiselect, optional, supports quantity).

ControlItem

The `ControlItem` class represents a domain member, and contains display information on the domain member and its attributes. `ControlItem` objects are obtained from a `ControlData` object that represents the domain member's decision point. The `ControlItem` class includes methods for:

- Getting display attributes and delta-pricing value for the domain member.
- Getting current configuration values of the domain member (state, elimination level, validity, and violations).

Choice

`Choice` is the superclass for `DMChoice` (for domain member choices) and `EVChoice` (for extern variable choices). You pass a vector of `Choice` objects (possibly including both `DMChoice` objects and `EVChoice` objects), one for each user choice, to the `Configurator` in the `ClientOperations` method `processChoices`, which then processes the choices to create a solution state.

In previous versions of the `Configurator`, objects of type `Choice` were used to represent domain member choices. For compatibility, the current `Choice` class still retains a number of methods that only make sense for domain member choices, but these methods are deprecated, and identical methods have been included in the `DMChoice` class. Use the methods in the `DMChoice` class instead of the deprecated methods in the `Choice` class.

The `Choice` class also contains non-deprecated methods for a few actions that are meaningful for both `DMChoice` and `EVChoice`, including:

- Getting the XML tag for this choice.
- Determining if the choice is a user selection.
- Getting the name of the decision point or extern variable associated with the choice. (The method for this is called `getDecisionPointName` for backward compatibility.)

DMChoice

DMChoice is a subclass of Choice.

The DMChoice class is used to represent domain member choices (selections and eliminations). You create a DMChoice object by calling the ClientOperations method `makeSelectedChoice` (when the user wishes to include a domain member) or `makeEliminatedChoice` (when the user wishes to exclude a domain member).

The DMChoice objects generated by `makeSelectedChoice` and `makeEliminatedChoice` represent user choices. However, by using the DMChoice method `setState`, you can change them to represent computer or default choices (or various combinations).

EVChoice

EVChoice is a subclass of Choice.

The EVChoice class is used to represent extern variable choices. You create an EVChoice object by calling the ClientOperations method `makeExternVarChoice`.

ItemFilter

The ItemFilter class specifies a filter for a decision point's domain members. You can use it to filter out all eliminated domain members, or all eliminated domain members whose elimination values fall outside some given range.

The ClientOperations method `getControlData` has an ItemFilter parameter, which you can use to filter out domain members that, in some models, the UI designer does not wish the user to see (such as all eliminated items). The filter parameter is optional. If you supply null instead, no filtering will be done. The exception is discarded domain members, which are always filtered out.

See [and Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

ItemIterator

The ItemIterator class is used to iterate through the domain members of a decision point—more specifically, through the `ControlItem` array of a `ControlData` object. An iterator (object of type `ItemIterator`) returns the `ControlItem` objects both sorted and filtered, as specified by your software. (The `ControlItem` array itself is neither sorted nor filtered by the COP.)

The sorting done by an iterator can either be a standard sort order implemented by the COP or a custom sort order determined by a comparator you provide. You can also have more than one iterator for a single `ControlData` object.

[Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195](#)

ExternVar

The ExternVar class represents an extern variable, and gives access to its name, type, and value.

NumericData

The NumericData class is used to get the type and value of numeric variables. Some models contain variables that you may wish to display in the UI, such as "total grams of saturated fat" or "number of video card slots remaining." These values are generated by the Configurator Engine, based on formulas specified in the model. From the point of view of the COP, they are read-only.

Numeric data are distinct from: configuration attributes; extern variables; and domain member attributes, prices, and quantities.

Violation

The Violation class is used to report on violations associated with the configuration, decision points, and domain members. It returns a user-readable explanation for the violation.

Chapter 11

Using the COP Java API

This chapter describes how to use the COP Java API to accomplish tasks required by the UI, including the following:

- ClientOperations.
- Initializing the COP.
- Processing and displaying a page.
- Saving and restoring a configuration.

ClientOperations

This is the primary class you will use. It includes methods for initializing a session, creating objects to represent user choices, submitting user choices to the Configurator Engine, getting back the results in the form of displayable information, and ending a session.

Note. Several ClientOperations methods, such as `getDecisionPointNames`, make a distinction between "public" decision points and "all" (public and private) decision points. The current version of the Configurator does not implement this distinction; all decision points are considered public.

Methods

The following methods are contained in the ClientOperations class:

```

void release()
void initialize(Locale appLocale, String modelName, String modelVersion, String⇒
    compileID, boolean needHtmlEncoding)
void initialize(Locale appLocale, String modelName, String modelVersion, boolean⇒
    needHtmlEncoding)
Configuration getConfiguration()
String[] getDecisionPointNames(boolean allObjects)
String[] getNumericDataNames()
String[] getExternVarNames()
ControlData getControl(String objectName)
ControlData getControlData(String objectName, String[] attributes, boolean sort,⇒
    ItemFilter filter)
ControlData getControlData(String objectName, String attribute, boolean sort, Item⇒
    Filter filter)
NumericData getNumericData(String objectName)
ExternVar getExternVar(String objectName)
double getTotalPrice()
void processChoices(Vector choices)
Violation[] getViolations()
boolean verifyConfiguration(Vector choices)
boolean verifyConfiguration(Configuration config)
DMChoice makeSelectedChoice(String dpName, String dmName, double qty)
DMChoice makeEliminatedChoice(String dpName, String dmName)
EVChoice makeExternVarChoice(String name, Collection values)
String getModelVersion()
String getModelCompileVersion()
Locale getLocale()
ffBaseBillOfMaterials getBOM()
String[] getCompileVersions(String modelName, String modelVersion)
String getModelName()
String[] getModelNames()
String[] getModelVersions(String modelName)
int restore(Configuration config, Locale appLocale, boolean needHtmlEncoding, int⇒
    policy)
void setPricingData(Map dpNamesAndAttributes)
String[] getIncompleteDecisionPointNames()
String[] getViolatedConstraintNames()
String[] getViolatedDecisionPointNames()
Date getSolveDate()
void setSolveDate(Date solveDate)

```

Initializing the COP

Before calling any other ClientOperations methods, you must attach the COP to a particular model to initialize your session. Do this by calling the ClientOperations methods initialize or restore. There are two different forms of initialize:

```

void initialize(Locale appLocale, String modelName, String modelVersion, boolean⇒
    needHtmlEncoding)

```

```

void initialize(Locale appLocale, String modelName, String modelVersion, String⇒
    compileID, boolean needHtmlEncoding)

```

```

void restore(Configuration config, Locale appLocale, boolean needHtmlEncoding, int⇒
    policy)

```

Use the first form when you have a model name and version, and wish to use the most recently compiled version of the model. In this case, you simply call the first form of initialize with the indicated parameters.

The second form is used when there is, in addition to the model name and version, a specific compilation version (indicated by `compileID`) of the model that you wish to use. In this case, call the second form of `initialize` with the indicated parameters, including the `compileID`.

There is one form of `restore`. It is used when you wish to load a previously saved configuration when initializing the COP.

To load a previously saved configuration at initialization:

1. Create a Configuration object.
2. Call the Configuration object's `fromXML` method to read the previously saved configuration from an input stream.

(Alternatively, if the configuration has been stored in a format other than the Configurator's standard XML format, it may be necessary to read the saved configuration, parse it, and set the Configuration object's values directly by using its "set" methods - `setModelName`, `setChoices`, etc.)
3. Call `restore`, with the Configuration object as the `config` parameter. The COP will then be attached to the model identified by the model name, version, and `compileID` found in the `config` parameter, with the previously saved configuration data restored.

In all cases, you must also provide an `appLocale` and `needHtmlEncoding` parameter. `appLocale` specifies the language that should be used for user-readable text. `needHtmlEncoding` specifies whether attribute data returned by the COP should be in HTML-encoded format. When using the `restore` method you must also provide a `policy.parameter.policy` specifies how to handle the retrieval of the model to attach to before loading the configuration.

Policy options are:

Option	Description
1	Use the model version stored in the Configuration object. Fail if that version is not found.
2	Use the model version stored in Configuration object. Use the latest version if that version is not found.
3	Always use the latest model version.
4	If multiple versions exist, ask which to use. If only one version exists, automatically use it. If no versions exist, fail.

With option 4, if multiple versions exist, the `restore` method returns a status code indicating that there are multiple versions. The methods `getModelVersions` and `getCompileVersions` could then be used to determine available model versions. When the desired version is found, call the `setModelVersion` and/or `setModelCompileVersion` on the Configuration object. Once these initial calls are made, you can use the Configuration object in a subsequent call to `restore` with the `policy` parameter set to `1`.

Additionally, you can specify the solve date for the COP to use when processing choices by calling the `setSolveDate` method. This method takes a `java.util.Date` object as a parameter. The COP constructor defaults the solve date to the current date. An example of overriding the default date is restoring a previously saved configuration. You may want to use the date that the configuration was saved as the solve date rather than the current date.

Example (without using a previously saved configuration): there are values for the model name, model version, and `compileID`, but if the `compileID` is empty (null or of zero length), we'll initialize without it.

```

ClientOperations cop = new ClientOperationsImpl();
String modelName, modelVersion, compileID;
{
    //set modelName, modelVersion, compileID here - not COP code
}
try
{
    if ((compileID == null) || (compileID.length() == 0))
    {
        cop.initialize(Locale.getDefault(), modelName, modelVersion, false);
        compileID = cop.getModelCompileVersion();
    }
    else
    {
        cop.initialize(Locale.getDefault(), modelName, modelVersion, compileID, false);
    }
}
catch (Exception e)
{
    System.out.println("Error: Unable to initialize COP - " + e);
}

```

Releasing the COP

When you are done with your session, call `release`. This allows the system to dispose of cached resources associated with the session. After calling `release`, you will not be able to make `ClientOperations` calls without first calling `initialize` again.

Processing and Displaying a Page

Processing and displaying a page is one of the most common tasks to accomplish using the COP Java API. It consists of several subtasks.

Circumstances that require you to process and display a page are:

- Initial page display, before the user has made any choices. In this case, the "processing" is done to retrieve the model's default choices and process a solution state for them.
- Subsequent page displays, after the user has made some choices and submitted a page.
- In some user interfaces, every time the user makes a choice the value is submitted to the Configurator Engine (this is called "auto-submit"). Auto-submit gives the user more immediate feedback. Obviously this has performance implications, since processing and redrawing are being done more frequently.

To process and display a page:

1. If you want delta-pricing information for one or more domain members and/or a total price for the configuration, call `setPricingData` if you are running the Configurator in stand-alone mode.

If you are running the Configurator integrated with Order Capture, setup for pricing data is handled within the Configurator schema setup pages.

See [Chapter 21, "Setting Up Integration," Establishing Configuration Display and Pricing Options, page 309](#).

If you don't want delta-pricing information, skip this step.

2. If the user has made domain member choices (which is usually the case, except for the initial page display), call `makeSelectedChoice` and `makeEliminatedChoice` to create one `DMChoice` object for each user choice or elimination.

The COP does not indicate which domain members in the UI have been selected or eliminated by the user; you must examine the UI controls and tell the COP by passing `Choice` objects to `processChoices` - see Step 4.

3. If the user has entered extern variable choices, call `makeExternVarChoice` to create one `EVChoice` object for each extern variable choice.
4. Call `processChoices`. *This step is mandatory.*

If there are user choices (domain member selections or eliminations, or extern variable choices), pass them to `processChoices` in a vector of `Choice` objects. This vector can contain both `DMChoice` objects and `EVChoice` objects, since both are subclasses of `Choice`.

If there are no selections, pass null to `processChoices`.

The Configurator Engine creates a solution state representing the choices and their implications—which domain members are user-selected, user-eliminated, computer-selected, computer-eliminated, and so on—and the COP generates any delta-pricing information you requested in Step 2. This information is cached by the COP until the next time you call `processChoices` (or `release`), and can be retrieved by calling `getControlData` (and other methods), as described in Step 5.

5. For each decision point for which you need display information, call `getControlData`.

This call will return a `ControlData` object representing that decision point. The `ControlData` object contains an array of `ControlItem` objects, representing the decision point's domain members. Also, the `ControlData` method `iterator` can be called to obtain iterators (objects of type `ItemIterator`), which are used to access the `ControlItem` objects.

When you call `getControlData`, you specify two parameters (*sort* and *filter*) that determine how you want domain members to be sorted and filtered. The `ControlData` object's iterator(s) will return the `ControlItem` objects in sorted order and filtered as specified. (You can further control the sort order by supplying a custom `Comparator` routine.)

See [Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

6. Using the `ControlData` and `ControlItem` classes, retrieve any display data you want: domain members (sorted and filtered as desired); their attribute values; and their states (such as user-selected and computer-eliminated).
7. If you wish to display the values of any extern variables, call the `getExternVar` method.
8. Render your page with the display information from Step 6 and Step 7.

In addition to the methods of the `ControlData` and `ControlItem` classes, you can use the `ClientOperations` methods `getTotalPrice`, `getViolations`, and `getNumericData`, and the `Configuration` method `getAttribute` for other information you might wish to display.

Getting a ControlData Object

In Step 5 of the preceding instructions for processing and displaying a page, you get one `ControlData` object for each decision point for which you need display information (or for whose domain members for which you need display information). You do this by calling the `getControlData` method.

This section describes that method in more detail. There are two forms of `getControlData`:

```
ControlData getControlData(String objectName, String attribute, boolean sort, Item⇒
Filter filter)
```

```
ControlData getControlData(String objectName, String[] attributes, boolean sort,⇒
ItemFilter filter)
```

Use the first form when you are only interested in obtaining values for a single attribute (one value for each domain member of the decision point). Use the second form when you are interested in the values of multiple attributes.

The call returns a `ControlData` object, representing a decision point. The `ControlData` object includes an array of `ControlItem` objects, representing all the domain members of that decision point. You can also obtain one or more iterators (objects of type `ItemIterator`) from the `ControlData` object, which are used to access the `ControlItem` objects.

In many cases, you will want the domain members in the UI to be sorted in a particular way. The sort order can be either a standard one implemented by the COP (based on the domain members' states and elimination levels), or a custom sort order based on a `Comparator` routine you supply.

See [and Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

You may also want some domain members to be filtered out, so they don't appear in the UI at all. For example: filter out all eliminated domain members. Specify the sort and filter as parameters to the `getControlData` call. The `ControlData` object's iterator(s) will return the `ControlItem` objects (domain members) in the requested sort order, and filter out (skips over) any domain members as specified.

Note. Although you can access the `ControlItem` array directly using the standard array methods, you will almost never want to. The array is neither sorted nor filtered by the COP. Use the `ControlData` object's iterators; they will return the `ControlItem` objects in the correct sort order, and filter (skip over) any `ControlItem` outside the specified range.

The parameters to `getControlData` have the following meanings:

objectName	The name of the decision point.
attribute	In the first (single-attribute) form of the call, the name of the attribute whose values you wish to obtain. After making the <code>getControlData</code> call, you can get <code>ControlItem</code> objects from the resulting <code>ControlData</code> object, then get the attribute value for each <code>ControlItem</code> (domain member) by using the <code>ControlItem</code> method <code>getAttributes</code> (which, in this case, will return a vector with one element).

attributes

In the second (multiple-attributes) form of the call, an array containing the names of all the attributes whose values you wish to obtain. After making the `getControlData` call, you can get `ControlItem` objects from the resulting `ControlData` object, then get the attribute values for all the attributes you specified for each `ControlItem` (domain member) by using the `ControlItem` method `getAttributes`.

sort

If true, the `ControlItem` objects returned by an iterator (object of type `ItemIterator`, obtained by calling the `ControlData` object's iterator method) will be sorted. The sort order will either be a standard one implemented by the COP, or a custom sort order based on a `Comparator` object that you supply.

See and [Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

The standard sort order implemented by the COP is based on the state and elimination level of the `ControlItem` objects (domain members). The domain members are sorted as follows:

1. Selected domain members in conflict.
2. Selected domain members not in conflict.
3. Selectable domain members.
4. Eliminated domain members—high elimination level.
5. Eliminated domain members—low elimination level.

If there is more than one domain member in a category, they will be sorted in their "default order." (This is the order in which they were originally supplied by the modeler or the data base.) In other words, within each category the default order will be preserved. This applies to eliminated domain members only if their elimination level is equal.

If `sort` is true and you supply a `Comparator` object, your `Comparator` routine will be used to sort the domain members.

If `sort` is false, the COP will do no sorting of domain members. Any iterator obtained from this `ControlData` object's iterator method will return the domain members in their default order.

filter

Filters out certain `ControlItem` objects (domain members), based on their state and elimination level. The `ControlData` object's iterator simply skips over these `ControlItem` objects. For example: this can be used to filter out all eliminated items (so the user doesn't even see them), or all eliminated items with an elimination level below a certain number.

If filter is null, no filtering is done (except for "deleted" domain members).

See and [Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

Given a decision point name (*dpName*) and attribute (*attribute*), get and display the domain members—sorted but not filtered.

```
ControlData ctrlData = null;
ControlItem ctrlItem = null;
boolean sortFlag = true;
ItemFilter filter = null;
ItemIterator ctrlItemIterator = null;
try
{
    ctrlData = cop.getControlData(dpName, attribute, sortFlag, filter);
}
catch (Exception e)
{
    System.out.println("Error: Unable to retrieve ctrlData -> " + e);
    ctrlData = null;
}
if (ctrlData != null)
{
    ctrlItemIterator = ctrlData.iterator();
}
if (ctrlItemIterator != null)
{
    while (ctrlItemIterator.hasNext())
    {
        ctrlItem = (ControlItem) ctrlItemIterator.next();
        if (ctrlItem != null)
        {
            // you have ctrlItem - examine and display it here
        }
    }
}
```

It's important to note that the methods of `ControlData` and `ControlItem` objects return the most recent display information, which is based on the most recent calls to `processChoices`, `getControlData`, `setPricingData`, and so on, regardless of when the `ControlData` or `ControlItem` object was first created. They do not "remember" old values. So, for example, if you do the following:

1. Make some user choices.
2. Call `processChoices`.
3. Call `getControlData` to get a `ControlData` object for a decision point.
4. Make different user choices.

5. Call `processChoices` again.
6. Call `getFlags` on the `ControlData` object created in Step 3 to get the state of the decision point.

You would get the current state of the decision point, not the state it had as of Step 3. So there is no reason to save a `ControlData` or `ControlItem` object in order to hold old display information. It won't work. (You could, of course, call `getFlags` immediately after Step 3 and save the value itself.)

Specifying Delta-Pricing and Total-Pricing Requirements

The procedure to process and display a page specifies those domain members (if any) for which you need pricing-related information.

See and [Chapter 11, "Using the COP Java API," Getting Display Information for a Domain Member, page 198.](#)

There are two ways you can accomplish this:

- By calling the `setPricingData` method.

Use this method if you are running the Configurator in stand-alone mode. This section describes that method in more detail.

- By integrating Configurator with Order Capture.

Setup for pricing data is handled within the Configurator schema setup pages. When using this method of specifying pricing data, use the `ClientOperationsImpl` constructor that takes a `solutionId` as a parameter when creating the COP. The `solutionId` tells the COP which schema to reference for the appropriate pricing data.

Calling `setPricingData` describes a set of domain members for which you want pricing-related information. This information is cached by the Configurator (until you call `setPricingData` again, or release). The next time `getControlData` is called, the COP will be called to generate pricing-related information for those domain members. The delta-price value for a domain member can then be retrieved from the `ControlItem` representing the domain member using the `ControlItem` method `getDeltaPrice`. The total price for the configuration can also be retrieved using the `ClientOperations` method `getTotalPrice`.

There is one form of `setPricingData`:

```
void setPricingData(Map dpNamesAndAttributes)
```

This method takes a `Map` of decision point names and the corresponding price attribute for that decision point. Only the domain members in the specified decision points will be delta-priced. Also, only the specified decision points will be used when calculating the total price for the configuration.

Note. Configurator remembers only the most recent `setPricingData` call. Subsequent calls do not "accumulate" domain members for which to get delta-pricing data.

Getting Other Display Information

Some `ClientOperations` methods return information that you may wish to display, but that is not included in `ControlData` or `ControlItem` objects. These calls include:

- *getExternVar*—returns an extern variable (object of type *ExternVar*), based on its name. The *ClientOperations* method *getExternVarNames* returns a vector of the names of all the extern variables that are part of the model.
- *getTotalPrice*—returns the total price of the current configuration.
- *getViolations*—returns all violations associated with the configuration.
- *getNumericData*—returns a *NumericData* object. Some models contain variables that you may wish to display in the UI, such as "total grams of saturated fat" or "number of video card slots remaining," that are distinct from domain member attributes, prices, and quantities. These variables are represented by *NumericData* objects. Given the name of such a variable, this call returns a *NumericData* object representing it. You can then use the *NumericData* class methods to get the variable's type and value.

See and [Chapter 11, "Using the COP Java API," *NumericData*, page 205.](#)

You may also wish to display one or more configuration attributes. To obtain them, call the *ClientOperations* method *getConfiguration* to get the current configuration, and then the *Configuration* method *getAttribute* for each attribute whose value you want to display.

Verifying a Configuration

When the user wishes to finalize the configuration, as in making a purchase, you can verify the configuration by calling the *ClientOperations* method *verifyConfiguration*. This method is similar to *processChoices*; it takes a vector of *Choice* objects (representing the configuration) as input, and calls the *Configurator Engine* to generate a solution state. The vector can contain both *DMChoice* objects and *EVChoice* objects. *verifyConfiguration* also returns a boolean value: true if the configuration is complete and consistent, false if otherwise. Complete means that every required (non-optional) decision point in the configuration has a selection. Consistent means the configuration has no violations.

Note. There is an alternate version of *verifyConfiguration* that takes a *Configuration* object as a parameter. With the exception of this additional parameter, it functions the same as the other version.

Configuration

This class represents a set of choices for the model, any configuration attributes, and the model's name, version, and *compileID*.

The choices may include both *DMChoice* objects and *EVChoice* objects.

You can obtain the current configuration by calling the *ClientOperations* method *getConfiguration*. This configuration will include user, default, and computer choices.

The *Configuration* object can be used to write out the configuration to an external format (usually XML), or to read in a configuration that has been saved in that format. You can also directly set and get the information in the configuration: choices, configuration attributes, and the model's name, version, and id.

You can also save and restore a configuration in other formats, but this requires a significant amount of custom code and is generally not worthwhile.

Methods

The Configuration class contains the following methods:

```
void convertElement(org.w3c.dom.Element elem)
void fromXML(InputStream is)
String getAttribute(String attribute)
Map getAttributeMap()
Vector getChoices()
String getModelCompileVersion()
String getModelName()
String getModelVersion()
String getTagName()
Vector getUserChoices()
String removeAttribute(String attribute)
void setAttribute(String attribute, String value)
void setChoices(Vector choices)
void setModelCompileVersion(String modelCompileVersion)
void setModelName(String modelName)
void setModelVersion(String modelVersion)
org.w3c.dom.DocumentFragment toXML(org.w3c.dom.Document doc)
Object clone()
DeltaConfig delta(Configuration newCfg)
boolean equals(Configuration newCfg)
Date getLastSavedDate()
Vector getNumericDatas()
boolean hasViolations()
void toXML(OutputStream out)
Date getSolveDate()
```

Saving and Restoring a Configuration

The COP can be used to save the current configuration in an external form, or to read a previously saved configuration and make it current. The COP uses a Configurator-defined XML format and standard Java input and output techniques for these operations. Provided the property `calico.na.db.compression` in the `Advisor.properties` file is set to true, it also compresses the data during the save and de-compresses it (if needed) during a restore.

To save the current configuration:

1. Call the `ClientOperations` method `getConfiguration` to obtain a `Configuration` object representing the current configuration.
2. Call that object's `toXML` method to write out an XML representation of the configuration to a specified output stream.

To restore a previously saved configuration (that is, make it current):

1. Create a `Configuration` object.
2. Call that object's `fromXML` method to read the previously saved configuration from a specified input stream.

3. Call the ClientOperations method restore, with the Configuration object as its config parameter.

Note. The Configuration methods toXML and fromXML assume the use of the Configurator's standard XML format for configurations. It is also possible to represent a configuration in some other format, defined either by the programmer or by some other (non-Configurator) standard. In this case you can not use toXML or fromXML. Instead, to save the configuration, you would examine each item in the configuration (including all the choices, configuration attributes, and model identification information) and write it out in the desired format. To restore a saved configuration, reverse the process: create a Configuration object, read in and parse the representation of the stored configuration, and set the values of all items in the Configuration object accordingly.

Obviously, using a non-standard format to represent a configuration entails much more work than using the Configurator's XML representation. It is generally not worthwhile.

ControlData

This class represents a decision point. You create a ControlData object for a decision point by calling the ClientOperations method getControlData. The ControlData object contains an array of ControlItem objects, representing all its domain members. It also enables you to obtain one or more iterators (objects of type ItemIterator) for accessing the ControlItem objects.

If you set the sort parameter of the getControlData call to true, then an iterator obtained from the ControlData object will return the ControlItem objects in a sort order determined by the software.

See and [Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

Iterators can also filter out (skip over) certain domain members, such as all eliminated domain members. Specify the filtering you want by using the filter parameter of getControlData.

See and [Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

Note. Although you can access the ControlItem array directly using the standard array methods, you will almost never want to. The array is neither sorted nor filtered by the COP. Use an iterator obtained from the ControlData object; the iterator will return the ControlItem objects sorted, and filter them as specified.

See and [Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

Note. Each optional decision point has a special domain member with the reserved name "\$NADA", representing a choice of "none." This domain member is supplied by the Configurator Engine; it does not come from the modeler or an external source. It does not appear in either the ControlData object's ControlItem array or in the ControlItem objects returned by the ItemIterator. Instead, it can only be obtained by calling the ControlData method getControlItem, with a String parameter that has been set to \$NADA.

If, for a given optional decision point, you want to give your users the option of "none" (including displaying the option, displaying its state, and so on), you need to handle it specially, using the \$NADA domain member and the getControlItem call.

Note. The ControlData method isPublic indicates whether a decision point is public or private. However, the current version of the Configurator does not implement this distinction; all decision points are considered public.

Methods

The following methods are contained in the `ControlData` class:

```
Object[] getAllItems()
Choice[] getChoices()
String getClassID()
ControlItem getControlItem(String domainName)
long getFlags()
String getName()
double getQty()
Violation[] getViolations()
boolean hasDeletedItems()
boolean isMultiSelect()
boolean isOptional()
boolean qtySupported()
boolean isPublic()
ItemIterator iterator()
ItemIterator iterator(Comparator comp)
int getMinChoices()
int getMaxChoices()
String[] getAttributeNames()
String getAttributeValue(String name)
String[] getAttributeValues(String[] names)
```

Getting Display Information for a Decision Point and Its Domain Members

Most of the display information is associated with the decision point's domain members, rather than the decision point. To get at this information, call the `ControlData` method `iterator` to get an iterator, and use it to access the `ControlItem` objects. They will be sorted and filtered as specified by the software.

You can also call `getAllItems`, which returns the `ControlItem` array directly. But this array is not sorted or filtered by the COP, regardless of the `getControlData` parameters. It contains all of the decision point's domain members, in whatever order they were supplied by the Visual Modeler or an external source.

For each `ControlItem`, use the `ControlItem` methods to retrieve its display information.

See [and Chapter 11, "Using the COP Java API," ControlItem, page 197.](#)

There is some information that you may wish to display that applies to the decision point as a whole. Methods that return such information include:

getQty	Returns the total of all the quantities for all the selected domain members of this decision point. Only some decision points, determined by the modeler, permit their domain members to have quantities. You can determine if a decision point permits quantities by using the <code>ControlData</code> method <code>qtySupported</code> .
---------------	---

getState	Returns the state of the decision point.
-----------------	--

See [and Chapter 11, "Using the COP Java API," Getting the State of a Domain Member, page 199.](#)

getViolations	Returns all violations associated with this decision point.
int getMinChoices	Returns the minimum selection quantity value for this decision point.
int getMaxChoices	Returns the maximum selection quantity value for this decision point.
String[] getAttributeNames()	Returns the names of the selection point attributes for this decision point.
String getAttributeValue(String name)	Returns the value of the specified attribute.
String[] getAttributeValues(String[] names)	Returns the specified attribute values.

Getting the State of a Decision Point

Based on the configuration and solution state at any given time, a decision point has one or more states, which can be obtained by calling the `ControlData` method `getFlags`. The state of a decision point depends completely on the state of its domain members.

See [and Chapter 11, "Using the COP Java API," Getting the State of a Domain Member, page 199.](#)

There are four decision point states:

selectable	If one or more of the domain members is selectable.
selected	If one or more of the domain members is selected.
conflicted	If one or more of the domain members is conflicted
undefined	Neither selectable, selected, nor conflicted.

Combinations are certainly possible. For example, a decision point can be simultaneously selected (because at least one of its domain members is selected) and selectable (because some other of its domain members are selectable).

All of a decision point's domain members are used in determining the domain member's state, not just the domain members that have not been filtered out by the `ControlData` object's iterator(s).

The `ControlData` interface defines three different state bits, which can be used to test a selection point (decision point's state flags:

Decision point state flags	Bits
SELECTABLE	0x01
SELECTED	0x02
CONFLICTED	0x04

Note. The particular values of the state bits are not important, and are only included for illustration. They might be changed in a later release. It is important that they are single, distinct bits. The bit values are not the same as the bit values for the similarly named field constants in the `ControlItem` interface.

The `ControlData` interface also defines:

Decision point state	Bits
UNDEFINED	0x00

You can use these field constants with the value returned by the `ControlData` method `getFlags` to determine the decision point's current state or states.

Sorting and Filtering

A `ControlData` object contains an array of `ControlItem` objects, representing its domain members. This array is not sorted or filtered by the COP. All the `ControlData` object's `ControlItem` objects (domain members) appear in the array. The `ControlItem` objects are arranged in the order that the corresponding domain members were loaded into the engine at model load time. For external domain members, this is the order specified by the SQL statement for the domain member query. For internal domain members, it is the order they were entered into the class by the modeler. This is called the domain member's default order.

However, the COP does permit you to sort and filter the `ControlItem` objects in certain ways. This is not implemented through the `ControlItem` array, but through objects of type `ItemIterator`, which can be obtained by calling the `ControlData` method `iterator`.

A `ControlData` object is created by a call to the `ClientOperation` method `getControlData`. If the `getControlData` parameter `sort` is set to `true`, then iterators (objects of type `ItemIterator`) obtained from the `ControlData` object's `iterator` method will return the `ControlItem` objects in a sorted order. This sort order will either be a standard one implemented by the COP, or a custom sort order based on a `Comparator` object that you supply, depending on which form of the `ControlData` method `iterator` you use.

You can also have multiple iterators at the same time, for simultaneous access to standard sorting, custom sorting (one or more), and multiple traverses of the `ControlData` object's domain members. But this will not usually be necessary.

Standard Sorting

The first form of the `ControlData` method `iterator` takes no parameters: `iterator()`. If you call this form, the resulting iterator returns the `ControlItem` objects sorted in a standard manner implemented by the COP. The sort order, one that many User Interfaces prefer, is as follows:

1. Selected domain members in conflict (that is, both selected and eliminated).

2. Selected domain members not in conflict.
3. Selectable domain members (neither selected nor eliminated).
4. Eliminated (but not conflicted) domain members—sorted from highest elimination value to lowest elimination value.

Within each category (for 1, 2, and 3), if the category has more than one domain member, its domain members are arranged in the same order in which they appear in the `ControlItem` array. That is, the original (default) order is maintained within each category.

Similarly, for category 4, multiple domain members with the same elimination value will be arranged in their original (default) order.

Every eliminated domain member has an elimination value. If it's not determined by constraints for which the modeler has defined elimination levels, it defaults to 1.

Custom Sorting

The second form of the `ControlData` method iterator takes a `Comparator` object as its parameter: `iterator(Comparator comp)`. If you call this form, the resulting iterator returns the `ControlItem` objects sorted in the order determined by your `Comparator` object. This enables you to create a completely customized sort order by writing your own `Comparator` object. Your `Comparator` will have access to all the methods of the `ControlItem` objects it is comparing, enabling you to sort on attribute values, states, and other domain member aspects.

Note. A `Comparator` is a Java object that is used to impose a sort order on a collection of objects by comparing pairs of objects and returning a result indicating which object is "greater" and which is "lesser?" (or that the two are to be considered "equal" in the sort order). In this case the objects are the `ControlItem` objects of a given `ControlData` object. `Comparators` implement the `java.util.Comparator` interface.

No Sorting

If you call the `ClientOperations` method `getControlData` with the sort parameter set to false, then the `ControlItem` objects of the resulting `ControlData` object will not be sorted. Any iterator returned by that `ControlData` object's iterator method will return `ControlItem` objects in their original (default) order—exactly as they appear in the `ControlItem` array—with no sorting by the COP. This is true regardless of which form of the iterator method you call. However, filtering may still occur.

See and [Chapter 11, "Using the COP Java API," Sorting and Filtering, page 195.](#)

Filtering

If the `getControlData` call has a non-null filter parameter, then iterators obtained from the resulting `ControlData` object will filter out (skip over) certain `ControlItem` objects, and only return the ones that are not filtered. This makes it easier for the UI to conceal from the user a certain class of domain members (commonly, all eliminated domain members, or eliminated domain members whose elimination value is below a certain number). The filtering depends on the filter parameter, as follows:

- If you call the first version of the `ItemFilter` method `setRange`—`setRange(boolean filterAllEliminatedItems)`—with the parameter set to true, the filter will filter out all eliminated (but not conflicted) items.

- If you call the second version of the `ItemFilter` method `setRange`—`setRange(int lower, int upper)`—then any eliminated (but not conflicted) domain members whose elimination values are outside the range from `lower` to `upper` (inclusive) will be filtered out.

Specifically, if you want to filter out all eliminated (but not conflicted) domain members with an elimination value less than some integer `N`, you would call `setRange(N + 1, ItemFilter.maxEliminationValue)`.

Every eliminated domain member has an elimination value. If it's not determined by constraints for which the modeler has defined elimination levels, it defaults to 1.

- Regardless of the value of the filter parameter—even if it is null—the `ControlData` object's iterators will always filter out "deleted" domain members—that is, an external domain member that has been removed from its database after the model was compiled. These deleted domain members are still present in `ControlData` object's `ControlItem` array, so they can be retrieved if necessary.

See [Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

If the `getControlData` range parameter is null, the `ControlItem` object's iterators will only filter out deleted domain members. No other domain members will be filtered out.

Handling Deleted Domain Members

In systems that load domain members from external databases, it is sometimes possible to have "deleted" domain members—that is, an external domain member that has been removed from its database after the model was compiled. It might be necessary to inform the user that a domain member has been deleted, especially if it had been user-selected.

A `ControlData` object's iterators automatically filter out (skips over) any deleted domain members, so they are not helpful in handling them. But the deleted domain members are still present in the `ControlData` object's `ControlItem` array. Use the `ControlData` method `hasDeletedItem` to see if the decision point has a deleted domain member. If it does, you can use `getAllItems` to get the `ControlItem` array, then use the standard array operators to look at all the `ControlItem` objects in the `ControlItem` array. The `ControlItem` method `isValid` (false for deleted domain members, true otherwise) will tell you if a given domain member is deleted. If it is, you can then check the domain member's state to determine if the user needs to be notified.

ControlItem

This class represents a domain member. It contains display information for that domain member.

Note. A `ControlItem` always comes from a `ControlData` object, which was originally obtained from a call to the `ClientOperations` method `getControlData`. So every `ControlItem` can be traced back to a particular `getControlData` call. The attributes parameter to the `getControlData` (or attribute parameter, for the other version of the call) determines which attribute values can be obtained from the `ControlItem`.

Methods

The `ControlItem` class contains the following methods:

```

Vector getAttributes()
String getAttributeValue(String attribute)
String getClassID()
double getDeltaPrice()
long getEliminationLevel()
long getFlags()
String getName()
double getQty()
Violation[] getViolations()
boolean hasEliminationLevel()
boolean isValid()
public double getMaxQty()
public double getMinQty()
void setDeltaPrice(double newDelta)

```

Getting Display Information for a Domain Member

You can use these `ControlItem` class methods to get display information for a domain member:

Method	Description
<code>getAttributes</code>	Returns a vector of attribute values for the domain member represented by this <code>ControlItem</code> . The attributes whose values will be returned are those that were included in the attributes input to the <code>getControlData</code> call that this <code>ControlItem</code> can be traced back to. The order of the values will be the same as the order of the attributes in that parameter. The UI could display these values in whatever format you decide.
<code>getFlags</code>	Returns the current state flags for the domain member. This tells you whether the domain member is user-selected, user-eliminated, computer-selected, computer-eliminated, and so on. The UI should mark the domain member appropriately. See and Chapter 11, "Using the COP Java API," Getting the State of a Decision Point, page 194.
<code>getQty</code>	Returns the quantity of this domain member. Only some decision points, determined by the modeler, permit their domain members to have quantities. You can determine if a decision point permits quantities by calling the <code>ControlData</code> method <code>qtySupported</code> on the associated <code>ControlData</code> object.
<code>getDeltaPrice</code>	Returns the delta price for this domain member. This information will only be available if the decision point this domain member belongs to was specified in the pricing definition setup.
<code>getViolations</code>	Returns an array of all the violations (if any) associated with this domain member.
<code>isValid</code>	Returns false for a deleted domain member, true otherwise. See and Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.
<code>hasEliminationLevel</code>	Returns the elimination level for an eliminated domain member. Every eliminated domain member has an elimination value. If it's not determined by constraints for which the modeler has defined elimination levels, it defaults to 1.
<code>double getMinQty</code>	Returns the minimum quantity value for this domain member.

<i>Method</i>	<i>Description</i>
<code>double getMaxQty</code>	Returns the maximum quantity value for this domain member.

Getting the State of a Domain Member

Based on the configuration and solution state at any given time, each domain member has one or more states, indicating whether the domain member is user-selected, computer-selected, user-eliminated, and so on. Multiple states are certainly possible. For example, a domain member can be both user-selected and computer-selected.

A domain member that is both selected and eliminated (for example, user-selected but computer-eliminated) is called conflicted. A domain member that is neither selected nor eliminated is called selectable.

The possible states for a domain member are: eliminated, selected, conflicted, selectable, computer-selected, default-selected, user-selected, computer-eliminated, default-eliminated, user-eliminated.

Note. The Configurator engine does not support "default-eliminated."

The `ControllItem` interface defines five different state bits, which can be used to test a domain member's state flags:

<i>Domain member state flag</i>	<i>Bits</i>
ELIMINATED	0x01
SELECTED	0x02
COMPUTER	0x10
DEFAULT	0x20
USER	0x40

Note. The particular values of the state bits are not important, and are only included to make some of the examples clearer. It is important that they are single, distinct bits

These bits do not occur in isolation; you would not expect to find a domain member state with only one of these bits set. In fact, you would expect at least one from ELIMINATED and SELECTED, and at least one from COMPUTER, DEFAULT, and USER. These combinations define other states in the `ControllItem` interface:

<i>Domain member state</i>	<i>Bits</i>
COMPUTER_ELIMINATED	0x11
DEFAULT_ELIMINATED	0x21
USER_ELIMINATED	0x41

Domain member state	Bits
COMPUTER_SELECTED	0x12
DEFAULT_SELECTED	0x22
USER_SELECTED	0x42

The fields can be combined by the bitwise OR operation into a number that represents the domain member's state or states. This number is called the domain member's state flags (or just flags). You can use the `ControlItem` method `getFlags` to get the state flags for a domain member, and then use these field constants to determine the precise state or states of the domain member—and thus how to display it in your UI.

Note. If a domain member is conflicted, then it is both eliminated and selected. But it may be difficult or impossible to get more detailed information from the state flags—such as whether the domain member is computer-selected, user-selected, computer-eliminated, and so on. For example, a domain member that is user-selected and computer-eliminated has exactly the same state bits set as a domain member that is user-eliminated and computer-selected (namely, `USER`, `COMPUTER`, `SELECTED`, `ELIMINATED`). So there's no way to tell from the state flags if the domain member is, for example, computer-selected or computer-eliminated. The convention, in this case, is to say that the domain member is conflicted, selected, and eliminated—and not try to go into any more detail than that.

It's up to you to decide how to use the states for display purposes in your UI. For example, most User Interfaces will display a domain member that is simply user-selected (0x42) the same way they will display one that is user-selected and computer-selected (0x52)—with an icon indicating it is user-selected. In this case user selection is considered more important than computer selection, and the UI doesn't bother to indicate both states. However, other User Interfaces may be required to display more information depending on the model needs.

The mapping from state flags to states is not always obvious, and you need to be careful. This is particularly true when dealing with conflicted domain members. For example, suppose you want to see if a domain member is computer-selected. When you examine the `COMPUTER` bit and the `SELECTED` bit, they are both 1.

It is possible that the domain member is computer-eliminated and user-selected—a conflicted combination. This combination (0x53) has the `COMPUTER` and `SELECTED` bits set, but the domain member is not computer-selected. You need to check the `SELECTED` bit to rule out this and similar possibilities.

The following two examples illustrate the use of the state flags to determine the state or states of a domain member.

Example 1: Check to see if a domain member is computer-selected (a conflicted item is not considered computer-eliminated, regardless of the other state bits that are set).

```
long stateFlags = 0;
stateFlags = ctrlItem.getFlags();
if ((stateFlags & ControlItem.COMPUTER_SELECTED) == ControlItem.COMPUTER_SELECTED) =>
    && ((stateFlags & ControlItem.CONFLICTED) != ControlItem.CONFLICTED))
{
    // domain member is computer-selected
}
else
{
    //domain member is not computer-selected
}
```

Example 2: Classifying a domain member as conflicted, selected, selectable, or eliminated.

```
long stateFlags = 0;
stateFlags = ctrlItem.getFlags();
if (stateFlags & ControlItem.CONFLICTED) == ControlItem.CONFLICTED)
{
    // domain member is conflicted
}
else if ((stateFlags & ControlItem.SELECTED) == ControlItem.SELECTED)
{
    //domain member is selected (and not conflicted)
}
else if ((stateFlags & ControlItem.ELIMINATED) != ControlItem.ELIMINATED)
{
    //not selected, not eliminated - domain member is selectable
}
else
{
    //domain member is eliminated
}
```

Choice

This class is the superclass for DMChoice and EVChoice. Several important methods in the COP Java API (such as the ClientOperations methods processChoices and verifyConfiguration) either accept or return a vector of objects of type Choice. These vectors can include both objects of type DMChoice and objects of type EVChoice, since, by inheritance, both are objects of type Choice.

In this version of the Configurator, many Choice class methods are deprecated and reintroduced in DMChoice because they apply only to domain member choices and not extern variables. For this reason there are very few Choice methods that are actually called; instead, the appropriate DMChoice methods and EVChoice methods are called.

The Choice class contains the following methods:

```
String getDecisionPointName()
String getDomainMemberName() //Deprecated. Use DMChoice.getDomainMemberName
double getQuantity() //Deprecated. Use DMChoice.getQuantity
long getState() //Deprecated. Use DMChoice.getState
abstract String getTagName()
boolean isSelection() //Deprecated. Use DMChoice.isSelection
boolean isUserChoice()
void setDecisionPointName(String dpName)
void setState(long newState) //Deprecated. Use DMChoice.setState
Object clone()
boolean isDMChoice()
void toXML(StringBuffer buffer)
```

When called on an object of type EVChoice:

- The method getDecisionPointName() returns the name of the extern variable.
- The method getType() returns the type of the extern variable.
- The method setDecisionPointName() changes the name of the EVChoice object (that is, associates the EVChoice object with a new extern variable, specified by name).
- The method isUserChoice() returns *false* if the extern value was defaulted in the model, until the user overrides the default value, in which case it will return *true*.

DMChoice

This class is a subclass of `Choice`. Objects of type `DMChoice` represent a domain member choice, that is, a selection or elimination. You create `DMChoice` objects by calling the `ClientOperations` methods `makeSelectedChoice` and `makeEliminatedChoice`. These `DMChoice` objects (along with `EVChoice` objects) can be passed in a vector to the `ClientOperations` method `processChoices`. No `DMChoice` or `Choice` class methods are required for this.

The `DMChoice` objects created by `makeSelectedChoice` and `makeEliminatedChoice` represent, by default, user domain member choices. However, by using the `DMChoice` method `setState`, you can change them to represent computer or default domain member choices (or various combinations). This may be necessary when you are creating `DMChoice` objects to include in a `Configuration` object that represents a configuration containing user, computer, and default domain member choices.

Methods

The following methods are contained in the `DMChoice` class:

```
String getDomainMemberName()  
double getQuantity()  
long getState()  
String getTagName()  
boolean isSelection()  
boolean isUserChoice()  
void setState(long newState)  
boolean equals(Object newChoice)  
void toXML(OutputStream out)
```

Examining a DMChoice

Given an object of type `DMChoice`, you can determine what domain member choice it represents in the following manner:

- Call `getDecisionPointName` and `getDomainMemberName` to get the decision point and domain member for the choice.
- Call `isSelection` to determine whether the choice represents a user selection or a user elimination. `isSelection` returns *true* for selections, *false* for eliminations.
- If the `DMChoice` object represents a user selection, and the associated decision point supports quantities for its domain members, you can call `getQuantity` to get the quantity associated with the selection. To determine if the decision point supports quantities, use the method `qtySupported()` in the `ControlDate` class.
- Call `getState()` to get the current state flags of the domain member associated with the `DMChoice` object.

EVChoice

This class is a subclass of Choice. Objects of type EVChoice represent extern variables. The value of an extern variable is a collection of floating-point numbers, strings, dates, boolean values, or integers.

You create EVChoice objects by calling the ClientOperations method makeExternVarChoice. These EVChoice objects (along with DMChoice objects) can be passed in a vector to the ClientOperations method processChoices. No EVChoice or Choice methods are required for this.

Methods

The following methods are contained in the EVChoice class:

```
String getTagName()  
int getValueCount()  
Collection getValues()  
void setValues(Collection values)  
boolean equals(Object newChoice)  
void toXML(OutputStream out)  
Object clone()  
boolean isUserChoice()
```

Examining an EVChoice

By using the Choice method getDecisionPointName on an EVChoice object, you can get the name of the associated extern variable. You can then use the ClientOperations method getExternVar to get an object of class ExternVar representing the extern variable itself. Alternatively, you can bypass the ExternVar object and get the value of the extern variable associated with the EVChoice by using the EVChoice method getValues.

ItemFilter

The ClientOperations method getControlData has an ItemFilter parameter that enables the method to filter out certain domain members.

The most common use of an ItemFilter parameter is to filter out all eliminated domain members, or all eliminated domain members whose elimination level is below a certain threshold. Depending on the model and the User Interface, these are domain members that the user may not be interested in.

The ItemFilter parameter to getControlData causes the ItemIterator (belonging to the ControlData object created by the getControlData call) to filter out (skip over) the specified domain members. This makes it easy for the UI not to display those domain members. Note that the filtering is done by the ItemIterator; the ControlData object's ControlItem array still contains all the ControlItem objects (domain members) of the ControlData object (decision point).

Methods

The following methods are contained in the `ItemFilter` class:

```
void setRange(boolean filterAllEliminatedItems)
void setRange(int lower, int upper)
```

Filtering Out Domain Members

There are two versions of the `ItemFilter` method `setRange`. One takes a boolean parameter, `filterAllEliminatedItems`. The other takes two integers, `lower` and `upper`. Before using a parameter of type `ItemFilter` do one of the following:

- Call `setRange(true)` on the parameter to filter out all eliminated (but not conflicted) domain members; or
- Call `setRange(lower, upper)` on the parameter to filter out those eliminated (but not conflicted) domain members whose elimination values are outside the range from `lower` to `upper` (inclusive).

Specifically, if you want to filter out all eliminated (but not conflicted) domain members with an elimination value less than some integer `N`, you would call `setRange(N + 1, maxEliminationValue)`.

Every eliminated domain member has an elimination value. If it's not determined by constraints for which the modeler has defined elimination levels, it defaults to 1.

Note. Regardless of the value of the filter parameter—even if it is null—the `ControlData` object's iterators will always filter out "deleted" domain members—that is, an external domain member that has been removed from its database after the model was compiled. These discarded domain members are still present in `ControlData` object's `ControlItem` array, so they can be retrieved if necessary.

See [Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

ItemIterator

The `ControlData` method `iterator` returns an object of the `ItemIterator` class. The `ItemIterator` object, called an iterator, is used to access the `ControlItem` objects (domain members) of the `ControlData` object (decision point). The iterator returns the domain members in a specified sort order, which may either be a standard sort order implemented by the COP or a custom sort order determined by a `Comparator` object you supply. The iterator also filters out (skips over) any domain members specified in the filter parameter to that `getControlData` call, as well as any deleted domain members.

It is possible to have more than one iterator for the same `ControlData` object at the same time. However, this is not usually necessary.

`ItemIterator` implements the Java interface `java.util.Iterator`.

The following methods are contained in the `ItemIterator` class:

```
boolean hasNext()
Object next()
```

ExternVar

This class represents an extern variable, and can be used to get the name, type, and value of the extern variable. The value of an extern variable is a collection of floating-point numbers, strings, dates, boolean values, or integers.

The ClientOperations method `getExternVarNames` returns a vector of the names of all the extern variables in a model. The ClientOperations method `getExternVar` can then be used to retrieve the extern variable itself.

The value of an extern variable can be used as a choice in a configuration.

See [and Chapter 11, "Using the COP Java API," Handling Deleted Domain Members, page 197.](#)

The ExternVar class methods are:

```
String getName()  
Collection getValues()  
String getType()  
Violation[] getViolations()  
boolean isDefault()
```

NumericData

This class represents a variable in the model. Some models contain variables that you might wish to display in the UI, such as "total grams of saturated fat" or "number of video card slots remaining." These are distinct from domain member attributes, prices, and quantities. Obtain a NumericData object representing a model variable by using the ClientOperations method `getNumericData`. Then you can use the methods in this class to get the type and value of the variable.

Numeric data values are generated by the Configurator Engine, based on formulas specified in the model. From the point of view of the COP, they are read-only.

The NumericData class:

```
String getName()  
String getValue()  
String getType()  
boolean equals(Object obj)
```

Violation

This class returns information on a violation. Retrieve Violation objects associated with a configuration, a given decision point, or a given domain member by using the `getViolations` method of the ClientOperations, ControlData, or ControlItem classes, respectively.

The Violation class has one method, `getExplanation`, which returns a user-readable explanation for the violation.

The Violation method contains this method:

```
String getExplanation()
```

Chapter 12

Understanding the Configurator XML Interface

This chapter provides an overview of the Advanced Configurator XML interface and discusses:

- Request-response.
- Elements and attributes.
- Retrieving model information.
- Updating a configuration.

Request-Response

The COPXMLServlet translates COP XML to COP Java calls, and COP Java returns to COP XML. The servlet is installed with Advanced Configurator. If you installed Advanced Configurator in the default directory, the COPXMLServlet is in this file:

```
.\bea\wlserver_10.3.1\config\Calico\applications\Calico\WEB-INF\lib\advisor.jar
```

You post a request to, and receive a response from, the servlet at COPXML on the computer where you installed the Configurator; for example, to post directly to the application server, use an URL like this:

```
http://MyComputer:7777/copxml
```

The COPXMLServlet and COP XML do not mimic the COP Java API. Instead, in one round trip, the COPXMLServlet:

- Bundles all of the requests included in the COP XML HTTP POST request.
- Makes all of the necessary COP Java calls required to process the requests.
- Processes everything that is returned by the COP, bundles it, and returns it in a single COP XML HTTP POST response.

Elements and Attributes

The COP XML request may include these elements:

```
CONFIGURATION
  DECISION_POINTS
  CHOICES
    CH
    EVCH
  CONTROL_DATA
    ATTR
    DP
    ATTR
  NUMERIC_VALUES
  EXTERN_VARS
  EV
  VIOLATIONS
```

The Configurator XML interface lets you retrieve information about a model, including:

- Model name, version, and compile version, using attributes of the CONFIGURATION element.
- Error messages for an invalid element name, attribute name, or attribute value; omitting an attribute; or an abnormal processing error.
- A set of decision points, using the ALL attribute of the DECISION_POINTS element.

The CONFIGURATION element is required. Other elements are optional. Attributes of elements further specify the request. The COP XML response can include other elements and attributes, but is similar to the request.

The COP XML request-response pair can:

- Retrieve information about a model.
- Update a configuration (interactive mode).
- Retrieve information about a configuration (interactive mode).
- Create, update, save, or retrieve a configuration (batch mode).
- Change the order status of a configuration.

Retrieving Model Information

The Configurator XML interface lets you retrieve information about a model, including:

- Model name, version, and compile version.
- Error messages for an invalid request, or an abnormal processing error.
- A list of decision points.

See Also

[Chapter 13, "Retrieving Model Information," page 213](#)

Updating a Configuration Interactively

The Configurator XML interface lets you update a configuration interactively by making choices or entering values for an external variable, that is, by:

- Selecting a domain member for a single-select decision point.
- Selecting one or more domain members for a multi-select decision point.
- Entering one or more values for an external variable.

See Also

[Chapter 14, "Updating a Configuration," page 219](#)

Retrieving Configuration Information

The Configurator XML interface lets you retrieve this information about a configuration:

- Total price.
- Choices.
- Domain member data, including:
 - Domain members for all, or selected decision points.
 - Constraint violation explanations for decision points.
 - Value of domain member attributes.
 - Delta prices for domain members.
 - Changes that occurred between two versions of the configuration.
 - Class name for domain members.
 - State, and quantity of domain members.
- Whether a decision point is multi-select.
- Constraint violation explanations for the configuration.
- Numeric values.

The Configurator XML interface also lets you:

- Sort domain members that are returned by the COP.
- Filter domain members that are returned by the COP.

See Also

[Chapter 15, "Retrieving Configuration Information," page 225](#)

Copying a Configuration

The Configurator XML interface lets you copy a configuration.

See [and Chapter 17, "Copying a Configuration," page 287.](#)

Using Batch Configuration Mode

The Configurator XML interface lets you create, update, save and/or retrieve configurations in batch mode.

See [and Chapter 18, "Using Batch Configuration Mode," page 289.](#)

Changing the Order Status of a Configuration

The Configurator XML interface lets you change the order status of a configuration.

See [and Chapter 19, "Changing the Order Status of a Configuration," page 293.](#)

COP.dtd

COP.dtd defines which XML elements and attributes the Configurator XML interface can use to send requests to, and return responses from, the COP Java interface. COP.dtd also defines which elements and attributes the COP may use to save and restore configurations.

Studying the COP.dtd may help you better understand the COP XML that is used by the Configurator XML interface. An annotated version is located in
`\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\dtd.`

Element-Attribute Trees

COP XML is defined by the COP.dtd. This means that some of its elements and attributes are not used by the Configurator XML interface, but are used by the COP to save and restore configurations.

COP XML may be viewed as a tree of elements, with some elements having attributes. Studying these element-attribute trees—especially trees that have only those elements and attributes that may be used in a request or response—may help you better understand the COP XML that is used by the Configurator XML interface.

Chapter 13

Retrieving Model Information

The Configurator XML interface lets you retrieve information about a model, including:

- Model name, version, and compile version, using attributes of the CONFIGURATION element.
- Error messages for an invalid element name, attribute name, or attribute value; omitting an attribute; or an abnormal processing error.
- A set of decision points, using the ALL attribute of the DECISION_POINTS element.

Elements and Attributes

The COP XML request may include these elements and attributes to retrieve information about a model.

```
CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION  
DECISION_POINTS ALL
```

The COP XML response may include these elements and attributes to return information about a model.

```
CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE  
DECISION_POINTS  
DP NM  
ERROR
```

Version and Compile Version

The CONFIGURATION element, and its MODEL_ID, MODEL_VERSION, and COMPILE_VERSION attributes let you retrieve the model version and model compile version.

Any COP XML request must include at least the top level CONFIGURATION element, with at least the MODEL_ID and MODEL_VERSION attributes. The value for the MODEL_ID attribute must be the name of a valid model. The value for the MODEL_VERSION attribute may be a valid version number, valid partial version number, or an empty string.

Latest Version and Compile Version

The CONFIGURATION element, without a value for its MODEL_VERSION attribute, lets you retrieve the latest version and compile version for the model.

Including in the REQUEST

- The CONFIGURATION element with:
- A valid value (model name) for the MODEL_ID attribute, and
 - An empty string as the value for the MODEL_VERSION attribute.

Causes the COP to return in the RESPONSE

- The CONFIGURATION element with values of:
- The given model name for the MODEL_ID attribute.
 - The latest model version for the MODEL_VERSION attribute.
 - The latest compile version for the COMPILE_VERSION attribute.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample"=>
  MODEL_VERSION=" " />
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=>
  "1-0-0" COMPILE_VERSION="20001030-102408->
606"> </CONFIGURATION>
```

Latest Compile Version

The CONFIGURATION element, with a valid value (full or partial version) for its MODEL_VERSION attribute lets you retrieve the latest version and compile version for the given version.

Including in the REQUEST

- The CONFIGURATION element with valid values for:
- The MODEL_ID attribute.
 - The MODEL_VERSION attribute.

Causes the COP to return in the RESPONSE

- The CONFIGURATION element with values of:
- The given model name for the MODEL_ID attribute.
 - The full, latest, given model version for the MODEL_VERSION attribute.
 - The latest compile version for the COMPILE_VERSION attribute.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample"=>
  MODEL_VERSION="1" />

<CONFIGURATION MODEL_ID="Audio"=>
  MODEL_VERSION="3-1" />
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_>
VERSION="1-0-0" COMPILE_VERSION="20001030->
102408-606">

<CONFIGURATION MODEL_ID="Audio" MODEL_>
VERSION="3-1-0" COMPILE_VERSION="20001105->
115320-323">
</CONFIGURATION>
```

Note. The response for any valid request always includes the full model version and compile version. You may want to include the version and compile version from the first response in all subsequent requests.

Error Messages

An abnormal processing error or a request with invalid or omitted information causes the COP XML to return an error message.

Including in the REQUEST

One of the following:

- An invalid element name.
- An invalid attribute name.
- An invalid value for a valid attribute name.

OR omitting a required attribute

For example:

REQUEST

(An invalid element name)

```
<CONFIGURATION/>
```

(An invalid attribute name)

```
<CONFIGURATION MODEL_ID=" " />
```

(An invalid value for an attribute)

```
<CONFIGURATION MODEL_ID="Sample_2">
/>
```

(An invalid value for an attribute)

```
<CONFIGURATION MODEL_ID="Sample" =>
MODEL_VERSION="1-1" />
```

(Omitting the required MODEL_VERSION attribute)

```
<CONFIGURATION MODEL_ID="Sample" />
```

Causes the COP XML to return in the RESPONSE

The ERROR element as a child element of the CONFIGURATION element. The ERROR element's content is a textual description of the error.

RESPONSE

```
<CONFIGURATION>
  <ERROR>com.calicotech.xml.ffInvalidChild=>
Exception: Child CONFIGURATION found where=>
CONFIGURATION required</ERROR>
</CONFIGURATION>
```

```
<CONFIGURATION>
  <ERROR>calico.configurator.exceptions.COPExce=>
=>
ption: Problem TestModel:0-0-0 not found.<=>
/ERROR>
</CONFIGURATION>
```

```
<CONFIGURATION>
  <ERROR>calico.configurator.exceptions.COPExce=>
=>
ption: Problem Sample_2:0-0-0 not found.<=>
/ERROR>
</CONFIGURATION>
```

```
<CONFIGURATION>
  <ERROR>calico.configurator.exceptions.COPExce=>
=>
ption: Version not found for Sample:1-1.<=>
/ERROR>
</CONFIGURATION>
```

```
<CONFIGURATION>
  <ERROR>calico.configurator.exceptions.COPExce=>
=>
ption: Version not found for Sample:0-0-0.<=>
/ERROR>
</CONFIGURATION>
```

Decision Points

The `DECISION_POINTS` element and its `ALL` attribute let you retrieve two different sets of decision points for the model.

All Decision Points

The `DECISION_POINTS` element, with its `ALL` attribute set to "true" lets you retrieve every decision point for the model.

By default, including in the `REQUEST` the `DECISION_POINTS` element also includes the element's `ALL` attribute with its value set to true.

REQUEST

```
<CONFIGURATION MODEL_ID=
"Sample" MODEL_VERSION=""><DECIS=
=>
ION_POINTS/>
</CONFIGURATION>

<CONFIGURATION MODEL_ID=
"Sample" MODEL_VERSION=""><DECIS=
=>
ION_POINTS ALL="true"/>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-
0-0" COMPILE_VERSION="20001030-102408-606">
<DECISION_POINTS ALL="true">
<DP NM="BaseSelection"/>
<DP NM="HardDrivesSelection"/>
<DP NM="DVDorCDRomSelection"/>
<DP NM="OperatingSystemSelection"/>
<DP NM="DeviceControllersSelection"/>
<DP NM="MonitorsSelection"/>
<DP NM="WattsDisplaySelection"/>
<DP NM="ChassisSelection"/>
<DP NM="PowerCordSelection"/>
<DP NM="WarrantySelection"/>
<DP NM="AdditionalSoftwareSelection"/>
<DP NM="TravelSelection"/>
<DP NM="PrimaryPurposeSelection"/>
<DP NM="UserTypeSelection"/>
<DP NM="SpeakersSelection"/>
<DP NM="PrintersSelection"/>
<DP NM="ScannersSelection"/>
<DP NM="TapeBackDriveSelection"/>
<DP NM="ZipDriveSelection"/>
<DP NM="CDRWSelection"/>
<DP NM="ModemSelection"/>
<DP NM="SoundSelection"/>
<DP NM="NetworkSelection"/>
<DP NM="MemorySelection"/>
<DP NM="VideoSelection"/>
</DECISION_POINTS>
</CONFIGURATION>
```

Note. Either request in the example causes the COP to return in the `RESPONSE` the `DECISION_POINTS` element with its `ALL` attribute set to "true", and, as child elements, all of the `DP` elements for the model. The name of each decision point is the value of the `NM` attribute for each `DP` element.

Public Decision Points

The `DECISION_POINTS` element, with its `ALL` attribute set to "false" lets you retrieve every public decision point for the model.

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The MODEL_ID attribute.
- The MODEL_VERSION attribute.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">  
  <DECISION_POINTS ALL="false"/>  
</CONFIGURATION>
```

Causes the COP to return in the RESPONSE

The CONFIGURATION element with values of:

- The DECISION_POINTS element with its ALL attribute set to "false".
- As child elements, only the public DP elements for the model.

RESPONSE

Causes the COP to return only the public decision points for the Sample model.

Chapter 14

Updating a Configuration

This chapter discusses

- Updating a configuration.
- Elements and attributes
- Choices
- Choices and Response

Chapter 12, "Understanding the Configurator XML Interface," Retrieving Model Information, page 208

Chapter 12, "Understanding the Configurator XML Interface," Retrieving Configuration Information, page 209

Updating a Configuration

The Configurator XML interface lets you update a configuration by making choices—that is, by selecting a domain member for a single-select decision point, or one or more domain members for a multi-select decision point, or entering one or more values for an external variable.

To select a domain member using COP XML, the request must include:

- A CHOICES element.
- The child element CH for each domain member that you want to select.
- These attributes of the child element CH:
 - DP—The name of the decision point for the domain member you want.
 - DM—The name of the domain member you want.
 - BY—Indicates that the choice is made by the user (U).
 - QTY—The number of copies of the domain member you want.

To enter values for external variables using COP XML, the request must include:

- A CHOICES element.
- The child element EVCH for each external variable that you want to enter a value(s) for.
- These attributes of the child element EVCH:
 - DP—the name of the decision point for the external variable you want.
 - VAL—the value you want to set on the external variable.

Note. You must enter a separate VAL attribute for each of the values you want to set on the external variable.

Note. The Configurator is stateless. Each request must include all user choices.

Elements and Attributes

The COP XML request may include these elements and attributes to update a configuration.

```
CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE
CHOICES RET
  CH DP DM BY QTY
  EVCH DP VAL
```

The COP XML response may include these elements and attributes to return information about a configuration.

```
CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE
CHOICES
  CH DP DM BY ST SL EL QTY
  EVCH DP VAL TY
```

Choices

The RET attribute of the CHOICES element lets you control whether the COP returns a response when you choose one or more domain members.

By default, including in the REQUEST the CHOICES element also includes the element's RET attribute with its value set to "false".

As mentioned above, a CHOICES request to update the configuration must also include, as a child element of the CHOICES element, EITHER the CH element with valid values for:

- The DP attribute
- The DM attribute
- The BY attribute
- The QTY attribute

OR the EVCH element with valid values for:

- The DP attribute
- The VAL attribute(s)

For example, these requests are, in effect, the same:

REQUEST 1 (RET not set):

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CHOICES>
    <CH DP="PrintersSelection" DM="HP Laserjet" BY="U"
QTY="1" />
  </CHOICES>
</CONFIGURATION>
```

REQUEST 2 (RET set to an empty string):

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CHOICES RET=" ">
    <CH DP="PrintersSelection" DM="HP Laserjet" BY="U"
QTY="1" />
  </CHOICES>
</CONFIGURATION>
```

REQUEST 3 (RET set to "false")

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CHOICES RET="false">
    <CH DP="PrintersSelection" DM="HP Laserjet" BY="U"
QTY="1" />
  </CHOICES>
</CONFIGURATION>
```

Each of these requests—REQUEST 1, 2, and 3—updates the configuration by making a user choice of one copy of the HP Laserjet for the printer's decision point. None of the requests cause the COP to return a RESPONSE.

Note. The Configurator is stateless. Each request must include all user choices.

Choices and Response

Including in the REQUEST the CHOICES element with the RET attribute set to "true" causes the COP to return in the RESPONSE:

- Every non-null attribute-value pair for every choice (pick) of a domain member in the configuration. The attributes of a domain member (DM) that may be returned are:
 - DP
 - DM
 - BY
 - QTY
 - ST
 - SL
 - EL
 - TY
- Every non-null, attribute-value pair for every external variable in the configuration.

The attributes of an external variable that may be returned are:

- DP
- VAL
- TY

For example:

REQUEST

(Without the CH child element)

```
<CONFIGURATION MODEL_ID=
"Sample" MODEL_VERSION=""><CHOICES>
  RET="true"/>
</CONFIGURATION>
```

(With the CH element PrintersSelection)

```
<CONFIGURATION MODEL_ID=
"Sample" MODEL_VERSION=""><CHOICES>
  RET="true">
    <CH DP="PrintersSelection" DM="HP">
      Laserjet" BY="U" QTY="1"/>
    </CHOICES>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_⇒
VERSION="1-0-0"
COMPILE_VERSION="20001128-143111-404">
  <CHOICES>
    <CH DP="HardDrivesSelection" DM="4.3 GB"⇒
      BATRA-33" BY="D" ST="34"/>
    <CH DP="ChassisSelection" DM="Mini Tower"⇒
      BY="C" ST="18"/>
    </CHOICES>
  </CONFIGURATION>
```

```
<CONFIGURATION MODEL_ID="Sample" MODEL_⇒
VERSION="1-0-0"
COMPILE_VERSION="20001030-102408-606">
  <CHOICES>
    <CH DP="PrintersSelection" DM="HP Laserjet"⇒
      ⇒
      ⇒
      BY="U" ST="66"/>
    </CHOICES>
  </CONFIGURATION>
```

REQUEST

(With the CH element BaseSelection)

```
<CONFIGURATION MODEL_ID=
"Sample" MODEL_VERSION=""><CHOICES>
  RET="true">
    <CH DP="BaseSelection" BY="U" QTY=>
      "1" DM="Prima Base Celeron=>
        433Mhz MiniTower"/>
    </CHOICES>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_
VERSION="1-0-0" COMPILE_VERSION="20001030-
102408-606">
  <CHOICES>
    <CH DP="BaseSelection" DM="Prima Base
Celeron 433Mhz MiniTower" BY="U" ST="66"/>
    <CH DP="HardDrivesSelection" DM="4.3 GB
BATRA-33" BY="D" ST="34"/>
    <CH DP="MonitorsSelection" DM="15 Inch
Monitor" BY="D" ST="34"/>
    <CH DP="ChassisSelection" DM="Mini Tower"
BY="C" ST="18"/>
    <CH DP="PowerCordSelection" DM="10 Foot PC
Power Cord" BY="C" ST="18"/>
    <CH DP="AdditionalSoftwareSelection" DM=
"ISP Direct Connect" BY="C" ST="18"/>
    <CH DP="TravelSelection" DM="No" BY="C" ST=
"18"/>
    <CH DP="ModemSelection" DM="Internal 56K"
BY="D" ST="34"/>
  </CHOICES>
</CONFIGURATION>
```

Note. The Configurator is stateless. Each request must include all user choices.

Chapter 15

Retrieving Configuration Information

This chapter discusses how to retrieve configuration information using COP XML:

- Elements and attributes
- Total Price
- Domain member data
- Multi-select decision points
- Global explanations
- Numeric values

Understanding Configuration Information

The Configurator XML interface lets you retrieve information about a configuration, including:

- Total price, using the `TOTAL_PRICE` attribute of the `CONFIGURATION` element.
- Choices—using the `CHOICES` element, the child elements `CH` and `EVCH`, and attributes of both elements.
- Domain member data, including:
 - Every domain member for every decision point in the configuration, using the `CONTROL_DATA` element.
 - Every domain member for specific decision points in the configuration, using the `CONTROL_DATA` element, the `DP` element, and the `NM` attribute of the `DP` element.
 - Constraint violation explanations for decision points, using the `EXPLANATIONS` attribute of the `CONTROL_DATA` element.
 - Values for domain member attributes, using the `ATTR` element and its `NM` attribute.
 - Delta prices for domain members, using the `DPR` attribute of the `DP` element.
 - Class name for domain members, using the `CL` attribute of the `DP` element.
 - State and quantity of domain members, using the `DP` element.
- Whether a decision point is multi-select, using the `MS` element.

- Global explanations—that is, constraint violation explanations for the configuration as a whole—using the VIOLATIONS element and its EXPLANATIONS attribute.
- Numeric values, using the NUMERIC_VALUES element, the child element NUM, and the NM attribute of the NUM element.

The Configurator XML interface also lets you:

- Sort domain members that are returned by the COP by state using the DMSORT_ST attribute of the CONTROL_DATA element.
- Filter domain members that are returned by the COP by elimination level using the FILTER_EL, FILTER_LO, and FILTER_HI attributes of the CONTROL_DATA element.

Note. The Configurator is stateless, so the examples in this chapter include user choices (picks) to create configurations that provide appropriate control data.

See Also

[Chapter 14, "Updating a Configuration," page 219](#)

[Chapter 15, "Retrieving Configuration Information," page 225](#)

Elements and Attributes

The COP XML request may include these elements and attributes to retrieve information about a configuration.

```

CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE
CHOICES RET
  CH DP DM BY QTY
  EVCH DP VAL
CONTROL_DATA DMSORT_ST FILTER_EL_LO FILTER_EL_HI
  FILTER_EL EXPLANATIONS
  ATTR NM
  DP NM CL DPR
  ATTR NM
NUMERIC_VALUES
EXTERN_VARS
  EV NM TY
  VAL
VIOLATIONS EXPLANATIONS

```

The COP XML response may include these elements and attributes to return information about a configuration. Attributes are in small italic print.

```

CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE
DECISION_POINTS
  DP NM
CHOICES
  CH DP DM BY ST SL EL QTY TY
  EVCH DP VAL TY
CONTROL_DATA
  DP NM CL MS
  DM NM CL ST QTY SL EL PR
  ATTR NM
  EXPLANATION
NUMERIC_VALUES
  NUM NM VL
EXTERN_VARS
  EV NM
VIOLATIONS EXPLANATIONS
  EXPLANATION

```

Total Price

The CONFIGURATION element and its TOTAL_PRICE attribute let you retrieve the configuration's total price.

Including in the REQUEST the CONFIGURATION element with an empty string value for its TOTAL_PRICE attribute causes the COP to return in the RESPONSE the value for the TOTAL_PRICE attribute.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" TOTAL_PRICE=" " />
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20000426-113936-314" TOTAL_PRICE="964.95" />
```

Choices

The CHOICES element, its children elements CH and EVCH, and attributes of these elements let you retrieve choices for the configuration.

Including the CHOICES element in the request updates the configuration by setting choices. Setting the RET attribute of the CHOICES element to "true" in the request causes the COP to return all choices in the configuration.

More accurately, including in the REQUEST the CHOICES element with the RET attribute set to "true" causes the COP to return in the RESPONSE:

- Every non-null attribute-value pair for every choice (pick) of a domain member in the configuration. The attributes of a domain member (DM) that may be returned are:
 - DP
 - DM
 - BY
 - QTY
 - ST
 - SL
 - EL
- Every non-null, attribute-value pair for every external variable in the configuration.

The attributes of an external variable that may be returned are:

- DP
- VAL
- TY

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES RET="true">
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="MonitorsSelection" BY="U" QTY="1" DM="15 Inch Monitor"/>
  </CHOICES>
</CONFIGURATION>
```

RESPONSE

```
CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-
102408-606">
  <CHOICES>
    <CH DP="BaseSelection" DM="Prima Base Celeron 433Mhz MiniTower" BY="U" ST="66"/>
    <CH DP="HardDrivesSelection" DM="4.3 GB BATRA-33" BY="D" ST="34"/>
    <CH DP="MonitorsSelection" DM="15 Inch Monitor" BY="U" ST="66"/>
    <CH DP="ChassisSelection" DM="Mini Tower" BY="C" ST="18"/>
    <CH DP="PowerCordSelection" DM="10 Foot PC Power Cord" BY="C" ST="18"/>
    <CH DP="AdditionalSoftwareSelection" DM="ISP Direct Connect" BY="C" ST="18"/>
    <CH DP="TravelSelection" DM="No" BY="C" ST="18"/>
    <CH DP="ModemSelection" DM="Internal 56K" BY="D" ST="34"/>
  </CHOICES>
</CONFIGURATION>
```

[Chapter 12, "Understanding the Configurator XML Interface," Updating a Configuration Interactively, page 209](#)

Domain Member Data

The CONTROL_DATA element, DP element, ATTR element, and attributes of these elements let you retrieve information on domain members.

Every Decision Point

The CONTROL_DATA element lets you retrieve every domain member for every decision point (selection point) in the configuration by decision point.

Including in the REQUEST

The CONTROL_DATA element without an attribute.

Causes the COP to return in the RESPONSE

Every DM element for every DP element in the configuration. Each DP element represents a decision point in the configuration. Each DM element is a child element of a DP element, and represents a domain member of that decision point.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CONTROL_DATA/>
</CONFIGURATION>
```

RESPONSE

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-
102408-606">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
    </DP>
    <DP NM="HardDrivesSelection">
      <DM NM="4.3 GB BATRA-33">
      </DM>
      <DM NM="8.4 GB BATA-33">
      </DM>
      <DM NM="13.6 GB BATA-33">
      </DM>
      <DM NM="Quantum 27.3 GB SCSI">
      </DM>
    </DP>
    <DP NM="DVDorCDRomSelection">
      <DM NM="Pioneer DVD-A115">
      </DM>
      <DM NM="Sharp DVD-A100U">
      </DM>
      <DM NM="48X Max Variable CD-ROM">
      </DM>
    </DP>
    <DP NM="....">
      <DM NM="....">
      </DM>
    </DP>
    ....
  </CONTROL_DATA>
</CONFIGURATION>

```

Selected Decision Points

The CONTROL_DATA element, its child element DP, and the NM attribute of the DP element let you retrieve every domain member for a selected decision point in the configuration.

A Single Decision Point

Including in the REQUEST the CONTROL_DATA element, and its child element DP with a valid value (decision point name) for the NM attribute of DP causes the COP to return in the RESPONSE every DM element for the named DP element. Each DM is a child element of the named DP, and represents a domain member of that decision point.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <DP NM="HardDrivesSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-102408-606">
  <CONTROL_DATA>
    <DP NM="HardDrivesSelection">
      <DM NM="4.3 GB BATA-33">
      </DM>
      <DM NM="8.4 GB BATA-33">
      </DM>
      <DM NM="13.6 GB BATA-33">
      </DM>
      <DM NM="Quantum 27.3 GB SCSI">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Multiple Decision Points

The request may include more than one DP element, each with a valid value (decision point name) for its NM attribute:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <DP NM="ScannersSelection"/>
    <DP NM="PrintersSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-102408-606">
  <CONTROL_DATA>
    <DP NM="PrintersSelection">
      <DM NM="HP Laserjet">
      </DM>
      <DM NM="Epson 1500">
      </DM>
    </DP>
    <DP NM="ScannersSelection">
      <DM NM="NEC Technologies PediScan">
      </DM>
      <DM NM="Fujitsu ScanPartner 15C">
      </DM>
      <DM NM="Canon DR5080C">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

No Decision Points

Including in the REQUEST the CONTROL_DATA element and its child element DP with an empty string value for the NM attribute of DP, causes the COP to return in the RESPONSE no DM elements and no DP elements.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <DP NM="" />
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-102408-606">
  <CONTROL_DATA>
  </CONTROL_DATA>
</CONFIGURATION>
```

Sorting Domain Members

The DMSORT_ST attribute of the CONTROL_DATA element lets you sort domain members returned in the response, by state.

Including in the REQUEST the CONTROL_DATA element with its DMSORT_ST attribute set to "true" causes the COP to return in the RESPONSE domain members (DM's) sorted by state (ST).

For example:

REQUEST (with a request to sort domain members by state)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="Power Brick Cord"/>
  </CHOICES>
  <CONTROL_DATA DMSORT_ST="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with domain members sorted by state)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-134209-537">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Example using the same request and response but without sorting:

REQUEST (with no request to sort domain members by state)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="Power Brick Cord"/>
  </CHOICES>
  <CONTROL_DATA>
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE 2 (with domain members not sorted by state)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-134209-537">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Note. A custom sort may be installed using COP Extensions.

Filtering Domain Members

The FILTER_EL, FILTER_LO, and FILTER_HI attributes of the CONTROL_DATA element let you filter domain members returned in the response, by elimination level.

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The CONTROL_DATA element with:
- The DP element.
 - Its FILTER_EL attribute set to "true".
 - Its FILTER_EL_LO and FILTER_EL_HI attributes set to valid elimination levels.

Causes the COP to return in the RESPONSE

DM elements whose elimination levels are between FILTER_EL_LO and FILTER_EL_HI, inclusive.

For example:

This REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CONTROL_DATA FILTER_EL="true" FILTER_EL_LO="2" FILTER_EL_HI="5">
    <DP NM="HardDrivesSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

returns a RESPONSE that includes only those DM elements for the HardDrives DP element that have elimination levels between 2 and 5, inclusive.

Explanations

The EXPLANATIONS attribute of the CONTROL_DATA element lets you retrieve constraint violation explanations for decisions points in the configuration.

See [and Chapter 15, "Retrieving Configuration Information," Global Explanations, page 245.](#)

Constraint Violations

Including in the REQUEST the CONTROL_DATA element with its EXPLANATIONS attribute set to "true" causes the COP to return in the RESPONSE all EXPLANATION elements for every decision point (DP element) returned. Each EXPLANATION element is a child element of a DP element, and its content is a textual explanation of the constraint violation.

To return an explanation, the request must include incompatible picks—a constraint violation—for a specified decision point.

For example:

REQUEST (with two incompatible picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="Power Brick Cord"/>
  </CHOICES>
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>

```

RESPONSE (with a constraint violation explanation for the specified decision point)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-134209-537">
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
        </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
        </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
        </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
        </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
        </DM>
      <EXPLANATION>The C433Mini base requires the 10Foot power cord and Mini chassis.
    </EXPLANATION>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

An example of a constraint violation explanation for a specified decision point:

REQUEST (with two incompatible picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="ChassisSelection" BY="U" QTY="1" DM="Full Tower"/>
  </CHOICES>
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>

```

RESPONSE (with a constraint violation explanation for the specified decision point)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
        </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
        </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower">
        </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC" ST="17">
        </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC" ST="17">
        </DM>
      <EXPLANATION>The C433Mini base requires the 10Foot power cord and Mini chassis.
    </EXPLANATION>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

No Constraint Violation

If the request includes compatible picks, there are no constraint violations, and asking for explanations will not return any explanations.

For example:

REQUEST (with two compatible picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="10 Foot PC Power Cord"/>
  </CHOICES>
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>

```

RESPONSE (without any explanations for the specified decision point)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="66">
        </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
        </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
        </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC" ST="17">
        </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC" ST="17">
        </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

An example of a request for explanations failing to return any explanations for the specified decision point, because the picks are compatible:

REQUEST (with two compatible picks)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="ChassisSelection" BY="U" QTY="1" DM="Mini Tower"/>
  </CHOICES>
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (without any explanations for the specified decision point)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-134209-537">
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="66">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC" ST="17">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC" ST="17">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Attributes

The ATTR element and its NM attribute let you retrieve the values for a selected attribute for either:

- Every domain member returned in the response.
- Selected domain members returned in the response.

Either way, the response includes the values for the selected attribute for all of the appropriate domain members, by domain member.

Every Domain Member

The ATTR element and its NM attribute let you retrieve the values for a named attribute for every domain member of every decision point returned in the response.

Including in the REQUEST the CONTROL_DATA element and its child element ATTR with a valid value for the NM attribute of the ATTR element causes the COP to return in the RESPONSE:

- The named ATTR element for every DM element of every DP element returned in the response.
- Attribute-value content for each ATTR element of every returned DM element that has the named attribute.

In the following example, all domain members of both decision points—Scanners, and Printers—have the ShortName attribute:

REQUEST (requesting values for the ShortName attribute for every domain member of two decision points)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CONTROL_DATA>
    <ATTR NM="ShortName" />
    <DP NM="ScannersSelection" />
    <DP NM="PrintersSelection" />
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with ShortName attribute-value content for every domain member of both decision points)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-
102408-606">
  <CONTROL_DATA>
    <DP NM="PrintersSelection">
      <DM NM="HP Laserjet">
        <ATTR NM="SHORTNAME">HPLJ</ATTR>
      </DM>
      <DM NM="Epson 1500">
        <ATTR NM="SHORTNAME">Ep1500</ATTR>
      </DM>
    </DP>
    <DP NM="ScannersSelection">
      <DM NM="NEC Technologies PediScan">
        <ATTR NM="SHORTNAME">NECPeSc</ATTR>
      </DM>
      <DM NM="Fujitsu ScanPartner 15C">
        <ATTR NM="SHORTNAME">FScP15C</ATTR>
      </DM>
      <DM NM="Canon DR5080C">
        <ATTR NM="SHORTNAME">CDR5080C</ATTR>
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

In the following example, all domain members of the Base decision point have only the SystemType attribute, whereas all domain members of the Monitors decision point have only the Watts attribute:

REQUEST (requesting values for two attributes for every domain member of two decision points)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower" />
  </CHOICES>
  <CONTROL_DATA>
    <ATTR NM="Watts" />
    <ATTR NM="SystemType" />
    <DP NM="BaseSelection" />
    <DP NM="MonitorsSelection" />
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with SystemType attribute-value content for every domain member of the Base decision point, and Watts attribute-value content for every domain member of the Monitors decision point)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="66">
        <ATTR NM="WATTS"></ATTR>
        <ATTR NM="SYSTEMTYPE">LowEnd</ATTR>
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower">
        <ATTR NM="WATTS"></ATTR>

      </DM>
      <DM NM="21 Inch Monitor">
        <ATTR NM="WATTS">5.0</ATTR>
        <ATTR NM="SYSTEMTYPE"></ATTR>
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

Selected Domain Members

The ATTR element and its NM attribute let you retrieve the values for a named attribute for every domain member of selected decision points returned in the response.

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The CONTROL_DATA element.
- The DP element.
- The ATTR element (as a child of the DP element) with a valid value for its NM attribute.

Causes the COP to return in the RESPONSE

- The named ATTR element for every DM element of the selected DP element.
- Attribute-value content for each ATTR element of every returned DM element that has the named attribute.

REQUEST (requesting values for the ShortName attribute for every domain member of the Printers decision point)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  <CONTROL_DATA>
    <DP NM="ScannersSelection"/>
    <DP NM="PrintersSelection">
      <ATTR NM="ShortName"/>
    </DP>
    <DP NM="SpeakersSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with ShortName attribute-value content for every domain member of the Printers decision point)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-102408-606">
  <CONTROL_DATA>
    <DP NM="SpeakersSelection">
      <DM NM="Altec Lansing 2000">
        </DM>
      <DM NM="Cambridge SoundWorks SP">
        </DM>
    </DP>
    <DP NM="PrintersSelection">
      <DM NM="HP Laserjet">
        <ATTR NM="SHORTNAME">HPLJ</ATTR>
      </DM>
      <DM NM="Epson 1500">
        <ATTR NM="SHORTNAME">Ep1500</ATTR>
      </DM>
    </DP>
    <DP NM="ScannersSelection">
      <DM NM="NEC Technologies PediScan">
        </DM>
      <DM NM="Fujitsu ScanPartner 15C">
        </DM>
      <DM NM="Canon DR5080C">
        </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Combining Requests

The request may include both types of requests for the values for selected domain member attributes.

The following example requests the values for these domain member attributes:

- Watts—for every domain member of every decision point.
- ShortName—for every domain member of the Printers, and Speakers decision points.
- Description—for every domain member of the Printers decision point.

REQUEST

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <ATTR NM="Watts"/>
    <DP NM="ScannersSelection"/>
    <DP NM="PrintersSelection">
      <ATTR NM="Description"/>
      <ATTR NM="ShortName"/>
    </DP>
    <DP NM="SpeakersSelection">
      <ATTR NM="ShortName"/>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

RESPONSE

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-
102408-606">
  <CONTROL_DATA>
    <DP NM="SpeakersSelection">
      <DM NM="Altec Lansing 2000">
        <ATTR NM="SHORTNAME">AL2000</ATTR>
        <ATTR NM="WATTS">1.0</ATTR>
      </DM>
      <DM NM="Cambridge SoundWorks SP">
        <ATTR NM="SHORTNAME">CSWSP</ATTR>
        <ATTR NM="WATTS">1.0</ATTR>
      </DM>

      <DM NM="Canon DR5080C">
        <ATTR NM="WATTS">4.0</ATTR>
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>

```

Delta Price

The DPR attribute of the DP element lets you retrieve the delta prices for domain members of a selected decision point.

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The CONTROL_DATA element.
- The child element DP with:
 - A valid value (decision point name) for its NM attribute.
 - Its DPR attribute set to "true".

Causes the COP to return in the RESPONSE

The delta price for each DM element of the named DP element, included as the value for the PR attribute of each DM element.

For example:

REQUEST (requesting delta pricing)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <DP NM="ScannersSelection" DPR="true"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with delta pricing as the value for each PR)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA>
    <DP NM="ScannersSelection" DPR="true">
      <DM NM="NEC Technologies PediScan" PR="-25.0">
    </DM>
      <DM NM="Fujitsu ScanPartner 15C" PR="0.0">
    </DM>
      <DM NM="Canon DR5080C" PR="35.0">
    </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Class

The CL attribute of the DP element lets you retrieve the class name for domain members of a selected decision point.

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The CONTROL_DATA element.
- The child element DP with:
 - A valid value (decision point name) for its NM attribute.
 - An empty string value for its CL attribute.

Causes the COP to return in the RESPONSE

The class name for each DM element of the named DP element, included as the value for the CL attribute of each DM element.

For example:

REQUEST

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION=" ">
  , <CONTROL_DATA>
    <DP NM="ScannersSelection" CL=""/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA>
    <DP NM="ScannersSelection">
      <DM NM="NEC Technologies PediScan" CL="Scanners">
        </DM>
      <DM NM="Fujitsu ScanPartner 15C" CL="Scanners">
        </DM>
      <DM NM="Canon DR5080C" CL="Scanners">
        </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

State and Quantity

The DP element without any special attributes lets you retrieve the state and quantity of domain members of a selected decision point.

Including in the REQUEST

The CONTROL_DATA element.

- The CONTROL_DATA element.
- The child element DP with a valid value (decision point name) for its NM attribute.

Causes the COP to return in the RESPONSE

Non-null values for the state (ST) and quantity (QTY) attributes of all domain members (DM elements) of the named decision point (DP elements).

Note. The request should not include the ST and QTY attributes for the named DP elements.

For example:

REQUEST (without any special DP attributes)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES RET="false">
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
  </CHOICES>
  <CONTROL_DATA>
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (with a non-null value for ST)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-0" COMPILE_VERSION="20001030-102408-606">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="66">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Multi-Select Decision Points

Specifics of the request/response are:

Including in the REQUEST

The DECISION_POINTS element, with its ALL attribute set to "false."

- The CONTROL_DATA element.
- The DP element with:
 - A valid value (decision point name) for its NM attribute.
 - Its MS attribute set to "true".

Causes the COP to return in the RESPONSE

Whether or not the named decision point is multi-select. If the decision point (DP element) is multi-select, its MS attribute is set to "true"; if the decision point is single-select, it has no MS attribute.

For example:

REQUEST (asking whether two decision points are multi-select)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CONTROL_DATA>
    <DP NM="ScannersSelection" MS="true"/>
    <DP NM="DeviceControllersSelection" MS="true"/>
  </CONTROL_DATA>
</CONFIGURATION>
```

RESPONSE (answering that only the DeviceControllers decision point is multi-select)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA>
    <DP NM="DeviceControllersSelection" MS="true">
      <DM NM="IDE Cable">
      </DM>
      <DM NM="SCSI Cable">
      </DM>
      <DM NM="ATAPI">
      </DM>
    </DP>
    <DP NM="ScannersSelection">
      <DM NM="NEC Technologies PediScan">
      </DM>
      <DM NM="Fujitsu ScanPartner 15C">
      </DM>
      <DM NM="Canon DR5080C">
      </DM>
    </DP>
  </CONTROL_DATA>
</CONFIGURATION>
```

Global Explanations

The EXPLANATIONS attribute of the VIOLATIONS element lets you retrieve constraint violation explanations for the configuration as a whole.

See Also

[Chapter 15, "Retrieving Configuration Information," Explanations, page 234](#)

Global Only

Including in the REQUEST the VIOLATIONS element with its EXPLANATIONS attribute set to "true" causes the COP to return in the RESPONSE all EXPLANATION elements for the configuration. Each EXPLANATION element is a child element of a VIOLATIONS element, and its content is a textual explanation of the constraint violation.

To return an explanation, the request must include incompatible picks—a constraint violation—for the configuration.

For example:

REQUEST (with two incompatible picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="Power Brick Cord"/>
  </CHOICES>
  <CONTROL_DATA>
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
  <VIOLATIONS EXPLANATIONS="true"/>
</CONFIGURATION>

```

RESPONSE (with a global explanation of the constraint violation)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-134209-537">
  <CONTROL_DATA>
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
    </DP>
  </CONTROL_DATA>
  <VIOLATIONS>
    <EXPLANATION>The C433Mini base requires the 10Foot power cord and Mini chassis.
  </EXPLANATION>
  </VIOLATIONS>
</CONFIGURATION>

```

Global and Decision Point

The request and response can include explanations for both decision points and the configuration.

See [and Chapter 15, "Retrieving Configuration Information," Explanations, page 234.](#)

For example: REQUEST (with two incompatible picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
    <CH DP="PowerCordSelection" BY="U" QTY="1" DM="Power Brick Cord"/>
  </CHOICES>
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection"/>
  </CONTROL_DATA>
  <VIOLATIONS EXPLANATIONS="true"/>
</CONFIGURATION>

```

RESPONSE (with an explanation for the specified decision point and a global explanation)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA EXPLANATIONS="true">
    <DP NM="BaseSelection">
      <DM NM="Prima Base Celeron 433Mhz MiniTower" ST="83">
      </DM>
      <DM NM="Suprema Base Pentium III 750 Mhz MidTower" ST="17">
      </DM>
      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" ST="17">
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC">
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC">
      </DM>
      <EXPLANATION>The C433Mini base requires the 10Foot power cord and Mini chassis.
    </EXPLANATION>
    </DP>
  </CONTROL_DATA>
  <VIOLATIONS>
    <EXPLANATION>The C433Mini base requires the 10Foot power cord and Mini chassis.
  </EXPLANATION>
  </VIOLATIONS>
</CONFIGURATION>

```

Numeric Values

The NUMERIC_VALUES element, the child element NUM, and the NM attribute of the NUM element let you retrieve numeric values for the configuration.

All Values

Including in the REQUEST the NUMERIC_VALUES element causes the COP to return in the RESPONSE all NUM elements for the configuration. Each NUM element is a child element of NUMERIC_VALUES that has attribute-value pairs for its NM and VL attributes.

For example:

REQUEST

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
  </CHOICES>
  <NUMERIC_VALUES/>
</CONFIGURATION>

```

RESPONSE

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <NUMERIC_VALUES>
    <NUM NM="[_Application].WattsSummation" VL="3.0" >
    </NUM>
    <NUM NM="[_Application].StorageCapacitySummation" VL="4300" >
    </NUM>
    <NUM NM="[_Application].PCISlotsResourceBalancing-Provider" VL="3" >
    </NUM>
    <NUM NM="[_Application].PCISlotsResourceBalancing-Consumer" VL="1" >
    </NUM>
    <NUM NM="[_Application].AGPSlotsResourceBalancing-Provider" VL="0" >
    </NUM>
    <NUM NM="[_Application].AGPSlotsResourceBalancing-Consumer" VL="0" >
    </NUM>
    <NUM NM="[_Application].ISASlotsResourceBalancing-Provider" VL="4" >
    </NUM>
    <NUM NM="[_Application].ISASlotsResourceBalancing-Consumer" VL="0" >
    </NUM>
  </NUMERIC_VALUES>
</CONFIGURATION>

```

Selected Values

Including in the REQUEST the NUMERIC_VALUES element, and the child element NUM with a valid value for its NM attribute causes the COP to return in the RESPONSE the NUMERIC_VALUES element, and as a child element, the NUM element named in the request with a value for its VL attribute.

For example:

REQUEST

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
  </CHOICES>
  <NUMERIC_VALUES>
    <NUM NM="[_Application].WattsSummation"/>
  </NUMERIC_VALUES>
</CONFIGURATION>

```

RESPONSE

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <NUMERIC_VALUES>
    <NUM NM="[_Application].WattsSummation" VL="3.0" >
    </NUM>
  </NUMERIC_VALUES>
</CONFIGURATION>

```

Value (VL)

The value for the VL attribute for the named NUM element is the numeric value for the configuration. It is the total value for the named NUM element for all picks in the configuration that have the element as an attribute.

For example:

REQUEST 1 (with one user pick)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>
  </CHOICES>
  <CONTROL_DATA>
    <ATTR NM="Watts"/>
    <DP NM="BaseSelection"/>
    <DP NM="MonitorsSelection"/>
    <DP NM="HardDrivesSelection"/>
  </CONTROL_DATA>
  <NUMERIC_VALUES>
    <NUM NM="[_Application].WattsSummation"/>
  </NUMERIC_VALUES>
</CONFIGURATION>
```

RESPONSE 1 (with the one user pick and two computer picks)

```

<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="1-0-1" COMPILE_VERSION="20001215-
134209-537">
  <CONTROL_DATA>
    <DP NM="BaseSelection">

      <DM NM="Magna Base Pentium III Xeon 100 Mhz FullTower" >
        <ATTR NM="WATTS"></ATTR>
      </DM>
      <DM NM="Advanta Base TM3120 400 Mhz Mobile PC" >
        <ATTR NM="WATTS"></ATTR>
      </DM>
      <DM NM="Extra Base Tm5400 700 Mhz Mobile PC" >
        <ATTR NM="WATTS"></ATTR>
      </DM>
    </DP>
    <DP NM="HardDrivesSelection">
      <DM NM="4.3 GB BATRA-33" ST="34" >
        <ATTR NM="WATTS">2.0</ATTR>
      </DM>
      <DM NM="8.4 GB BATA-33" >
        <ATTR NM="WATTS">2.0</ATTR>
      </DM>
      <DM NM="13.6 GB BATA-33" >
        <ATTR NM="WATTS">2.0</ATTR>
      </DM>
      <DM NM="Quantum 27.3 GB SCSI" >
        <ATTR NM="WATTS">2.0</ATTR>
      </DM>
    </DP>
    <DP NM="MonitorsSelection">
      <DM NM="15 Inch Monitor" ST="34" >
        <ATTR NM="WATTS">1.0</ATTR>
      </DM>
      <DM NM="17 Inch Monitor" >
        <ATTR NM="WATTS">3.0</ATTR>
      </DM>
      <DM NM="21 Inch Monitor" >
        <ATTR NM="WATTS">5.0</ATTR>
      </DM>
    </DP>
  </CONTROL_DATA>
  <NUMERIC_VALUES>
    <NUM NM="[_Application].WattsSummation" VL="3.0" >
      </NUM>
    </NUMERIC_VALUES>
  </CONFIGURATION>

```

The value for [_Application].WattsSummation is 3.0—the total watts for all picks in the configuration that have WATTS as an attribute. The user pick Prima Base Celeron 433Mhz MiniTower does not have WATTS as an attribute. Two computer picks required by the user pick have WATTS as an attribute. The total value for the WATTS attribute for those picks is 3.0:

- 2.0 watts for the 4.3 GB BATRA-33 hard drive pick, plus
- 1.0 watts for the 15 Inch Monitor pick .

In the following example, there are two user picks and one computer pick. The total value (VL) for the WATTS attribute for all picks in the configuration having the WATTS attribute is 7.0:

REQUEST 2 (with two user picks)

```
<CONFIGURATION MODEL_ID="Sample" MODEL_VERSION="">
  <CHOICES>
    <CH DP="BaseSelection" BY="U" QTY="1" DM="Prima Base Celeron 433Mhz MiniTower"/>

Chapter 16

Retrieving Saved Configuration Information

This chapter describes how to retrieve configuration details using the XML request and provides sample snippets of both the request and response for the different details that can be retrieved. This chapter has these sections:

- Elements and Attributes
- The CONFIGURATION element
- The CONFIG_DETAILS element
- The SECTION element
- Total Price
- Compound Violations
- Components
- Choices
- Choice Violations
- Component Violations
- Externs
- Numeric Values
- External Variables
- Configuration Attributes
- Hierarchical Component Structure
- Connections
- Completeness Information
- Summary, Configuration Information Elements and Attributes

Understanding Saved Configuration Information

The COPXML ConfigDetails feature lets you retrieve details about a saved configuration, including:

- Total price for the configuration.
- Delta information for changes between two versions of a configuration.
- Information regarding configuration validity and violations.
- Any existing conflicts in the configuration whether at the compound, component, or choice level.
- Completeness information.
- Component data, when returned, can include:
 - Name, type, ID, Total Price, SolveDate.
 - Choices—All choices, those specified by name, or those filtered by an attribute value. Selection point name, domain member name, state, and quantity (returned by default). Specified attribute values for each selection, optionally mapped to a different attribute name.
 - Externs—All or only those specified by name. Name and value(s). Values can be a collection of one or more.
 - Numeric Values—All or only those specified by name. Name, value, and type.
 - Config attributes—All or only those specified by name. Name and value.
- Hierarchical component structure for compounds.
Name, type, ID, Total Price, SolveDate.
- Connection data for compounds, when returned, includes:
 - Name, type, and ID.
 - Name, type, and ID of the connecting (from) component.
 - Name, type, and ID of the connected (to) component.

Note. The ConfigDetails request is processed separately from and supersedes any other elements included in the same request. Thus, if the CONFIG_DETAILS element is included in the request, the only operation performed during that post to the servlet is the configuration details request. Any other elements/attributes in the request will be ignored.

Elements and Attributes

The COPXML ConfigDetails request may include these elements and attributes to retrieve details about a configuration.

```

CONFIGURATION configId solutionID validate
CONFIG_DETAILS
  FLAG name value
  SECTION nm
  COMPONENTS
    FLAG name value
    COMPONENT_DEFINITION component
    FLAG name value
    VALUE
    FLAG_SET name
    VALUE
    SELECTION_ATTRIBUTES
    SELECTION_POINT name
    ATTRIBUTE name mapto
  STRUCTURE value
  SUBSTRUCTURE type value
  CONNECTIONS
    FLAG name value

```

The COPXML ConfigDetails response may include these elements and attributes to return details about a configuration.

```

CONFIG_DETAILS configId solutionId hasViolations isValid TOTAL_PRICE
VIOLATIONS
  EXPLANATION
  COMPOUND_CONFIGURATION name type
  SECTION nm
  COMPONENTS
    CONFIGURABLE_COMPONENT name component id TOTAL_PRICE

      CONFIGURABLE_COMPONENT name id component
    CONNECTIONS
      CONNECTION id name ref fromCompId fromCompName fromCompType toCompId
toCompName toCompType

```

The CONFIGURATION Element

The CONFIGURATION element must be included in the request. There can be only one CONFIGURATION element per request. It has a child element CONFIG_DETAILS and the attributes *configId*, *solutionId* and *validate*.

The `CONFIG_DETAILS` element is described in the next subsection. The attribute *configId* lets you specify the id of the configuration that you want to retrieve details for.

The attribute *solutionId* defines the solutionId for the configuration.

The attribute *validate* lets you retrieve information about whether the configuration is valid and if it has any violations.

Including in the REQUEST

```
<CONFIGURATION configId="1676995129" solutionId="Construction"
validate="true">
```

causes the `ConfigDetails` to return in the `RESPONSE` the `configId`, `solutionId`, and the boolean values for whether the configuration is valid and whether it has violations.

For example:

```
<CONFIGURATION configId="1676995129" solutionId="Construction" validate="true"> RESPONSE
<CONFIG_DETAILS configId="1676995129" solutionId="Construction" hasViolations="true"
isValid="false">
```

REQUEST

```
<CONFIGURATION configId="1676995129" solutionId="Construction"
validate="true">
```

RESPONSE

```
<CONFIG_DETAILS configId="1676995129" solutionId="Construction"
hasViolations="true" isValid="false">
```

Information about the validity of the configuration and whether it has violations is not returned in the response if the attribute *validate* is not included or if it is set to "false" in the request.

For example:

REQUEST

```
<CONFIGURATION configId="1676995129" solutionId="Construction"
validate="false">
```

OR

```
<CONFIGURATION configId="1676995129" solutionId="Construction">
```

RESPONSE

```
<CONFIG_DETAILS configId="1676995129" solutionId="Construction">
```

The `CONFIG_DETAILS` Element

The `CONFIG_DETAILS` element is a child element of the `CONFIGURATION` element and must be included in the request to return details of a saved configuration. There can be only one `CONFIG_DETAILS` element for a request.

The `CONFIG_DETAILS` element lets you define one or more sections for the information to be returned in the response using the `SECTION` child element. It also lets you define whether you want total price (for component configurations and compounds) and compound conflicts (for compounds) returned in the response using the `FLAG` child element.

Differences between the currently displayed configuration and another version include:

- Added, changed, or deleted choices.
- Added, changed, or deleted configuration attributes.
- Changed expression values.
- Additions, deletions, and relocation of components and connections in compound models.

The DELTA_INFO Element

The DELTA_INFO element is a child element of the CONFIG_DETAILS element and must be included in the request to return delta details of a saved configuration.

Differences between the currently displayed configuration and another version include:

- Added, changed, or deleted choices.
- Added, changed, or deleted configuration attributes.
- Changed expression values.
- Additions, deletions, and relocation of components and connections in compound models.

By default, the delta information returned is between the most recently saved version of the configuration and the last version of the configuration whose order status was set to submitted. Optionally, the DELTA_INFO element lets you specify a range of dates to retrieve deltas for.

Components

Including the DELTA_INFO element in a request for CONFIG_DETAILS of a component configuration will result in a response with the following structure:

```

CONFIG_DETAILS configId solutionId hasViolations isValid TOTAL_PRICE
SECTION nm ".
DELTA_INFO startDate endDate
COMPONENT id name type modDate
CONFIG_DELTA

```

The SECTION Element

The SECTION element is a child element of the CONFIG_DETAILS element. There may be one or more SECTION elements for a given request.

Each SECTION element can be used to define the different components and their details, connections and their details (for compounds) and the hierarchical component structure (for compounds) to be returned in the response by using the COMPONENTS, CONNECTIONS and STRUCTURE child elements respectively. There can be only one each of the COMPONENTS, CONNECTIONS and STRUCTURE child elements in each SECTION element and they are optional. The detailed descriptions of the child elements are discussed in further subsections of this section.

The attribute *nm* of the SECTION element lets you define a title for the section that can be used by the application receiving the response in any manner appropriate for the application. The *nm* attribute is optional and the value for the *nm* attribute does not have to be unique across the request, that is, one or more sections may define the same string for *nm*.

For example:

REQUEST

```
<SECTION nm="PackageDetails">
```

RESPONSE

```
<SECTION nm="PackageDetails">
```

Total Price

The FLAG child element of the CONFIG_DETAILS element lets you retrieve the configuration's total price.

Including in the REQUEST FLAG type= "detailsReturned" value="totalPrice" causes the ConfigDetails to return in the RESPONSE the value for the TOTAL_PRICE attribute for the whole configuration as well as the total price for each component in the respective components's section.

For example:

REQUEST

```
<FLAG type="detailsReturned" value="totalPrice"/>
```

RESPONSE

```
<CONFIG_DETAILS configId="1676995129" solutionId="OutputUtil"
TOTAL_PRICE="211200.00">
<COMPONENTS>
<CONFIGURABLE_COMPONENT name="Building-1" component= "Building" id="1676995126"
TOTAL_PRICE="2120.00" solveDate="20010625">
```

Compound Violations

The FLAG child element of the CONFIG_DETAILS element lets you retrieve a compound configuration's violations.

Including in the REQUEST

FLAG type="detailsReturned" value="compoundConflicts" causes the ConfigDetails to return in the RESPONSE the compound violation explanations.

For example:

REQUEST

```
<FLAG type="detailsReturned" value="compoundConflicts"/>
```

RESPONSE

```
<VIOLATIONS>
<EXPLANATION>Component Building has an invalid configuration.</
EXPLANATION>
</VIOLATIONS>
```

Components

The COMPONENTS child element of the SECTION element and its FLAG and COMPONENT_DEFINITION child elements let you retrieve components and their details. There can be only one COMPONENTS element per SECTION element. The FLAG element under COMPONENTS lets you define the component type filter and the COMPONENT_DEFINITION element lets you define what details to return for a component type. There may be zero or more FLAG elements, each defining a different component type filter.

Case 1

Including in the REQUEST both the FLAG and COMPONENT_DEFINITION elements for one or more component types and every type defined in FLAG that has a matching type defined in COMPONENT_DEFINITION causes ConfigDetails to return in the RESPONSE all components of the requested type(s) and the requested details for those components.

For example:

REQUEST

```

<SECTION nm="PackageDetails">
<COMPONENTS>
<FLAG type="componentFilterType" value="Building"/>
  <FLAG type="componentFilterType" value="Floor"/>
    <COMPONENT_DEFINITION component="Building">
      <FLAG type="detailsReturned" value="selections"/>
      <FLAG type="detailsReturned" value="externs"/>
      <FLAG type="detailsReturned" value="expressions"/>
      <FLAG type="detailsReturned" value="configAttributes"/>
      <FLAG type="detailsReturned" value="componentConflicts"/>
      <FLAG type="detailsReturned" value="selectionConflicts"/>
    </COMPONENT_DEFINITION>
    <COMPONENT_DEFINITION component="Floor">
      <FLAG type="detailsReturned" value="selections"/>
      <FLAG type="detailsReturned" value="externs"/>
    </COMPONENT_DEFINITION>
  </COMPONENTS>

```

RESPONSE

```

<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id=
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">

      <EXTERN_VARS>
        <<---Details--->>
      </EXTERN_VARS>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Case 2

Including in the REQUEST the FLAG elements for one or more component types and COMPONENT_DEFINITION elements for some, but not all, component types defined in the FLAG element causes ConfigDetails to return in the RESPONSE all components of the requested type(s) that have a matching type defined in a COMPONENT_DEFINITION element and the requested details for those components.

For example:

REQUEST

```
<SECTION nm="PackageDetails">
<COMPONENTS>
<FLAG type="componentFilterType" value="Building"/>
  <FLAG type="componentFilterType" value="Floor"/>
    <COMPONENT_DEFINITION component="Floor">
      <FLAG type="detailsReturned" value="selections"/>
      <FLAG type="detailsReturned" value="externs"/>
    </COMPONENT_DEFINITION>
```

RESPONSE

```
<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor" id="1676995128"
TOTAL_PRICE="1900.00" solveDate="20010625">
    <CONFIGURATION>
      <CHOICES>
        <<---Details--->>
      </CHOICES>
      <EXTERN_VARS>
        <<---Details--->>
      </EXTERN_VARS>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>
```

Note that components for type Building were not returned as there was no corresponding COMPONENT_DEFINITION element supplied in the request.

Case 3

Including in the REQUEST both the FLAG and COMPONENT_DEFINITION elements for one or more component types causes ConfigDetails to return in the RESPONSE all components of the requested type(s) that have a matching type defined in the COMPONENT_DEFINITION element and the requested details for those components. For those components with no matching type in COMPONENT_DEFINITION, the default definition is used to determine what details to return in the response. Every type defined in FLAG does not have a matching type defined in COMPONENT_DEFINITION). However, it defines a COMPONENT_DEFINITION element without specifying a component type (the default definition).

For example:

REQUEST

```

<SECTION nm="PackageDetails">
<COMPONENTS>
<FLAG type="componentFilterType" value="Building"/>
  <FLAG type="componentFilterType" value="Floor"/>
    <COMPONENT_DEFINITION component="Building">
      <FLAG type="detailsReturned" value="expressions"/>
    </COMPONENT_DEFINITION>
    <COMPONENT_DEFINITION> (or <COMPONENT_DEFINITION component="">
      <FLAG type="detailsReturned" value="selections"/>
      <FLAG type="detailsReturned" value="externs"/>
      <FLAG type="detailsReturned" value="configAttributes"/>
    </COMPONENT_DEFINITION>

```

RESPONSE

```

<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id=
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      <NUMERIC_VALUES>
        <<---Details--->>
      </NUMERIC_VALUES>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor"      id="1676995128"
TOTAL_PRICE="1900.00" solveDate="20010625">
    <CONFIGURATION>
      <CHOICES>
        <<---Details--->>
      </CHOICES>
      <EXTERN_VARS>
        <<---Details--->>
      </EXTERN_VARS>
      <CONFIG_ATTRIBUTES>
        <<---Details--->>
      </CONFIG_ATTRIBUTES>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Case 4

Including in the REQUEST only the COMPONENT_DEFINITION elements for one or more component types, but no FLAG elements, causes ConfigDetails to return in the RESPONSE all components of the compound, or the single component in the case of a component configuration. The corresponding COMPONENT_DEFINITION element is used to return the details. If a COMPONENT_DEFINITION does not exist for a component type, the default definition is used to return details. If a default definition does not exist, only high-level details are returned for components of that type.

For example:

REQUEST

```

<SECTION nm="PackageDetails">
<COMPONENTS>
  <COMPONENT_DEFINITION component="Building">
    <FLAG type="detailsReturned" value="expressions"/>
  </COMPONENT_DEFINITION>
  <COMPONENT_DEFINITION> (or <COMPONENT_DEFINITION component="">
    <FLAG type="detailsReturned" value="externs"/>
    <FLAG type="detailsReturned" value="configAttributes"/>
  </COMPONENT_DEFINITION>
  <COMPONENT_DEFINITION component="Room">
    <FLAG type="detailsReturned" value="externs"/>
  </COMPONENT_DEFINITION>

```

RESPONSE

```

<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id=>
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      <NUMERIC_VALUES>
        <<---Details--->>
      </NUMERIC_VALUES>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor"      id="1676995128">
TOTAL_PRICE="1900.00" solveDate="20010625">
    <CONFIGURATION>
      <EXTERN_VARS>
        <<---Details--->>
      </EXTERN_VARS>
      <CONFIG_ATTRIBUTES>
        <<---Details--->>
      </CONFIG_ATTRIBUTES>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Room-1" component="Room"      id="1676995129">
TOTAL_PRICE="130.00" solveDate="20010625">
    <CONFIGURATION>
      <EXTERN_VARS>
        <<---Details--->>
      </EXTERN_VARS>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Note that details for components of type Building and Room were returned based on the corresponding COMPONENT_DEFINITION elements and that details for components of type Floor were based on the default COMPONENT_DEFINITION element.

Case 5

Including in the REQUEST only the FLAG elements for one or more component types, but no COMPONENT_DEFINITION elements, causes ConfigDetails to return in the RESPONSE only high-level details for all components of the requested type(s) defined in the FLAG elements.

For example:

REQUEST

```
<SECTION nm="PackageDetails">
<COMPONENTS>
<FLAG type="componentFilterType" value="Building"/>
< FLAG type="componentFilterType" value="Floor"/>
```

RESPONSE

```
<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id=>
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor"      id="1676995128">=>
TOTAL_PRICE="1900.00" solveDate="20010625">
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>
```

Case 6

Including in the REQUEST neither the FLAG element nor the COMPONENT_DEFINITION element causes ConfigDetails to return in the RESPONSE only high-level details for all components of the compound or the single component in case of a component configuration.

For example:

REQUEST

```
<SECTION nm="PackageDetails">
<COMPONENTS>
```

RESPONSE

```
<SECTION nm="PackageDetails">
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id=>
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor"      id="1676995128">=>
TOTAL_PRICE="1900.00" solveDate="20010625">
  </CONFIGURABLE_COMPONENT>
  <CONFIGURABLE_COMPONENT name="Room-1" component="Room"      id="1676995129" TOTAL_=>
PRICE="1300.00" solveDate="20010625">
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>
```

Note. In the case of a single component configuration, the element FLAG is ignored. The details for the single component are returned in the response as defined in the COMPONENT_DEFINITION.

In the case of a compound configuration, an extra child element of the CONFIG_DETAILS element is included in the response indicating the name and type of the compound.

Choices

The FLAG and FLAG_SET child elements of the COMPONENT_DEFINITION element let you retrieve choices and their details for a component. The SELECTION_ATTRIBUTES child element of COMPONENT_DEFINITION lets you retrieve attributes for choices and also lets you map the attribute name to a different name to be returned in the response.

Case 1

Including in the REQUEST only the FLAG element specifying choices to be returned, causes ConfigDetails to return in the RESPONSE all choices for a component. Details returned are decision point name, domain member name, state, and quantity.

For example:

REQUEST

```
<COMPONENT_DEFINITION component="Building">
  <FLAG type="detailsReturned" value="selections"/>
  - - -
</COMPONENT_DEFINITION>
```

RESPONSE

```
<COMPONENTS>
<CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
TOTAL_PRICE="2120.00" solveDate="20010625">
  <CONFIGURATION>
    <CHOICES>
      <CH DP="BuildingTypeSelection" DM="Apartment" ST="66" QTY="1.0">
        </CH>
      <CH DP="BuildingColorSelection" DM="Blue" ST="66" QTY="1.0">
        </CH>
      <CH DP="BuildingHeightSelection" DM="300" ST="66" QTY="1.0">
        </CH>
    </CHOICES>
    - - -
  </CONFIGURATION>
</CONFIGURABLE_COMPONENT>
</COMPONENTS>
```

Case 2

Including in the REQUEST the FLAG element specifying choices to be returned and the SELECTION_ATTRIBUTES element specifying the attributes to be returned, causes ConfigDetails to return in the RESPONSE all choices for a component. Details returned are decision point name, domain member name, state, quantity, and the requested attribute names. Please note the use of the mapTo attribute in the example below.

For example:

REQUEST

```

<COMPONENT_DEFINITION component="Building">
  <FLAG type="detailsReturned" value="selections"/>
  - - -
  <SELECTION_ATTRIBUTES>
    <SELECTION_POINT type="BuildingTypeSelection">
      <ATTRIBUTE nm="listPrice" mapto=""/>
      <ATTRIBUTE nm="description" mapto="desc"/>
    </SELECTION_POINT>
    <SELECTION_POINT type="BuildingColorSelection">
      <ATTRIBUTE nm="sku"/>
    </SELECTION_POINT>
  </SELECTION_ATTRIBUTES>
</COMPONENT_DEFINITION>

```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
      <CONFIGURATION>
        <CHOICES>
          <CH DP="BuildingTypeSelection" DM="Apartment" ST="66" QTY="1.0">
            <ATTR NM="listPrice">2000.0</ATTR>
            <ATTR NM="desc">Apartment</ATTR>
          </CH>
          <CH DP="BuildingColorSelection" DM="Blue" ST="66" QTY="1.0">
            <ATTR NM="sku">CB00255</ATTR>
          </CH>
          <CH DP="BuildingHeightSelection" DM="300" ST="66" QTY="1.0">
          </CH>
        </CHOICES>
      </CONFIGURATION>
    </CONFIGURABLE_COMPONENT>
  </COMPONENTS>

```

Note. To return the same attributes for all the choices, specify the SELECTION_POINT element only once, specifying the attributes you want returned and without specifying the type attribute. Specifying mapTo="" is equivalent to not specifying the mapTo attribute.

Case 3

Including in the REQUEST the FLAG element specifying choices to be returned and the FLAG element specifying the type selectionFilterAttribute, causes ConfigDetails to return in the RESPONSE all choices for a component that have the attribute(s) specified in the selectionFilterAttribute filter (the attribute(s) is not returned in the response in this case). Details returned are decision point name, domain member name, state, and quantity.

The selectionFilterAttribute defines an attribute that must exist on the choice for the choice to be returned in the response. Further, if it has a child element VALUE (this is optional), the value specified must match the value of the attribute on that choice for that choice to be returned. If more than one selectionFilterAttribute is specified, all of them must exist and satisfy the equality condition specified by VALUE for that choice to be returned.

For example:

REQUEST

```
<COMPONENT_DEFINITION component="Building">
  <FLAG type="detailsReturned" value="selections"/>
  <FLAG type="selectionFilterAttribute" value="listPrice">
    <VALUE>2000.0</VALUE>
  </FLAG>
</COMPONENT_DEFINITION>
```

RESPONSE

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
      <CONFIGURATION>
        <CHOICES>
          <CH DP="BuildingTypeSelection" DM="Apartment" ST="66" QTY="1.0">
            </CH>
          </CHOICES>
        </CONFIGURATION>
      <CONFIGURABLE_COMPONENT>
    </COMPONENTS>
```

Case 4

Including in the REQUEST the FLAG element specifying choices to be returned, the FLAG element specifying the type selectionFilterAttribute, and the SELECTION_ATTRIBUTES element specifying the attributes to be returned causes ConfigDetails to return in the RESPONSE all choices for a component that have the attribute(s) specified in the selectionFilterAttribute filter (the attribute(s) is returned in the response in this case).

Details returned are decision point name, domain member name, state, quantity and the requested attributes.

For example:

REQUEST

```
<FLAG type="detailsReturned" value="selections"/>
<FLAG type="selectionFilterAttribute" value="listPrice">
  <VALUE>2000.0</VALUE>
</FLAG>
<SELECTION_ATTRIBUTES>
  <SELECTION_POINT type="BuildingTypeSelection">
    <ATTRIBUTE nm="listPrice" mapto=""/>
    <ATTRIBUTE nm="description" mapto="desc"/>
  </SELECTION_POINT>
  <SELECTION_POINT type="BuildingColorSelection">
    <ATTRIBUTE nm="sku"/>
  </SELECTION_POINT>
</SELECTION_ATTRIBUTES>
</COMPONENT_DEFINITION>
```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126"=>
    TOTAL_PRICE="2120.00" solveDate="20010625">
      <CONFIGURATION>
        <CHOICES>
          <CH DP="BuildingTypeSelection" DM="Apartment" ST="66" QTY="1.0">
            <ATTR NM="listPrice">2000.0</ATTR>

            <ATTR NM="desc">Apartment</ATTR>
          </CH>
        </CHOICES>
      </CONFIGURATION>
    </CONFIGURABLE_COMPONENT>
  </COMPONENTS>

```

Note. To return the same attributes for all the choices, specify the SELECTION_POINT element only once, specifying the attributes you want returned but not the type attribute.

Case 5

Including in the REQUEST the FLAG element specifying choices to be returned and the FLAG_SET element specifying the specific choice(s) to be returned causes ConfigDetails to return in the RESPONSE the requested choices for a component. Details returned are decision point name, domain member name, state, and quantity.

For example:

REQUEST

```

<COMPONENT_DEFINITION component="Building">
  <FLAG type="detailsReturned" value="selections"/>
  <FLAG_SET type="selectionFilterNames">
    <VALUE>BuildingTypeSelection</VALUE>
    <VALUE>BuildingColorSelection</VALUE>
  </FLAG_SET>
</COMPONENT_DEFINITION>

```

RESPONSE

```

V<COMPONENTS>

  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Choice Violations

The Flag child element of the COMPONENT_DEFINITION element lets you retrieve component violations for a choice. Note that choices have to be requested in order to return choice conflicts.

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element for a component type specifying choices to be returned, and another FLAG element specifying choice violations to be returned, causes ConfigDetails to return in the RESPONSE the choice violations for each of the choices returned for components of the specified type.

For example:

REQUEST

```

<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="selections"/>
    <FLAG type="detailsReturned" value="selectionConflicts"/>
    - - -
  </COMPONENT_DEFINITION>
</COMPONENTS>

```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126"⇒
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>

        <CH DP="BuildingTypeSelection" DM="Apartment" ST="66" QTY="1.0">
          <VIOLATIONS>
            <EXPLANATION>The country and building type are not compatible.
          </EXPLANATION>
          </VIOLATIONS>
        </CH>
      </CHOICES>
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Component Violations

The `Flag` child element of the `COMPONENT_DEFINITION` element lets you retrieve component violations for a component.

Including in the `REQUEST` the `FLAG` element under the `COMPONENT_DEFINITION` element for a component type specifying component violations to be returned, causes `ConfigDetails` to return in the `RESPONSE` the component violations for components of the specified type.

For example:

REQUEST

```
<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="componentConflicts"/>
    - - -
```

RESPONSE

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
  <CONFIGURATION>
    <VIOLATIONS>
      <EXPLANATION>The building height cannot exceed 500 feet.</
    EXPLANATION>
  </VIOLATIONS>
```

Externs

The `FLAG` and `FLAG_SET` child elements of the `COMPONENT_DEFINITION` element let you retrieve extern values for a component.

Case 1

Including in the `REQUEST` a `FLAG` element under the `COMPONENT_DEFINITION` element for a component type specifying externs to be returned, causes `ConfigDetails` to return in the `RESPONSE` all externs for components of the specified type.

For example:

REQUEST

```
<COMPONENTS>
  <FLAG type="componentFilterType" value="ZSer"/>
  <COMPONENT_DEFINITION component="ZSer">
    - - -
    <FLAG type="detailsReturned" value="externs"/>
    - - -
  </COMPONENT_DEFINITION>
```

RESPONSE

```

<COMPONENTS>

    <EXTERN_VARS>
    <EV NM="# of doors" TY="INT">
      <VAL>2</VAL>
    </EV>
    <EV NM="Delivery date" TY="DATE">
      <VAL>20041231</VAL>
    </EV>
    <EV NM="PriceLimit" TY="DOUBLE">
      <VAL>40000</VAL>
    </EV>
    <EV NM="Undercoating?" TY="BOOL">
      <VAL>false</VAL>
    </EV>
    <EV NM="Wheel type" TY="STRING">
      <VAL>ALLOY</VAL>
    </EV>
  </EXTERN_VARS>
  - - -
  </CONFIGURATION>

```

Case 2

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element for a component type specifying externs to be returned, and a FLAG_SET element under the same COMPONENT_DEFINITION element defining the specific extern(s) to be returned, causes ConfigDetails to return in the RESPONSE only the requested extern(s) for components of the specified type.

For example:

REQUEST

```

<COMPONENTS>
  <FLAG type="componentFilterType" value="ZSER"/>
  <COMPONENT_DEFINITION component="ZSER">
    - - -
    <FLAG type="detailsReturned" value="externs"/>
    <FLAG_SET type="externFilterNames">
      <VALUE># of doors</VALUE>
    </FLAG_SET>
    - - -
  </COMPONENT_DEFINITION>

```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="ZSeries05" component="ZSER"      id="1676995126"⇒
    TOTAL_PRICE="42120.00" solveDate="20040625">
    <CONFIGURATION>
      - - -
      <EXTERN_VARS>
        <EV NM="# of Doors" TY="2">
          <VAL>2</VAL>
        </EV>
      </EXTERN_VARS>
      - - -
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Numeric Values

The FLAG and FLAG_SET child elements of the COMPONENT_DEFINITION element let you retrieve numeric values for a component.

Case 1

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element specifying numeric values to be returned for a component type causes ConfigDetails to return in the RESPONSE all numeric values for components of the specified type.

For example:

REQUEST

```

<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="expressions"/>
    - - -
  </COMPONENT_DEFINITION>
</COMPONENTS>

```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id="1676995126"⇒
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      - - -
      <NUMERIC_VALUES>
        <NUM NM="TotalListPrice" VL="2001.0" TY="FLOAT"/>
        <NUM NM="OccupantsPerFloor" VL="1.3333334" TY="FLOAT"/>
      </NUMERIC_VALUES>
      - - -
    </CONFIGURATION>
  </CONFIGURABLE_COMPONENT>
</COMPONENTS>

```

Case 2

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element for a component type specifying numeric values to be returned, and a FLAG_SET element under the same COMPONENT_DEFINITION element defining the specific numeric value(s) to be returned, causes ConfigDetails to return in the RESPONSE only the requested numeric value(s) for components of the specified type.

For example:

REQUEST

```
<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="expressionsterns"/>
    <FLAG_SET type="expressionFilterNames">
      <VALUE>OccupantsPerFloor</VALUE>
    </FLAG_SET>
    - - -
  </COMPONENT_DEFINITION>
```

RESPONSE

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
      <CONFIGURATION>
        - - -
        <NUMERIC_VALUES>
          <NUM NM="OccupantsPerFloor" VL="1.3333334" TY="FLOAT"/>
        </NUMERIC_VALUES>
        - - -
      </CONFIGURATION>
```

External Variables

The EXTERN_VARS element, the child element EV, and the NM attribute of the EV element let you retrieve extern variable values for the configuration.

All Values

Including in the REQUEST the EXTERN_VARS element causes the COP to return in the RESPONSE all EV elements for the configuration. Each EV element is a child element of EXTERN_VARS that has attribute-value pairs for its NM and TP attributes and one or more VAL child elements that contain the value(s) for the extern variable.

For example:

REQUEST

```

<CONFIGURATION MODEL_ID="AutoInsGeneralCRM" MODEL_VERSION="8-8-1">
  <CHOICES>
    <CH DP="LeadClSelection" DM="DEALER" BY="U" SL="1" QTY="1"/>
    <EVCH DP="ClaimCount">
      <VAL>5</VAL>
    </EVCH>
    <EVCH DP="ContinuousYearsEntry">
      <VAL>15</VAL>
    </EVCH>
  </CHOICES>
  <EXTERN_VARS/>
</CONFIGURATION>

```

RESPONSE

```

<CONFIGURATION MODEL_ID="AutoInsGeneralCRM" MODEL_VERSION="8-8-1"
COMPILE_VERSION="20020927-152727-590">
  <EXTERN_VARS>
    <EV NM="ClaimCount">
      <VAL>5.0</VAL>
    </EV>
    <EV NM="ContinuousYearsEntry">
      <VAL>15.0</VAL>
    </EV>
    <EV NM="GeneralZipCode">
    </EV>
    <EV NM="VehicleCostsEntry">
    </EV>
    <EV NM="DriverRiskFromCoverage">
    </EV>
  </EXTERN_VARS>
</CONFIGURATION>

```

Selected Values

Including in the REQUEST the EXTERN_VARS element, and the child element EV with a valid value for its NM attribute causes the COP to return in the RESPONSE the EXTERN_VARS element, and as a child element, the EV element named in the request with value(s) for its VAL element(s).

For example:

REQUEST

```

<CONFIGURATION MODEL_ID="AutoInsGeneralCRM" MODEL_VERSION="8-8-1">
  <CHOICES>
    <CH DP="LeadClSelection" DM="DEALER" BY="U" SL="1" QTY="1"/>
    <EVCH DP="ClaimCount">
      <VAL>5</VAL>
    </EVCH>
    <EVCH DP="ContinuousYearsEntry">
      <VAL>15</VAL>
      <VAL>25</VAL>
    </EVCH>
  </CHOICES>
  <EXTERN_VARS>
    <EV NM="ContinuousYearsEntry"/>
  </EXTERN_VARS>
</CONFIGURATION>

```

Configuration Attributes

The FLAG and FLAG_SET child elements of the COMPONENT_DEFINITION element let you retrieve configuration attributes for a component.

Case 1

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element for a component type specifying configuration attribute values to be returned causes ConfigDetails to return in the RESPONSE all configuration attributes for components of the specified type.

For example:

REQUEST

```
<COMPONENTS>
  <FLAG type="componentFilterType" value="Building" />
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="configAttributes" />
    - - -
  </COMPONENT_DEFINITION>
```

RESPONSE

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">=>
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      - - -
      <CONFIG_ATTRIBUTES>
        <ATTR NM="Customer name">John Smith
        </ATTR>
        <ATTR NM="Phone number">(123)456-7890
        </ATTR>
      </CONFIG_ATTRIBUTES>
      - - -
    </CONFIGURATION>
```

Case 2

Including in the REQUEST a FLAG element under the COMPONENT_DEFINITION element for a component type specifying configuration attributes to be returned and a FLAG_SET element under the same COMPONENT_DEFINITION element defining the specific configuration attribute(s) to be returned causes ConfigDetails to return in the RESPONSE only the requested configuration attribute(s) for components of the specified type.

For example:

REQUEST

```

<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="externs"/>
    <FLAG_SET type="configAttributesFilterNames">
      <VALUE>CustomerName</VALUE>
    </FLAG_SET>
    - - -
  </COMPONENT_DEFINITION>

```

RESPONSE

```

<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      - - -
      <CONFIG_ATTRIBUTES>
        <ATTR NM="Customer name">John Smith
      </ATTR>
      </CONFIG_ATTRIBUTES>
      - - -
    </CONFIGURATION>

```

Hierarchical Component Structure

The STRUCTURE and SUBSTRUCTURE child elements of the SECTION element let you return high-level details for components of a compound configuration in a hierarchical structure. The STRUCTURE element always defines a component type filter whereas the SUBSTRUCTURE elements may define either a component type filter or a connection type filter. There can be only one STRUCTURE element per SECTION element. However there can be one or more SUBSTRUCTURE elements under the STRUCTURE element and nested SUBSTRUCTURE elements as well.

Including in the REQUEST the STRUCTURE element defined as

```

<SECTION>
  <STRUCTURE value="Building">
    <SUBSTRUCTURE type="componentFilterType" value="Floor">
    <SUBSTRUCTURE type="connectionFilterType"
value="RoomOnFloor"/>
    </SUBSTRUCTURE>
  </STRUCTURE>

```

causes ConfigDetails to return in the RESPONSE all components of type Building, all components of type Floor connected to each Building, and all components connected to each Floor by the connection type RoomOnFloor in a hierarchical structure.

For example:

REQUEST

```

<SECTION>
  <STRUCTURE value="Building">
    <SUBSTRUCTURE type="componentFilterType" value="Floor">
      <SUBSTRUCTURE type="connectionFilterType" value="RoomOnFloor"/>
    </SUBSTRUCTURE>
  </STRUCTURE>

```

RESPONSE

```

<SECTION>
  <STRUCTURE>
    <CONFIGURABLE_COMPONENT name="Building-1" component="Building"      id=>
"1676995126" TOTAL_PRICE="2120.00" solveDate="20010625">
      <CONNECTED_COMPONENT>
        <CONNECTION id="" name="BtF" ref="FloorInBuilding"      fromCompId=>
"1676995126" fromCompName="Building-1" fromCompType=      "Building" to=>
CompId="1676995128" toCompName="Floor-1" toCompType="Floor"/>
        <CONFIGURABLE_COMPONENT name="Floor-1" component="Floor" id=""      TOTAL_>
PRICE="1900.00" solveDate="20010625">
          <CONNECTED_COMPONENT>
            <CONNECTION id="" name="FtR" ref="RoomOnFloor" fromCompId=      "1676995128">=>
=>
=>
            fromCompName="Floor-1" fromCompType="Floor" toCompId=      "1676995127" toComp=>
Name="Room-1" toCompType="Room"/>
            <CONFIGURABLE_COMPONENT name="Room-1" component="Room" id=""      TOTAL_>
PRICE="1120.00" solveDate="20010625" />
          </CONNECTED_COMPONENT>
        </CONFIGURABLE_COMPONENT>
      </CONNECTED_COMPONENT>
    </CONFIGURABLE_COMPONENT>
  </STRUCTURE>
</SECTION>

```

Connections

The CONNECTIONS child element of the SECTION element and its FLAG child element let you retrieve connections and their details. There can be only one CONNECTIONS element per SECTION element. The FLAG element of CONNECTIONS lets you define the connection type filter. There may be zero or more FLAG elements, each defining a different connection type filter.

Case 1

Including in the REQUEST only the CONNECTIONS element without defining the FLAG element causes ConfigDetails to return in the RESPONSE all details for connections if connected to components that are returned in the response.

For example:

REQUEST

```

<SECTION nm="PackageDetails">
  <CONNECTIONS>
</CONNECTIONS>

```

RESPONSE

```
<SECTION nm="PackageDetails">
  <CONNECTIONS>
    <CONNECTION id="" name="BtF" ref="FloorInBuilding" fromCompId=    "1676995126"⇒
      fromCompName="Building-1" fromCompType="Building" toCompId=    "1676995128" toComp⇒
Name="Floor-1" toCompType="Floor"/>
    <CONNECTION id="" name="FtR" ref="RoomOnFloor" fromCompId=    "1676995128" from⇒
CompName="Floor-1" fromCompType="Floor" toCompId=    "1676995127" toCompName="Room-⇒
1" toCompType="Room"/>
  </CONNECTIONS>
```

Case 2

Including in the REQUEST the CONNECTIONS element and the FLAG child element defining one or more connection type filter(s) causes ConfigDetails to return in the RESPONSE details for connections of the requested connection type(s) if connected to components that are returned in the response.

For example:

REQUEST

```
<SECTION nm="PackageDetails">
  <CONNECTIONS>
    <FLAG type="connectionFilterType" value="RoomOnFloor"/>
  </CONNECTIONS>
```

RESPONSE

```
<SECTION nm="PackageDetails">
  <CONNECTIONS>
    <CONNECTION id="" name="FtR" ref="RoomOnFloor"
      fromCompId="1676995128" fromCompName="Floor-1" fromCompType="Floor"      toCompId=
"1676995127" toCompName="Room-1" toCompType="Room"/>
  </CONNECTIONS>
```

Completeness Information

Completeness information will be returned in the response for those components for which component conflicts have been requested and if the attribute *validate* of the CONFIGURATION element is set to "true" in the request. "The CONFIGURATION element" and "ComponentConflicts"

See [and Chapter 16, "Retrieving Saved Configuration Information," The CONFIGURATION Element, page 255.](#)

Including in the REQUEST

```
<CONFIGURATION configId="1676995129" solutionId="OutputUtil"
validate="true">
```

and

```
<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="componentConflicts"/>
    - - -
```

causes ConfigDetails to return in the RESPONSE a status of FALSE along with the required decision point name(s) that do not have a selection if components of type Building have a completeness violation, OR, a status of TRUE if the components of type Building do not have any completeness violations.

For example:

REQUEST

```
<CONFIGURATION configId="1676995129" solutionId="OutputUtil" validate="true">
and
<COMPONENTS>
  <FLAG type="componentFilterType" value="Building"/>
  <COMPONENT_DEFINITION component="Building">
    - - -
    <FLAG type="detailsReturned" value="componentConflicts"/>
    - - -
```

RESPONSE

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      <COMPLETE STATUS="FALSE">
        <DP NM="BuildingHeightSelection"/>
        <DP NM="BuildingStyleSelection"/>
      </COMPLETE>
```

OR

```
<COMPONENTS>
  <CONFIGURABLE_COMPONENT name="Building-1" component="Building" id="1676995126">
    TOTAL_PRICE="2120.00" solveDate="20010625">
    <CONFIGURATION>
      <COMPLETE STATUS="TRUE">
      </COMPLETE>
```

Summary of Configuration Information Elements and Attributes

These tables provide a quick reference to configuration information elements and attributes.

<i>Element CONFIGURATION</i>		
<i>Attribute</i>	<i>Possible Values</i>	<i>Case-Sensitive?</i>
validate	true	no
	false	no

Element DELTA_INFO – child of element CONFIG_DETAILS		
Attribute	Possible Values	Case-Sensitive?
returnDeltas	true false	no no
startDate	valid Java date	no
endDate	valid Java date	no

Element FLAG – child of element CONFIG_DETAILS				
Attribute	Possible Values	Attribute	Possible Values	Case-Sensitive?
type	detailsReturned	value	totalPrice	no
			compoundConflicts	no

Element SECTION – child of Element CONFIG_DETAILS		
Attribute	Possible Values	Case-Sensitive?
nm	Any string	no

Element FLAG – child of element COMPONENTS				
Attribute	Possible Values	Attribute	Possible Values	Case-Sensitive?
type	componentFilterType	value	Any component type	yes

Element FLAG – child of element CONNECTIONS				
Attribute	Possible Values	Attribute	Possible Values	Case-Sensitive?
type	connectionFilterType	value	Any connection type	yes

Element COMPONENT_DEFINITION – child of element COMPONENTS		
Attribute	Possible Values	Case-Sensitive?
component	Any component type	yes

Element STRUCTURE – child of element SECTION		
Attribute	Possible Values	Case-Sensitive?
value	Any component type	yes

Element SUBSTRUCTURE – child of elements STRUCTURE or SUBSTRUCTURE				
Attribute	Possible Values	Attribute	Possible Values	Case-Sensitive?
type	componentFilterType	value	Any component type	no
	connectionFilterType		Any connection type	no

Element FLAG – child of element COMPONENT_DEFINITION				
Attribute	Possible Values	Child/Attribute	Possible Values	Case-Sensitive?
type	detailsReturned	value	selections	no
	detailsReturned		externs	no
	detailsReturned		expressions	no
	detailsReturned		configAttributes	no
	detailsReturned		selectionConflicts	no
	detailsReturned		componentConflicts	no
type	selectionFilterAttribute	value	Any attribute name	yes
		value	The value for the attribute	yes

Element FLAG_SET – child of element COMPONENT_DEFINITION				
Attribute	Possible Values	Child	Possible Values	Case-Sensitive?
type	selectionFilterNames	VALUE	Any choice name	yes
type	externFilterNames	VALUE	Any extern name	yes
type	expressionFilterNames	VALUE	Any numeric value name	yes
type	configAttributeFilterNames	VALUE	Any config attribute name	yes

Element SELECTION_POINT – child of element SELECTION_ATTRIBUTES		
Attribute	Possible Values	Case-Sensitive?
type	Any choice name	yes

Element ATTRIBUTE – child of element SELECTION_POINT

<i>Attribute</i>	<i>Possible Values</i>	<i>Case-Sensitive?</i>
nm	Any attribute name	yes
mapTo	Any string	yes

Chapter 17

Copying a Configuration

The Configurator XML interface lets you copy and save a previously saved configuration. The copy request is processed separately from, and supersedes any other elements included in the same request. Therefore, if the `configCopy` attribute is included in the request and its value is true, then the only operation performed during that post to the servlet will be the configuration copy. Any other elements/attributes in the request will be ignored.

Elements and Attributes

The COP XML request must include these attributes to copy a configuration.

```
CONFIGURATION configId solutionId configCopy copyName
```

The COP XML response may include these elements and attributes to return information about a copied configuration.

```
ConfigCopy configId solutionId configCopy copyName  
  Copy status configId
```

Attributes are:

configId	Specifies the id of the configuration that you want to copy.
solutionId	Indicates the solution for the configuration. (A solution is the implementation of the PeopleSoft Configurator application.)
configCopy	Indicates that this is a copy operation.
copyName	Indicates the name to give to the new copy of the configuration.

The following is a sample copy request:

```
<CONFIGURATION configId="1438491808" solutionId="TelcoDemo" configCopy="true"→  
  copyName="New Compound" />
```

Copy and Response

The Copy element and its attributes *status* and *configId* are returned in the response from a `configCopy` request. The attribute status indicates the results of the copy operation. The following lists valid status codes and descriptions:

0	Copy was successful.
101	Invalid solution ID.
102	Invalid Config ID.
103	Solution doesn't allow new configurations.
104	Database error on save.

The attribute *configId* is the configId of the new copy of the configuration if the copy was successful, otherwise it is 0.

The following is a sample response for a *SUCCESSFUL* copy:

```
<ConfigCopy solutionId="TelcoDemo" configId="1438491808" copyName="New→  
Compound"><Copy status="0" configId="932435623"/></ConfigCopy>
```

The following is a sample response for an *UNSUCCESSFUL* copy:

```
<ConfigCopy solutionId="TelcoDemo" configId="1438491808"  
copyName="New Compound"><Copy status="102" configId="0"/></ConfigCopy>
```

Chapter 18

Using Batch Configuration Mode

The Configurator XML interface lets you both configure and save configurations in batch mode.

The batch request is processed separately from other elements in the request. In addition, it supersedes any other elements included in the same request. Therefore, if the batch attribute is included in the request and its value is true, then the only operation performed during that post to the servlet will be the batch configuration processing. Any other elements/attributes in the request will be ignored.

Elements and Attributes

The COP XML request must include these attributes to process a configuration in batch mode.

```
CONFIGURATION batch
CONFIG_XML
```

The batch attribute indicates whether this is a batch request. Valid values are true/false.

The COP XML response may include these elements and attributes to return information about a batch configuration.

```
CONFIG_XML isValid wasSaved
VIOLATIONS
  EXPLANATION
Component/CompoundConfiguration
```

isValid indicates if the configuration was valid. Values are true/false.

The method *wasSaved* indicates whether the configuration was saved. Values are true/false.

The VIOLATIONS element contains an EXPLANATION element for every violation in the configuration. Each EXPLANATION element contains the why help for that particular violation.

See Also

[Chapter 18, "Using Batch Configuration Mode," Configuring a Component, page 290](#)

[Chapter 18, "Using Batch Configuration Mode," Configuring a Compound Configuration, page 290](#)

Configuring a Component

To configure a component configuration in batch mode, the CONFIG_XML element in the request may include these elements and attributes to contain the information about the configuration:

```
Component name comment solutionId id
CONFIGURATION COMPILE_VERSION SOLVE_DATE MODEL_ID MODEL_VERSION
ATTRIBUTE_SET
  ATTRIBUTE name
  CH DM DP QTY TY
  EVCH DP TY VAL
  NUM NM TP VAL
```

The COP XML response may include these elements and attributes to return information about a component configuration.

```
Component name comment solutionId id configCode
CONFIGURATION COMPILE_VERSION XML_GENERATED_DATE SOLVE_DATE MODEL_ID MODEL_VERSION
ATTRIBUTE_SET
  ATTRIBUTE name
  CH DM DP QTY TY
  EVCH DP TY VAL
  NUM NM TP VAL
```

Note that the request and response are essentially identical and are the product of a call to the calico.configurator.cop.Component.toXML method.

Note. The ST attribute is not used.

Configuring a Compound Configuration

To configure a compound configuration in batch mode the CONFIG_XML element in the request may include these elements and attributes to contain the information about the configuration:

```
CompoundConfiguration name type version owner comment solutionId id
Components
  ConfigurableComponent name component comment id violation
  CONFIGURATION COMPILE_VERSION SOLVE_DATE MODEL_ID MODEL_VERSION
  ATTRIBUTE_SET
    ATTRIBUTE name
    CH DM DP QTY TY
    EVCH DP TY VAL
    NUM NM TP VAL
Connections
  Connection id name ref comment component ReverseConnection
  Structure
    ConnectedComponent id component name
```

The COP XML response may include these elements and attributes to return information about a compound configuration.

```

CompoundConfiguration name type version owner comment solutionId id configCode
Components
  ConfigurableComponent name component comment id violation
    CONFIGURATION COMPILE_VERSION XML_GENERATED_DATE SOLVE_DATE MODEL_ID MODEL_⇒
VERSION
  ATTRIBUTE_SET
    ATTRIBUTE name
    CH DM DP QTY TY
    EVCH DP TY VAL
    NUM NM TP VAL
Connections
  Connection id name ref comment component ReverseConnection
  Structure
    ConnectedComponent id component name

```

Note that the request and response are virtually identical and are the product of a call to the method `calico.cms.runtime.CompoundConfiguration.toXML`.

Note. The ST attribute is not used.

Note. When creating a compound configuration using the COPXML servlet batch mode for a compound with multiple components, only the last component described in the XML message is created. Unless you include the same ID twice in the XML, Advanced Configurator sees both objects as the same thing (and therefore, the second element with the ID 0 overwrites the first).

Saving a Configuration

The COPXML request to save a component/compound configuration in batch mode is the same as the request to configure with the addition of a `saveConfig` attribute on the `CONFIGURATION` element.

Valid values for the `saveConfig` attribute are:

ALWAYS	Always saves the configuration.
VALID	Only saves the configuration if it is valid.

The COPXML response from a request to save a component/compound configuration in batch mode contains the same structure as the response to a configure request.

Retrieving a Configuration

The COPXML request must include these attributes to retrieve the XML for a configuration in batch mode.

```
CONFIGURATION configId solutionId configXml validate
```

Attributes are:

configId	Specifies the id of the configuration that you want to retrieve.
-----------------	--

solutionId	Indicates the solution for the configuration.
configXml	Indicates that this is a retrieve operation.
validate	Indicates to validate the configuration before generating the response.

The COPXML response contains the same structure as the response to a configure request. Please refer to appropriate configure section for details.

Chapter 19

Changing the Order Status of a Configuration

The Configurator XML interface lets you change the order status of a previously saved configuration.

The order change request is processed separately from other elements in the request. In addition, it supersedes any other elements included in the same request. Therefore, if the `orderChange` attribute is included in the request and its value is true, then the only operation performed during that post to the servlet will be the order change. Any other elements/attributes in the request are ignored. This chapter describes how to change the order status of a configuration using COPXML.

Elements and Attributes

The COP XML request must include these attributes to change the order status of a configuration.

```
CONFIGURATION configId solutionId orderChange newState
```

The COP XML response may include these elements and attributes to return information about an order change request.

```
OrderChange configId solutionId newState stateChanged
```

Attributes are:

configId	Specifies the id of the configuration for which you want to change the status.
solutionId	Indicates the solution for the configuration.
orderChange	Indicates that this is a order change operation.
newState	Indicates the new state value for the order status. Valid values are <i>Save</i> , <i>Submit</i> , <i>Cancel</i> , and <i>Delete</i> .

Example order change request:

```
<CONFIGURATION configId="1004316094" solutionId="BMWTest" orderChange="true" newState="Submit"/>
```

Order Change and Response

The `OrderChange` element and its attributes `configId`, `solutionId`, `newState`, and `stateChanged` are returned in the response from an `orderChange` request.

The attribute `stateChanged` indicates the results of the order change operation. The attribute `newState` indicates the new order status value.

Part 5

PeopleSoft CRM Order Capture Integration

Chapter 20

Understanding Integration with PeopleSoft CRM Order Capture

Chapter 21

Setting Up Integration

Chapter 20

Understanding Integration with PeopleSoft CRM Order Capture

This chapter discusses:

- Integration with PeopleSoft Order Capture applications.
- Security.

Integration with PeopleSoft Order Capture Applications

A customer or service agent using a PeopleSoft CRM Order Capture application can sign in to PeopleSoft Order Capture, create a new order or open an existing one, click the Configurator icon on the Order page, display the product configuration page, make changes to the order, save it, and pass the configuration and order data to the CRM system for storage or further processing.

Users can perform these operations from PeopleSoft Order Capture and Order Capture Self Service. Integrating Advanced Configurator enhances:

- Quote and order processes.
- Pricing.
- Installed product configuration and service maintenance.

When integrated with Order Capture applications, Advanced Configurator:

- Ensures that the product selections are compatible and correct.
- (Optionally) provides the list price of the configured product.

This price may be further surcharged or discounted by the Enterprise Pricer engine.

- Calculates and displays delta pricing, in which users can observe the effects of their selections on pricing.
- Displays the details of a configuration within Order Capture.
- After the configuration session, returns the user to the calling component (such as Order Capture).

Insurance and Financial Products

Agents can use PeopleSoft Order Capture to take applications for financial services and process them. If the services are configurable, the configuration user interface (UI) appears for selections to be made. When the session is complete, the agent returns to the order form and continues. Customers can perform these actions through Order Capture Self Service.

Similarly, insurance products such as coverages and deductibles are more efficiently ordered and maintained when you use the integrated Advanced Configurator.

Service Products

Users can quote and order services through Order Capture. If the services are configurable, the user can access the configuration page from the order or quote in the same way as any other configurable product.

Security

Advanced Configurator can optionally utilize the user sign-in and authentication that is provided when you sign in to the PeopleSoft Order Capture application. Invoking the configuration UI from an Order page requires no additional sign-in.

Chapter 21

Setting Up Integration

This chapter discusses how to:

- Set up PeopleSoft Advanced Configurator for integration.
- Set up PeopleSoft CRM to integrate with Advanced Configurator.
- Create Advanced Configurator schemas.
- Access the Advanced Configurator Solution from Within PeopleSoft CRM.

Setting Up PeopleSoft Advanced Configurator for Integration

Perform the following steps to set up your PeopleSoft Advanced Configurator integration with PeopleSoft CRM.

1. Install PeopleSoft Advanced Configurator Server and deploy the desired solutions on this Configurator Server.

See PeopleSoft CRM 9.1 Installation Guide

2. Navigate to PeopleTools, Integration Broker, Gateways, and click the Search button on the Gateways search page.

This accesses the Gateway ID: LOCAL page.

3. Enter the Gateway Uniform Resource Locator (URL) as `http://<< PeopleSoft Web Server >>/PSIGW/PeopleSoftListeningConnector`, and click Save.

Note. Remember that the URL is case-sensitive.

4. Load the Connector information by clicking the Load button.

A Loading Process was successful message appears.

5. Click OK to continue.

6. A grid appears.

This grid displays all of the loaded connectors. For each connector ID, a connector class name exists.

7. Click Save.

8. Click the Refresh button next to Refresh Integration Gateway.properties file.

A Gateway Refresh Process was successful message appears.

9. Click OK to continue, then Save.
10. Access the Node Definitions page from PeopleTools, Integration Broker, Node Definitions.
11. Open node PSFT_CFG.
12. On the Connectors tab for the new node name, (where the value of Gateway ID should be LOCAL and Connector ID should be HTTPTARGET), change the "PRIMARYURL" property to be the URL of your Advanced Configurator server. (The URL is case-sensitive.)

Note. Advanced Configurator integration does not support URLs beginning with *https* for use with Secure Socket Layers (SSL).

13. Save these settings.
14. Enter PSFT_CFG in the Message Node Name field.

You may want to set up two nodes: one for internally facing applications and one for Self Service (external) applications. If so, you can create another node that is identical to the shipped PSFT_CFG node in every respect other than its name and the associated URL

15. Navigate to the Installations page (Set Up CRM, Product Related, Advanced Configurator, Installation) and identify an internal node, an external node, or both.

The internal node is used for all internally facing applications. The external node is the one that is used for all Self Service applications (see below).

16. Navigate to the Schemas page (Set Up CRM, Product Related, Advanced Configurator, Schemas) to create schemas and link them to solutions on the PeopleSoft Advanced Configurator Server.

See [Chapter 21, "Setting Up Integration," Creating Advanced Configurator Schemas, page 303.](#)

17. When you set up items, products, or packages in the PeopleSoft CRM Item Definition and Product Definition components, be sure to link them to the correct PeopleSoft Advanced Configurator schemas that were established in step 5.

See [PeopleSoft CRM 9.1 Product and Item Management PeopleBook, "Defining Items."](#) and [PeopleSoft CRM 9.1 Product and Item Management PeopleBook, "Setting Up Products."](#)

Setting Up PeopleSoft CRM to Integrate with Advanced Configurator

This section provides an overview of integration setup features and explains how to use PeopleSoft CRM setup pages to activate the integration between PeopleSoft Advanced Configurator and PeopleSoft CRM applications. Specifically, it explains how to associate configuration messaging nodes with the CRM Application and enable Advanced Configurator debugging

To associate Advanced Configurator Messaging Node and enable debugging, use the Installation (CFG_SETUP) component.

Page Used to Set Up Configurator Integration with PeopleSoft CRM

Page Name	Definition Name	Navigation	Usage
Installation Table	CFG_SETUP	Set Up CRM, Product Related, Advanced Configurator, Installation, Installation Table	Use the Installation Table page to associate configuration messaging nodes with CRM Applications and enable Configurator debugging

Associating Advanced Configurator Messaging Node and Enabling Debugging

Access the Installation Table page (Set Up CRM, Product Related, Advanced Configurator, Installation, Installation Table).

The screenshot shows the 'Installation Table' page. At the top, there are two tabs: 'Installation Setup' (selected) and 'Multilevel Configurator Setup'. Below the tabs, the title 'Installation Table' is displayed. The page is divided into two main sections. The first section, 'Integration Broker Setup', contains a dropdown menu for '*Configurator Server Node' with the value 'Define Internal/External Nodes'. Below this, there are two text input fields: 'Internal Node' and 'External Node', both containing the value 'PSFT_CFG'. The second section, 'Configurator Debug Information', contains a dropdown menu for 'Debug' with the value 'Off'.

Installation Table page

The Installation Table page enables you to specify the PeopleSoft Integration Broker Messaging Node for internal CRM applications, such as Order Capture. You also can specify an external node for customer-facing applications such as Order Capture Self Service. Be sure to specify at least one node; otherwise, an error message is generated. Order Capture and Order Capture Self Service use these nodes to call the Advanced Configurator server at run time.

Integration Broker Setup

Configurator Server Node

Select *Define External Node Only*, *Define Internal Node Only*, or *Define Internal/External Nodes*, depending on whether you want to use Advanced Configurator with internal applications, external self-service CRM applications, or both. When using both internal and external CRM applications, you can define a separate node for the self-service application so that transactions are stored on a separate, secure server.

Note. The Internal Node and External Node fields appear or disappear depending on your selection.

Internal Node

Enter a configurator node name. This node is used to integrate the configurator server with internal-facing CRM applications, such as PeopleSoft Order Capture.

Note. Nodes are available from the drop-down list, which prompts against the PSMSGNODEDEFN table.

External Node

Enter a configurator node name. This node is used to integrate the configurator server with customer-facing CRM applications, such as Order Capture Self Service.

Configurator Debug Information

Debug

When you turn debugging on, raw configuration details are displayed in XML format at runtime. Specifically, this means that when you have completed your configuration session, you are presented with two pages prior to returning to the application that invoked PeopleSoft Advanced Configurator. These two pages contain an XML request and an XML response. The XML request page displays the XML data that was sent to the configurator server to retrieve information about the configuration; the XML response page displays the XML data that was returned by the configurator server. This is a useful tool for debugging your schemas because you can quickly verify that XML configuration details are being returned from the calling application just as you would like them to be. When you turn debugging off (default), you do not see the two XML pages prior to returning to the calling application from your configuration session.

The Configurator Solution Tester also enables this request and response XML to be displayed, as well as providing further debugging options.

Note. Log files are available from the appropriate directory on the configurator server when Configurator Debug is activated. For example, if your Advanced Configurator server is running on Microsoft Windows, the logs are stored in C:\bea\wlserver_10.3.1\config\CalicoDomain\logs

Creating Advanced Configurator Schemas

This section provides an overview of configurator schemas and discusses how to:

- Create schemas for external solutions.
- Create schemas for internal solutions.
- Establish configuration display and pricing options.
- Specify request details.

To create schemas for external solutions, use the Schema (CFG_SCHEMA_GBL) component.

Pages Used to Create Advanced Configurator Schemas

<i>Page Name</i>	<i>Definition Name</i>	<i>Navigation</i>	<i>Usage</i>
Display	CFG_SCHEMA_DISPLAY	Set Up CRM, Product Related, Advanced Configurator, Schemas, Schema Setup Set Up CRM, Product Related, Advanced Configurator, Schemas, Display Select Internal Solution.	Create schemas for external solutions. Create schemas for internal solutions.
Price	CFG_SCHEMA_PRICE	Set Up CRM, Product Related, Advanced Configurator, Schemas, Price	Use the Price page to specify options to return the configuration list price, as well as to establish recurring pricing for configured products.
Request Details	CFG_SCHEMA_OUTPUT	Set Up CRM, Product Related, Advanced Configurator, Request Details	Use the Request Details page to select the configuration information that you want the user to receive.

Understanding Configurator Schemas

Configuration schemas establish the display, pricing, and configuration details for specific a configuration and what information to retrieve from the configuration models on the configurator server. Three schema setup pages are available for Advanced Configurator:

Display	Schemas	Define the Configuration User Interface to be displayed at run time.
Price	Schemas	Define the configuration pricing options.
Request Details	Schemas	Define the configuration details to be sent to and received from the configurator server.

External Solutions and Internal Solutions

Two types of configurator schemas are available: externally created solutions and internally defined solutions. External and internal solutions can be distinguished like this:

External Solution

Enables you to direct runtime data from the model to an HTML-based user interface (UI) that is built specifically for this solution with Java Server Pages (JSP) and external HTML editing tools (such as Macromedia Dreamweaver).

Note. Templates for Micromedia Dreamweaver are bundled with the PeopleSoft Advanced Configurator application.

Internal Solution

Enables you to define the user interface from within the PeopleSoft CRM schema setup pages.

Creating Schemas for External Solutions

Access the Display page (Set Up CRM, Product Related, Advanced Configurator, Schemas, Display). Select *External Solution* as the solution type.

The screenshot shows the 'Display' page for an external solution. At the top, there are three tabs: 'Display' (selected), 'Price', and 'Request Details'. Below the tabs, the 'Schema ID' is 'DSL_COMPUTER'. The '*Description' field contains 'DSL Computer' with a checkmark icon. Below this is a section titled 'Solution Properties'. Inside this section, 'Frame Dimensions' are set to '800 x 1200'. The '*Solution Type' dropdown menu is set to 'External Solution'. The 'External Solution' field contains 'DSLComputer' with a magnifying glass icon. To the right of the 'Solution Properties' section, there are two links: 'Solution Tester' and 'Model Tester'.

Display page for external solution

Schema ID	<p>The schema ID is a unique identifier for the configuration schema. The schema ID is the identifier that is associated with an item or product so that the system knows how to properly configure the product or package.</p> <hr/> <p>Note. The schema ID should match the solution ID if you are using an external solution.</p> <hr/>
Description	Enter a description for the schema ID.
<i>Solution Properties</i>	
Frame Dimensions	<p>Specify the width and height of the embedded, runtime configuration page in pixels.</p> <hr/> <p>Note. When you save the page, validation logic ensures that neither page width nor height are fewer than 800 pixels.</p> <hr/>
Solution Type	Select <i>External Solution</i> to select from the existing (externally defined) sets of configurator solutions on the configurator server.
External Solution	When the solution type is <i>External</i> , you use a predetermined list of solutions, each of which already has the user interface display set. Click the Lookup button to select an external (predefined) solution from a list of all the current configurator solutions that exist on the configurator server.
Solution Tester	Select to launch the Configurator Solution Test tool, which displays the user interface for this solution ID.
Model Tester link	Select to test model functionality for the underlying model of this solution ID.

Creating Schemas for Internal Solutions

Access the Display page (Set Up CRM, Product Related, Advanced Configurator, Schemas, Display).

Select *Internal Solution* as your solution type.

Note. This page appears when you select a solution type of *Internal Solution*. This page enables you to specify your own solution type instead of choosing one from the default list that is available when you select an external solution. Note that internal configurations can only be used when the configuration server is using the PeopleSoft CRM database and not when it is using its own standalone database.

Display page for internal solution (1 of 3)

Schema ID	The schema ID is a unique identifier for the configuration schema.
Description	Enter a unique description for the schema ID.
Solution Properties	
Frame Dimensions	Specify the width and height of the runtime configuration page in pixels. <div>Note. When you save the page, validation logic ensures that neither page width or height are fewer than 800 pixels.</div>
Solution Type	Select <i>Internal Solution</i> , which enables you to define your own solution without returning to the environment of the PeopleSoft Advanced Configurator. <div>Note. When you select <i>Internal Solution</i>, the page is updated to display additional sections, which are explained subsequently.</div>
Configuration Type	Select <i>Component</i> when the solution contains a single model. Select <i>Compound</i> if the solution contains multiple models. If you select <i>Component</i> , the list displays only the solutions on the server that contain a single component model. Likewise, selecting <i>Compound</i> displays a list of the solutions on the server that contain multiple models. <div>Note. If you select <i>Component</i>, all fields on the Display page will be available for updating.</div> <div>If you select <i>Compound</i>, the only modifiable fields will be the Compound ID, Model Version, Page Title, Validation on Return, and Captions fields. You need to have the individual component schemas already defined.</div>

Model ID or Compound ID	Select a model ID (or, in the case of a compound model, a compound ID) for the internal solution.
Use Most Current Version	Select to use the most current model. <div>Note. When you select this check box, the Model Version options disappear.</div>
Solution Tester	Click to launch the Configurator Solution Test Tool, which launches the model, any database connections, and the actual user interface. Use this tool to verify that the results from the business logic are properly displayed and to check and tune presentation layout (if it is a custom UI) and navigation. This link is keyed by solution ID.
Model Tester	Click to test constraints and conditions that are defined in the model. A test UI is launched, so you can divide testing into two phases: business logic (model constraints and calculations) and presentation (UI, using the Solution Tester). This link is keyed by solution ID.

Display Properties

Page Title	Enter a title for the configuration display.
------------	--

Restore Policy

You can select a restore policy that selects either the original model version or the most current model version. This option gives you control over whether the user's older, saved configurations are run against the newest model version if the user requests a saved configuration to view or to use as the basis for a new configuration. The problem to consider is whether the new model, which can change substantially through updates, can properly display and process configuration data that is produced by an older model.

Page Information**Tab**

You can control the number of tabs that appear on the page. Enter the number of the tab here, and make your selections for the content of the tab in the Control Setup section.

Tab Caption

Define a label for each tab.

Number of Columns

Define the number of column controls that you want to appear in the configuration page for this tab.

Control Setup**Sequence**

Determine the sequence of the controls that are displayed on the tabs that you create for the configuration page.

Type

Select *Configuration Attribute*, *Expression*, *External Variable*, or *Selection*.

Name

Enter a name for the configuration attribute, expression, external variable, or selection.

Attribute

Define the attribute that appears in the drop-down list or as a radio button selection.

Caption

Enter a descriptive caption that appears on the page.

Control Type

Select to render the control type as either a drop-down list, or radio button..

Field Processing

Select whether this runtime page uses dynamic or deferred processing. The *Dynamic* option causes the page to refresh automatically when the user enters data and presses the Tab key to move out of a field. The *Deferred* option leaves processing until the user clicks the Submit button.

Control Size

Specify the maximum number of characters to allow in the control. This option appears if the control type is Configuration Attribute or External Variable.

Display Options

These options appear only for control type Selection.

- Show Violations

Select to display red violations text on the selections.
- Show Eliminated

Select to show options that are constrained away by previous selections. If this check box is cleared, invalid selections will not appear at all.
- Show Delta Price

If you have pricing information, select this check box to display pricing change in the form of how much has been added to or subtracted from the price. This is also known as the ability to show *plus-minus pricing*.

Price page (2 of 2)

Price Mode

The Price Mode group box appears when you specify *Configurator* in the List Price Source option.

Mode

Indicates which price mode, Standard or Advanced, is employed to define the pricing schema as shown on the Configuration List Price grid. Clicking the *Advanced* link makes operators and expressions available to further define each control's pricing.

Click Standard to change the mode from Advanced and remove the operators and expressions. See the following explanation.

Pricing Properties

List Price Source

Select *Configurator* or *Product Definition* to indicate whether to draw pricing data for the controls from the configurator model or from the product definition.

Selecting *Configurator* displays the Configurator List Price grid, in which you specify the controls to be priced and their definitions. The product definition contains this information already.

Configuration List Price

The configuration list price is a list price. PeopleSoft Enterprise Pricer can act further on this price and may place a surcharge on it or discount it, depending on the setup in the Enterprise Pricer application. However, you can operate on these values using the Operator drop-down described subsequently. In addition, the values that are represented on each of the rows in the grid are summed to yield the total price.

This section is available only when you have selected *Configurator* in the List Price Source field.

Type

Select *Expression* to identify and define an expression from the configurator model to be used to deliver a list price. Select *Selection* to indicate that an attribute of the specified selection is the source for a list price for that selection.

Note. When the Type is Expression, Name is the only field available for editing. The Delta Price Only check box remains available for selection.

Name

Type or select a name for the selection or expression from the Name lookup list. Names are supplied by the model.

Attribute

Select the attribute of the specified selection from which to take the list price value.

Operator

Appears when Price Mode is set to Advanced. Use the Operator drop-down list to define an expression to operate on the list price that is passed to it from the left-hand side of the row.

Delta Price Only

Select to return delta price information for the selection or expression. Delta information is a price value that indicates the difference, plus or minus, that the picking of a particular selection had on a price. Delta pricing must be enabled in the model as well.

Recurring Price Source

Select *Product Definition* to indicate that recurring pricing information is to be taken from the product definition. Select *Configurator* to define the source for recurring pricing for the product. The Recurring Price grid appears when you select the *Configurator* option.

Recurring Price

Recurring and Expression

Select expressions, defined in the configurator model, for:

- **Recurring Price:** Select an expression that provides a value for a recurring charge to be added to the list price.
- **Recurring Frequency:** Select an expression that defines which recurring frequency to use when you add the recurring charge order line, for example, MNTHLY.
- **Frequency Description:** Select text that describes the recurring frequency in words, such as Monthly.

Specifying Request Details

The Request Details page enables you to specify in detail what the request will look like that goes from Order Capture to the Advanced Configurator server and in turn, what details on the configuration will be returned to Order Capture from the Advanced Configurator server (all by way of XML). Finally, it enables you to specify what XSLT StyleSheet to use when rendering the configuration details to the user in HTML on the line details page of Order Capture.

Access the Request Details page (Set Up CRM, Product Related, Advanced Configurator, Request Details).

Request Details page (2 of 2)

You should recognize that the Request Details page is affected by the Configuration Type option on the Display page, but is not affected by Solution Type. The option to include components, connections, and structure in the configuration details is not available for the configuration type of Component. However, all options on the Request Details page are available to the user when the configuration type is compound.

Request Details

Request Message	Specify a <i>Custom XML</i> or <i>Default XML</i> output. Configuration details are in XML, and a default XSLT is provided with Configurator. Select <i>Custom XML</i> to access a text entry field where you can define a request.
Define Request	When you select <i>Custom XML</i> , the Define Request link appears. Click the link to access a text entry field into which you can enter the XML request.
Render With	Determines how the information that is returned by the request is displayed. Enter <i>Custom Stylesheet</i> or <i>Default Stylesheet</i> stylesheet. When you select the <i>Custom</i> option, the <i>Define Stylesheet</i> link appears and you can define your own stylesheet. By using a custom stylesheet, you can change the order in which the information is displayed or the amount of information displayed. For example, a custom stylesheet could be used to display expressions first, followed by selection points, and then conflicts. Or you could display just the selection points with selections and not bother to display the actual domain members that are selected or their quantity.
Define Stylesheet	Click to define a custom XSLT stylesheet for this schema ID. The link accesses a page containing a large text entry field into which you can insert a text defining a stylesheet.

Request Properties

Configuration Details	Select this check box to request configuration details that are provided by Configurator. When you select this box, a Configuration Details group box (described in the next section) appears and enables you to make detailed selections. The Configuration Details options determine what is included in part of the default xml request.
Package Components	Select to choose name and attribute options for package components. A Package Components grid appears at the bottom of the page. A package component is one of many products that will eventually make up a package. For example, a computer product may actually consist of several products such as a monitor, keyboard, and mouse, as well as the actual computer.
Product Selector	Select to choose name and attribute options for product selections. A Product Selector grid appears at the bottom of the page. The option replaces the product ID on the order capture line with the product ID that is specified in the chosen selection point.
Purchased Components	Select to choose name and attribute options for purchased components. A Purchased Components grid appears at the bottom of the page. Selecting this option categorizes purchased components for display purposes; no additional processing is performed.

Manufactured Components	Select to choose name and attribute options for manufactured components. A Manufactured Components grid appears at the bottom of the page. As with Purchased Components, selecting Manufactured Components categorizes manufactured components for display purposes; no additional processing is performed.
Routing Operations	Select to choose name and attribute options for routing operations. A Routing Operations grid appears at the bottom of the page. As with Purchased Components, selecting Routing Operations categorizes routing operations for display purposes; no additional processing is performed.
Delta Information	Requests the display of the differences between this configuration and the last submitted configuration. Differences include additions, deletions, and changes to selection points, expressions, and externs.
Compound Violations	Select to return a list of configuration violations for a solution based on a compound model. This check box is displayed only when you select a configuration type of Compound on the Display page.

Configuration Details

Options in this section of the page determine what information about the configurations that are generated under this schema will be returned to, and stored in, Order Capture. The first three fields—Components, Connections, and Structure—are available only when you select a configuration type of Compound on the Display page.

Components	Select <i>All Components</i> or <i>None</i> .
Connections	Select <i>All Connections</i> , <i>Filtered List</i> , or <i>None</i> .
Structure	Select <i>Include Structure</i> or <i>None</i> .
Selections	Select <i>All Selections</i> , <i>Filtered List</i> , or <i>None</i> .
Expressions	Advanced Configurator uses Boolean, date, string, and numeric logic as key parts of its configuration capabilities. Select this check box to return values that are calculated by expressions (in the model) during the configuration session.
External Variables	PeopleSoft Advanced Configurator can retrieve external data for the configuration session at runtime. Select this check box to return external value details during the order capture configuration session.
Configuration Attributes	Configuration attributes data is normally not essential to the function of the Configurator, and includes data such as a person's name, phone, or email. Select this check box to return configuration attribute data at runtime.

Display Options

Display Component Violations Select to return component violation information at runtime.

Display Selection Violations Select to return selection violation information at runtime.

Package Components

The Package Components grid appears when you select the Package Component check box in the Request the Following section, which is described previously. If the product is a package item, you can select which of the package components and their attributes to include in the request details.

Accessing the Advanced Configurator Solution from Within PeopleSoft CRM

This section provides an overview of how to access Advanced Configurator, a sample product configuration, and discusses how to view configuration details:

Understanding How to Access Advanced Configurator

You can access the Advanced Configurator from:

- PeopleSoft Order Capture.
- PeopleSoft Order Capture Self Service.
- PeopleSoft Installed Products.
- Product Catalog (Product Details).

The following table identifies the Collaborative Selling entry points from which you can access PeopleSoft Advanced Configurator:

<i>Application/Access Point</i>	<i>Page Name</i>	<i>Navigation</i>
Order Capture (RO_CAPTURE)	Entry Form Order (RO_FORM)	Create Order/Create Quote, Entry Form Add a (configurable) product to the order line, and click the Configurator button.
Order Capture Self Service (RE_CART)	Shopping Cart (RE_CART)	Add a (configurable) product to the shopping cart, and click the Configurator button.

<i>Application/Access Point</i>	<i>Page Name</i>	<i>Navigation</i>
Product Catalog (RB_CATALOG)	Product Details (RB_PROD_DTL)	Access a product catalog, select a product from the Product Display page, and click the Configurator button.

Users can configure their products and product packages by clicking the Configurator button within the calling application. When the product is configured, the configuration is saved to the database. This occurs for both simple and compound configurations. When the configuration session is complete, and order information is updated, the system returns the user to the main calling application.

Page Used to Access the Advanced Configurator Solution from Within PeopleSoft CRM

<i>Page Name</i>	<i>Definition Name</i>	<i>Navigation</i>	<i>Usage</i>
Configuration HTML Page	CFG_HTML_SEC	<p>Create Order/Quote, Entry Form</p> <p>Add (configured) Product to Lines. Click the  button.</p> <p>Add (configured) Product to Cart, Shopping Cart. Click the  button.</p> <p>Service Management, Maintain Service, add (configurable) product, click the  button</p> <p>360 Degree View, Browse Catalog, Product Application page, Select configurable product, Click the  button.</p> <p>Access a product catalog, select a product from the Product Display page, click the  button.</p>	Configure a product using a PeopleSoft Advanced Configurator session.

Sample Product Configuration

The following example illustrates a configuration session that is initiated from within PeopleSoft Order Capture. It shows the custom user interface for a complete sample solution that is supplied with Advanced Configurator.

Example of a configuration user interface

Viewing Configuration Details

Advanced Configurator enables you to extract information from individual configurations for additional processing and record-keeping. A common use of configuration details is the populating of the line details of an order or quote. When you set up the schema for the solution, you specify whether you want to extract configuration information and which data you want. Advanced Configurator delivers the data in XML form. Because you also specify an XSLT or stylesheet in the schema, the XML formatted data is rendered in a meaningful form.

Compound Modeling

Chapter 22

Understanding the Runtime System

This chapter discusses:

- Deployment framework.
- Advanced Configurator web components.
- Sequential application JSP pages.
- Deployment for a web application based on a single component model.
- Deployment for a web application based on a compound model.

Deployment Framework

The PeopleSoft Advanced Configurator web deployment framework enables both rapid web-application development and good web performance.

The web application framework requires Java scripting and HTML coding skills; however, it separates the functionality into small components, or pages, that you can quickly compose and easily maintain.

The PeopleSoft Advanced Configurator engine is decoupled from the web application service, keeping the engine stateless and the entire state of each user's configuration session maintained solely by the web application. This is done by embedding all the information needed to recreate each user's session within hidden input fields on each page of the web application. This information is then sent back to the web server with every HTML form submission.

The Configurator engine is accessed through its public interfaces, which run on the application server. The following diagram shows the architecture of a midtier application managing the data flow between the Configurator engine service and the web user, in which the midtier proxies as the client:

User environment is decoupled from the processing

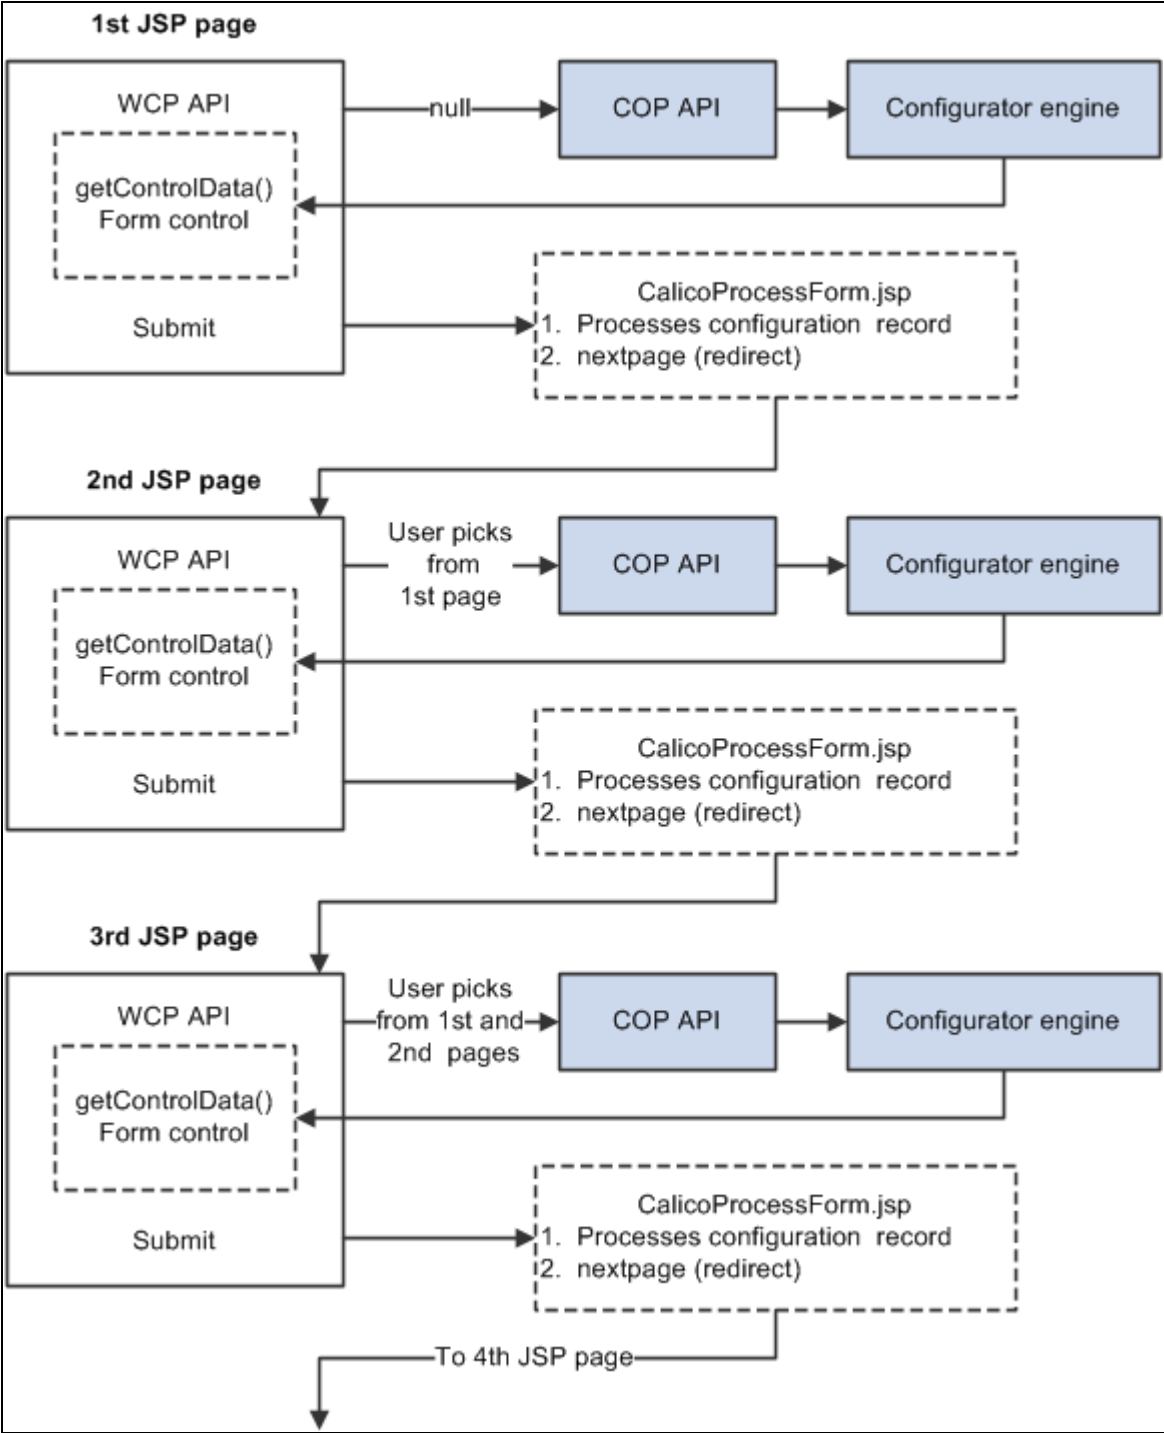

Create a Web client application for the Configurator by creating application JavaServer pages (JSP) that also run on the application server. Your JSP application pages call the Configurator interfaces and run other supporting Configurator JSP pages. JSP pages are web pages written using both Java scriptlets and HTML syntax.

See [and Chapter 23, "JSP and Page Templates," page 331.](#)

You can design your web pages entirely using HTML, except for the form controls that access data from the configuration models that are processed by the Configurator Engine. Each decision point in the model maps to a selection point for the client, or web application, and can be implemented by a PeopleSoft-specific HTML form control. Simple Java scriptlets in the JSP pages are necessary to manually include the Configurator form control templates, which implement the HTML selection points.

Note. For even faster and easier application development, you can use the popular Dreamweaver web-authoring tool's extensions to drag-and-drop Configurator's form control templates into your application pages.

During the configuration session, the user steps through a series of HTML form-based JSP pages, submitting a set of picks, or configuration records, for each page. The following diagram illustrates how the user's picks are sent to the Configurator engine, which processes the model's constraints and redirects the configuration state back to the subsequent JSP page:

Data submission and return

Form Controls

HTML provides these user-selection input/output mechanisms for related choices (or picks), such as:

- Option buttons, enabling the user to make a single selection from the displayed items; for example, the domain members of a decision point.
- Check boxes, enabling the user to make more than one selection from the displayed items
- Drop-down list boxes, enabling the user to make a single selection from a list of items.
- Selection lists, enabling the user to make more than one selection from a list of items.

Form controls are rendered by all the code between the <FORM> and </FORM> HTML tags.

Form Control Item

A user-selectable choice on a form control that maps to a domain member in a decision point in the model.

JSP Pages (JavaServer Pages)

Scripted pages that consist of both HTML and simplified Java that is scripted along with the HTML. JSP pages are processed into pure HTML with runtime data included. A JSP page is a file or URL with a .jsp extension instead of an .html extension.

See <http://java.sun.com/products/jsp/>.

Application JSP Pages

JSP pages that correspond to web pages that you create as a client application, which runs on a midtier environment, not in a browser. The JSP environment represents a client application connecting the web user to one or more server-side services.

Page template

An application JSP page that is processed to dynamically generate data to return to the web user along with the HTML web page. The data typically is provided by a specialized service; for example, the PeopleSoft Advanced Configurator Engine.

Form control template

A relatively small JSP page (provided) representing a form control that is included during the processing of an application JSP page.

Note. Configurator form control templates display selection points for a model on the users' web pages and accept users' picks.

Processor pages

JSP pages (provided) necessary to preprocess the user's picks before sending them to the Configurator Engine.

Advanced Configurator Web Components

The following interfaces enable you to create a dynamic web client application for the PeopleSoft Advanced Configurator Engine:

- Configurator form control templates: JSP pages that retrieve information from the Client Operations Processor (COP) about decision points and domain members, and dynamically generate HTML for user input and messages on pick violations.
- CalicoUI.properties: A text file that sets display properties for the HTML generated by Configurator form control templates.
- Configurator JSP processor pages: Enable you to use the Configurator controls templates from your application JSP pages.
- Web Client Processor (WCP): Converts user picks from strings to objects, and passes them to the COP for processing.
- Client Operations Processor (COP): Processes user picks to retrieve the current state of decision points and domain members from the engine.

See [Chapter 11, "Using the COP Java API," page 181.](#)

A dynamic Web client application is created by including Configurator JSP pages (among them, the Configurator control templates) in your application JSP pages, and setting template parameters and display properties for the form control template JSP pages.

The Configurator JSP pages make the necessary calls to the WCP and COP to generate an HTML page that has:

- Option buttons, check boxes, selection lists, and drop-down list boxes that display the current state of selection points and domain members.
- Text lists that display messages about constraint violations.
- A hidden INPUT tag that submits all previous user picks when the page is submitted.

Note. The Web client's request for the first JSP page has no user picks, so the hidden INPUT tag has and submits none.

Sequential Application JSP Pages

In building an application, assume that:

- Page1.jsp contains the code for grouped radio buttons that let the Web client user choose either a coupe or a pickup automobile.
- Page2.jsp contains the code for grouped radio buttons that let the Web client user choose one of these interiors: leather, cloth, or vinyl.
- Neither page has default picks.

- The configuration model for the two pages, Vehicles01, has this constraint: a pickup cannot have a leather interior.
- When the user submits his/her picks on Page1.jsp, the next page, Page2.jsp is processed.

If the web client requests Page1.jsp, the special servlet for Page1.jsp creates an HTML page with radio buttons for *coupe* and *pickup* displayed as selectable—that is, neither selected nor eliminated. If the web client user chooses *pickup* and submits the HTML page, the servlet (the CLASS file of a JSP page) for Page2.jsp creates an HTML page with the radio buttons for cloth and vinyl displayed as selectable, and the radio button for leather displayed as computer-eliminated. If the web client user chooses a cloth interior and submits the second HTML page, a hidden INPUT tag submits the user's previous pick of a pickup, while the radio button submits the user's pick of a cloth interior.

Note. A JSP page that has both groups of radio buttons has the same effect when submitted: that is, if the user chooses a pickup, the hidden INPUT tag stores that choice and the radio button for leather is displayed as computer-eliminated.

Deployment for a Web Application Based on a Single Component Model

A component model is a single, standalone representation of a product or a component of a product that contains relationships based on its own objects rather than those of another model. A set of component models whose relationships are interdependent is called a compound model.

To deploy a solution:

1. Create a directory for your application JSP pages in the following directory:

```
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\
CalicoApp\solutions
```

Note. It is good practice to create your application directory name only of lower-case characters.

The application JSP pages belong in an application folder; by default the application folders should be in the CalicoApp directory. The application server looks for application JSP pages according to the value resulting from a concatenation of the Name and Path attributes of the Application element in the config.xml file for the Configurator domain:

```
(\\bea\wlserver_10.3.1\config\CalicoDomain\config.xml) in the format Path + \ + Name
```

2. Copy these two files in the same application folder:

CalicoProcessForm.jsp

CalicoUI.properties

3. Modify `\bea\wlserver_10.3.1\config\CalicoDomain\config.xml` to the desired settings.

See <http://e-docs.bea.com/wls/docs81/index.html>.

and

PeopleSoft CRM 9.1 Installation Guide

4. Modify `\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\config\verify.properties` by setting the "messages" flag to FALSE.
5. You are responsible for creating or modifying only the following files for an entire Configurator web application:
 - a. You must implement your application JSP pages.
 - b. You should modify the display configuration file, `CalicoUI.properties`.
 - c. You can customize the application's copy of `CalicoProcessForm.jsp`.
 - d. You can copy one of the form control templates (rename the copy, but put it in the application directory), and then customize the copy.

Optimizing Performance

For better performance, you should disable session support by starting your JSP application pages (that do not access the implicit session object) with the following tag:

```
<%@ page session="false" %>
```

This will prevent the JSP compiler from generating code to create session objects. However, you will not be able to implement any supporting JavaBeans with session scope for these applications.

Restore Policy

A user's request to recover a saved configuration presents a challenge in light of the requirement for that configuration to run on a compatible version of the model that it was created with. It is conceivable that the picks on the saved configuration correspond to selection points that were removed in an intervening model update.

Deployment for a Web Application Based on a Compound Model

To deploy a compound model-based solution:

1. Deploy the compound model's component models (the `.cms` files) to the server by compiling them on the Visual Modeler or deploying them using the Administration Tool.
2. Similarly, deploy the compound model's XML compound structure document to the server by compiling it on the Visual Modeler or deploying it using the Administration Tool.

3. Create a directory for the compound model in the following directory:

```
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\
```

4. Following the procedure described in "Create a directory for your application JSP pages in the following directory", deploy, in the compound model directory you just created, each component model as if it is a single, standalone model.

When you are done, the directory structure should look similar to this example:

```
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\
<Compound Model>
\Modell
  \pages
    CalicoProcessForm.jsp
    CalicoUI.properties
\Model2\
  \pages
    CalicoProcessForm.jsp
    CalicoUI.properties
\Model3\
  \pages
    CalicoProcessForm.jsp
    CalicoUI.properties
```

5. Update the compound model properties file CalicoNA.properties with the appropriate values.

See [Appendix D, "Compound Model Properties File," page 471.](#)

6. Place CalicoNA.properties in the compound model's root:

```
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\
<Compound Model>
CalicoNA.properties
<compound model schema>.xml
...
\Modell
  \pages
  ...
```

Chapter 23

JSP and Page Templates

This chapter discusses:

- The midtier framework.
- Scope of the servlet.
- Using JSP processing.
- Writing JSP.
- Using generated Java and class files.

The Midtier Framework

The source code for the midtier applications is put into a set of text files that resemble HTML pages. Each file, or page, contains the HTML code for the generic style of the web server's HTTP response to the types of HTTP requests from the user. These generic response pages are called page templates.

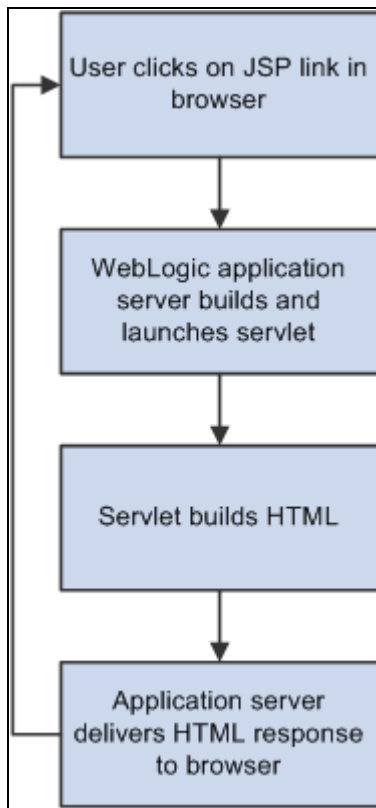

The emergence of JavaServer Pages (JSP) technology enables web page designers to intersperse Java source code with the HTML code to script server-side servlets that will compile and execute on the midtier host at run time. JSP includes the following languages:

- Java (scriptlets)
- HTML and JavaScript
- JSP tags

Note. JSP does not include, but does allow, client-side JavaScript, which is treated the same as HTML.

The web server passes incoming user requests to an application server specified by the port number portion of the URL. The application server converts the JSP source into pure Java source (for a servlet implementation). Then the application server runs the newly created servlet in its servlet engine. The output of the servlet is a stream of HTML text that the application passes to the web server to return to the user's browser.

The following diagram shows the flow of communication between the midtier and the user:

Flow of communication between the midtier and the user

PeopleSoft Advanced Configurator's framework employs the WebLogic application server in its environment. WebLogic application servers by default employ the port number 7777, but may be set to listen to the standard port 80.

Note. An external web server can be configured to proxy requests for JSP pages to the application server using port 7777.

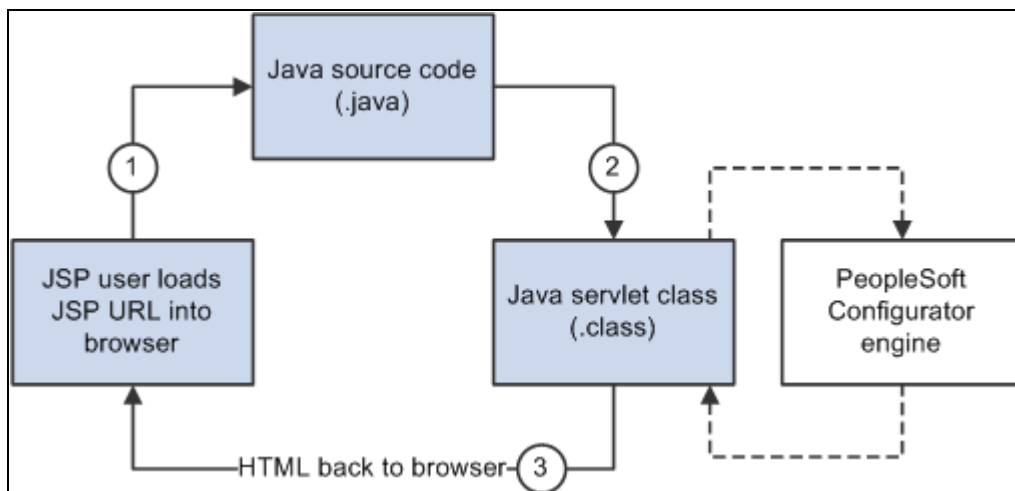

Users would load the JSP pages using the web server's host name (and port number if not port 80), as shown in the following URL:

`http://WebServerHostName:7777/sample/myPC-page1.jsp`

Whenever the user loads a JSP page in a browser, the WebLogic application server converts the JSP into a servlet JAVA file and a corresponding servlet CLASS file that implements the servlet interface. These files live securely on the machine hosting the WebLogic server, not in the browser. The WebLogic server then runs the servlet, which generates HTML that is served back to the browser. During a Configurator session, the user is linking to and loading JSP pages, yet only sees HTML output in the browser.

Note. You can compare the JSP source (on the midtier server) with the generated HTML (in the user's browser: use the View/Page Source menus).

The following diagram shows the transition from JSP source code to an executing servlet:

JSP executes on the midtier and displays HTML in the browser

Note. This compilation only occurs the first time that the JSP page is requested; however, if that JSP source file is modified, then WebLogic recompiles it.

Scope of the Servlet

Each page template defines a separate servlet that executes the complete Configurator response to an HTTP user request. Each servlet binary remains cached to rapidly respond to a particular request from any subsequent user or any subsequent session.

The Configurator's midtier servlets are like any other servlets—their scope is not limited to the source in a single JSP page or file. The Java code can call out to objects and methods in external CLASS or JAR files anywhere in the servlet CLASSPATH.

Best practices for JSP design use a scripting philosophy, keeping the page size small and complexity per page at a minimum. This enables rapid code development/deployment and easier maintenance. However, JSP-based applications need not be small or simple. JSP uses special directive tags to call out to JavaBeans or other components where much of the application logic can be delegated (and be transparent to the JSP source).

Using JSP Processing

A JSP source file is processed in two stages—translation time and request processing time. At translation time, which occurs when a user first loads a JSP page, the JSP source file is compiled to a Java class, usually a Java servlet. The HTML tags and as many JSP tags as possible are processed at this stage, before the user makes a request.

Request processing time occurs when the user clicks in the JSP page to make a request. The request is sent from the client to the server by way of the request object. The JSP engine then executes the compiled JSP file, or servlet, using the request values the user submitted.

When you use scripting elements in a JSP file, you should know when they are evaluated. Declarations are processed at translation time and are available to other declarations, expressions, and scriptlets in the compiled JSP file. Both expressions and scriptlets are also evaluated at translation time. The value of each expression is converted to a string and inserted in place in the compiled JSP file. Scriptlets, however, are evaluated at request processing time, using the values of any declarations and expressions that are made available to them.

The JSP page finally responds to the request as the source reads sequentially; that means that each block of Java code—and its resulting display—fires in the normal sequence of the HTML page, just as you've written it.

Writing JSP

JSP programming is beyond the scope of this document; however, you can access a very useful online tutorial for JSP at the following URL:

<http://e-docs.bea.com/wls/docs81/jsp/index.html>

You can comfortably read JSP code simply by knowing how the Java code can be embedded within the HTML, and how the HTML code can be embedded within the Java.

- The scriptlet syntax `<% ... %>` can handle declarations, expressions, or any other type of code fragment valid in the page scripting language, for example, Java.
- The include syntax `<%@ include file="anotherJspFile" %>` includes a specified external JSP page.
- JSP uses special tags to embed Java code within the HTML: The expression syntax `<%= ... %>` defines a scripting language expression and casts the result as a string.
- The declaration syntax `<%! ... %>` declares variables or methods.
- When you mingle scripting elements with HTML and JSP tags, you must always end a (JSP) scripting element before you start using (HTML) tags and then reopen the scripting element afterwards, as shown in the following JSP code:

```
<%
    if    (condition) {
%> <!-- closing the scriptlet before the HTML tags start -->
    <!-- HTML text goes here outside the scripting tags...-->
<%    }
    else {
%> <!-- closing the scriptlet before the HTML tags start -->
    <!-- HTML text goes here outside the scripting tags...-->
<%    }           %> <!-- reopening a scriptlet to close the else {} block -->
```

- HTML text can be embedded within print statements in the Java code portions, for example

```
out.println("<P><BR><BR>collection:" +
currCollectionProperty.getName()+"</P><BR>");
```

You can have multiple blocks of Java code throughout a JSP page. You can switch between HTML and Java code anywhere, even within Java constructs and blocks. Notice in the loop shown here that declares a Java loop, switches to HTML, then back to Java to close the loop. The HTML is output multiple times as the loop iterates.

The following JSP code generates the typical "Hello World" HTML web page:

```
<html>
<head><title>Hello World in JSP</title></head>
<body>
<h1> Hello World Test </h1>
<p><i> This is HTML. The following is Java! </i><p>
  <%
    for (int i = 1; i<=5; i++)
      out.print("This is a Java loop! " + i + "Hello World<p>");
  %>
</body>
</html>
```

You can use the implicit object `out` to print directly to the servlet output stream from your Java code. Therefore, the servlet can output HTML text directly, as illustrated in the following line of JSP code:

```
out.print("This is a Java loop! <i>" + i + "</i> <p>");
```

Using Generated Java and Class Files

When the application server first compiles one of your JSP pages within your client application directory, the application server also creates the following folder and files, all named with a prepending underscore "_" character:

- A corresponding application directory by the same application name.
- A JAVA source file.
- A Java CLASS file.

WebLogic stores this new directory structure in:

```
\bea\wlserver_10.3.1\config\CalicoDomain\myserver\.wlnotdelete\extract\myserver_⇒
CalicoDomain_CalicoApp\jsp_servlet
```

The application server also creates a corresponding JAVA source file and Java CLASS file with an underscore prefix for the Configurator JSP processor page.

For example, a Web client application contains these JSP pages:

```
C:\WirelessPlan\pages\myappdirectory\MyPage1.jsp
C:\WirelessPlan\pages\myappdirectory\CalicoProcessForm.jsp
C:\WirelessPlan\pages\myappdirectory\alicoUI.properties
```

The application server creates the following directory and files for saving the JAVA and CLASS files:

```
\bea\wlserver_10.3.1\config\CalicoDomain\myserver\.wlnotdelete\extract\    myserver_
CalicoDomain_CalicoApp\jsp_servlet\_myapp
directory\_myPage1.java
_myPage1.class
_CalicoProcessForm.java
_CalicoProcessForm.class
```

The application server generates only a Java source file and compiles it each time the Web client first requests a newly installed, or modified, JSP page.

Chapter 24

Processing User Picks and Entries

This chapter provides an overview of runtime processing and discusses how to:

- Initialize the web client processor (WCP).
- Process user picks and entries.
- Make Client Operations Processor (COP) calls.
- Use WCP methods.

Understanding Runtime Processing

The WCP communicates with the COP about the runtime configuration state of a PeopleSoft Advanced Configurator model. The COP is the public interface for the PeopleSoft Advanced Configurator Engine. It processes user picks to retrieve the current state of selection points and form control items.

The WCP interfaces are convenience application programming interfaces (API), and therefore are optional. You could implement the WCP behavior completely using the COP API.

The WCP API is used exclusively within the Configurator JavaServer Page (JSP) processor page, `CalicoStartFormInc.jsp`. The WCP has the following methods:

- `initialize`: Initializes the `WebClientOperations` object and starts a configuration session for the given model. This method has four signatures. Two of them take a `ClientOperations` object as an argument.
- `processConfigurationRecords`: Converts a configuration records string to `Choice` objects and passes those objects to the COP for processing.
- `getClientOperations`: Returns the `ClientOperations` object for the current configuration session. This enables calls to the COP.
- `getObjectNames`: Returns a string array of all of the decision points or selection points in the current model.
- `getConfigurationRecords`: Returns a configuration records string for the current configuration session.
- `loadConfigurationRecords`: Converts a stored configuration records string to `Choice` objects and passes those objects to the COP to load a configuration.
- `getModelName`, `getModelVersion`, and `getModelCompileVersion`: Return the requested information, as a string, for the current configuration session.
- `resetConfiguration`: Clears the internal state for the current configuration session.

- `release`: Releases the `WebClientOperations` object.

See Also

[Chapter 11, "Using the COP Java API," page 181](#)

[Chapter 12, "Understanding the Configurator XML Interface," page 207](#)

Initializing the WCP

To initialize the WCP object created by the application server, call the WCP method `initialize`, which has four signatures.

All four signatures take the following arguments:

- Name and version of the model.
- The locale of the form control data.
- Whether you want the control data to be HTML-encoded.

Two of the signatures also take as an argument the compile version of the model. Two signatures—one that takes a compile version argument and one that does not—also take a `ClientOperations` object as an argument.

Initializing the WCP with your own `ClientOperations` object enables you to extend the normal `ClientOperations` processing by implementing the `ClientOperations` interface with your own custom class and using an instance of that class to initialize the WCP. There are many reasons for extending the normal `ClientOperations` processing. One is to perform additional processing before or after normal processing. Another is to track and perform processing on nonconfiguration data that may be included on your JSP page, but that is not part of the actual model.

See [Chapter 11, "Using the COP Java API," page 181](#).

Syntax

The following is the syntax to initialize the WCP:

```

void initialize (Locale appLocale,
String modelName String modelVersion
boolean HtmlEncoding)

void initialize (Locale appLocale,
String modelName String modelVersion String modelCompileVersion
boolean HtmlEncoding)

void initialize (ClientOperations clientOperations
Locale appLocale,
String modelName String modelVersion
boolean HtmlEncoding)

void initialize (ClientOperations clientOperations
Locale appLocale,
String modelName String modelVersion String modelCompileVersion
boolean HtmlEncoding)

```

Processing User Picks and Entries

If a web client user picks an item using a Configurator form control and submits the pick, the system posts the pick to a Configurator JSP page, `CalicoProcessFormInc.jsp`, which bundles user picks into a string. The string includes not only all of the picks that the user explicitly submitted, but also all prior user picks (which are stored in a hidden HTML input tag).

See Also

[Chapter 26, "Using JSP Form Control Templates," page 351](#)

Configuration Records

Each user pick in the string created by `CalicoProcessFormInc.jsp` is called a configuration record. There are two types of configuration records, one for selection points and one for extern variables. A selection point configuration record has three parts, separated by a tilde (~):

- Selection point.
- Form control item: The form control item that is picked by the user.

Note. A form control item represents a domain member in a selection point in the model.

- **Quantity:** The number of copies of the form control item that is picked by the user.

The string of user picks (configuration records) is called a configuration records string. Each record in the string is separated by a pipe (|). Thus, the configuration records string has the following syntax:

```
<selectionPoint>~<controlItem>~<quantity>|<externVariable>~<value1>~<value2>|<selectionPoint>~<controlItem>~<quantity>
```

For example, if a web client user selects the form control item called Coupe at the selection point called Vehicle, and also picks the form control item called Leather at the selection point called Interior, the Configurator form control JSP processor page creates the following configuration record:

```
vehicleSelection~Coupe~1.0|interiorSelection~Leather~1.
```

Processing

To determine the runtime state of a Configurator model, the COP processes the user picks that are passed to it as Choice objects.

The WCP method `processConfigurationRecords`:

- Takes as an argument the configuration records string that is created by the Configurator JSP page that bundles user picks.
- Converts each record in the configuration records string to a Choice object.
- Passes all of those Choice objects to the COP to determine the runtime state of the current Configurator model.

Syntax

The syntax for `processConfigurationRecords` is:

```
void processConfigurationRecords (String configurationRecords)
```

Attribute Records

Each text input entry in the string created by `CalicoProcessFormInc.jsp` is called an attribute record.

An attribute record has two parts, separated by a tilde (~):

- Text input name
- Text input value

The string of text input entries (attribute records) is called an attribute records string. Each record in the string is separated by a pipe (|). The syntax of the attribute records string is:

```
<textInputName>~<textInputValue>[|<textInputName>~<textInputValue>]+
```

For example, if a web client user enters the value *Coupe* into the text input control Vehicle, and also enters the value *Leather* into the text input control Interior, the Configurator form control JSP processor page creates the following attribute record:

```
Vehicle~Coupe|Interior~Leather|
```

Processing

The values in text input controls are kept separate from the configuration record because they are *not* passed to the Configurator engine. Instead, the `CalicoStartFormInc.jsp` uses the `setAttribute` method to retrieve the processed attribute record from the request object and save it to the configuration object of the COP. Although this information is not used directly in determining the configuration, it is stored as part of the configuration record for the purpose of integration with other applications (and databases).

Syntax

The syntax for `setAttribute` is:

```
void setAttribute(String textInputCtrl, String textInputValue);
```

Making COP Calls

As the public interface for the PeopleSoft Advanced Configurator engine, the COP processes the user picks to retrieve the runtime state of selection points and form control items.

The WCP method `getClientOperations` functions differently in different situations:

- If you initialized WCP with your own `ClientOperations` object (that is, with an instance of the `ClientOperationsImpl` class), it returns that object for the current configuration session.
- If you did not initialize WCP with a `ClientOperations` object, it creates and returns a default instance of the `ClientOperationsImpl` class for the current configuration session.

This method does not take an argument.

Using the `ClientOperations` object enables you to directly retrieve the runtime state of selection points and form control items through the COP.

See [and Chapter 11, "Using the COP Java API," page 181.](#)

Syntax

The syntax for `getClientOperations` is:

```
ClientOperations getClientOperations()
```

Using WCP Methods

The WCP has other methods to help you design a web client application. The following sections describe these methods and provide their syntax.

Getting Decision or Selection Points

The WCP method `getObjectNames` returns an array of string objects containing either:

- All selection points in the current Configurator model.
- Public selection points in the current Configurator model.

This method takes a Boolean argument: True returns all selection points; False returns only public selection points. It does not return private selection points—that is, selection points that are not displayed to and cannot be selected by the web client user.

Syntax

The syntax for getObjectNames is:

```
String[] getObjectNames(boolean allObjects)
```

Getting and Processing Stored Configuration Records

The WCP method getConfigurationRecords returns a configuration records string with all user picks for the current configuration session. It takes no argument.

Syntax

The syntax for getConfigurationRecords is:

```
String getConfigurationRecords()
```

If you save a configuration records string in an external database, you can pass it to the WCP method loadConfigurationRecords, which does the following:

- Converts each record in the configuration records string to a Choice object.
- Passes all of those Choice objects to the COP to load a configuration.

Syntax

The syntax for loadConfigurationRecords is:

```
void loadConfigurationRecords(String configurationRecords)
```

Getting Model Name, Version, and Compile Version

The WCP methods getModelName, getModelVersion, and getModelCompileVersion, each return a string with the requested information for the current configuration session. None of them take an argument.

Syntax

The syntax for these methods is:

```
String getModelName()  
String getModelVersion()  
String getModelCompileVersion()
```

Clearing Model State

The WCP method `resetConfiguration` clears the state for the current configuration session. It does not take an argument.

Syntax

The syntax for these methods is:

```
void resetConfiguration()
```

Releasing the WCP

The WCP method `release` releases:

- The `ClientOperations` object, which is either the default instance of the `ClientOperationsImpl` class that was created by `getClientOperations`, or the instance of the `COPEExtensionImpl` class that you passed to `initialize`.
- Internal objects for the current configuration session.

This method does not take an argument.

Syntax

The syntax for these methods is:

```
void release()
```

Chapter 25

Processing Configurator Form Controls in JSP Pages

This chapter provides an overview of the JSP pages that process a Configurator form control and discusses:

- Configurator JSP page flow.
- Processing Configurator form controls.
- Using Configurator JSP pages in a solution.

Understanding Configurator Form Control Processing

To create a client application for the Configurator, create JSP pages that use Configurator JSP pages. There are two types of Configurator JSP pages:

- Form control template: A JSP page that creates an HTML form control (option button, check box, or selection list) for a selection point for your model.
- (Form control) processor page: A JSP page that helps process a Configurator form control.

You can use a Configurator form control template in your Web client application without modification, setting only its parameters and perhaps its display properties. You can also modify a Configurator form control template and use the modified template in your application.

See [Chapter 26, "Using JSP Form Control Templates," page 351](#).

You must correctly use all of the Configurator form controls framework in your Web client application. Normally, the JSP processor pages require no modification. Together, they receive, process, and return the information needed to implement the Configurator form controls that you include in your application. Although you can call the WCP or COP directly in the JSP pages that you create, the Configurator JSP pages normally make all the necessary calls to these two interfaces.

Configurator JSP Page Flow

JSP page statements are interpreted in the order that they are written.

The following steps through the execution path by way of the Configurator JSP pages that are included in each application JSP page:

1. Initialization of settings in the application JSP pages, (such as including delta pricing in the display) with the JSP built-in `jspInit()` function.
2. Application JSP pages execute the HTML `<FORM>` start tag, which specifies the name, method, and action HTML tag attributes as follows:

```
<FORM name="form" method="POST" action="CalicoProcessForm.jsp">
```

3. Application JSP pages executes the JSP include directive as follows:

```
<%@ include file="/calico/CalicoStartFormInc.jsp" %>
```

Note. `CalicoStartFormInc.jsp` includes both `CalicoConstantsInc.jsp` and `CalicoControlInc.jsp`.

4. Application JSP pages execute the include directive for a Configurator JSP form control template (only once per type of Configurator form control template, regardless of how many of that type of template you use in that application JSP page).

Note. There may be more than one Configurator form control template per application page.

5. Application JSP pages ends its HTML form block by including `CalicoEndFormInc.jsp`.
6. Application JSP pages uses the HTML end form tag, `</FORM>` on the line following the JSP include directive that includes `CalicoEndFormInc.jsp`.
7. After the user clicks the Submit or Reset button, `CalicoProcessForm.jsp` processes HTTP POST information to generate the configuration records for the user's picks.

These picks are then processed by the COP and the Configurator Engine.

8. The Configurator Engine runs the constraints on the user's picks, and then returns the new configuration state to the redirected next page application JSP page in the application sequence.

Processing Configurator Form Controls

The Configurator uses the following JSP pages to process Configurator form controls:

- `CalicoProcessForm.jsp`: Includes `CalicoProcessFormInc.jsp`.
- `CalicoProcessFormInc.jsp`: Constructs a string of user picks made on a Configurator form control, and redirects the application server to the next page of the Web client application.
- `CalicoConstantsInc.jsp`: Declares string constants that are used by every Configurator form control and several Configurator JSP processor pages.
- `CalicoStartFormInc.jsp`: Creates several hidden HTML input tags, sets display properties and pricing attributes for Configurator form controls, initializes WCP, and processes user picks.
- `CalicoControlInc.jsp`: Declares several methods that are used by every Configurator form control.
- `CalicoEndFormInc.jsp`: Creates hidden input tags on Configurator form controls and the next page, and releases the WCP object.

The next six sections describe these JSP pages in more detail.

Pre-Process Form Page

CalicoProcessForm.jsp does the following to help process Configurator form controls:

- Lets you preprocess information posted by the Web client before you pass it on to be processed by the other Configurator JSP pages.
- Includes CalicoProcessFormInc.jsp.

Post any form having a Configurator form control to CalicoProcessForm.jsp. If you do not alter this JSP page to preprocess information posted by the browser, it always includes CalicoProcessFormInc.jsp, which redirects to that page.

Process Form Page

CalicoProcessFormInc.jsp does the following to help process Configurator form controls:

- Constructs a string of user picks made on Configurator form controls and updates the configuration record.
- Constructs a string of attributes entered into text-entry controls and updates the attribute record.
- Redirects the application to the next JSP page of your Web client application.

Unless you preprocess information posted by the Web client, you effectively post to this JSP page.

CalicoProcessFormInc.jsp creates a configuration records string that the WCP parses to pass user picks to the COP for processing. This string includes two types of user picks:

- Previous user picks posted from a hidden HTML input tag.
- Current user picks explicitly submitted by the user (this action updates the configuration record).

Note. CalicoStartFormInc.jsp creates the hidden HTML input tag by aggregating explicit user picks.

CalicoProcessFormInc.jsp redirects to the page whose path you set in the name attribute of the HTML input tag that submits your application page with a Configurator form control. You set the path by using the "Redirect_" prefix; for example:

```
name="Redirect_/myjspapplication/Page1.jsp" type="submit" value="Next Page">
```

Reset a page in the same way, using the "Reset_" prefix, which clears all user pick. For example:

```
<INPUT name="Reset_/myjspapplication/Page1.jsp" type="submit" value="Clear">
```

Constants Page

CalicoConstantsInc.jsp declares string constants. This page is included in the following form controls processor JSP pages:

- CalicoProcessFormInc.jsp

- CalicoStartFormInc.jsp

Start Form Page

CalicoStartFormInc.jsp does the following to help process Configurator form controls:

- Creates hidden HTML input tags for the following:
 - Configuration records string
 - Attribute records string
 - UI version
 - Current page
 - Model information
- Initializes a WCP object, and processes the configuration records string.
- Gets a ClientOperations object.
- Reads the CalicoUI.properties file and sets the display properties for Configurator form controls.
- Sets pricing attributes for Configurator form control items.

Include this JSP page in every form that has a Configurator form control immediately after the <FORM> tag.

CalicoProcessFormInc.jsp creates the configuration records string by aggregating previous and current user picks. By creating a hidden HTML input tag for the configuration records string, CalicoStartFormInc.jsp ensures that previous user picks are submitted with explicit user picks, and effectively preserves the state of your Configurator model.

See Also

[Chapter 25, "Processing Configurator Form Controls in JSP Pages," Process Form Page, page 347](#)

Control Page

CalicoControlInc.jsp declares several methods that are used by every Configurator form control. These methods do the following for each Configurator form control:

- Add the form control to a form control map: register a Configurator form control.
- Get the model's control data, including elimination levels, for the form control.
- Determine if the form control is priced, and format delta pricing.
- Get the form control's display properties for conflicted and selectable.
- Parse the input string into an array of strings for each attribute of the domain member's display attributes.

End Form Page

CalicoEndFormInc.jsp does the following to help process Configurator form controls:

- Creates hidden input tags to later post the following information:
 - A map of Configurator form controls created as each form control appends its control ID using the mapping method declared in CalicoControlInc.jsp.
 - The next page.
- Releases the WCP object created in CalicoStartFormInc.jsp.

Include this JSP page in every form that has a Configurator form control, immediately before the `</FORM>` tag.

Using Configurator JSP Pages in a Solution

When you design a Web client application for the Configurator, you typically use the JSP pages provided, including the form control templates, and submit to or include them on your JSP pages without change.

To implement the Configurator JSP pages, you must do the following:

- Initialize your JSP page to include pricing information if you want it. Use the standard JSP built-in method, `JspInit()`.
- Include the Configurator form control templates that you want, where you want them on the page.
- Set the parameters for each form control template, including at least the following:
 - Object name, which is the model's decision point class name.
 - Form control ID.
 - Form control caption.
 - Domain member attributes (such as description, size, and price), which are displayable alongside the form control items.
 - Whether to provide the option of choosing none of the form control items, and if so, the text to use for displaying that choice: this is option for single-selection selection points.
- Modify the UI version, model name, and model compile version in `CalicoUI.properties`
- Set the HTML display properties (such as images, text, and text colors) for indicating the state of an item (such as user-selected) in `CalicoUI.properties`.

Note. This is optional. Change these configurations properties only if you would like to customize the HTML look-and-feel of your form controls (application scope).

- Include other `CalicoStartFormInc.jsp`, `CalicoEndFormInc.jsp`, and include Configurator form control templates where needed.

The following code example is an application JSP page that uses the Configurator interfaces:

```
<HTML>
<HEAD>
  <TITLE>Sample Page</TITLE>
</HEAD>
<BODY>
<%!
public void jspInit()
{
  // turn on pricing for controls
  setPricing(true);

  // set pricingControls to specify specific controls
  // that need to be priced and their pricing attributes.
}
%>
<FORM name="SampleForm" method="POST" action="CalicoProcessForm.jsp">
<%@ include file="/calico/CalicoStartFormInc.jsp" %>
<%@ include file="/calico/templates/html/SingleSelectGroup.jsp" %>
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null) {
    params.clear();
    params.put(PARAM_OBJECTNAME, "VehicleSelection");
    params.put(PARAM_ATTRIBUTES, "Description");
    params.put(PARAM_CAPTION, "Select a Vehicle");
    params.put(PARAM_CONTROLID, "VehicleSelectionCtrl");
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
<%@ include file="/calico/CalicoEndFormInc.jsp" %>
</FORM>
</BODY>
</HTML>
```

The methods for setting pricing information mentioned in the code comments to `jspInit()` are declared in `CalicoStartFormInc.jsp`. They have the following syntax:

```
setPricing(boolean obtainPricingInformation)
setPricingControls(Map[] selectionPoints)
```

You can also set the range of the levels of eliminated items that you want to display. The commented code in the sample JSP page displays eliminated items having levels from 4 to 9, inclusive.

More specifically, you must do the following on each JSP page:

- Specify `action="CalicoProcessForm.jsp"` in the `<FORM>` tag.
- Include `CalicoStartFormInc.jsp` just after the `<FORM>` tag.
- Insert Configurator-related scriptlets and include all the Configurator form control templates after `CalicoStartFormInc.jsp`, but before `CalicoEndFormInc.jsp`.
- Include `CalicoEndFormInc.jsp` just before the `</FORM>` tag.

Chapter 26

Using JSP Form Control Templates

This chapter provides overviews of form control templates; properties, parameters, and attributes; and form control templates, and discusses how to:

- Use configuration form control templates.
- Specify the model and locale properties for the solution.
- Application page example.
- Configure a form control template.
- Register custom form control templates.
- Custom form control template example.
- Common errors.

Understanding Form Control Templates

Each decision point in the model maps to a selection point for the client and can be implemented by an HTML form control. This chapter describes the configurator templates for the form controls that are supported in the Configuration Client, which is the midtier application. A form control template is a separate Java Server Page (JSP) page that generates a form control, using the selection point data, for a web page. Configurator provides a JSP template file for each type of form control.

Your application JSP pages can contain form controls if you include their corresponding form control templates.

Note. All form control templates, Configurator-specific related scriptlets, and Java code should be inserted between the inclusion of the `CalicoStartFormInc.jsp` and `CalicoEndFormInc.jsp` processor pages. The JSP initializing method, `jspInit()`, must precede `CalicoStartFormInc.jsp`.

You can modify the appearance and behavior of the form control display in the following ways:

- **Application scope:** Modifying the definitions of display properties in a configuration file that an application page passes to the form control templates.

- Form control scope:
 - Setting parameters in the application pages.
 - Configuring a Configurator template: Extending the form control template by copying the JSP template, modifying that copy, and saving it as a configured template file that you can include in the application pages.

With the existing Configurator form-control templates, you can set either the HTML-level display properties, such as the text color of the display data and selection state of the form control item, or configure the presentation of the data of the form control.

You can specify the data display in the form control to:

- Display domain member attribute information.
- Sort the form control items.
- Eliminate form control items of eliminated domain members.
- Eliminate the form control items of the eliminated domain members whose elimination levels are beyond an inclusionary range.
- Display delta pricing and the total price.

Understanding Properties, Parameters, and Attributes

The presentation of a form control is determined by the display properties of the HTML for the application, by the included display properties and data of the HTML for the form control and its data, and by the display attributes of the domain member of the decision point.

Properties

The properties for a form control are the configurable display characteristics of the form control items that present their selection states and their delta pricing. All form controls properties are located in the CalicoUI.properties file. These properties are available application-wide, but to be used by a form control, they must be passed to the form control as parameters.

Parameters

The parameters for a form control are both HTML and data presentation characteristics that your application pages pass to included form control templates. Typically, the properties are passed to the templates as parameter values.

Attributes

The attributes for a form control are determined by the attributes in the model for the domain members. Typically, the attributes are passed to the templates as parameter values. Use the `PARAM_ATTRIBUTES` parameter to display the data for the specified attributes.

Understanding JSP Code Templates

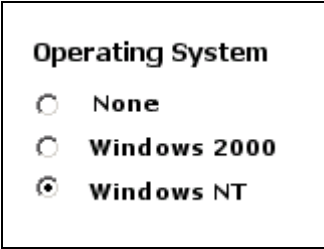

PeopleSoft Advanced Configurator provides a JSP code template for all HTML-compatible form controls. This section describes the usage and behavior of each. JSP code and the HTML output is located in the referenced appendix for each.

Note. The filenames for the form control templates are in mixed case, that is, `SingleSelectGroup.jsp`. For the deployments running on Solaris systems, make sure the characters of the filename match correctly (case-sensitive) with the template filenames.

Single-Select Group

The single-select group form control *SingleSelectGroup.jsp* consists of a list of form control items, of which only one can be chosen. If one item in a list is selected, any previously selected item in the same list is deselected. The items of a form control are displayed as radio buttons.

You can create the following single-select group form control for the decision point `OSSelection`, with the caption *Operating System*, and the Generate None option.

A single-select group control

The following code generates the previous form control:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].OSSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CONTROLID, "OSSelectionCtrl");
    params.put(PARAM_CAPTION, "Operating System");
    params.put(PARAM_GENERATENONEMODE, "1");
    params.put(PARAM_GENERATENONETEXT, "None");
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endsan -->
```

See [Appendix C, "Advanced Configurator Form Controls," Single-Select Group Form Control, page 461.](#)

MultiSelect Group

A multiselect group form control consists of a list of form control items, of which more than one item can be chosen. The items of a form control are displayed as check boxes. Each item can be either selected or deselected.

You can create the following multiselect option group form control for the decision point CDSelection with the caption *Multimedia*.

Multiple-select group form control

The following code generates the control in the figure:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].CDSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CONTROLID, "CDSelectionCtrl");
    params.put(PARAM_CAPTION, "Multimedia");
    generateMultiSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [and Appendix C, "Advanced Configurator Form Controls," Multi-Select Group Form Control, page 462.](#)

Single-Select List

A single-select list form control consists of form control items in a drop-down list, of which only one can be chosen. It's similar in functionality to a single-select group form control, but it requires less form control space for the display.

The StateTag indicates the domain member state of the form control item in the drop-down list. The following table shows the default text symbols that are used to connote the domain member states:

Symbolic tags	Domain member states
–	Selectable
>>	User-selected

Symbolic tags	Domain member states
>	Computer-selected
>	Default-selected
X	User-eliminated
X	Computer-eliminated
!	Conflict

Note. You can configure these state tags by modifying the property values in the CalicoUI.properties file, which is located in your application directory.

You can create the following single-select list form control for the decision point OSSelection with the caption *Operating System* and the None option.

Single-select list

The following code generates the form control in the figure:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].OSSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CONTROLID, "OSSelectionCtrl");
    params.put(PARAM_CAPTION, "Operating System");
    params.put(PARAM_GENERATENONEMODE, "1");
    params.put(PARAM_GENERATENONETEXT, "None");
    generateSingleSelectList(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [and Appendix C, "Advanced Configurator Form Controls," Single-Select List Form Control, page 464.](#)

Multi-Select List

A multi-select list form control consists of form control items in a list, of which more than one item can be chosen. To select or deselect more than one item, a user presses the Ctrl/Shift keys and clicks the subsequent items to select them or clicks (selected items) to deselect them.

The StateTag indicates the domain member state of the form control item in the drop-down list. The following table shows the default text symbols that are used to connote the domain member states:

Symbolic tags	Domain member states
–	Selectable
>>	User-selected
>	Computer-selected
>	Default-selected
X	User-eliminated
X	Computer-eliminated
!	Conflict

Note. You can configure these state tags by modifying the property values in the CalicoUI.properties file, which is located in your application directory.

You can create the following multiselect list form control for the decision point CDSelection with the caption *Multimedia*.

Multiselect list control form

The following code generates the previous form control:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].CDSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CONTROLID, "CDSelectionCtrl");
    params.put(PARAM_CAPTION, "Multimedia");
    generateMultiSelectList(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [Appendix C, "Advanced Configurator Form Controls," Multi-Select List Form Control, page 463.](#)

Single-Select Table

A single-select table form control consists of form control items in the row or column format based on radio buttons and table HTML elements. Each row in the table contains a radio button and attributes for each available form control item. Only one of the form control items can be chosen at a time.

You can create the following single-select table form control for the decision point *OSSelection* with the caption *Multimedia* and the None option.

	Description	Part Number	Unit Cost
<input type="radio"/>	None		
<input type="radio"/>	Windows 98 MSFT-854		80.00
<input type="radio"/>	NT MSFT-898		99.00

Single-select table form control

The following code generates the form control in the figure:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].OSSelection");
    params.put(PARAM_ATTRIBUTES, "Desc, PN, UC");
    params.put(PARAM_CONTROLID, "OSSelectionCtrl");
    params.put(PARAM_CAPTIONIMAGE, "/MyComputer/images/cd.gif");
    params.put(PARAM_COLUMNHEADINGS, "Description, Part Number, Unit Cost");
    params.put(PARAM_GENERATENONEMODE, "1");
    params.put(PARAM_GENERATENONETEXT, "None");
    generateSingleSelectTable(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

In the preceding code block, the `PARAM_OBJECTNAME` example value `[MyComputerConfig].OSSelection` is the name of a decision point in the model. *MyComputer* is the model name, appended with the string, *Config*. *MyComputerConfig* must be bracketed between [and] characters. `[MyComputerConfig].OSSelection` is the decision point name.

See [and Appendix C, "Advanced Configurator Form Controls," Single-Select List Form Control, page 464.](#)

Multi-Select Table

A multi-select table form control consists of form control items in the row or column format based on check boxes and table HTML elements. Each row in the table contains a check box and attributes for each available form control item. More than one of the form control items can be chosen at a time.

You can create the following multi-select table form control for the decision point *CDSelection* with the caption *Multimedia*.

MultiMedia			
	Description	Part Number	Unit Cost
<input type="checkbox"/>	CD 40x	SONY-40	60.00
<input type="checkbox"/>	CD 20x	SONY-20	40.00
<input type="checkbox"/>	DVD	SONY-DVD	80.00

Multi-select table form control

The following code generates the form control in the figure:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].CDSelection");
    params.put(PARAM_ATTRIBUTES, "Desc, PN, UC");
    params.put(PARAM_CONTROLID, "CDSelectionCtrl");
    params.put(PARAM_CAPTION, "MultiMedia");
    params.put(PARAM_COLUMNHEADINGS, "Description, Part Number, Unit Cost");
    generateMultiSelectTable(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [and Appendix C, "Advanced Configurator Form Controls," Multi-Select Table Form Control, page 464.](#)

Single-Select Image

The single-select image template places an image on the page where you indicate, to select a domain member. Specify an image and location for each domain member of the selection point. At runtime, selecting one image deselects another. Include the template for the single-select image in the following way:

```
<%@ include file="/calico/templates/html/SingleSelectImage.jsp" %>
```

For example, you can create the following single-select image controls for a selection point with three domain members.

Two single-select image controls, before and after selecting an image

When you select and submit the selectable blue image, it is replaced by a corresponding selected blue image.

Note. Single-select images can be placed on the page where you specify. If you do not specify a location, they are placed on a line, bottom-aligned.

The following code generates the first (the blue image) of the two controls in the figure.

```
<!-- METADATA TYPE="CalicoControl" startspan -->
<%
if (params != null)
{
    params.clear();
    params.put(PARAM_OBJECTNAME, "[AudioConfig].kitSelection");
    params.put(PARAM_DOMAINMEMBERNAME, "DashSpacer");
    params.put(PARAM_IMAGE_NAME, "blue.gif");
    params.put(PARAM_IMAGEPATH, "SSImages");
    params.put(PARAM_AUTOSUBMIT, "true");
    generateSingleSelectImage(params, request, out);
}
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

Parameters are:

- **PARAM_OBJECTNAME:** The unique object name ("`<modelNameConfig>.decisionpointname`"), which is used to retrieve the items of a form control.
- **PARAM_DOMAINMEMBERNAME:** The name of the domain member that the image selects.
- **PARAM_IMAGEATTRIBUTE:** The name of the domain member attribute whose value is the image that selects the domain member.
- **PARAM_IMAGE_NAME:** The name of the image that selects the domain member.

See [Appendix C, "Advanced Configurator Form Controls," Single-Select Image, page 465.](#) and [Chapter 26, "Using JSP Form Control Templates," Parameters in the Inclusion Set, page 371.](#)

Note. Provide either the image attribute or the image name, but not both.

Optional image parameters are:

- **PARAM_IMAGEPATH:** The Uniform Resource Locator (URL) path to the directory that has the images.
- **PARAM_IMAGEWIDTH:** The width of the image.
- **PARAM_IMAGEHEIGHT:** The height of the image.

- **PARAM_IMAGESTATES:** A comma-delimited list of states, other than selectable, for which alternative images exist whose names follow a naming convention.

The naming convention appends an underscore followed by one or two letters to either the image name or the value of the image attribute. For example, `image1.gif` becomes `image1_s.gif` and `image1_c.gif`. The comma-delimited list of states for which images exist uses the same letters (without the underscore) that are appended to the image name; for example, "us, es, e, c."

Other possible states and the naming convention for their images are:

- Selected (`_s`): Use if you do not display computer-user variations.
- User-selected (`_us`).
- Computer-selected (`_cs`): Default-selected can share this image.
- Default-selected (`_ds`): Computer-selected can share this image.
- Eliminated (`_e`): Use if you do not display computer-user variations.
- User-eliminated (`_ue`).
- Computer-eliminated (`_ce`).
- Conflicted (`_c`).
- **PARAM_MOUSEOVERIMAGES:** "True" means that mouseover images are available. The default value is "False."

You must also provide mouseover images whose names follow a naming convention. The convention appends an underscore and the letters "mo" to the name of any image that changes when the mouse moves over it, for example, `image1_mo.gif` or `image1_us_mo.gif`.

- **PARAM_ALTTEXTATTRIBUTE:** The name of the domain member attribute whose value is the text that is used as an alternative for the image. Most browsers display this text as a tool tip when the mouse is over the image.
- **PARAM_ALTTEX:** The text that is used as an alternative for the image, if the domain member does not have an alternative text attribute.
- **PARAM_ADDITIONALATTRIBUTES:** Comma-delimited list of domain member attributes that are available to client-side script. Do not include the image attribute or the alternative text attribute.
- **PARAM_AUTOSUBMIT:** *True* means that the form should be submitted when the user selects the image. The default value is *False*.

A JavaScript object, **calicoSSI**, is created for each image that is generated by the image templates, and is passed to JavaScript callback functions to identify the image that is being created, selected, deselected, moused over, moused off of, or auto-submitted. Each of these objects has these properties:

Property Name	Property Type	Description
<code>objectName</code>	String	The decision point of the control.
<code>ctrItemName</code>	String	The domain member of the item's.

Property Name	Property Type	Description
state	Number	1 if the image is selected, 0 if it is not selected.
tagName	String	Value of the attribute for the item.
attributes	Array of Strings	An array having all of the attributes of the item.
altText	String	Alternative text for the image of the item.
priced	Boolean	True if the control is priced.
delta price	Number	The delta price of the item.

Optional callback parameters are:

- **PARAM_CREATECALLBACK:** The name of the JavaScript function that is called when a client-side single-select image object is created.

Parameter: the newly created object.

Return value: *None*

For example, createCB():

```
function createCB(calicoSSI)
{
    calicoSSI.myCustomImg = new Image(143, 126)
    calicoSSI.myCustomImg.src = calicoSSI.attributes[0]
}
```

createCB() caches an image specified by a domain member attribute.

- **PARAM_SELECTCALLBACK:** The name of the JavaScript function that is called when a domain member image is selected.

Parameter: The object for the image that is being selected

Return value: *True* if the selection can proceed; otherwise, *False*.

For example, selectCB():

```
function selectCB(calicoSSI)
{
    document.images["myCustomImg"].src = calico.SSI.customImg.src
    return true
}
```

selectCB() updates an image with an image cached by createCB().

- **PARAM_UNSELECTCALLBACK:** The name of the JavaScript function that is called when a domain member image is deselected—that is, when another domain member image is selected.

Parameter: The object for the image that is being deselected.

Return value: "True" if the deselection can proceed; otherwise, "False."

For example, `unselectCB()`:

```
function unselectCB(calicoSSI)
{
    var retval = true
    if (someRareCondition(calicoSSI))
    {
        var retval = false
        alert("Explanation of problem")
    }
    return retval
}
```

`unselectCB()` may prevent deselecting the item, which would prevent selecting another item.

- **PARAM_MOUSEOVERCALLBACK:** The name of the JavaScript function that is called when the mouse moves over a domain member image.

Parameter: The object for the image that the mouse is over.

Return value: "False" if the function updates the browser's status bar. The default value of "True" lets the alternative text for the image appear in the status bar.

For example, `mouseoverCB()`:

```
function mouseOverCB(calicoSSI)
{
    window.status = calicoSSI.attributes[1]
    return false
}
```

`mouseoverCB()` puts text from a domain member attribute in the status bar.

- **PARAM_MOUSEOUTCALLBACK:** The name of the JavaScript function that is called when the mouse moves off a domain member image.

Parameter: The object for the image that the mouse is moving off

Return value: "False" if the function updates the status bar of the browser. The default value of "True" allows text to be cleared from the status bar.

For example, `mouseoutCB()`:

```
function mouseOutCB(calicoSSI)
{
    window.status = "Eat at Joe's"
    return false
}
```

`mouseoutCB()` puts a static string in the status bar.

- **PARAM_AUTOSUBMITCALLBACK:** The name of the JavaScript function that is called before the form is submitted because an image is selected whose auto-submit attribute is "True".

Parameter: The object for the image that is being auto-submitted Return value: "True" if the form can be submitted; otherwise, "False."

For example, autoSubmitCB():

```
function autoSubmitCB(calicoSSI)
{
    return confirm("Submit your choices?")
}
```

autoSubmitCB() asks the user to confirm that the form can be submitted.

Single-Select Image Table

The single-select image table template places images for every domain member of a selection point either horizontally in a row, or vertically in a column on the page, to select among them. Specify an image for each domain member of the selection point, and whether you want them placed in a row or a column. At runtime, selecting one image deselects another.

Include the template for the single-select image table in the following way:

```
<%@ include file="/calico/templates/html/SingleSelectImageTable.jsp" %>
```

For example, you can create the following single-select image table control for a selection point with three domain members.

Single-select Image table, before and after you select an image

When the selectable green image is selected and submitted, it is replaced by a corresponding selected green image.

Note. The images of a single-select table image control are placed in a table row (in a table cell) and centered.

The following code generates the control in the figure:

```

<!-- METADATA TYPE="CalicoControl" startspan -->
<%
if (params != null)
{
    params.clear();
    params.put(PARAM_OBJECTNAME, "[AudioConfig].kitSelection");
    params.put(PARAM_IMAGEATTRIBUTE, "SSImage");
    params.put(PARAM_IMAGEPATH, "SSImages");
    params.put(PARAM_AUTOSUBMIT, "true");
    generateSingleSelectImageTable(params, request, out);
}
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

See and [Chapter 26, "Using JSP Form Control Templates," Parameters in the Inclusion Set, page 371.](#)

The optional table parameters are:

- **PARAM_IMAGEATTRIBUTE:** The name of the domain member attribute whose value is the image that selects the domain member.
- **PARAM_COLUMNS:** The number of columns in the table. The number of domain members that are displayed at runtime determines the number of rows.
- **PARAM_ROWS:** The number of rows in the table. The number of domain members that are displayed at runtime determines the number of columns.

Note. Runtime performance is better if you specify the number of columns, rather than the number of rows.

- **PARAM_BORDER:** The border attribute for the generated table. The default value is 0.
- **PARAM_CELLSPACING:** The cell spacing attribute for the generated table. The default value is 0.
- **PARAM_CELLPADDING:** The cell padding attribute for the generated table. The default value is 0.

See and [Appendix C, "Advanced Configurator Form Controls," Single-Select Image Table, page 466.](#)

Application Why Help

Use an Application Why Help template to represent a set of violation items of the current configuration in an unordered list format.

You can create the following application-level why help:

Application Why Help

The following code generates the form control in the figure:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_CAPTION, "Application Why Help:");
    generateApplicationWhyHelp(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

See [and Appendix C, "Advanced Configurator Form Controls," Application Why Help, page 467.](#)

Form Control Why Help

Use a Form Control Why Help template to represent a set of violation items of a form control for the current configuration in the unordered list format.

You can create a Form Control Why Help like the example in the Application Why Help:

Application Why Help:

- 27.7 GB hard drives aren't available in South America.

Form Control Why Help

The following code generates the example form control:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[MyComputerConfig].HDSelection");
    params.put(PARAM_CAPTION, "Control Why Help:");
    generateControlWhyHelp(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

See [and Appendix C, "Advanced Configurator Form Controls," Form Control Why Help, page 468.](#)

Text Input Form Control

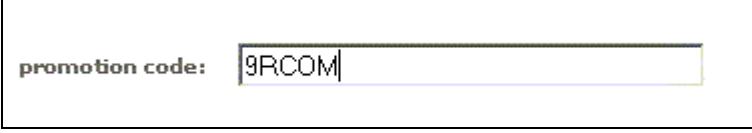

The text input template generates a text box for entering any text value. Unlike values that are entered into extern entry templates, text input values are not submitted to the engine. They are instead passed from page to page and loaded into the configuration object that is contained within the COP on each page. This allows any information that you store using the text input template to be included with standard configuration information, such as that acquired when you use the BOM item generator, which is saved when you run it against a compound model or integrate it with other applications.

Important! Use text input templates for all text related entries. Use extern entry templates for entering external values that need to be processed by the Configurator engine.

Include the template for the extern entry text box in the following way:

```
<%@ include file="/calico/templates/html/TextInput.jsp" %>
```

For example, you can create the following text input control with an initial default value.

Text Input control

The following code generates the control in the example.

```
<!-- METADATA TYPE="CalicoControl" startspan -->
<%
if (params != null)
{
    params.clear();
    params.put(PARAM_OBJECTNAME, "TextInput_Ctrl01");
    params.put(PARAM_CAPTION, "Phone Number:");
    params.put(PARAM_TEXTINPUTDEFAULT, "212-555-1212");
    params.put(PARAM_ENTRYSIZE, "12");
    generateTextInput(params, request, out, session, cop.getConfiguration());
}
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [Chapter 26, "Using JSP Form Control Templates," Parameters in the Inclusion Set, page 371.](#)

The two optional parameters are:

PARAM_TEXTINPUTDEFAULT: A default value that shows up when the text input box is initially shown.

PARAM_ENTRYSIZE: The width in characters of the text entry field. The default value is *15*.

See [Appendix C, "Advanced Configurator Form Controls," Text Input Form Control, page 468.](#)

Numeric Data Form Control

A numeric data control consists of a control caption or a caption image and a value of the numeric data that are displayed in the same line.

The include file that is required for the numeric data template is:

```
<%@ include file="/calico/templates/html/NumericData.jsp" %>
```

For example, you can create the following numeric data control for the decision point WattsSummation with the caption *Total Watts*.

Pick a Speaker >> Altec Lansing 2000 - Cambridge SoundWorks SP	Pick a Printer >> HP Laserjet - Epson 1500	Pick a Scanner - NEC Technologies PediScan >> Fujitsu ScanPartner 15C - Canon DR5080C
Pick a Hard Drive - 4.3 GB BATRA-33 - 8.4 GB BATA-33 >> 13.6 GB BATA-33 - Quantum 27.3 GB SCSI		Pick a Monitor - No Monitor - 15 Inch Monitor >> 17 Inch Monitor - 21 Inch Monitor
<input type="button" value="Submit Picks"/>	Total Watts: 13.0	<input type="button" value="Clear Picks"/>

Numeric data for watts after submitting picks

The following code generates the control in the figure:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[_Application].WattsSummation");
    params.put(PARAM_CAPTION, "Total Watts");
    generateNumericData(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See and [Appendix C, "Advanced Configurator Form Controls," Numeric Data Form Control, page 469.](#)

Extern Entry Form Control

The extern entry template generates a text box for entering a value (for example, float, numeric, boolean or date-related value) that is submitted to the Configurator engine using the `extern()` function.

Important! Use text input templates for all text related entries that do not need to be processed by the Configurator engine.

Include the template for the extern entry text box in the following way:

```
<%@ include file="/calico/templates/html/ExternEntry.jsp" %>
```

For example, you can create the following extern entry control to enter a floating point value.

Extern Entry control with a numeric value entered

The following code generates the previous control.

```
<!-- METADATA TYPE="CalicoControl" startspan -->
<%
if (params != null)
{
    params.clear();
    params.put(PARAM_OBJECTNAME, "[_Application].ExtVar1");
    params.put(PARAM_CONTROLID, "ExEn01");
    params.put(PARAM_CAPTION, "Enter Number Here");
    params.put(PARAM_FLOATENTRY, "true");
    params.put(PARAM_ENTRYSIZE, "3");
    generateExternEntry(params, request, out);
}
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

See [Chapter 26, "Using JSP Form Control Templates," Parameters in the Inclusion Set, page 371.](#)

The two optional parameters are:

- **PARAM_FLOATENTRY:** "True" processes the entered number as a floating point value. The default value "False" processes the number as an integer.
- **PARAM_ENTRYSIZE:** The width in characters of the text entry field. The default value is 3.

Using Configuration Form Control Templates

PeopleSoft Advanced Configurator supplies 11 form control templates. Each is a JSP page that generates HTML. Six of them enable the web user to select an item on an HTML form, using radio buttons, check boxes, drop-down lists, or selection lists. The other four form control templates generate output display information. One enables the web user to enter a text value using an edit box. Two of these form controls display constraint violations; one for the entire configuration session, and the other for its corresponding form control. The last display form control template generates a visible numeric value.

Three types of user-selectable form controls are available:

- **Group:** radio buttons and check boxes that are grouped as part of the selection point.
- **List:** drop-down or selection lists; one for each selection point.
- **Table:** Table form controls and Group form controls are alike, except that the Table form controls provide, in addition to the item name, columnar information for each form control item. The Table templates generate extra columns that are determined by the additional field descriptors in the model.

Each type of user-selectable form control can be either single-selectable or multiselectable. A multiselect form control enables the web client user to select more than one item for the selection point, whereas a single-select form control limits the user to a single selection for the selection point. A single-select list is drop-down, whereas a multiselect list is a list, typically scrollable. The following table itemizes the form control templates that are available in this release.

JSP Filename	HTML Implementation	Comment
SingleSelectGroup	<INPUT TYPE="radio">	Radio buttons
MultiSelectGroup	<INPUT TYPE="checkbox">	Check boxes
SingleSelectList	<SELECT>	Drop-down list; single-selectable
MultiSelectList	<SELECT MULTIPLE>	List: multiselectable
SingleSelectTable	<INPUT TYPE="radio"> and <TABLE></TABLE>	Multiple columnar radio buttons
MultiSelectTable	<INPUT TYPE="checkbox"> and <TABLE></TABLE>	Multiple columnar check boxes
SingleSelectImage		An image for selecting a domain member
SingleSelectImageTable	 and <TABLE></TABLE>	A row or column of images for selecting among domain members
ApplicationWhyHelp		Violation messages for all form controls: application scope
ControlWhyHelp		Violation messages for an individual form control: form control scope
NumericData	caption text or image, and number text	Display number value aside caption or image
ExternEntry	<INPUT TYPE="text">	A text box for entering a value
TextInput	<INPUT TYPE="text">	A text box for entering a text value

Plugging Form Controls into the Application Pages

To use the form control templates, you need to be familiar with the following directories:

- Applications and processing JSP pages for the form control templates:

Solaris: /opt/bea/wlserver_10.3.1/config/CalicoDomain/ applications⇒
 /CalicoApp/

Windows NT: \bea\wlserver_10.3.1\config\CalicoDomain\ applications\Calico⇒
 App\

- Configuration models:

Solaris: `/opt/beamwserver_10.3.1/config/CalicoDomain/ applications=>
/CalicoApp/Web-inf/models`

Windows NT: \bea\wlserver_10.3.1\config\CalicoDomain\ applications\Calico⇒
App\Web-inf\models\

To use a form control template, your application pages need:

- A JSP `include` directive that includes the specified form control template.
- A specialized code-block that passes the required parameters to the specified form control template followed by a method call to generate and include it. This information is called the form control *inclusion set*.

Using a JSP Include Directive

The syntax to include a form control template, such as the `SingleSelectGroup` template, is:

```
<%@ include file="/calico/templates/html/SingleSelectGroup.jsp" %>
```

Place the include directives for the form control templates immediately following the include directive for the CalicoStartFormInc.jsp that is in each application JSP page.

For example:

```
<%@ include file="/calico/CalicoStartFormInc.jsp" %>
<%@ include file="/calico/templates/html/SingleSelectGroup.jsp" %>
<%@ include file="/calico/templates/html/MultiSelectTable.jsp" %>...
```

Note. Only one include directive `<% include file="templateFile" %>` is required for each type of form control template in the application JSP page. If you have five single-select list form control templates in an application JSP page, use only one JSP include directive to include them.

Using a Form Control Inclusion Set

To include a form control template using an inclusion set, bracket the inclusion set within these start and end tags:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
// set the parameters and include the path name for a form
// control template here
<!-- METADATA TYPE="CalicoControl" endspan -->
```

Between the start and end tags, insert these required statements:

<code>params.clear();</code>	Initializes all parameters.
------------------------------	-----------------------------

<code>params.put(parameter, value);</code>	Sets the required and optional parameters after <code>params.clear()</code> .
	The four required parameters for the interactive form controls are: <code>PARAM_OBJECTNAME</code> <code>PARAM_ATTRIBUTES</code> <code>PARAM_CAPTION</code> or <code>PARAM_CAPTIONIMAGE</code> <code>PARAM_CONTROLID</code>
<code>generateTemplateName(params, request, out);</code>	Generates the included form control template file after the <code>params.put()</code> calls where you've set parameters. The <code>params.put()</code> statements can be in any order, provided that <code>params.clear()</code> precedes them and that <code>generateTemplateName()</code> follows them.

Example:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "VehicleSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CAPTION, "Select a Vehicle");
    params.put(PARAM_CONTROLID, "VehicleSelectionControlID");
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

Parameters in the Inclusion Set

At runtime, the parameters in the inclusion set are passed to the form control template, which uses them when it runs at the point where `generateTemplateName()` is called.

Any blank spaces between the values are ignored. For example, "Description, Part Number, Unit Cost" (with spaces) is the same as "Description,Part Number,Unit Cost" (without spaces).

Form control parameter values are specified as a string. The syntax for assigning multivalued parameters (in the application page) is a single string that uses a comma character delimiter between each value. Both the `PARAM_ATTRIBUTES` and `PARAM_COLUMNHEADINGS` parameter values may be multivalued.

These parameters are required for using the selection point form control templates:

Required parameter	Comments
PARAM_OBJECTNAME	The object name is the unique object name (" <code><modelnameConfig>.decisionpointname</code> "), which is used to retrieve the items of a form control.

Required parameter	Comments
PARAM_CONTROLID	The control ID is the unique identifier for the HTML form control. The application needs a unique identifier for each form control other than the object name because multiple controls might map to the same decision point. This identifier is used for client-side scripting and server-side processing.
PARAM_ATTRIBUTES	<p>The attributes are the data attributes for the selection point that are to be displayed on the form control in the UI. Only Table form controls can use <i>multiple</i> display attributes from the model.</p> <p>For internal domain members that are specified in the if PARAM_ATTRIBUTES parameter, corresponding attributes must be defined in the model for the domain members.</p> <p>For external domain members, if the attribute name (column names of the table that stores the description for the domain members) is ambiguous (more than one table has the same column name), you must specify its fully qualified database name—tablename.columnname.</p> <pre>params.put(PARAM_ATTRIBUTES, <attribute name, attribute name ...>);</pre> <p>or</p> <pre>params.put(PARAM_ATTRIBUTES, <tablename. columnname, tablename.columnname ...>)</pre> <p>Setting the PARAM_ATTRIBUTES parameter in your inclusion set is optional; however, for deployment you should set it so that the attributes of the model are displayed. If PARAM_ATTRIBUTES is not explicitly set, the default display will be the domain member names, which may be useful during development in that you do not need to add attributes to test-case models.</p>
PARAM_CAPTION	The caption is the string to be displayed as the form control caption. This parameter is applicable to all the form control templates.
PARAM_CAPTIONIMAGE	<p>The caption Image is the image to be displayed as the form control caption. This parameter is applicable to all the form control templates</p> <p>Specify either a caption or a caption image, but not both.</p>

The following table lists optional parameters for the form control templates:

Optional parameter	Comments
PARAM_SORT	The sort parameter specifies whether to sort form control data based on the form control states; <i>true</i> and <i>false</i> are the valid values.

Optional parameter	Comments
PARAM_FILTERELIMINATEDITEMS	<p>The filter-eliminated items parameter renders all eliminated domain members in the model unavailable to the form controls in the application page. If the parameter is set to <i>true</i>, the eliminated domain members in the model are not available to the form control. If it is unspecified or set to <i>false</i>, the eliminated domain members in the model are available to the form control.</p> <p>You can restrict the filtering to outside a range of elimination levels that are captured between a lower and an upper elimination level that is specified by the parameters PARAM_ELIMINATIONLEVEL_LOWER and PARAM_ELIMINATIONLEVEL_UPPER.</p> <p>Therefore, if PARAM_ELIMINATIONLEVEL_LOWER is 4, and PARAM_ELIMINATIONLEVEL_UPPER is 7, then the eliminated domain members with elimination levels greater than 3 and less than 8 are available to the form control.</p>
PARAM_ELIMINATIONLEVEL_LOWER	The lower elimination level is used to specify the lower bound of the elimination level range for form control items.
PARAM_ELIMINATIONLEVEL_UPPER	<p>The upper elimination level is used to specify the upper bound of the elimination level range for form control items.</p> <p>Note. To specify the range for elimination levels, you must set <i>both</i> parameters, PARAM_ELIMINATIONLEVEL_LOWER and PARAM_ELIMINATIONLEVEL_UPPER.</p>
PARAM_COMPARATOR	Specifies a Java class name to be used with a custom comparator for sorting control items. The class that is specified must implement the java.util.Comparator interface. It passes a custom-written Comparator object to the ControlData.iterator method. The iterator method then sorts domain members using Comparator before returning the iterator to the front-end. Sort can be performed on quantity or any other attribute from the model.
PARAM_COLUMNHEADINGS	The column headings are the labels that the Table form control displays for the columns of domain member attributes.
PARAM_GENERATENONEMODE	<p>The Generate None mode is the position for the None item (explicitly selecting none of the picks). This option is available only for single-select controls. The corresponding decision point must be optional. Available options are:</p> <p>0: Do not generate <i>none</i> value.</p> <p>1: Generate <i>none</i> value before other options.</p> <p>2: Generate <i>none</i> value after other options</p>
PARAM_GENERATENONETEXT	The Generate None text is the string to be displayed for the None item. This option is available only for single-select controls. The corresponding decision point must be optional.

Optional parameter	Comments
PARAM_EVENTHANDER	<p>The event handler is the JavaScript event handler for the standard JavaScript events of form control items.</p> <p>Put your JavaScript event-handler function in the body of the application pages, outside of the inclusion set.</p> <p>For the event handlers, you must write your own JavaScript function to handle the events, such as <code>onClick</code> or <code>onBlur</code>, and then set the parameter <code>PARAM_EVENTHANDER</code> to that function name. Otherwise, you can use the standard event handlers, such as:</p> <pre>this.<form-name>.submit()</pre> <p>Syntax:</p> <pre>params.put(PARAM_EVENTHANDER, "onClick==> 'this.<form-name>.submit()' " or params.put(PARAM_EVENTHANDER, "onChange='my JavascriptSubmit()' "</pre> <p>Note. Common functions such as <code>onClick</code>, <code>onChange</code>, and <code>onFocus</code> are JavaScript events. <code>onClick</code> is an event for Group and Table form controls, but you can use different JavaScript events. <code>onChange</code> typically is used for List form controls, but you can use other JavaScript built-ins such as <code>onFocus</code> and <code>onBlur</code>.</p>
PARAM_CONTROLSIZE	<p>The control size is the number of visible items for the HTML form control. This parameter applies only to the List form controls.</p>
PARAM_GENERATEFIRSTITEMTEXT	<p>You can add an item with any description (string type) to the beginning of a single-select list control. For example, you can add "Select a hard drive" to be displayed as the top element in the drop-down list. When the user selects an item from the drop-down list, (for example, "12 GB Hard Drive"), the first item entry ("Select a hard drive") then disappears.</p>

Specifying the Model and Locale Properties for the Solution

The user interface (UI) properties for a solution are contained in the configuration file, `CalicoUI.properties`. Each solution, or version of a solution, requires a separate copy of `CalicoUI.properties` to be modified and maintained for that solution only. It must be placed in the application folder that houses your application JSP pages.

`CalicoUI.properties` contains mainly display properties, which are optionally used by the application. However, four model properties and two locale properties exist that the form control templates need and that you must specify in the solution `CalicoUI.properties` file:

- `calico.ui.version`: A unique number for each application that is hosted by the same application server; one entry per `CalicoUI.properties` file.
- `calico.model.name`: Holds the model name. Valid model names are any subfolder name under `<install_dir>/PeopleSoft Applications/Configurator/`, which houses the models. The modeler sets the model name when it is created.

- `calico.model.version`: Gets the latest compiled model with the specified version number.
- `calico.model.compileversion`: The generated ID for a compiled model, for example, `20010221-161729-588`.
- `calico.locale.language=en`: Indicates which set of text in the XX file that provides text for captions and controls in the desired language.
- `calico.locale.country=US`: Indicates which country variant of the locale language that is specified. If a custom language variant is used, the `calico.locale.variant=` property is provided for specification instead.

To specify model and locale properties:

1. If you haven't already done so, transfer a copy of `CalicoUI.properties` from `<install directory>\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\solutions\ComponentSample` to the application folder where the JSP pages are kept.
2. Call the property values from each form control that uses the display properties:

- If it is a template form control, insert the property as a parameter in its JSP inclusion set. For example:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, "[SmallBusTelecom].ServicePlanSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CAPTION, "Select a Service Plan");
    params.put(PARAM_CONTROLID, "ServPlanSelectionControlID");
    params.put(calico.ui.version, "SBQ01.04.01");
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

- If it is a custom form control, fetch the property values with calls from your code.
3. If the language to use in the UI is other than the United States variant of English, specify which by inserting the code for the desired language and variant. If you have a custom language variant set, specify the desired language code in `calico.locale.country=en`, comment out `calico.locale.country=US`, uncomment `calico.locale.variant=`, and insert in it the correct code.

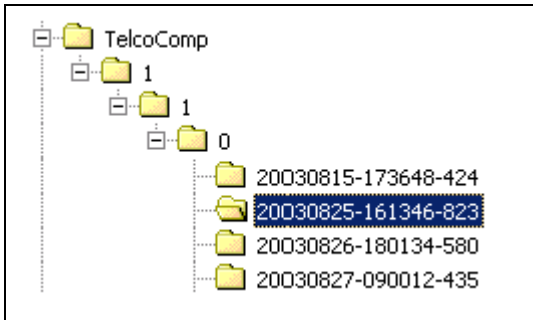

Assigning a Specific Model Version to Use for Configuration

If you use only the major number and the minor number of the model version for setting the `calico.model.version` property (such as `calico.model.version=0-1`), then by default, the form control templates use the latest compiled version from among all models within the subversions folder under version 0.1.

The model name and version (major-minor) are set in the model by the modeler. By changing these in the `CalicoUI.properties` file, you tell the application which model to use rather than the default latest compiled version. The compiler assigns the micro (sub-version) and compile versions. The WebLogic server by default loads only the most recent version (major-minor-micro) and compile version of every model.

To assign a specific model version to use:

1. Set the `calico.model.version` property to the complete version number. For example, `calico.model.version=0-1-4` represents version 0.1.4.
2. Uncomment the `calico.model.compileversion` property in `CalicoUI.properties`.
3. Set the `calico.model.compileversion` property to the name of the folder that houses the compiled model. For example, using the following directory tree for Configurator models, you would set `calico.model.compiledversion` property to `200030825-161346-823`.

Setting the compile version (optional)

Specifying Solution Information Properties

You use solution information property values to generate a Solution List for Configurator client application. A solution is the collection of pages, images, model files, and supporting files that make up the applications that solve a business problem, such as online configuration and order management. The solution list is the filenames, structures, and version information for that solution.

The solution list could also be used in a server-based deployment.

Solution properties are:

calico.solution.name	Name of the solution. This acts as the key in the solution list. By default (if this property isn't specified), the name is the name of the directory that the solution resides in (the value of <code>calico.solution.root</code> , which is not specified here). Default is the name of the directory in which the solution resides.
calico.solution.version	The version of the solution. This helps identify different versions (revisions) of the same solution, but isn't used in this version of Configurator. Default is <code>calico.solution.root</code> or as specified in the properties file.
calico.solution.description	The text to be displayed in the solution list as a link to this application. The default is <i>calico.solution.name</i> or as specified in properties file.
calico.solution.restorePolicy	The restore policy to use when you launch stored configurations. The policy determines which version of the model to use in launching the configuration in the web application. The default is <i>1</i> or as specified in the properties file.
calico.page.start	The page to redirect to when starting a new configuration.

calico.page.restore

The page to redirect to when restoring an existing configuration. If calico.page.restore is blank, the restore goes to the page that is specified in calico.page.start.

If these properties aren't specified, the SolutionInfo class assigns default values.

Specifying Display Properties

The names of the form control property types correspond to the names of the display attributes, as shown in the following list:

<i>Display property types in CalicoUI.properties file</i>	<i>Applicable form control template types</i>
calico.control.tag.<property>	List
calico.control.image.<property>	Group and Table
calico.control.textcolor.<property>	Group and Table
calico.control.captioncolor.<property>	List, Group, and Table

PeopleSoft Advanced Configurator provides the following set of properties to indicate the state of an item in a control:

- Selectable
- User-selected
- Computer-selected
- Default-selected
- User-eliminated
- Computer-eliminated
- Conflict

These properties cause the display of designated text symbols, images, or both that are beside the items in a control to indicate to the user their availability for selection.

You can use the item state properties as examples for creating your own properties or modify them to meet your needs.

Displaying Delta Information

Using the COP XML interface, Advanced Configurator generates two types of delta configuration information at runtime:

- Structural

Structural deltas include component additions, deletions and changes, and connection additions, deletions, and moves. Structural and component delta information applies to configurations that are generated from compound models.

- Component

Component information deltas indicate changes between two configurations for a single component and apply to the components in both component and compound configurations. The information can include:

- Added, changed, and deleted configuration attributes.
- Added, changed, and deleted choices.

Advanced Configurator returns delta information using an XML interface. The existing ConfigDetails request in the messaging interface (COPXML) can include requests for delta information. By default, the deltas that are returned represent the latest set of saved changes or those from a specified date range. In addition, the available component delta information will be enhanced to include changed expression values. PeopleSoft CRM 9.1 Order Capture and Service Management use delta information in transactions.

Chapter 15, "Retrieving Configuration Information," page 225

Displaying Delta Pricing

You can modify the pricing display for either all form control items or for the form control items belonging to specified selection points. To display delta prices, you must first enable delta pricing in the application and then specify how it is displayed. Enabling delta pricing occurs in initial implementation of `jspInit()` in the body of your application pages.

1. Enable delta pricing:

To enable delta pricing for all form controls, use this statement:

```
setPricing(true);
```

This statement also enables total pricing for the entire configuration.

To enable delta pricing for *specific* form controls, use this statement:

```
setPricingControls(); // accepts as arguments a map of the
                     // decision points' object names (strings)
                     // and price attributes (strings).
```

Pass to `setPricingControls()` the object names that you specify in the `PARAM_OBJECTNAME` parameters of the form controls, along with the price attribute for that object.

Note. For better performance, set the pricing variables rather than calling the corresponding set methods.

2. Set display properties.

The basic format is:

```
calico.pricing.add=[+ {0}]  
calico.pricing.subtract=[- {0}]
```

The values that are shown result in a display string that appears alongside the selection. If the delta price is an additional 20.00 USD, the delta price appears in the following way:

[+ \$20.00]

By replacing the characters, you can change the display. For example, if you replace the square brackets with angle brackets, and + with Add, the display becomes *<Add \$20.00>* for a positive delta price.

Replacing - with Subtract gives *[Subtract \$20.00]* for negative deltas.

Sample code:

```
public void jspInit()  
{  
    setPricing(true);  
  
    Map pricingControls = new HashMap();  
    pricingControls.put("[BMWConfig].SeriesSelection", "UnitPrice");  
    pricingControls.put("[BMWConfig].OptionsSelection", "UnitPrice");  
    pricingControls.put("[BMWConfig].EngineSelection", "basePrice");  
  
    setPricingControls(pricingControls);  
}
```

Application Page Example

The following code provides a complete example of an application JSP page.

```

<HTML>
<HEAD>
  <TITLE>Sample Page</TITLE>
</HEAD>
<BODY>

<%!
  public void jspInit()

    // turn on pricing for controls
    setPricing(true);

  Map pricingControls = new HashMap();
  pricingControls.put("[myPCConfig].ProcessorSelection", "UnitPrice");

  setPricingControls(pricingControls);
  }
%>
<FORM name="TestForm" method="POST" action="CalicoProcessForm.jsp">
<%@ include file="/calico/CalicoStartFormInc.jsp" %>
<%@ include file="/calico/templates/html/SingleSelectGroup.jsp" %>

<!-- Inclusion set starts below -->
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME,
      "[myPCConfig].ProcessorSelection");
    params.put(PARAM_ATTRIBUTES, "Desc");
    params.put(PARAM_CAPTION,
      "[myPCConfig].ProcessorSelection");
    params.put(PARAM_CONTROLID, "ProcessorSelectionCtrl");
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

<%@ include file="/calico/CalicoEndFormInc.jsp" %>
</FORM>
</BODY>
</HTML>

```

Configuring a Form Control Template

You must use `getControlData()` in configured form control template JSP pages, as in the following Java statement:

```
ControlData varName = getControlData(objectName, request, params);
```

Application Scope

You can configure HTML-level display properties, such as the text color of the form controls, by modifying the properties in the `CalicoUI.properties` file. The form control templates load these properties upon their initialization.

Template Scope

You can configure how the display data is altered depending on the data for the model. You can configure the behavior of the display to:

- Display domain member attribute information.
- Sort the form control items.
- Eliminate form control items of eliminated domain members.
- Eliminate the form control items of the eliminated domain members whose elimination levels are beyond an inclusionary range.
- Display delta pricing and the total price.

To configure the state of an individual instance of a form control:

1. Make a copy of the type of form control template that you want, rename the copy, and put that copy in your application directory.

When you use the JSP include directive to include your template, be sure to use the path to your application directory.

Note. Do not modify any of the form control template JSP files: they are installed as read-only files.

2. Modify its JSP code.
3. Include your custom form control template in any of your application JSP pages whenever you use that type of form control.

Loading the Form Control Data from the Model

The form control templates get their corresponding selection point (decision point) data from the model with the following JSP template code:

```
String objectName = (String)params.get(PARAM_OBJECTNAME);
ControlData ctrlData = getControlData(objectName, request, params);
```

Loading the UI Properties for a Control

The form control templates load the specified UI properties (from the CalicoUI.properties file) with the following JSP template code:

```
// set up display properties
String[] stateMap = (String[])request.getAttribute(STATEMAP);
String[] tagMap = (String[])request.getAttribute(TAGMAP);
String[] imgMap = (String[])request.getAttribute(IMAGEMAP);
String[] textColorMap = (String[])request.getAttribute(TEXTCOLORMAP);
Properties props = (Properties)request.getAttribute(UIPROPS);
```

The form control templates set their properties with the following JSP template code:

```
// set up the display properties for control items
state = (int)ctrlItem.getFlags();
stateFlags = stateMap[state];
tagItemState = tagMap[state];
imgItemState = imgMap[state];
colorItemText = textColorMap[state];
```

The names of the form control property types correspond to the names of the display attributes, as shown in the following list:

<i>Display property types in CalicoUI.properties file</i>	<i>Applicable form control template types</i>
calico.control.tag.<property>	List
calico.control.image.<property>	Group and Table
calico.control.textcolor.<property>	Group and Table
calico.control.captioncolor.<property>	List, Group, and Table

Registering Custom Form Control Templates

The `addCtrl()` function should be called within any configured form control template. `addCtrl()` registers a Configurator form control. It adds each control along with its selection point name to a form-hidden attribute called `CalicoCtrlMap`, which is generated by `CalicoEndFormInc.jsp` for each Configurator page. This is necessary so that the Configurator JSP processor page (`CalicoProcessFormInc.jsp`) knows which form controls need to be processed and which to ignore (non-Configurator form controls).

`addCtrl()` is used by most of the Configurator form control templates.

Custom Form Control Template Example

The purpose of providing the sample template is to explain how developers could configure the behavior of a Configurator control by displaying eliminated control items differently based on their elimination levels returned from COP:

If the elimination level for an eliminated control item is ≥ 0 and ≤ 4 , the item is hidden (not shown).

If the elimination level for an eliminated control item is ≥ 5 and ≤ 9 , the item is displayed as unavailable with the X image.

If the elimination level for an eliminated control item is ≥ 10 , the item is displayed as normal (without being unavailable for entry or the X image).

In this example template, we use 0, 4, 5, 9, 10 and so on for the lower and upper bounds to display control items differently. Developers can define a range of values for the elimination level that they want to handle in the template that they create because these values depend on the elimination levels that are defined for the constraints by the modelers.

In the following figures, after the Prima Base Celeron 43 Mhz MiniTower pick is submitted, the control on the right has only one item left and is shown as user-selected (finger icon). All other items in the control have elimination levels that are ≥ 0 and ≤ 4 . Therefore, they are not shown on the page.

The following web page illustrates using the same model decision point: the top left form control with the SingleSelectGroup.jsp template, and the top right form control with the SingleSelectGroupElimLevel.jsp template:

Model Name	Model ID	Compile Version
sample	1-0-0	20000322-1700-17-909

Next (page 1)

Reset

Web page

The next figure illustrates the differing effects of using the standard SingleSelectGroup.jsp form control template and of using a configured (sample) SingleSelectGroupElimLevel.jsp form control template. The top left form control was generated by the SingleSelectGroup.jsp template, and the top right form control was generated by the SingleSelectGroupElimLevel.jsp template:

SingleSelectGroup.jsp template generated this form control

SingleSelectGroupElimLevel.jsp template generated this form control

Second page

Common Errors

The following list describes common errors for those who implement the web applications using Configurator JSP pages:

- `calico.model.compileversion`: The `calico.model.compileversion` entry of the `CalicoUI.properties` file is used to specify the compiled version for the model to be loaded for the JSP page.

By default, this entry is commented out and the most recent compiled version is loaded for a model. Don't uncomment this entry unless a specific compiled version of a model is given.

- Better performance: Add `<%@ page session="false" %>` to a JSP page if the page does not reference the session-implicit variable. This should apply to the `CalicoProcessForm.jsp` file as well.
- `CalicoEndFormInc.jsp`: A Configurator JSP page must include both `CalicoStartFormInc.jsp` and `CalicoEndFormInc.jsp`. For example:

```
<%@ include file="/calico/CalicoStartFormInc.jsp" %>
.....
<%@ include file="/calico/CalicoEndFormInc.jsp" %>
```

`CalicoEndFormInc.jsp` calls the `release()` method for the COP. If a system quickly runs out of memory when running Configurator JSP pages, verify that `CalicoEndFormInc.jsp` is included properly on each page.

- Variables declared within JSP `<%! %>` blocks: Be careful using variables that are declared within `<%! %>` blocks of the JSP pages. For example:

```
<%!
    HashMap myMap = new HashMap();
    ...
%>
```

The values of the variables that are declared within the `<%! %>` blocks are accessed and modified by more than one user when multiple clients access the pages concurrently unless the access to such objects is properly synchronized. If such values are meant to be user-specific, the preceding variables that are used by other functions or codes may easily run into problems.

- Template files: The name of the control-generating function should be changed as well as in any custom templates (for example, `generateMyEnterpriseLargeSingleSelectTable(params, request, out)`, `generateMyEnterpriseSmallSingleSelectTable(params, request, out)`) so that no confusion results if multiple templates of the same control type exist on one page.
- Keep the custom templates in the application directory instead of in the calico directory.

You should include only template files that are used on the JSP page.

- `StringBuffer.append()`: Use `StringBuffer.append()` for string concatenation instead of using the `+` operator of the `String` class.
- Avoid unnecessary evaluations and object creations in Java codes, especially codes within loops—for example, `while` and `for` loops.

Chapter 27

Using the Page Editor Extensions for Dreamweaver

This chapter provides an overview of Dreamweaver extensions and discusses how to:

- Edit CalicoUI.properties.
- Insert a Configurator runtime object.
- Edit properties of Advanced Configurator objects.

Understanding Dreamweaver Extensions

PeopleSoft Advanced Configurator provides extensions for Macromedia® Dreamweaver™ that help the web developer build a website for a Configurator model. This chapter describes the Configurator extensions and how to use them. If you do not use Dreamweaver, skip this chapter.

See [and Chapter 26, "Using JSP Form Control Templates," page 351.](#)

Configurator extensions for Dreamweaver include:

- A Configurator item in the Commands menu of the taskbar of the Dreamweaver Document window.

This menu item tells you which version of the extensions you have, enables you to edit the CalicoUI.properties file, and add it to your website.

- A Configurator panel in the Dreamweaver Objects palette.

This panel enables you to insert Configurator objects into the active Document window.

- A Configurator item in the Insert menu of the task bar of the Dreamweaver Document window.

This menu item also enables you to insert Configurator objects into the active Document window.

- Dreamweaver Property inspectors for most of the Configurator objects.

These inspectors enable you to edit properties of Configurator objects that are in the active Document window.

Advanced Configurator Runtime Objects

A Configurator object is a graphical user interface that creates JavaServer Pages (JSP) syntax on a JSP page when you insert the object into the active document window in Dreamweaver. You can view the syntax created by an object by having the Dreamweaver HTML Source window open as you insert objects or edit their properties.

See [and Chapter 26, "Using JSP Form Control Templates," page 351.](#)

There are 10 Configurator objects that you can insert into the active Document window. Two of the objects are general purpose:

- Form
- Button

You need a Configurator Form to process other Configurator objects. A Configurator Button submits a page, or resets the picks on a page.

Note. You must use the form and button created by the Configurator Form and Configurator Button objects. They set attributes to work with your Configurator model.

Do not use more than one Configurator form on a JavaServer Page.

Three Configurator objects create form controls for selection points in the model:

- List
- Group
- Table

In fact, each of these three objects creates two types of form controls:

- Single-select: Enables the user to select only one item. A drop-down list box and radio-button group are single-select form controls.
- Multi-Select: Enables the user to select one or more items. A text list and check box group are multi-select form controls.

The type of selection point—whether it is optional or required—determines which type of form control these three Configurator objects create.

Note. The modeler creates the selection points in your model. A selection point is that point in your model where the user selects one or more items from two or more items. A selection point is optional if the user can select none of the items, and required if the user must select at least one item.

Two Configurator objects create a single-select form control that uses images to select an item:

- Single-select image control
- Image table

Single-Select Image Control places an image on the page where you indicate, to select one domain member of a selection point. Image Table places images for every domain member of a selection point in either a row or a column on the page, to select any domain member of a selection point.

Two Configurator objects create messages for constraint violations:

- Control Why Help
- Application Why Help

Control Why Help creates messages for a selection point. Application Why Help creates messages for the entire model.

Configurator NumericData is the tenth object. It displays the total—that is, the summation—for a numeric attribute of user picks, such as price, at runtime.

Creating a Solution

To create a Configurator web application in Dreamweaver, do the following:

1. In Windows Explorer, create a directory for your website files; for example:

D:\Dev\WebSites\myWebApp1

2. In Dreamweaver, create a site (select Site, New Site).
3. Edit the CalicoUI.properties file.

See [and Chapter 27, "Using the Page Editor Extensions for Dreamweaver," Editing CalicoUI.properties, page 387.](#)

4. Create JSP pages by inserting Configurator objects into an active Document.

See [and Chapter 27, "Using the Page Editor Extensions for Dreamweaver," Editing Properties of Advanced Configurator Objects, page 402.](#) and [Chapter 27, "Using the Page Editor Extensions for Dreamweaver," Inserting a Configurator Runtime Object, page 388.](#)

See Also

[Chapter 22, "Understanding the Runtime System," Deployment for a Web Application Based on a Single Component Model, page 328](#)

[Advanced Configurator System Administration](#)

Editing CalicoUI.properties

The CalicoUI.properties file must be in your web application directory with your JSP pages. Add it after you create your site in Dreamweaver. This file determines the display of the following Configurator objects in your application:

- List

- Group
- Table
- Numeric Data

Before you add the CalicoUI.properties file to your web application directory, you must first edit it to apply to your model.

To edit and add the CalicoUI.properties file to your web application directory, from an active Document window:

1. Select Commands, Edit Calico UI Properties File.

A dialog box asks if you want to add the Configurator UI properties file to your site.

2. Click OK.

The Add Calico UI Properties File To Site dialog box appears, so that you can edit the file before adding it to your application directory.

3. Set values for the following:

Model Information File	Browse to the model information file, and click it, or enter its full path and name.
<hr/>	
Note. The model information file is created when the model is created and compiled using the PeopleSoft Visual Modeler. Obtain this file from the modeler, or locate it in the appropriate Visual Modeler directory; for example, D:\Configurator\ViM\Audio\Audio.modelinfo.xml.	
<hr/>	
Model Name and Model Version Number	If you browsed to the model information file, the dialog box automatically fills these fields, reading from the file. Otherwise, enter the model name and version number.
UI Version Number (user interface version number)	Enter a unique number for your application. See and Advanced Configurator System Administration .

Inserting a Configurator Runtime Object

To insert a Configurator object into the active Document window:

1. Select Window, Objects.

The Dreamweaver Objects palette appears.

2. Click the down arrow in the upper right-hand corner of the Objects palette, and in the menu that appears, click Advisor.

The Advisor panel appears.

3. Drag and drop the object that you want to insert from the Advisor panel.

The object's insert dialog box appears.

Note. You can also insert Configurator objects from the Configurator item of the Insert menu.

4. Complete at least the required fields of the insert dialog box, and click OK.

For most of the Configurator objects, if you have not previously included CalicoProcessForm.jsp in your web application directory, a dialog box prompts you whether to include it.

5. Click OK.

CalicoProcessForm.jsp processes the Configurator form on your JSP page before CalicoProcessFormInc.jsp processes it in the normal way. By default, CalicoProcessForm.jsp does nothing, and adding it to your website has no effect. Modify this file only if you want to preprocess your Configurator form.

See [Chapter 26, "Using JSP Form Control Templates," page 351](#).

Inserting a Form

You need a Configurator form to process all of the other Configurator objects on the JSP page. All other Configurator objects on the page must be inserted in the same Configurator form.

You insert the Configurator Form object into the active Document window from the Advisor panel of the Dreamweaver Objects palette.

If you try to insert another Configurator object before you insert the Configurator form, a message prompts you to insert the form with the other object.

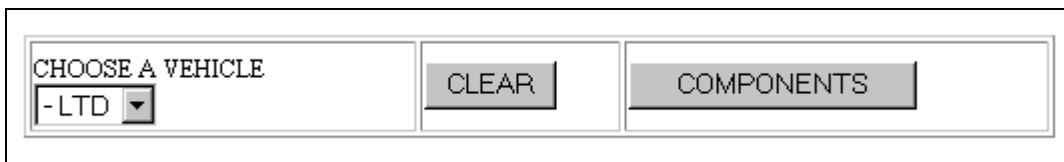

Warning! Do not use more than one Configurator form on a JavaServer Page.

Inserting a Button

A Configurator button does one of the following:

- Submits the page.
- Resets the page.

The submit button redirects to the URL that you set. The reset button sets picks on the page to the state that they had when the page was generated, and can redirect to another URL, if you want.

The screenshot shows a web form with a rectangular border. Inside, on the left, is a label "CHOOSE A VEHICLE" above a dropdown menu showing "- LTD" with a downward arrow. To the right of the dropdown are two buttons: "CLEAR" and "COMPONENTS".

Submit and reset buttons

CLEAR is a reset button. It sets the user's choice of a vehicle to what it was when the page was generated. COMPONENTS redirects to the URL of the page for choosing components.

Insert a Configurator Button object into the active document window from the Advisor panel of the Dreamweaver Objects palette.

Set the properties of a Configurator Button object in the Insert Calico Button dialog box.

Label	Enter a label for the button, such as CLEAR for a reset button, and GO TO PAGE 2 for a submit button.
Button Type	Click either Submit or Reset.
URL	Browse to the page that you want to redirect to, and click it. You need not set the URL for a reset button, if you want to remain on the same page.

Inserting a List

A Configurator List is one of the following:

- A drop-down list box for a single-select selection point.
- A text list for a multi-select selection point.

The drop-down list box initially displays only one item, but expands to display all of the items available for a selection point. The user can select only one item. The text list displays the number of items that you set, and scrolls through additional items, if any. The user can select one or more items.

A drop-down list and two text lists

PICK A VEHICLE is a drop-down list box of four items. The PICK COMPONENTS text list is set to display one item, and scrolls through three others. The PICK KITS text list is set to display three items. Because the selection point has only three items, the list has no scroll bars. Insert a Configurator List object into the active document window from the Advisor panel of the Dreamweaver Objects palette.

Inserting a Configurator List from the Advisor panel

Set the properties of a Configurator List object in the Insert Calico List dialog box:

ID	Enter an ID that is unique across all controls for your application.
Selection Point	Browse to the <ModelName>.modelinfo.xml file, click it, and choose one of the selection points in the drop-down list box. (The model information file is created when the model is created and compiled.)
Caption Type	Select either <i>text</i> or <i>image</i> from the drop-down list box.
String or Path	If you want the caption to be text, enter it. If you want the caption to be an image, browse to the image, and click it.
Control Size	Enter the number of items that you want to display. The user must scroll to see more items. (This field applies to only multi-select lists.)
Sort	Click to order picked items first in the list after a pick is submitted.
Show Eliminated	Click to display elimination levels, then enter the upper and lower limits, inclusive, for the elimination levels that you want to display. (The modeler defines elimination levels in the model.)
Show "None"	Select one of the items in the drop-down list box. First places the None item at the top of the list. Last places the None item at the bottom of the list. Do Not Show excludes a None item from the list. (This field applies only to single-select lists.)
Replace "None" With	Enter text to identify the item in the list that lets the user choose nothing. "None" is used if you leave this field blank.
First Item Text	For a single-select list, enter the name of the control item that you want to appear first in the list.
Events	Click, then enter the HTML syntax to handle an event for this control. For example: <code>onBlur = "foo()"; onClick= "foo2()"</code>

Attributes

Click, then enter the attributes that you want to include. Separate multiple attributes with commas. Attributes replace domain member names. To display attributes, the modeler should create an attribute for domain member names; for example, an attribute called "DomMbrName" or "Desc."

Note. If you want column headings for your attributes, you must use the Configurator Table object, which creates a radio-box group or check box group, with attributes in columns, and column headings.

Inserting a Group

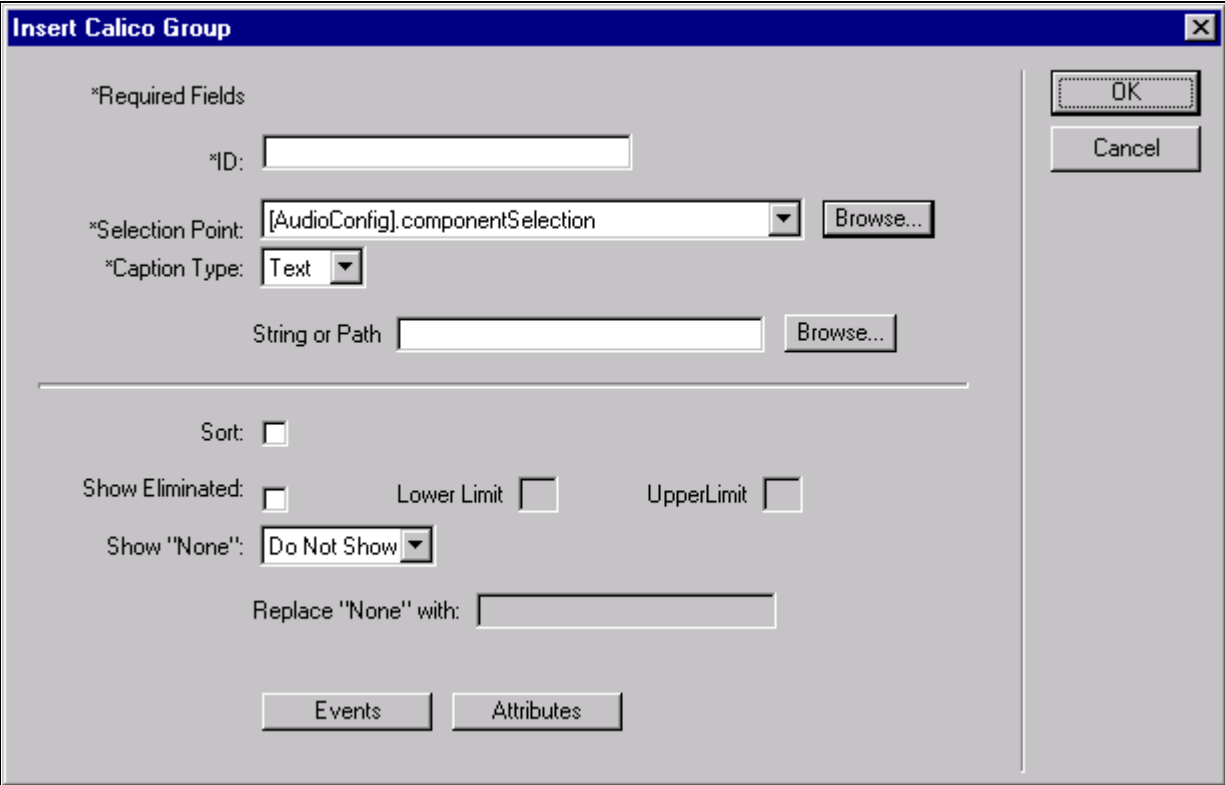

- A Configurator Group is one of the following:
- A radio-button group for a single-select selection point.
 - A check box group for a multi-select selection point.

With radio buttons, the user can select only one item. However, you can include an item at the top or bottom of the group to enable the user to select nothing, if the selection point is optional. With check boxes, the user can select one or more items, and can select nothing by clearing all of the check boxes.

SELECT A VEHICLE	SELECT COMPONENTS	SELECT KITS
<input type="radio"/> LTD	<input type="checkbox"/> RadioTapeCDSingle	<input type="checkbox"/> DashSpacer
<input type="radio"/> F150	<input type="checkbox"/> RadioTape	<input type="checkbox"/> Trunk
<input type="radio"/> XJ6	<input type="checkbox"/> RadioTapeCDmultiple	<input type="checkbox"/> UnderSeat
<input type="radio"/> Z3	<input type="checkbox"/> CDchanger	

A radio-button group and two check box groups

SELECT A VEHICLE enables the user to select only one vehicle. If the selection point is optional, you can include a None button at the top or bottom of the group to enable the user to select nothing. SELECT COMPONENTS and SELECT KITS enable the user to select one or more items, or nothing at all.

The dialog box is titled "Insert Calico Group" with a close button (X) in the top right corner. It contains several sections of controls. The first section, labeled "*Required Fields", includes an "*ID:" text box, a "*Selection Point:" dropdown menu currently showing "[AudioConfig].componentSelection" with a "Browse..." button to its right, and a "*Caption Type:" dropdown menu currently showing "Text". Below these is a "String or Path" text box with another "Browse..." button. A horizontal line separates this section from the next. The second section contains a "Sort:" checkbox, a "Show Eliminated:" checkbox, and two "Lower Limit" and "Upper Limit" checkboxes. Below these is a "Show 'None':" dropdown menu currently showing "Do Not Show", and a "Replace 'None' with:" text box. At the bottom are two buttons: "Events" and "Attributes". On the right side of the dialog, there are "OK" and "Cancel" buttons.

Insert Calico Group dialog box

To insert a group:

1. Insert a Configurator Group object into the active document window from the Advisor panel of the Dreamweaver Objects palette.
2. Set the properties of a Configurator Group object in the Insert Calico Group dialog box.

3. Set the following:

ID	Enter an ID that is unique across all controls for your application.
Selection Point	Browse to the <ModelName>.modelinfo.xml file, click it, and choose one of the selection points in the drop-down list box. (The model information file is created when the model is created and compiled.)
Caption Type	Select either <i>text</i> or <i>image</i> from the drop-down list box.
String or Path	If you want the caption to be text, enter it. If you want the caption to be an image, browse to the image, and click it.
Sort	Click to order picked items first in the list after a pick is submitted.
Show Eliminated	Click to display elimination levels, then enter the upper and lower limits, inclusive, for the elimination levels that you want to display. (The modeler defines elimination levels in the model.)
Show "None"	Select one of the items in the drop-down list box. First places the None item at the top of the list. Last places the None item at the bottom of the list. Do Not Show excludes a None item from the list. (This field applies only to single-select lists.)
Replace "None" With	Enter text to identify the item in the list that lets the user choose nothing. "None" is used if you leave this field blank.
Events	Click, then enter the HTML syntax to handle an event for this control. For example: <pre>onBlur = "foo()"; onClick= "foo2()"</pre>
Attributes	Click, then enter the attributes that you want to include. Separate multiple attributes with commas. Attributes replace domain member names. To display attributes, the modeler should create an attribute for domain member names; for example, an attribute called "DomMbrName" or "Desc."

Note. If you want column headings for your attributes, you must use the Configurator Table object, which creates a radio-box group or check box group, with attributes in columns, and column headings.

Inserting a Table

A Configurator Table is one of the following:

- A radio-button group for a single-select selection point.

This displays the button and attributes for each item in columns with column headings.

- A check box group for a multi-select selection point.

This displays the check box and attributes for each item in columns with column headings.

As with any radio button, the user can select only one item. However, with a Configurator Table object, you can include an item at the top or bottom of the radio-button group to enable the user to select nothing, if the selection point is optional. With check boxes, the user can select one or more items, and can select nothing by clearing all of the check boxes.

<p>DECIDE WHICH VEHICLE</p> <table> <tr> <th>Code</th> <th>Cost</th> </tr> <tr> <td><input type="radio"/> null</td> <td>null</td> </tr> <tr> <td><input type="radio"/> null</td> <td>null</td> </tr> <tr> <td><input type="radio"/> null</td> <td>null</td> </tr> <tr> <td><input type="radio"/> null</td> <td>null</td> </tr> </table>	Code	Cost	<input type="radio"/> null	null	<input type="radio"/> null	null	<input type="radio"/> null	null	<input type="radio"/> null	null	<p>DECIDE WHICH COMPONENTS</p> <table> <tr> <th>Code</th> <th>Cost</th> </tr> <tr> <td><input type="checkbox"/> cRTCDs</td> <td>179.99</td> </tr> <tr> <td><input type="checkbox"/> cRT</td> <td>99.5</td> </tr> <tr> <td><input type="checkbox"/> cRTCDM</td> <td>199.99</td> </tr> <tr> <td><input type="checkbox"/> cCDC</td> <td>63.75</td> </tr> </table>	Code	Cost	<input type="checkbox"/> cRTCDs	179.99	<input type="checkbox"/> cRT	99.5	<input type="checkbox"/> cRTCDM	199.99	<input type="checkbox"/> cCDC	63.75	<p>DECIDE WHICH KITS</p> <table> <tr> <th>Code</th> <th>Cost</th> </tr> <tr> <td><input type="checkbox"/> kDS</td> <td>12.5</td> </tr> <tr> <td><input type="checkbox"/> kT</td> <td>24.25</td> </tr> <tr> <td><input type="checkbox"/> kUS</td> <td>17.99</td> </tr> </table>	Code	Cost	<input type="checkbox"/> kDS	12.5	<input type="checkbox"/> kT	24.25	<input type="checkbox"/> kUS	17.99

<input type="checkbox"/> kDS	12.5																													
<input type="checkbox"/> kT	24.25																													
<input type="checkbox"/> kUS	17.99																													

A radio button table and two check box tables

DECIDE WHICH VEHICLE is a radio-button table. All of the items in it are null because the modeler did not assign values for the code and cost attributes for this selection point. DECIDE WHICH COMPONENTS and DECIDE WHICH KITS are check box tables. The modeler assigned values to the code and cost attributes for these two selection points. (Code and Cost are actually headings that the web designer assigned to these two attributes. The modeler named these attributes Abbreviation and Price.)

Notice that attributes replace item names. If you want to use the Configurator Table object, the modeler should create an attribute for the name of an item, so that you can display it.

To insert a table:

1. Insert a Table object into the active document window from the Advisor panel of the Dreamweaver Objects palette.

2. Set the properties of a Configurator Table object in the Insert Calico Table dialog box.

ID	Enter an ID that is unique across all controls for your application.
Selection Point	Browse to the <ModelName>.modelinfo.xml file, click it, and choose one of the selection points in the drop-down list box. (The model information file is created when the model is created and compiled.)
Caption Type	Select either <i>text</i> or <i>image</i> from the drop-down list box.
String or Path	If you want the caption to be text, enter it. If you want the caption to be an image, browse to the image, and click it.
Sort	Click to order picked items first in the list after a pick is submitted.
Show Eliminated	Click to display elimination levels, then enter the upper and lower limits, inclusive, for the elimination levels that you want to display. (The modeler defines elimination levels in the model.)
Show "None"	Select one of the items in the drop-down list box. First places the None item at the top of the list. Last places the None item at the bottom of the list. Do Not Show excludes a None item from the list. (This field applies only to single-select lists.)
Replace "None" With	Enter text to identify the item in the list that lets the user choose nothing. "None" is used if you leave this field blank.
Events	Click, then enter the HTML syntax to handle an event for this control. For example: <pre>onBlur = "foo()"; onClick= "foo2()"</pre>
Attributes	Click, then enter the attributes that you want to include. Separate multiple attributes with commas. Attributes replace domain member names. To display attributes, the modeler should create an attribute for domain member names; for example, an attribute called "DomMbrName" or "Desc."

Note. If you want column headings for your attributes, you must use the Configurator Table object, which creates a radio-box group or check box group, with attributes in columns, and column headings.

Column Heading

Enter the column heading for each attribute that you include. Separate multiple columns with commas.

Inserting an Image

The two image objects enable you to create a control for a single-select selection point that uses images to select a domain member:

- **Single-Select Image Control:** Generates an image to select one domain of a selection point.

You use the object multiple times to specify the image and location on the page for each domain member of a selection point. At runtime, selecting one image deselects another.

- **Image Table:** Generates either a column or a row of images for all of the domain members of a selection point.

You use it once to specify the image for every domain member of a selection point, and whether you want the images placed horizontally in a row, or vertically in a column. At runtime, selecting one image in the row or column de-selects another.

Single-Select Image controls, before and after selecting an image

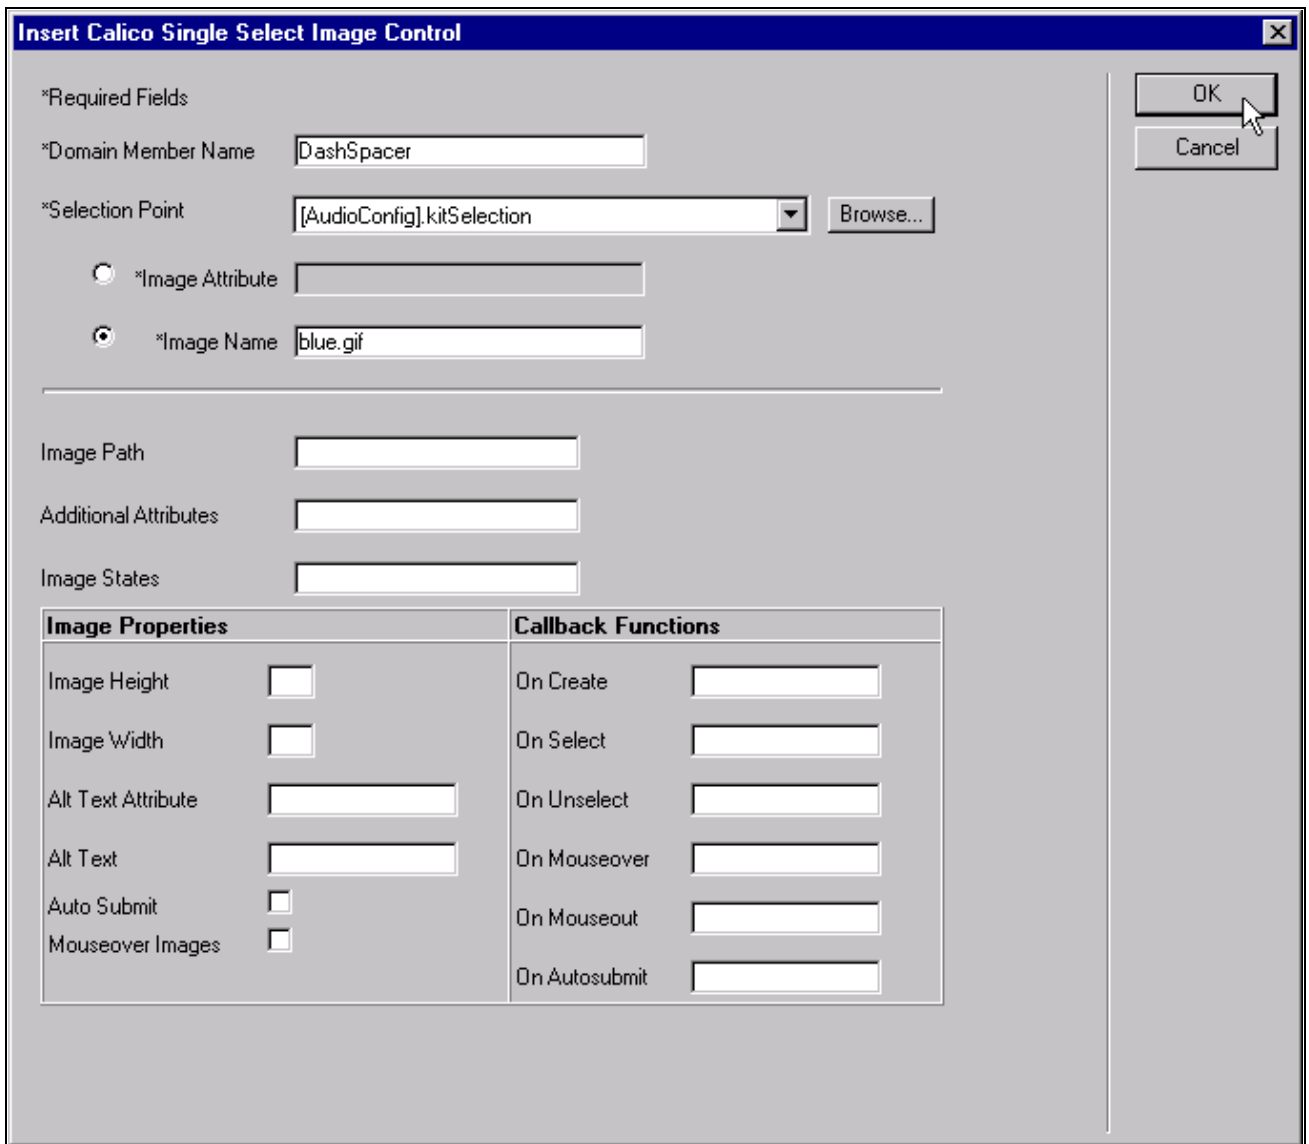

Single Select Image Table, before and after selecting an image

When the "selectable" green image is selected and submitted, it is replaced by a corresponding "selected" green image.

Note. The images of a Single-Select Table Image control are placed in a table row (in a table cell) and centered.

You set the properties of a Configurator Image object in one of the following dialog boxes:

Insert Calico Single Select Image Control

*Required Fields

*Domain Member Name:

*Selection Point:

☐ *Image Attribute

☒ *Image Name:

Image Path:

Additional Attributes:

Image States:

Image Properties		Callback Functions	
Image Height	<input type="text"/>	On Create	<input type="text"/>
Image Width	<input type="text"/>	On Select	<input type="text"/>
Alt Text Attribute	<input type="text"/>	On Unselect	<input type="text"/>
Alt Text	<input type="text"/>	On Mouseover	<input type="text"/>
Auto Submit	<input type="checkbox"/>	On Mouseout	<input type="text"/>
Mouseover Images	<input type="checkbox"/>	On Autosubmit	<input type="text"/>

Insert Calico Single Select Image Control dialog box

To insert a Single Select Image:

1. Insert an Image object into the active document window from the Advisor panel of the Dreamweaver Objects palette.
2. Specify the properties in the dialog boxes.

Because Image Table generates one control with images for every domain member of the selection point, whereas multiple instances of Single Select Image Control generate a control image by image, the dialog boxes differ from each another in that:

- Single Select Image Control requires a domain member name.

Image Table does not use domain member names.

- Image Table requires an image attribute in the Configurator model.
Single Select Image Control also accepts an image name.
- Image Table requires an alternative text attribute in the model.
Single Select Image Control also accepts an alternative text name.

Inserting Why Help

Configurator Why Help displays messages on constraints resulting from user picks. There are two types of Configurator Why Help:

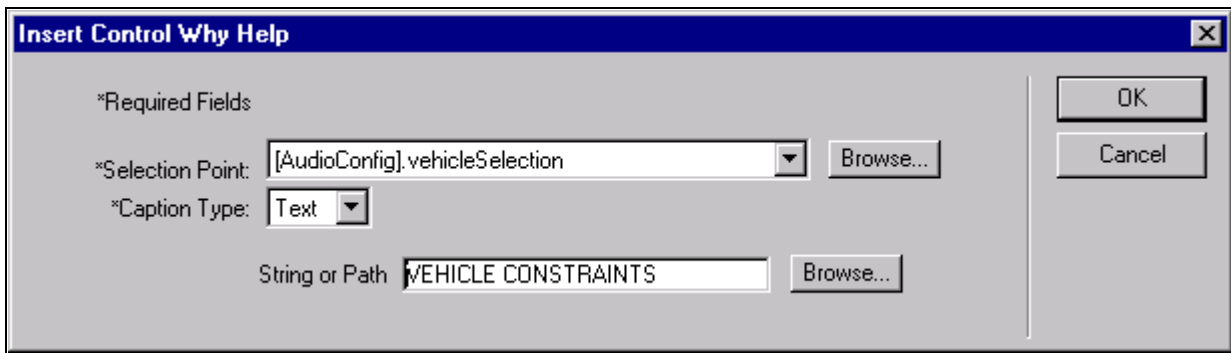

- Control Why Help: This object displays messages on constraints resulting from picks on the specified control.
- Application Why Help: This object displays messages on constraints resulting from picks anywhere in the application.

You can attach labels to the messages. The labels are displayed only when the messages are displayed.

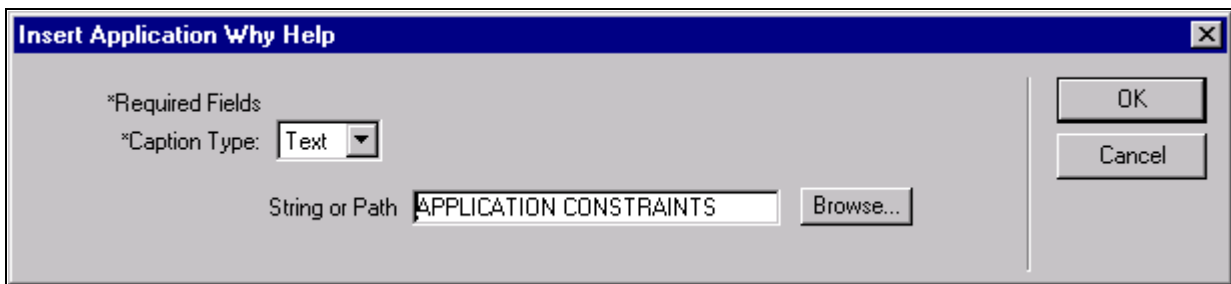

The screenshot shows a dialog box titled "HELP ON APPLICATION" in red text. Below the title, there are two red bullet points: "• Select at most one audio unit." and "• The LTD factory component is larger than your new system; a dash spacer is required. If your stereo has a multiple CD changer, pick either under seat or trunk installation." On the left side of the dialog, there is a section titled "CHOOSE KITS" with a "Price" header. Below this, there are three radio button options: a computer icon with a checked box next to "12.5", an unchecked box next to "24.25", and an unchecked box next to "17.99". At the bottom of the dialog, there are four buttons: "VEHICLE", "COMPONENTS", "CLEAR", and "DONE".

Two Application Why Help messages

You set the properties of a Configurator Why Help object in one of the following dialog boxes:

Insert Control Why Help dialog box

Insert Application Why Help dialog box

Selection Point

Browse to the <ModelName>.modelinfo.xml file, click it, and choose one of the selection points in the drop-down list box for which you want Control Why Help. (You do not set a selection point for Application Why Help, because it applies to all selection points in the model.)

Caption Type

Select either *text* or *image* from the drop-down list box.

Inserting a Numeric Data Object

The Configurator Numeric Data object displays a total—that is, a summation—for a numeric attribute of user picks, such as price, at runtime. The summation is preceded on the same line by a caption, followed by a colon (:).

Note. The modeler creates a selection point for each summation.

You can attach labels to the messages. The labels are displayed only when the messages are displayed.

Pick a Speaker SPEAKERS: - Altec Lansing 2000 - Cambridge SoundWorks SP	Pick a Printer PRINTERS: - HP Laserjet - Epson 1500	Pick a Scanner SCANNERS: - NEC Technologies PediScan - Fujitsu ScanPartner 15C - Canon DR5080C
Pick a Hard Drive HARD DRIVES: - 4.3 GB BATRA-33 - 8.4 GB BATA-33 - 13.6 GB BATA-33 - Quantum 27.3 GB SCSI		Pick a Monitor > No Monitor - 15 Inch Monitor - 17 Inch Monitor - 21 Inch Monitor
Submit Picks	Total Watts: 0.0	Clear Picks

Numeric Data for watts before submitting picks

Pick a Speaker >> Altec Lansing 2000 - Cambridge SoundWorks SP	Pick a Printer >> HP Laserjet - Epson 1500	Pick a Scanner - NEC Technologies PediScan >> Fujitsu ScanPartner 15C - Canon DR5080C
Pick a Hard Drive - 4.3 GB BATRA-33 - 8.4 GB BATA-33 >> 13.6 GB BATA-33 - Quantum 27.3 GB SCSI		Pick a Monitor - No Monitor - 15 Inch Monitor >> 17 Inch Monitor - 21 Inch Monitor
Submit Picks	Total Watts: 13.0	Clear Picks

Numeric Data for watts after submitting picks

Insert a Configurator Numeric Data object into the active document window from the Advisor panel of the Dreamweaver Objects palette.

Set the properties of a Configurator Numeric Data object in the Insert Numeric Data dialog box:

Insert Numeric Data dialog box

Selection Point

Browse to the <ModelName>.modelinfo.xml file, click it, and choose one of the selection points for numeric data—that is, the summation of a numeric attribute—in the drop-down list box. (The model information file is created when the model is created and compiled.)

Note. The modeler creates a selection point for each summation of a numeric attribute, and may constrain the summation to certain selection points. For example, the modeler may constrain a selection point called TotalPrice to the price (a numeric attribute) of HardDrive (one selection point) and PowerSupply (another selection point). At runtime, TotalPrice is the summation of the price attribute of all hard drive items and power supply items selected by the user.

Caption Type

Select either *text* or *image* from the drop-down list box. This caption precedes the numeric data on the same line.

String or Path

If you want the caption to be text, enter it. If you want the caption to be an image, browse to the image, and click it. The Numeric Data caption is displayed only when the numeric data is displayed.

Editing Properties of Advanced Configurator Objects

Each of the Configurator objects, except Form and Button, has a unique Dreamweaver Property inspector that enables you to edit the properties that you set when you inserted the object.

Property inspector for a Configurator List

To access the property inspector for a Configurator object:

1. In an active document window, select the Configurator object whose properties you want to edit.
2. Select Window, Properties.

The Property inspector appears.

3. If the arrow in the lower right-hand corner of the inspector is pointing down, click it to expand the Property inspector.

Editing Forms and Buttons

Configurator forms and buttons don't have a property inspector in which to change their property values. To achieve a form or button with different properties, delete it, then reinsert it, setting the desired properties on the new object.

Warning! The action type for both Configurator buttons is *submit*. Do not set the action type of any Configurator button to *reset* in either the standard Property inspector or HTML source.

Editing Lists, Groups, and Tables

The Property dialog boxes for Configurator List, Configurator Group, and Configurator Table are similar.

Chapter 28

Compound Modeling

This chapter provides an overview of the compound model at run time and discusses how to:

- Use the compound model JSP pages.
- Call the compound model API.
- Create an application from the sample.

Understanding the Compound Model at Run Time

PeopleSoft Advanced Configurator offers the functionality for developing a Web application that lets your user configure products based on a compound model.

Creating a compound model involves these steps:

1. Create the standard models.

Using the PeopleSoft Visual Modeler, create a model for each configurable component of your services offering. Decision points in each component can receive values from connected components, and use them in constraints, creating cross-constrained models.

2. Create a compound structure.

Also using the Visual Modeler, define which configurable components from the standard models to include in your offering, and how they connect to one another.

3. Create a user interface.

Using Configurator compound model APIs and JavaServer Pages, create an interface that lets your user dynamically create, configure, and connect instances of your configurable components.

Runtime Capabilities

PeopleSoft Advanced Configurator lets your user not only create a compound model configuration, but change it and generate a change order. It also lets your user save both the original and the revised configuration, and later retrieve information on changes between the two versions.

Configurator JavaServer Pages that you can use in your Web application let your user retrieve information on configuration changes. The pages are described in the following sections:

See [Chapter 28, "Compound Modeling," Creating an Application from the Sample, page 410.](#) and [Chapter 28, "Compound Modeling," Using Compound Model JSP Pages, page 407.](#)

A compound configuration must be able to add, delete, move, and change services (such as Web access or call forwarding in the sample application) on an ongoing basis. To generate a change order, the provider must be able to identify the following changes to the product configuration:

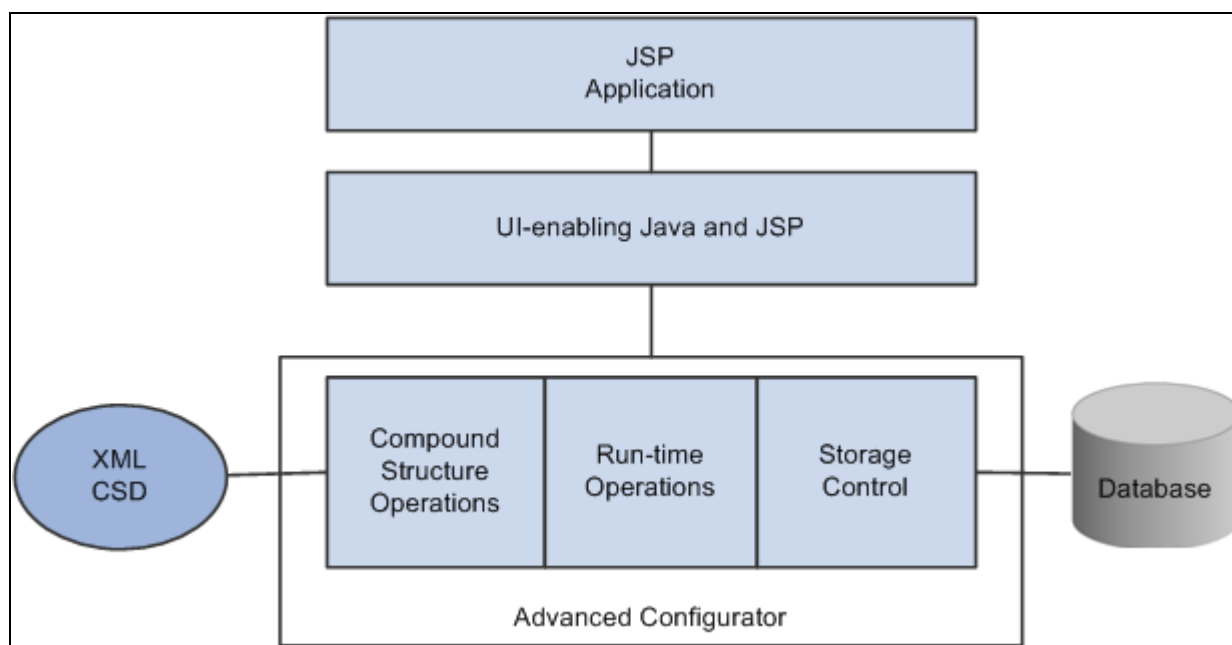

- Whether a component has been deleted.
- Whether a component has been added.
- Whether a component has moved.
- Whether a component has changed and how it has changed.

Deleting, adding, and moving a component is considered a structural change—that is, a change to the structure of the configuration. Revising how a component is configured does not change the structure of the configuration, and is considered to be a component change.

The Configurator has APIs to retrieve information on both structural and component changes made during the user's session. It also has APIs to retrieve configurations by date, which in turn let you retrieve information on changes in the configuration between two points in time.

Architecture

Compound structure components extend the Configurator, which runs on the WebLogic application service. The compound structure extensions include Java classes and JavaServer Pages.

Compound Structure Component Hierarchy

Some Compound Structure Java classes work behind the scenes to let you:

- Create multiple instances of models and configure them.
- Constrain the selection point of one model against the selection point of another model.

Other Compound Structure Java classes give you a public API that lets you create JavaServer Pages that let your user dynamically create, configure, and verify a configuration based on a compound model.

See Also

[Chapter 26, "Using JSP Form Control Templates," page 351](#)

Using Compound Model JSP Pages

Configurator provides JavaServer Pages that you can include in your Web application to let your user configure components and connect them, and then save the configuration.

In many cases, you may want to change the JavaServer Pages to suit your particular application. They illustrate how to make Configurator calls to accomplish various tasks.

Note. Configurator also has JavaServer Pages for a sample application. The sample application pages use the pages described in this chapter to create a Web application.

See [Chapter 28, "Compound Modeling," Creating an Application from the Sample, page 410.](#)

If you installed Configurator to the D drive, the JavaServer Pages for configuring and connecting components and for saving a configuration are in the following folder:

```
D:\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\solutions⇒  
\CompoundSample
```

The `networkadvisor` folder includes these categories of JavaServer Pages:

- Components—to let your user add, delete, and change components.
- Connections—to let your user add, delete, and change connections.
- Configurations—to let your user log in, and verify, save, and load a configuration.
- Changes—to let your user view information on changes that have been made to components and connections over time ("delta information").
- Application—central pages to let your user access the other pages, and pages containing common features.
- Form—to let your user edit the name of a component.

Components

Three JavaServer Pages let your user add, delete, and edit a component. (You can also move a component such as a hub, node, or circuit by editing a connection.)

They are:

```
CalicoNAAddComp.jsp
```

CalicoNADeleteComp.jsp

CalicoNAEditComp.jsp

Connections

Three JavaServer Pages let your user add, delete, and edit a connection:

CalicoNAAddConn.jsp

CalicoNADeleteConn.jsp

CalicoNAEditConn.jsp

Configurations

Five JavaServer Pages let your user log in, and verify, save, and load a configuration:

Page	Purpose
CalicoNAIdentification.jsp	Lets the user log in to your Web application.
CalicoNAVerify.jsp	Lets the user verify and display errors about whether the configuration is valid.
CalicoNASaveConfig.jsp	Lets the user save a configuration.
CalicoNALoadConfig.jsp	Lets the user load a saved configuration.
CalicoNAErrorInc.jsp	Displays various error messages to the user during the configuration session.

Changes

Two JavaServer Pages let your user view changes made to a compound configuration.

Page	Purpose
CalicoNAViewDeltas.jsp	Lets the user view which components and connections have been added, deleted, and moved.
CalicoNAViewDeltaDetail.jsp	Lets the user view a detailed change history for each component.

Application

Seven JavaServer Pages implement the sample application. Because they are included in other JavaServer Pages, their names end with Inc. You can use them as examples for JavaServer Pages to implement your own application.

Two JavaServer Pages help you display and navigate to other JavaServer Pages.

Page	Purpose
CalicoNAMangerInc.jsp	Lets the user view all of the components and connections.
CalicoNANavigateInc.jsp	Displays buttons on the Manager page to let your user choose to log in, and verify, save, load, and view changes to a configuration.

Four JavaServer Pages provide a common set of features for all of the sample application pages, except those used to configure the individual models of the compound configuration.

Page	Purpose
CalicoNAConstantsInc.jsp	A collection of constants used by Configurator JavaServer Pages.
CalicoNACommonInc.jsp	Contains a collection of common imports and properties for the application object and compound configuration.
CalicoNAHeaderInc.jsp	An include file that you can use to put the Configurator banner at the top of a page.
CalicoNAUtilityInc.jsp	A collection of utility functions, such as those used for logging errors.

Form

CalicoNAFormInc.jsp lets the user edit the name of a component.

Calling the Compound Model API

PeopleSoft Advanced Configurator has an API that lets you do the following:

- Structure a compound model from configurable components.
- Create multiple instances of configurable components.
- Create multiple instances of connections.
- Create, verify, save, and restore a compound configuration.

The Configurator JavaServer Pages contain examples of the use of the API, and can be altered to use in your application.

The Configurator compound modeling API consists of the following packages:

File	Purpose
calico.cms.definition	Handles parsing of the XML compound structure definition (CSD) and provides an API for accessing compound structure information.
calico.cms.dm	The data management package, which is used to access the database in order to store and retrieve compounds, components, and connections, and to retrieve compound delta information.

File	Purpose
calico.cms.runtime	Used for managing compound configurations at run time.
calico.cms.exceptions	Contains exceptions thrown by classes in the other compound modeling packages.
calico.cms.cache	Provides methods for accessing and managing the set of compound structures on the server
calico.cms.servlet	Contains a servlet class which provides an HTML interface for managing the compound structures on the server.

The Configurator installation also contains the JavaDoc for the following:

File	Purpose
calico.configurator.cop	This is the Configurator API. It includes modifications that have been made for Configurator.
calico.configurator.exceptions	exceptions thrown by the Configurator API (COP).

Creating an Application from the Sample

The Configurator includes a sample Web application, called TelcoSample, that demonstrates the basic features of a complex product application.

Its JavaServer Pages for the sample are located in:

```
\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\solutions\CompoundSample\
```

The sample includes:

- XML representation of a compound structure definition that has three configurable components—Node, Hub, and Circuit.
- Source files for the three component models.
- Web application JavaServer Pages that call the compound model API and employ Configurator JavaServer Pages.

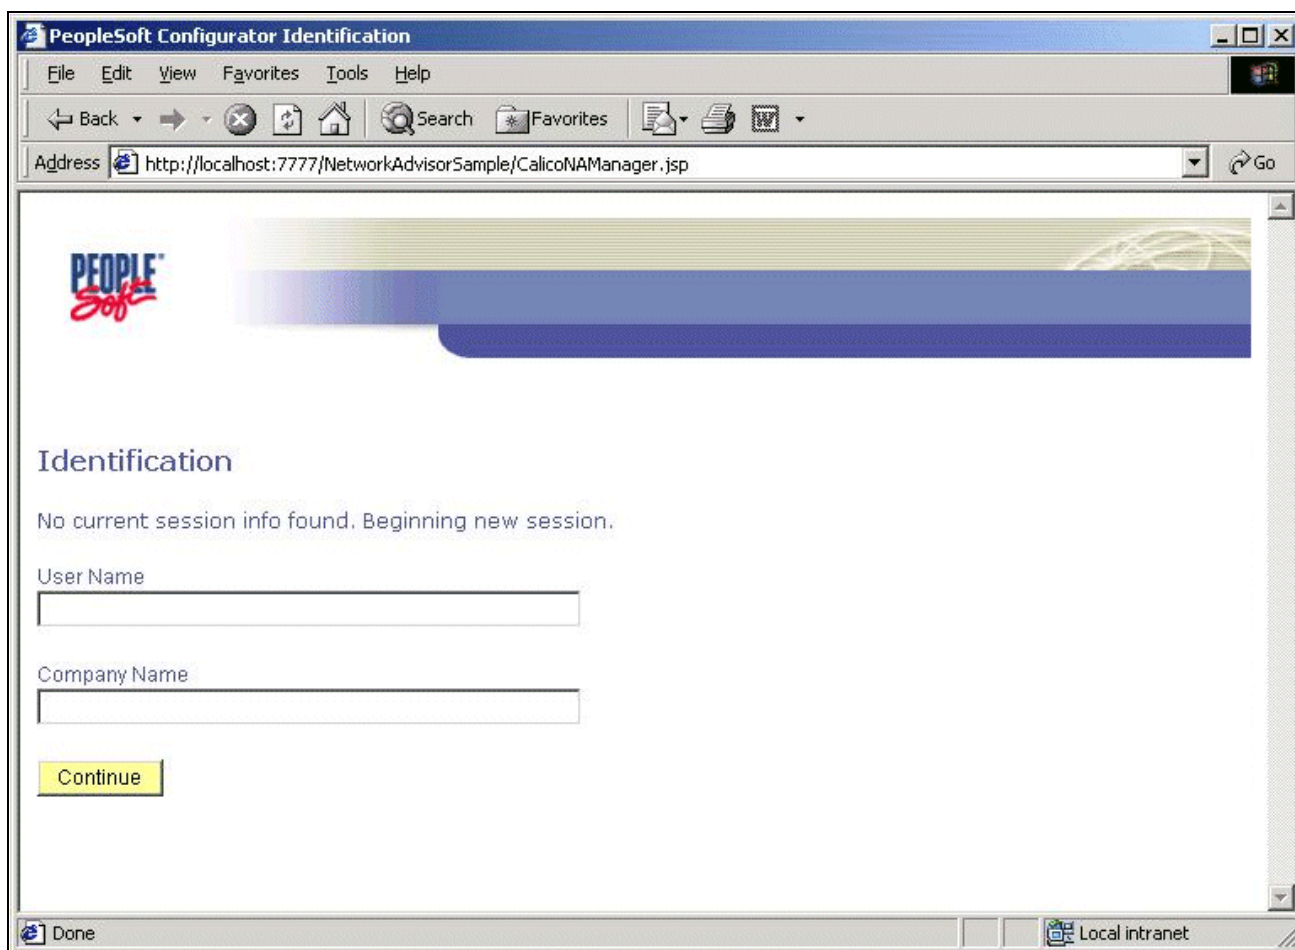

Viewing the Sample Application

This section tells you how to install the sample application, and describes each of its parts. It then shows you how to use the application to configure, save, restore, and reconfigure a network of communication services, and to obtain the delta between the first and second configurations.

To launch the sample application:

1. Make sure that the WebLogic application server is running.
2. From your browser, call the following URL for the application's index page:

`http://<hostname:port>/solutions/CompoundSample/CalicoNManager.jsp`

Sample application login page

Node-Hub-Circuit Services

The sample application's compound structure definition has three configurable components, and three connections (or relationships). It does not use Type or Instance elements.

See [Appendix E, "Node-Circuit-Hub Service," XML Representation of Compound Structure Definition, page 476.](#)

Configurable Components

The sample application has three components.

Node

A node is defined by the standard model TelcoComp. By creating a node (using "Add New Component") TelcoComp, and clicking on its name in the Manager page, you can see the decision points and choices of the nodes. The decision points are: Protocol, Access Option, Local Loop Service, CPE, Port Speed, and Local Loop Port Speed.

Hub

A hub is defined by the standard model TelcoCompHub. By creating a hub (using "Add New Component") in your standard model, and clicking on its name in the Manager page, you can see the decision points and choices of the hubs. The decision points are: Protocol, Access Option, and Port Speed.

Circuit

A circuit is defined by the standard model TelcoCompCircuit. By creating a circuit (using "Add New Component") in your standard model, and clicking on its name in the Manager page, you can see the decision points and choices of the nodes. This model defines a circuit with one decision point: circuit speed.

Relationships

The sample application has three relationships.

Connection

A connection is an element of Configurator that can be used to connect to configurable components. You can create new connections (using "Add New Connection"). Each connection is listed on the Manager page, along with the two components it connects. By clicking on the connection name, you can edit it.

The XML CSD (created with the Visual Modeler) for the sample application defines the connection, and in particular what information from one component can be used by another component when they have a connection between them. In this sample application, the CSD says:

- A circuit must have at least 1 and at most 2 connections.
- A circuit can connect to 0 to 2 nodes, and to 0 to 2 hubs (inclusive).

Note. These two rules give us the following possibilities: circuit-node, circuit-hub, node-circuit-node, hub-circuit-hub, and node-circuit-hub.

- A circuit can access the port speed choice of any component it is connected to. The circuit's names for these port speed choices are Ext_PortSpeedSelection_A and (if the circuit is connected to a second component) Ext_PortSpeedSelection_B.
- A circuit can access the protocol choice of any component it is connected to. The circuit's names for these protocol choices are Ext_ProtocolSelection_A and (if the circuit is connected to a second component) Ext_ProtocolSelection_B.

In its own (standard) model, the circuit can use these port speeds and protocols to constrain its own domain members. This is how cross-constrained models are created.

HubCircuits

According to the XML CSD definition of the HubCircuits relationship for the sample application, a hub can be connected to 1 to 24 circuits (inclusive). The hub has access to the collection (set) of the port speeds of all the circuits connecting to it. The hub's name for this set is Ext_PortSpeeds.

In its own (standard) model, the hub can use Ext_PortSpeeds to constrain its own domain members. Because Ext_PortSpeeds is a set, the model will probably apply an operator like "max" or "sum" to it.

NodeCircuit

According to the XML CSD definition of the NodeCircuit relationship, each node must be connected to exactly one circuit.

Modeling Node-Hub-Circuit Services

The sample application has three models with cross-constraints:

- TelcoComp—for a node.
- TelcoCompHub—for a hub.
- TelcoCompCircuit—for a circuit.

You can look at each model and see the use it makes of the cross-constraints that compound modeling makes available. For example, TelcoCompHub has a constraint that says "the port speed of the hub must be greater than or equal to the maximum of the port speeds of all the circuits connecting to the hub."

Configuring Node-Hub-Circuit Services

The sample application lets the user do the following:

- Create a compound Node-Hub-Circuit configuration, and save it.
- Restore a saved configuration, and reconfigure it.
- Obtain the delta between the first and second configuration.

Creating a Compound Configuration

On the Load Configuration page, use the New Configuration button to create a new configuration. This displays the Manager page. On the Manager page, create the components (in the sample application, hubs, nodes, and circuits) by using the Add New Component button. Then create connections between these components by using the Add New Connection button.

Reconfiguring a Compound Configuration

To add a new component or connection, use the Add New Component or Add New Connection button on the Manager page.

To delete a component or connection, click on that component's or connection's trash can icon on the Manager page.

By clicking on the name of a connection on the Manager page, you can edit the connection, including changing its name and changing which components it connects. You can move components in your compound model by editing the connection that connects the components.

By clicking on the name of a component on the Manager page, you can edit the component, including changing its name and making new choices for its decision points.

Obtaining the Configuration Delta

Clicking on the "View Deltas" button on the Manager page will take you to the View Deltas page, which has a list of all the model's components and connections and their modification date. By clicking on the name of a component or connection, you can view more detailed delta information for that element.

Part 7

Advanced Configurator System Administration

Chapter 29

Understanding Advanced Configurator Administration

Chapter 30

Using Administration Tools

Chapter 31

Maintaining the Advanced Configurator System

Chapter 29

Understanding Advanced Configurator Administration

Advanced Configurator provides two tools to help with the development, testing, and deployment of a model:

- Administration Console
- Solution Tester

Chapter 30

Using Administration Tools

Designing and developing a model begins with the PeopleSoft Visual Modeler. The model defines selection points, domain members, and constraints. Domain members and constraints can be stored externally.

After you create the mode, you build the web site application using extensions for Dreamweaver, or more directly, using the PeopleSoft JSP templates for HTML form controls. Your web site application connects standard HTML form controls to your model.

At runtime, the web site sends user picks to the PeopleSoft Configurator engine through the Web Client Processor and the Client Operations Processor (COP). The engine processes the picks and returns the state of each item in the form controls to the web site. The engine also returns explanations for constraints that have been violated.

If the model has external domain members or constraints, the engine gets them from the Configuration Data Manager. If the model has pricing, the Client Operations Processor calculates the pricing information.

The diagram on the next page shows PeopleSoft Configurator's design, compile, and runtime environments.

Administration Console

PeopleSoft Configurator Administration console helps you develop, test, and deploy both component models and compound models.

The Administration console can internalize model data. It can import externally referenced model data and translate it into internally defined data. The model then becomes self-contained. The console can internalize data that is stored in a database as well as attribute list files.

On Windows NT, start the Administration tool by clicking Start and selecting Programs, PeopleSoft Applications, Configurator 9.1, Administration.

Alternatively, access the console directly from a browser with the uniform resource locator (URL) `http://<host>:<port>/ConfigServerAdmin`.

PeopleSoft.

ATMFrameSite 8.9.0	Deploy Remove Deploy Remove Update Data

Configurator Administration console

The Administration console enables you to do the following actions with an Advanced Configurator component model:

- Compile

You can compile a model that is anywhere on the network, using any server on the network. To compile, select the model's XML file, the server, and the port.

- Run

You can run the compile version of any model on the network. This launches the PeopleSoft Configurator Model Tester, which the PeopleSoft Visual Modeler also uses to test models. With the test client, you can submit the model with various options—such as pricing, auto-submission, sorting, and formatting—and reset the model.

- Deploy

You can deploy a model from anywhere on the network to any host server and port on the network. Deploying a model copies it to another machine for use there. You can deploy a compile version of a model, a major version of a model, or all versions of a model.

- Disable

You can disable a compile version of a model that is anywhere on the network. Disabling a model restricts its use to the Administration console, which can still run the model. If a model is disabled, the test client or a midtier application can't run it. Disabling a model does not delete it.

- Enable

If a model is disabled, you can enable it.

- Remove

You can remove—that is, delete—a model (including a compound model) from the network. You can remove a compile version of a model, a major version of a model, or all versions of a model.

Warning! During a model compile, the model version number is incremented based on the latest version of the model that is present on the server. Therefore, do not remove the latest version of a model before you recompile, because the new version may be given the version number of the deleted latest version.

Note. Removing the model from the server doesn't cause the model to be removed from server memory if it has been loaded into memory. The server must be restarted to force the model to be removed from memory. The model load settings for the server may also need to be changed.

- Update data

You can update any version of a model with model data (domain members and constraints) that is stored in an external database.

- Generate a self-contained model

If a model's data is stored externally, you can read that data into the model for internal storage and access. That compilation of the model then becomes self-contained and can be deployed in a configuration environment needing no access to the product database. You can also include additional attributes in the internalization process.

Note. The Visual Modeler can also internalize data; however, it can internalize only data that is used within the model. Externally referenced data that is not used in the model, such as descriptions, can't be internalized by the Visual Modeler.

Furthermore, the internalize processes in the Visual Modeler are a one-time effort. After a model is internalized in the Visual Modeler, the source is internal and all subsequent compilations produce versions that are internal as well.

- View

You can view the following types of files that are created in the compile version directory when a model is compiled: GCL, RTP, SGCL, TMAP, and XML. This lets you describe the state of these files if you need help.

In addition, the Administration console enables you to manage compound models:

- Upload

You can upload a compound model (in XML format) to the server.

- Cross-check

You can verify a compound model against its component models to verify that selection points and domain members that are required by the compound model exist.

- View

You can view a compound model in XML format.

Note. The Administration console does not provide security, but is based on industry standards for security. The information technologist and system administrator must provide and limit access to PeopleSoft Configurator servers on the network.

Testing Solutions

You can use the Solution Tester to develop and test Configurator solutions outside of the complete CRM environment.

The Solution Tester simulates the integrated CRM/Configurator environment, enabling you to test a solution without setting up configurable products or creating quotes or orders.

The Solution Tester enables you to test:

- Model operation.
- Page display.
- User interaction.
- Configuration pricing.
- Configuration details request and display.

It also provides access to parameters and details about the operation of the solution that aren't available in normal operation within the CRM environment. The Solution Tester runs completely within the Configurator Server.

The Solution Tester is organized into three sections. The top section contains a number of buttons that perform the operations that are provided by the Solution Tester. The middle section displays the results of the operations, including the user interface for a solution and the display of the configuration details for a particular solution configuration. The bottom section allows values to be specified that are passed into the Configurator solution when it is launched. These sections are described in detail in the following section.

Page Used to Test Solutions

The Solution Tester top panel controls the tester operations and displays the status that is returned from certain operations.

Access the Solution Tester page by selecting Start, Programs, PeopleSoft Applications, Configurator 9.1, Server Index Page. Then select Solution Tester.

Solution	ATMFRAME	New	Restore	ConfigID		View Details
		Copy				View Details - XML
		List Configurations		RetCode		Save order
						Submit order
						Cancel order
						Delete order

Solution Tester page

New

Start a new configuration.

Clicking the New button starts a new configuration using the solution that was selected in the solution drop-down list. The solution's user interface is displayed in the center section of the Solution Tester. Interaction with the interface allows a new configuration to be created (see Configuring).

The New operation requires that a valid solution be selected in the solution drop-down list. The ConfigID and RetCode fields are cleared when you start a new configuration.

Restore

Restore an existing configuration.

Clicking the Restore button restores an existing configuration from the database. The solution's user interface appears in the center section of the Solution Tester with the current configuration values. Interaction with the interface modifies the current configuration (see Configuring).

The Restore operation requires that you select a valid solution in the Solution drop-down list and specify the Configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field. When you restore a configuration, the RetCode field is cleared.

Configuring

Configuring (from New or Restore).

Solutions that are designed to run within the integrated CRM/Advanced Configurator environment usually provide buttons that enable the user to exit the configuration without saving the current changes, or to save the current configuration and return (the labels on the buttons are defined in the user interface for the solution and cannot be Cancel and Return). Clicking these buttons on a solution's user interface within the Solution Tester initiates the same operations. Clicking Cancel returns the center section to the No Solutions Loaded state without saving the configuration. Clicking Return saves the current state of the configuration, updates the ConfigID and RetCode fields, and initiates the operation of retrieving and displaying the configuration details.

The status codes that are returned are:

0: Success.

101: Solution not found.

102: Invalid Config ID or Error restoring the configuration.

103: Error saving the configuration.

104: Error creating the configuration.

Copy

Copy an existing configuration.

Clicking the Copy button makes a copy of an existing configuration. A new configuration ID is returned and the ConfigID field is updated.

The Copy operation requires that you select a valid solution in the Solution drop-down list and specify the Configuration ID for an existing (saved) configuration of the appropriate solution type in the ConfigID field.

The status codes that are returned are:

0: Success.

101: Solution not found.

102: Invalid Config ID or Error restoring the configuration.

103: Error saving the configuration.

104: Error creating the configuration.

List Configurations

List the saved configurations. Clicking this button displays information about the configurations that is currently saved in the database. If you select a solution in the Solution drop-down list, only configurations of that type are displayed. If you don't select a solution, all of the saved configurations are displayed. Selecting a configuration from the list updates the Solution and ConfigID fields for use with the other operations.

View Details

View configuration details.

Clicking the View Details button requests, retrieves, and displays the returned configuration details for a configuration. The details are formatted using the style sheet that is defined for the solution.

For easy modification and testing, you can select the request (XML) and style sheet (XSLT) to use in the following way:

1. The Solution Tester checks the solution test directory (by default, `C:\bea_cfg\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\calico\solutiontest`) for a request XML file with the name `<solutionname>.xml` and for a style sheet XSLT file with the name `<solutionname>.xslt` (where `solutionname` is the name of the solution used for the configuration). If these are found, they are used for the request XML and the result formatting style sheet XSLT respectively.
2. If appropriate files are not found, the Solution Tester queries the database for the associated solution schema and attempts to retrieve the request XML and formatting style sheet XSLT that are defined by the schema.
3. If request XML and formatting XSLT cannot be found in the solution schema, or a solution schema cannot be found, the Solution Tester uses the default details request XML and formatting style sheet XSLT files in the solutiontest directory (`ConfigDetailsRequest.xml` and `default.xslt`).

The XML and XSLT data are read every time the details are requested. This sequence allows custom request XML and formatting XSLT to be tested, modified, and retested easily.

The View Details operation is automatically invoked when you return from a New or Restore operation using the return operation on the solution's user interface.

The View Details operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field.

View Details - XML

View request, response, and style sheet XML.

Clicking this button performs the same sequence of steps as the View Details button, except that the raw XML for the details request, details response, and formatting XSLT appears. Also provided is information indicating the source location and the size of the details request, and formatting XSLT. The three pieces of data are formatted into an XML document with the following structure:

```
<_details>
  <_request>
    [details request XML]
  </_request>
  <_response>
    [details response XML]
  </_response>
  <_stylesheet>
    [XSLT]
  </_stylesheet>
</_details>
```

The View Details- XML operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field.

Save order

Change the order status of the configuration to *saved*. The Save Order operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field. When you save an order, the *RetCode* field is cleared.

Submit order

Change the order status of the configuration to *submitted*.

The Submit order operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field. When you submit an order, the *RetCode* field is cleared.

Cancel order

Roll back the current configuration to the state it was in when the order was last saved.

The Cancel order operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field. When you cancel an order, the *RetCode* field is cleared.

Delete order

Roll back the current configuration to the state it was in when the order was last submitted

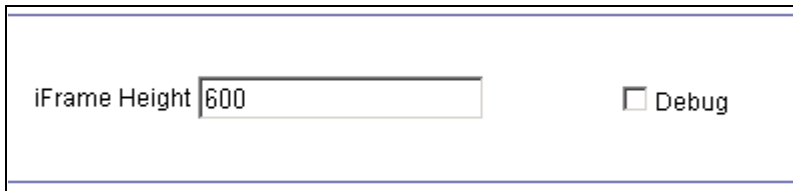

The Delete order operation requires that you select a valid solution in the Solution drop-down list and specify the configuration ID for an existing (saved) configuration of the appropriate type in the ConfigID field. When you delete an order, the *RetCode* field is cleared.

Accessing the Solution Tester

To access the Solution Tester pages, select Start, Programs, PeopleSoft Applications, Configurator 9.1, Server Index Page.

From the Server Index Page, click Solution Tester.

Note. If "500 - Internal Server Error" appears rather than the tester page, verify that your database server is running and that the database entry for Advanced Configurator is valid. This information is entered during Configurator installation and stored in
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp
\\WEB-INF\config\JNDIDBName.properties.

The screenshot shows a web form with two elements: a text input field labeled "iFrame Height" containing the value "600", and a checkbox labeled "Debug" which is currently unchecked.

Solution Tester parameters

iFrame Height

This parameter controls the height in pixels of the center (output) section of the Solution Tester.

Debug

This sets a flag within the Solution Tester and passes a debug parameter to the Configurator solution (debug=false or debug=true). You can use the value of this parameter within a solution user interface to control debugging messages and other debugging or testing operations. When Debug is selected, the Solution Tester sends messages to the console window of the Configurator Server containing information about the operations that are being performed.

Understanding the Output and Solution User Interface

The large main panel displays the results of the operations, including the user interface for a solution when you are performing the New or Restore operations.

Because the main panel is an inline frame (iframe), it may contain an independent scroll bar, depending on the height of the content compared to the height of the iframe. When initiating an operation, you can set the height of the iframe using the iFrame Height field in the bottom section (the height cannot be changed during an operation).

The full URL that the Solution Tester uses to initially navigate the frame appears. This allows inspection of the values that are initially passed to the Configurator solution for New and Restore operations.

Every effort has been made to make the Solution Tester environment (the environment that is provided to the solution running within the tester) match that of the runtime environment of the CRM applications with which the Configurator integrates. However, some technical limitations prevent the two environments from being identical. Therefore, some differences might exist in operation between the Solution Tester and the actual CRM runtime environment.

In many cases, identifying and correcting these differences can help provide a better, more robust solution by identifying environment-specific functionality. You should carefully review differences to determine whether the solution is relying on functionality that may not be the same on every platform or environment.

In all cases, you should thoroughly test within the actual CRM runtime environment before deploying a new or updated solution.

Setting Configuration Solution Parameters

Scroll to the bottom panel of the Solution Tester page:

The screenshot shows the bottom panel of the Solution Tester interface. It contains several input fields for configuration parameters:

- Property File:** A dropdown menu set to "- default -".
- BusinessUnit:** Text field with value "US001".
- CaptureID:** Text field with value "11111".
- Channel:** Text field with value "A".
- CurrencyCD:** Text field with value "USD".
- CurrencyCDBase:** Text field with value "USD".
- CustomerID:** Text field with value "112233445566".
- DBName:** Text field.
- LanguageCD:** Text field with value "ENG".
- LineNbr:** Text field with value "1".
- Qty:** Text field with value "1".
- UOM:** Text field with value "EA".
- UserID:** Text field with value "USER1".
- Date (YYYYMMDD):** Text field.
- ProductID (blank = Solution ID):** Text field.
- KeepNew:** Text field with value "TRUE".
- Additional URL Parameters:** Text field with value "moreParms=abc123".
- iFrame Height:** Text field with value "600".
- iFrame Width:** Text field with value "800".
- Debug:** A checkbox.

Example Solution Tester page (2 of 2)

The bottom panel contains a number of fields that enable you to specify parameter values that are passed to the Configurator solution. The parameters that are passed are the same as those that are passed from the CRM applications when you are interfacing with the Configurator. Additional, user-defined parameters can also be passed.

You can modify the values for these parameters before performing operations. When an operation is initiated, changes to the parameter values do not take effect until you initiate a new operation. For instance, after you have started a new configuration by clicking the New button, changing the value of BusinessUnit has no effect until you start another operation, such as starting a new configuration or restoring an existing one.

The labels on the parameter value fields match the names of the parameters that are passed to the Configurator solution. The initial values for the fields are taken from a combination of values that are read from property files (text files in a specific format) and default values that are contained in the Solution Tester. The parameter fields are updated with values when you first open the Solution Tester or when you select a new property file in the Property File list.

The Solution Tester determines the values to use for each parameter in the following sequence:

1. It looks in the property file that is identified by the Property File list. If it finds a parameter=value pair for this parameter, it uses the value that is specified.

2. If it doesn't find an appropriate parameter entry, it looks in the default property file (SolutionTest.properties, in the solutiontest directory).
3. If it doesn't find a parameter entry in the default property file, it uses a default value that is defined within the Solution Tester.
4. If it doesn't find a default value, it leaves the field blank.

The Solution Tester populates the Property File list with the names of the property files that it finds in the solutiontest directory. The example property file ExternalChannel.properties is included with the installation. This file contains the following code:

```
# This file contains specific properties that should be used in place of
# those in the 'default' properties file (SolutionTest.properties)
#
# Channel can be 'A' (internal) or 'W' (external/web)
Channel=W
```

Notice that the only entry is for the parameter to override. All other values are read from the default property file or the Solution Tester defaults, or they are omitted. If you create a new property file while you are using the Solution Tester, you need to open a new instance of the Solution Tester for it to be added to the Property File list. The Additional URL Parameters field allows any number of additional parameters to be passed to the Configurator solution.

Enter additional parameters in the following way:

- To pass a single additional parameter, enter: `parameter=value`.
- To pass more than one parameter, enter:
`parameter1=value1¶meter2=value2¶meter3=value3`.

Model Tester

Configurator also includes a web-based interface that you launch from the Visual Modeler with the Run command.

The Model Tester provides a standard, preformatted, front-end UI for testing a model's relationships, error message display, expression output, and control specifications. Using it, the modeler can perform the actions of the end user, making selections and entering data so as to observe actual model behavior at runtime.

For you to use the Model Tester, the Configurator Server must be installed and running at the time of its use.

Chapter 31

Maintaining the Advanced Configurator System

This chapter discusses how to:

- Manage model versions.
- Load models.
- Manage the memory usage of the Conifigurator server.
- Compress configuration data.
- Use the Explanations.properties file.
- Compile models from the command line.
- Access and use COPXML servlet statistics.

Managing Model Versioning

Different versions of the same model and multiple instances of the same version can coexist. Models have a three-part version number plus a compile version number.

The compile version number contains the date and time. For example:

20040320-184840-135

This example version number indicates that the model was compiled at 6:48 p.m. on March 20, 2004.

The version number is separated into parts by hyphens. The parts are the major, minor, and subminor versions of the model. The modeler assigns the major and minor version numbers in the PeopleSoft Visual Modeler. The compiler assigns the subminor version number. It performs a cyclical redundancy check and advances the subminor version number if the model changes. An example is 0-1-3.

This example indicates that the modeler assigned a version number of 0-1, and that the compiler has detected three changes in the model since it was first compiled as version 0-1-0.

Note. The following description assumes that you accepted default settings when you installed the PeopleSoft Configurator server.

All models are compiled in subdirectories of the PeopleSoft Configurator models directory. Subdirectories exist for the model, each part of the version number, and the compile version number. For example:

```
<weblogic home>\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\WEB-INF
\models\myBestModel
  0
  1
  0
    20000306-063520-356
```

The compile version directory contains all the files that are created during linking and compiling. The parent directories have no files, although you can move the `Explanations.properties` file to them. Each time the model is compiled, the compiler creates a new compile directory and all the files in it. It creates a subminor directory only if the model changes.

The compiler creates the following files in the compile version directory:

- `Explanations.properties`
- `Gcl`
- `Lep`
- `Map`
- `Rtp`
- `Sgcl`
- `Tmap`
- `Xml`

Loading Models

You can specify which models the PeopleSoft Configurator server loads at startup by setting one or two parameters for the Configurator's startup servlet in the WebLogic Administrative console.

To specify the Configurator server settings:

1. Open the WebLogic Administrative console in a browser using its domain address `http://<server>:<port>/console`.
2. Navigate to CalicoDomain, Deployments, Web Application, CalicoApp.
3. Click Edit Web Application Descriptor.

A new browser window appears where the parameters can be set.

4. In the new window, navigate to Web Descriptor, Web App Descriptor, Servlets, StartupServlet, Parameters.

The default is a single parameter with name=load and value=default. The load parameter can have one of these values:

- *All*, which loads every model in the models\ subdirectory.
- *Default*, which loads the latest compile version of the latest version of each model in the models\ subdirectory.
- *Specific*, which requires the second parameter, models.

5. Add the models parameter:

- a. Click Configure a new Parameter
- b. Set the name to *models*.
- c. Specify a value using one of the following approaches:

Specify at least one model name and its version and compile version. If you specify only the model name, the application server loads the latest compile version of the latest version of the model that you specify.

or

Specify the model name and one of the following versions or combinations:

major version

major and minor version

major,,minor, and sub-minor version

major,minor,sub-minor, and compile version (which fully specifies the model)

Example:

Version specification	Action taken
load=all	Loads all compile versions of all models in the models directory.
load=default	Loads the latest compile version of the latest version of all models in the models directory.
load=specific,models= myModelOne:0-1-0:20000306-185244-355;myModelTwo;myModelThree:0-2	Loads the specified compile version of myModelOne, the latest compile version of the latest version of myModelTwo, and the latest compile version of the latest subminor version of minor version 2 of major version 0 of myModelThree.

6. Navigate to the top level of the tree in the left-hand pane (called Web Descriptor), and click on the Persist button.
7. Restart the server.

Managing the Memory Usage of the Configurator Server

When a model is compiled on the Configurator server, it is translated from its XML representation into a set of object instances in the Java Virtual Machine (JVM). This set of object instances is then serialized to an RTP (runtime problem) disk file. When a client later requests the model, this file is used to reconstruct the needed object instances (hereafter referred to as a ModelSpec instance). Because reconstructing a ModelSpec from the RTP file significantly affects performance, ModelSpec instances are cached in memory.

To prevent the JVM from exhausting its available memory as new versions of models are added to the server, the administration servlet removes older ModelSpec instances from the cache. Administrators can control the cache size with the `model.cache.size` property in the `Advisor.properties` file:

```
model.cache.size=20
```

If not specified, the property's value is *10* versions by default.

To minimize the performance impact of a cache size setting that is too small, the cache comprises a primary and secondary cache. The cache size setting refers to the size of the primary cache alone. The secondary cache acts as a holding bin for the oldest ModelSpec instances, and they are subject to the regular deletion cycles of the JVM.

The primary cache contains the most recently used ModelSpec instances. As ModelSpec instances are requested from the cache, they are added to the primary cache if they are not already there. If the primary cache has reached its maximum size, then the least recently used ModelSpec instance in the primary cache is pushed to the secondary cache.

Compressing Configuration Data

PeopleSoft Configurator enables you to compress configuration xml data. Any compressed data is decompressed during a restore operation when the configuration is requested.

Two modes of data compression are available:

- Compression at runtime with the user's save request.
- Compression for maintenance of existing configuration data stores.

Use the maintenance compression mode to compress configuration data that has not been compressed during runtime saves.

To specify data compression at runtime:

1. Locate the `Advisor.properties` file in

```
\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\WEB-INF\config
```

2. Set the property `calico.na.db.compression` equal to `true` if you want to enable data compression.

The `calico.na.db.compression` property enables and disables compression for the saved configurations of all solutions that are deployed on the web application server. Its default setting is `true`.

To compress configuration data on existing databases, run the following code from a command line. A utility compresses the saved configurations on the specified database.

```
java -classpath <CONFIGURATOR_JAR_PATH>;<CONFIGURATOR_CONFIG_PATH>;
<DATABASE_DRIVER_PATHS> calico.cms.persistence.DBUtil -compress
```

where

<CONFIGURATOR_JAR_PATH> is the path to the Configurator jar file (advisor.jar).

<CONFIGURATOR_CONFIG_PATH> is the path to the Configurator properties files.

<DATABASE_DRIVER_PATHS> is the path to both of the database drivers.

Example:

```
java -classpath r:\MKTG_DEN_CRM\cfg\advisor.jar;r:\CRM_VOB\pscfg\3rdparty\jdbc⇒
\classes12.zip;r:\MKTG_DEN_CRM\cfg\jdbc\mssqldriver.zip;E:\bea\wlserver_10.3.1
\config\CalicoDomain\applications\CalicoApp\WEB-INF\config⇒
calico.cms.persistence.DBUtil -compress
```

Using the Explanations.properties File

The Explanations.properties file contains messages about constraint violations. The compiler creates an Explanations.properties file in each compile version directory. This file contains key-value pairs that describe constraint violations, which are displayed in the test client and in the midtier application. Each explanation is keyed by its constraint name. For example:

```
LeatherSeatsSedanCompatibility=Leather seats are not available with this vehicle.
WhiteMeatMustardCatsupCompatibility=White meat is not compatible with mustard or⇒
ketchup. The condiment you selected is not available with the meat you selected.⇒
ModemToMotherBoardDynDef=An external drive (floppy or CD-ROM) is recommended.⇒
FramesToTintDynDef=Constraint 4.B.2 RadioMultipleCDCDChangerRequired=The multiple⇒
CD radio requires a CD changer.
```

Copying the Explanations.properties File

You can move or copy the Explanations.properties file to the following directories:

- <ModelName>

Placing the Explanations.properties in the <ModelName> directory applies it to all versions and compile versions of that model, unless an Explanations.properties file is also in a child directory, that is, in a <MajorVersion>, <MinorVersion>, or <CompileVersion> directory for the model. The file in a child directory overrides the file in the parent (<ModelName>) directory.

- <MajorVersion>

Placing the Explanations.properties in the <MajorVersion> directory applies it to all minor versions and compile versions of that major version of the model, unless an Explanations.properties file is also in a child directory, that is, in a <MinorVersion> or <CompileVersion> directory for that major version of the model. The file in any child directory overrides the file in any parent (<MajorVersion> or <ModelName>) directory.

- <MinorVersion>

Placing the Explanations.properties in the <MinorVersion> directory applies it to all compile versions of that minor version of the model, unless an Explanations.properties file is also in a <CompileVersion> directory for that minor version of the model. The file in a <CompileVersion> directory overrides the file in any parent (<MinorVersion>, <MajorVersion>, or <ModelName>) directory.

Also, you can place an Explanations.properties file in the models directory. It applies to all compile versions of all models in the models directory. For example:

```
COMPLETENESS_CONSTRAINT=You must provide a selection for this choice.  
COMPATIBILITY_CONSTRAINT=The selections that you made are not compatible.
```

Searching for the Explanations.properties File

The Configurator test client that is used in the PeopleSoft Visual Modeler searches through directories for the Explanations.properties file in the following order:

1. <MinorVersion>
2. <MajorVersion>
3. \models\ (the root directory for all <ModelName>s)
4. <ModelName>
5. <CompileVersion>

You can design your JavaServer Pages (JSP) midtier application to search in another order.

Compiling Models from the Command Line

If Configurator implementation requires regular or frequent model updates, you can save time and effort by using the command-line compile utility. This compile command calls the executable for the Visual Modeler, which opens briefly to compile the ,csw files that you supply in the command. It also generates a log file.

The command is the Visual Modeler executable, `-compile`, and the full or relative path of the model that you want to compile:

```
ClicViM -compile mymodel.csw
```

To compile multiple models, call each separately.

The models can be local or remotely located; however, the filepath must be to a machine on which the Visual Modeler is installed. If you want, you can store the compiled files to an internet protocol (IP) address.

Accessing and Using COPXML Servlet Statistics

The COPXML servlet tracks various processing times for interactive xml requests:

- Hits: The total number of requests.
- Overall time(ms): The time to process a request.
- Start time(ms): The time that is spent parsing the request.
- Init time(ms): The time that is spent initializing the COP with the correct model and version.
- Execute time(ms): the time that is spent processing the request (creating choices and processing them through the engine).
- Extract tTime(ms).
- Generate time(ms): The time that is spent generating the response XML.
- Max simultaneous: The maximum number of simultaneous requests.

This is an example:

?@COPXMLServlet Statistics

@Hits 10 Total number of requests

@Overall Time(ms) 631 63 avg Total time to process request

@Start Time(ms) 380 38 avg Time spent parsing the request

@Init Time(ms) 90 9 avg Time spent initializing the cop with the correct model/version

@Execute Time(ms) 61 6 avg Time spent processing the request. (Creating choices and processing them through the engine)

@Extract Time(ms) 0 0 avg Not used

@Generate Time(ms) 100 10 avg Time spent generating the response XML

@Max Simultaneous 1 Maximum number of simultaneous requests

Note. All times are for processing interactive requests only. Times processing ConfigDetails, or ConfigCopy, requests are not included in the statistics with the exception of Start Time, which records the parsing of all requests. The first number in each row is the accumulated time since the server was started. The second number is the average per request.

To view the COPXML statistics, navigate to the copxml servlet in a browser window, using, for instance, <http://localhost:7777/copxml>

To reset the values without restarting the server, use the following post URL:

<http://localhost:7777/copxml?reset=true>

Appendix A

Visual Modeler Expression Editor Functions

The following table describes the functions and operators that are provided for creating expressions.

Tables are:

- Numeric operators and functions
- Boolean functions
- Date functions
- String functions

Numeric Operators and Functions

The Visual Modeler supports these operators and functions:

<i>Function</i>	<i>Description</i>	<i>Example</i>
-	Subtract.	$x - y$
%	Return the remainder of x divided by y.	$x \% y$
*	Multiply.	$x * y$
**	Return x raised to the power y.	$x ** y$
/	Divide.	x / y
+	Add.	$x + y$
<	Less Than.	$x < y$
<=	Less Than or Equal To.	$x <= y$
<>	Not Equal.	$x <> y$
=	Equal.	$x = y$

Function	Description	Example
>	Greater Than.	$x > y$
>=	Greater Than or Equal To.	$x \geq y$
abs()	Return the absolute value of x.	abs(x)
acos()	Return the arccosine of the radian value x.	acos(x)
addDays()	Add the integer value (1-31) of the day of a given date x.	addDays(x)
addMonths()	Add the integer value (1-12) of the month of a given date x.	addMonths(x)
addYears()	Add the integer value of the year of a given date x.	addYears(x)
asin()	Return the arcsine of the radian value x.	asin(x)
avgWithQty()	Total the value of all picks divided by the number of discrete items picked.	avgWithQty(x,y)
bnd()	Return the first argument that has a bound value. Unlike other functions, it will only propagate its value if one of the arguments is bound; thus it can be used to prevent automatic propagation of selection point attribute references. Note that if the last value is a constant, then that will be returned as the default value. So <i>bnd(sp1,sp2,4)</i> returns 4 if neither <i>sp1</i> nor <i>sp2</i> are bound.	bnd(x1,...,xn)
compareTo()	Compare value x to value y and return an integer value: < 0 if value x is less than value y, 0 if value x equals value y, and > 0 if value x is greater than value y.	compareTo(x,y)
concatenate()	Concatenate object values <i>x1</i> through <i>xn</i> into a string.	concatenate(x1,...,xn)
cos()	Return the cosine of the radian value x.	cos(x)
cot()	Return the cotangent of the radian value x.	cot(x)

Function	Description	Example
countWithQty()	Return the number of discrete items. For example, if the picks are drive (quantity of 3), cpu (1), and monitor (1), the count with quantity is 5.	countWithQty(x,y,z)
date()	Return a date constructed from integer year y, month m, and day d.	date(y,m,d)
dateToInt()	Convert the date x to an integer in the form YYYYMMDD.	dateToInt(x)
daysBetween()	Return the number of days (always positive) between dates x and y. If x and y are the same days, zero is returned.	daysBetween(x,y)
doesNotEqual()	Return a boolean value indicating whether value x has the same type and value as value y.	doesNotEqual(x,y)
equals()	Return a boolean value indicating whether value x has the same type and value as value y.	equals(x,y)
getDay()	Return the integer value (1-31) of the day of a given date x.	getDay(x)
getMonth()	Return the integer value (1-12) of the month of a given date x.	getMonth(x)
getYear()	Return the integer value of the year of a given date x.	getYear(x)
if()	Compare values and return the first output if the comparison is True, and the second output if False.	if(x>y,Out1,Out2)
indexOf()	Return an integer indicating the position of integer x within number y optionally beginning at integer position z. -1 is returned if integer x is not found within number y.	indexOf(x,y,z)
intToDate()	Convert the integer x to a date in the form YYMMDD.	intToDate(x)
length()	Return the length in characters of number value x.	length(x)
max()	Return the value of the largest argument	max(x,y,z)

Function	Description	Example
maxWithQty()	Multiply the value for each attribute by quantity, if any, then return the largest value.	maxWithQty(x,y,z)
min()	Return the smallest argument.	min(x,y,z)
minWithQty()	Multiply each argument by quantity, if any, then return the smallest value.	minWithQty(x,y,z)
pi()	Return the value of pi.	pi()
product()	Multiply arguments.	product(x,y,z)
quotient()	Return the integer result of x / y.	quotient(x,y)
round()	Return the value x rounded to integer precision y. If y is greater than 0, whole number rounding is performed, otherwise decimal rounding is performed. For example, round(126.456,1) is 126 and round(126.456,-1) is 126.5.	round(x,y)
sin()	Return the sine of the radian value x.	sin(x)
sqrt()	Return the square root of x.	sqrt(x)
substring()	Return the substring value of x starting at position y optionally ending at position z if specified.	substring(x,y,z)
sum()	Add arguments.	sum(x,y,z)
sumWithQty()	For each argument, multiply quantity (if used) times the attribute value and add the results.	sumWithQty(x,y,z)
tan()	Return the tangent of the radian value x.	tan(x)
toDegrees()	Return the radian value x converted to degrees.	toDegrees(x)
toFloat()	Convert a float, integer, string, or boolean value to a float.	toFloat(x)
toInteger()	Convert a float, integer, string, or boolean value to an integer.	toInteger(x)
toRadians()	Return the degree value x converted to radians.	toRadians(x)

Boolean Functions

The following table list the boolean functions provided for building expressions.

Function	Description	Sample
!	not()	NOT
&	and()	Logical AND
^	xor()	Exclusive OR
	or()	Logical OR
<	Less Than	$x < y$
<=	Less Than or Equal To	$x \leq y$
<>	Not Equal	$x \neq y$
=	Equal	$x = y$
>	Greater Than	$x > y$
>=	Greater Than or Equal To	$x \geq y$
and()	Returns true if all the inputs are true.	and(x,y,z)
bnd()	Returns the first argument that has a bound value. Unlike other functions, it will only propagate its value if one of the arguments is bound; thus it can be used to prevent automatic propagation of selection point attribute references. Note that if the last value is a constant, then that will be returned as the default value. So bnd(sp1,sp2,4) returns 4 if neither sp1 nor sp2 are bound.	bnd(x1,...,xn)
compareTo()	Compares value x to value y and returns an integer value: < 0 if value x is less than value y, 0 if value x equals value y, and > 0 if value x is greater than value y.	compareTo(x,y)
concatenate()	Concatenates object values x1 through xn into a string.	concatenate(x1,...,xn)
contains()	Returns a boolean value indicating whether string x contains string y.	contains(x,y)

Function	Description	Sample
countWithQty()	Returns the number of discrete items. For example, if the picks are drive (quantity of 3), cpu (1), and monitor (1), the count with quantity is 5.	countWithQty(x,y,z)
doesNotContain()	Returns a boolean value indicating whether string x does not contain string y.	doesNotContain(x,y)
doesNotEqual()	Returns a boolean value indicating whether value x has the same type and value as value y.	doesNotEqual(x,y)
endsWith()	Returns a boolean value indicating whether string x ends with string y.	endsWith(x,y)
equals()	Returns a boolean value indicating whether value x has the same type and value as value y.	equals(x,y)
if()	Compare values and return the first output if the comparison is True, and the second output if False.	if(x>y,Out1,Out2)
not()	Returns negated input value.	not(x)
occursAfter()	Returns the boolean value true if date x occurs after date y, otherwise the value false is returned.	occursAfter(x,y)
occursOnOrAfter()	Returns the boolean value true if date x occurs on or after date y, otherwise the value false is returned.	occursOnOrAfter(x,y)
occursOnOrBefore()	Returns the boolean value true if date x occurs on or before date y, otherwise the value false is returned.	occursOnOrBefore(x,y)
or()	Returns true if any input is true.	or(x,y,z)
sortsAfter()	Returns a boolean value indicating whether string x sorts after string y using a Collator object based on the current locale.	sortsAfter(x,y)
sortsBefore()	Returns a boolean value indicating whether string x sorts before string y using a Collator object based on the current locale.	sortsBefore(x,y)
startsWith()	Returns a boolean value indicating whether string x starts with string y.	startsWith(x,y)

Function	Description	Sample
toFloat()	Converts a float, integer, string, or boolean value to a float.	toFloat(x)
toInteger()	Converts a float, integer, string, or boolean value to an integer.	toInteger(x)
xor()	Returns true if only one input value is true.	xor(x,y,z)

Date Functions

The Visual Modeler supports these date functions:

Function	Description	Sample
addDays()	Adds y days to date x returning the new date.	addDays(x,y)
addMonths()	Adds y months to date x returning the new date.	addMonths(x,y)
addYears()	Adds y years to date x returning the new date.	addYears(x,y)
bnd()	Returns the first argument that has a bound value. Unlike other functions, it will only propagate its value if one of the arguments is bound; thus it can be used to prevent automatic propagation of selection point attribute references.	bnd(x1,...,xn)
compareTo()	Compares value x to value y and returns an integer value: < 0 if value x is less than value y, 0 if value x equals value y, and > 0 if value x is greater than value y.	compareTo(x,y)
concatenate()	Concatenates object values x1 through xn into a string.	concatenate(x1,...,xn)
countWithQty()	Returns the number of discrete items. For example, if the picks are drive (quantity of 3), cpu (1), and monitor (1), the count with quantity is 5.	countWithQty(x,y,z)
date()	Returns a date constructed from integer year y, month m, and day d.	date(y,m,d)

Function	Description	Sample
dateToInt()	Converts the date x to an integer in the form YYYYMMDD.	dateToInt(x)
daysBetween()	Returns the number of days (always positive) between dates x and y. If x and y are the same days, zero is returned.	daysBetween(x,y)
doesNotEqual()	Returns a boolean value indicating whether value x has the same type and value as value y.	doesNotEqual(x,y)
equals()	Returns a boolean value indicating whether value x has the same type and value as value y.	equals(x,y)
getBeginningOfMonth()	Returns the date of the beginning of the month (the 1st) for a given date x.	getBeginningOfMonth(x)
getBeginningofWeek()	Returns the date of the closest Monday on or before a given date x.	getBeginningofWeek(x)
getBeginningofYear()	Returns the date of the beginning of the year for a given date x. The first day of the year is considered to be January 1st.	getBeginningofYear(x)
getDay()	Returns the integer value (1-31) of the day of a given date x.	getDay(x)
getMonth()	Returns the integer value (1-12) of the month of a given date x.	getMonth(x)
getSolveDate()	Returns the date passed to the PSProblemState solve method (which is also the date used to calculate effectivity).	getSolveDate(x)
getToday()	Returns the current date	getToday(x)
getYear()	Returns the integer value of the year of a given date x.	getYear(x)
if()	Compare values and return the first output if the comparison is True, and the second output if False.	if(x>y,Out1,Out2)
intToDate()	Converts the integer x to a date with the YYYYMMDD format.	intToDate(x)

Function	Description	Sample
occursAfter()	Returns the boolean value true if date x occurs after date y, otherwise the value false is returned.	occursAfter(x,y)
occursBefore()	Returns the boolean value true if date x occurs before date y, otherwise false is returned.	occursBefore(x,y)
occursOnOrAfter()	Returns the boolean value true if date x occurs on or after date y, otherwise the value false is returned.	occursOnOrAfter(x,y)
occursOnOrBefore()	Returns the boolean value true if date x occurs on or before date y, otherwise the value false is returned.	occursOnOrBefore(x,y)
toDate()	Converts the string value x to a date. Format is YYYY-MM-DD.	toDate(x)
toFloat()	Converts a float, integer, String, or boolean value to a float.	toFloat(x)
toInteger()	Converts a float, integer, String, or boolean value to an integer.	toInteger(x)

String Functions

The following table describes the string functions available for creating expressions.

Function	Description	Sample
bnd()	Returns the first argument that has a bound value. Unlike other functions, it will only propagate its value if one of the arguments is bound; thus it can be used to prevent automatic propagation of selection point attribute references.	bnd(x1,...,xn)
compareTo()	Compares value x to value y and returns an integer value: < 0 if value x is less than value y, 0 if value x equals value y, and > 0 if value x is greater than value y.	compareTo(x,y)
concatenate()	Concatenates object values x1 through xn into a string.	concatenate(x1,...,xn)

Function	Description	Sample
<code>contains()</code>	Returns a boolean value indicating whether string x contains string y.	<code>contains(x,y)</code>
<code>countWithQty()</code>	Returns the number of discrete items. For example, if the picks are drive (quantity of 3), cpu (1), and monitor (1), the count with quantity is 5.	<code>countWithQty(x,y,z)</code>
<code>doesNotContain()</code>	Returns a boolean value indicating whether string x does not contain string y.	<code>doesNotContain(x,y)</code>
<code>doesNotEqual()</code>	Returns a boolean value indicating whether value x has the same type and value as value y.	<code>doesNotEqual(x,y)</code>
<code>endsWith()</code>	Returns a boolean value indicating whether string x ends with string y.	<code>endsWith(x,y)</code>
<code>equals()</code>	Returns a boolean value indicating whether value x has the same type and value as value y.	<code>equals(x,y)</code>
<code>if()</code>	Compare values and return the first output if the comparison is True, and the second output if False.	<code>if(x>y,Out1,Out2)</code>
<code>indexOf()</code>	Returns an integer indicating the position of string x within string y optionally beginning at integer position z. -1 is returned if string x is not found within string y.	<code>indexOf(x,y,z,)</code>
<code>length()</code>	Returns the length in characters of string value x.	<code>length(x)</code>
<code>sortsAfter()</code>	Returns a boolean value indicating whether string x sorts after string y using a Collator object based on the current locale.	<code>sortsAfter(x,y)</code>
<code>sortsBefore()</code>	Returns a boolean value indicating whether string x sorts before string y using a Collator object based on the current locale.	<code>sortsBefore(x,y)</code>
<code>startsWith()</code>	Returns a boolean value indicating whether string x starts with string y.	<code>startsWith(x,y)</code>
<code>substring()</code>	Returns the substring value of x starting at position y optionally ending at position z if specified.	<code>substring(x,y,z)</code>

Function	Description	Sample
toDate()	Converts the string value x to a date. Format is YYYY-MM-DD.	toDate(x)
toFloat()	Converts a float, integer, String, or boolean value to a float.	toFloat(x)
toInteger()	Converts a float, integer, String, or boolean value to an integer.	toInteger(x)
toLowerCase()	Returns a string in which all upper case letters in string x have been converted to lower-case letters.	toLowerCase(x)
toUpperCase()	Returns a string in which all lower case letters in string x have been converted to upper-case letters.	toUpperCase(x)
trim()	Returns a string in which all white space from both ends of string x has been removed.	trim(x)

Appendix B

Creating and Adding User-Defined Functions

This appendix discusses the use of user-defined functions.

User-defined functions allow model developers to extend the expression capabilities of PeopleSoft Advanced Configurator to meet specific needs not addressed by its pre-defined functions. This appendix provides instructions and information to help you add your own function.

In addition, a sample user-defined function called `getQuantity` is provided with the Configurator install. It consists of the compiled class file and Java source file, which are located in:
`\samples\Configurator\SampleSolutions\GetQuantity_UDF\classes` Also included is a model and a readme file describing the sample function and how to add it to your system for demonstration. You can also modify the sample source file to create your own function.

Adding a User-Defined Function

To add a user-defined function:

1. Stop the Configurator Server if it is running.
2. Create a Java source file that implements the `UserFunction` and `java.io.Serializable` interfaces. To implement the `UserFunction` interface, add a method to the class that calculates the function's return value. A number of functions are provided to access the arguments passed to the `calculate` method.

See [Appendix B, "Creating and Adding User-Defined Functions," Implementing the UserFunction Interface, page 452.](#)

3. Compile this source file.
4. Copy the newly compiled class file into the `\classes` directory of
`\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf`
You may need to create the `\classes` directory.
5. Locate `UserFunctions.xml` in
`\\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\config`

6. Add the following lines between the <FUNCTION_LIST> tags:

```
<FUNCTION NAME="getQuantity" CATEGORY="user" RETURN_TYPE="float" CLASS="Get=>
QuantityFunction"

1#####DEFAULT_ARGUMENT_TYPE="integer" DEFAULT_ARGUMENT_NAME="getQuantity-var"

1#####MIN_ARGUMENTS="2" MAX_ARGUMENTS="2"/>
```

See [Appendix B, "Creating and Adding User-Defined Functions," Editing UserFunctions.xml, page 454.](#)

The Visual Modeler queries the server or other supported source for the contents of the UserFunctions.xml file to determine the names of the functions to be displayed in the expression editor.

At compile time, the compiler employs the UserFunctions.xml file to detect the user-defined functions.

- 7. Save the file and restart the Configuration Server.
- 8. In the expression editor of the Visual Modeler, click the "Refresh Functions from Server" button. Visual Modeler queries the Configurator server for the contents of the UserFunctions.xml.
- 9. Compile the model to complete the process. The Visual Modeler connects to the Configurator Server, reads the UserFunctions.xml file, and updates the editor's list of user-defined functions available for modeling.

Implementing the UserFunction Interface

The primary method in the UserFunction interface is **calculate()** and must be defined by any class implementing the UserFunction interface.

The **calculate()** method is used to compute the result of the user-defined function, which is returned as an Object instance. Within the **calculate()** method, the function arguments can be retrieved from the *UserFunctionsArgument* instance using the methods provided by its class.

Methods

The UserFunction interface provides these methods:

numberOfArguments()	Returns the number of arguments that were passed into the user function. Each individual argument passed into the user function is actually a list of values. In the case of constants, return values from other functions, and single-select selection point attributes, the list will contain only one value. In the case of multiselect selection point attributes, the list can contain multiple values.
argumentContainsMultipleValues(int argumentPosition)	Returns true if an argument comprises multiple values, otherwise false is returned. As for Java arrays, references to the position of an argument begin at 0.

numberOfArgumentValues(int argumentPosition)	Returns the number of values associated with the specified argument position. If called for an argument for which <code>argumentContainsMultipleValues()</code> would return false, this method returns 1.
argumentIsInteger(int argumentPosition) argumentIsInteger(int argumentPosition, int valuePosition) argumentIsDouble(int argumentPosition) argumentIsDouble(int argumentPosition, int valuePosition) argumentIsNumber(int argumentPosition) argumentIsNumber(int argumentPosition, int valuePosition) argumentIsBoolean(int argumentPosition) argumentIsBoolean(int argumentPosition, int valuePosition) argumentIsString(int argumentPosition) argumentIsString (int argumentPosition, int valuePosition)	Used to determine the type of an argument value. These methods take either one argument, the argument position, or two arguments, the argument position and value position in the argument list. If only the argument position is specified, the value position is assumed to be 0. The return value of these methods is either true, if the value is of the specified type, or false, if the value is not of the specified type.
argumentIntegerValue(int argumentPosition) argumentIntegerValue(int argumentPosition, int valuePosition) argumentDoubleValue(int argumentPosition) argumentDoubleValue(int argumentPosition, int valuePosition) argumentBooleanValue(int argumentPosition) argumentBooleanValue(int argumentPosition, int valuePosition) argumentStringValue(int argumentPosition) argumentStringValue(int argumentPosition, int valuePosition)	Used to retrieve an argument value. These methods take either one argument, the argument position, or two arguments, the argument position and value position in the argument list. If only the argument position is specified, the value position is assumed to be 0. The return value of these methods is the specified value from the argument list. The method <code>argumentIntegerValue()</code> will coerce a float value to an integer value and <code>argumentDoubleValue()</code> will coerce an integer value to a float value.
argumentQuantity(int argumentPosition); argumentQuantity(int argumentPosition, int valuePosition);	Used to retrieve the quantity associated with argument values. In the case of constants and return values from other functions, the quantity returned is always 1. In the case of selection point attributes, the quantity returned is the quantity associated with the selected domain member that is associated with the attribute value.
argumentLongValue(int argumentPosition, int valuePosition) argumentLongValue(int argumentPosition);	These methods allow a user-defined function to request arguments as long integer values rather than integer values. These methods behave the same as the existing <code>argumentIntegerValue</code> methods except that they return a Java long rather than a Java int. Call these methods if you expect to retrieve numbers larger than 2,096,000,000 (a Java-imposed limit to the int type). If you don't, and such a huge number gets entered into your UDF, it will get truncated (and might become negative or some other funny effect)

Exceptions

If the argument or value positions are invalid or if an invalid type is requested, the **UserFunctionException** exception will be thrown by the argument access methods.

Editing UserFunctions.xml

Entries in UserFunctions.xml must contain either:

- The name of the Java class that implements the user-defined function (the NAME tag), or
- The name of the function as displayed by the Visual Modeler and referenced in expressions.

Or,

You can specify:

- The return type of the function (the RETURN_TYPE tag).
- The minimum and maximum number of arguments expected by the function (the MIN_ARGUMENTS and MAX_ARGUMENTS tags).
- The default argument type (the DEFAULT_ARGUMENT_TYPE tag).
- The default argument aggregation (the DEFAULT_ARGUMENT_AGGREGATION tag).
- The default argument name (the DEFAULT_ARGUMENT_NAME).

Tag definitions are:

RETURN_TYPE	Legal values are integer, float, double, number, string, date, boolean, long, and object. If this tag is unspecified, it is assumed to be object. Using number as the return type signifies that the return value will be either a double or integer. Using float as the return type is identical to using double as the return type. Using object as the return type signifies that the return value will be either integer, double, string, date, or boolean.
MIN_ARGUMENTS and MAX_ARGUMENTS	Should be integers or the symbol "variable". If unspecified, these tags are assumed to be variable.
DEFAULT_ARGUMENT_TYPE	Has the same allowed types as the RETURN_TYPE tag.
DEFAULT_ARGUMENT_AGGREGATION	Should be a Boolean value. By default it is assumed to be false.
DEFAULT_ARGUMENT_NAMED	Is a description of the function's arguments.

Specify information for each argument using the ARGUMENT tag.

For each argument, specify the NAME tag needs to be specified for each argument and is a description of the argument.

The type can be specified for each argument using the TYPE tag and aggregation can be specified using the AGGREGATOR tag. The TYPE tag has the same allowed types as the RETURN_TYPE tag. By default, the type is object.

The AGGREGATOR tag should be a boolean value and by default is false. If an argument is specified to be an aggregator, then the compiler enforces the restriction that only selection point/attribute references, function calls, and numeric variables can be specified for this argument in an expression.

Examples

The content portion of an example UserFunctions.xml file illustrates the use of the second method above:

```
public class TripleFunction
    implements UserFunction, java.io.Serializable
    {
        public Object calculate( UserFunctionArguments args)
        {
            try
            {
                if (args.argumentIsInteger(0))
                { return new Integer(3 * args.argumentIntegerValue(0)); }
                else if (args.argumentIsDouble(0))
                { return new Double(3.0 * args.argumentDoubleValue(0)); }

                return(new Integer(0));
            }
            catch (UserFunctionException e)
            {
                return(new Integer(0));
            }
        }
    }
```

The following example is of a user function called **tripleWithQty**, which takes 1 or more numeric arguments. Each argument value is multiplied by 3 and its associated quantity and the resulting values are summed and returned as a Double value.

```

import com.calico.engine.config.lightning.compiler.UserFunction;
import com.calico.engine.config.lightning.compiler.UserFunctionArguments;
import com.calico.engine.config.lightning.compiler.UserFunctionException;

public class TripleWithQtyFunction
    implements UserFunction, java.io.Serializable
    {
        public Object calculate( UserFunctionArguments args)
        {
            try
            {
                int i, j;
                double sum = 0.0;

                for (i = 0; i < args.numberOfArguments(); i++)
                {
                    for (j = 0; j < args.numberOfArgumentValues(i); j++)
                    {
                        if (args.argumentIsNumber(i,j))
                        {
                            sum += 3.0 * args.argumentDoubleValue(i,j) *
                                args.argumentQuantity(i,j);
                        }
                    }
                }

                return(new Double (sum));
            }
            catch (UserFunctionException e)
            {
                return(new Double(0.0));
            }
        }
    }

```

Using the Sample User-Defined Function getQuantity()

This section describes the sample user-defined function called `getQuantity()` that is provided with the Visual Modeler.

- Setting up `getQuantity()`.
- Viewing `getQuantity()` behavior.

Understanding the `getQuantity()` Sample Function

`getQuantity()` is a sample user-defined function that returns the selected quantity of a specific domain member within a multi-select selection point. The associated files and a sample model implementing this function are included on the Configurator CD. You can use this sample in your own modeling or simply to understand how to define and implement your own expression functions.

Suppose you want to know the quantity of the selected domain member in a single-selection point. You could use the pre-defined function `countWithQty()` to retrieve that value. However, this function cannot recognize more than one selected domain member, so you must use the `getQuantity()` sample function for multi-select selection points.

The sample `getQuantity()` user-defined function requires two files and a sample model to demonstrate its use:

- `GetQuantityFunction.java` Java user-defined function (for source use).
- `GetQuantityFunction.class` compiled Java user-defined function.
- `UserFunctions.xml` user-defined XML for `getQuantity()`.

The compiled class file and Java source file are located on the PeopleSoft Advanced Configurator CD at:

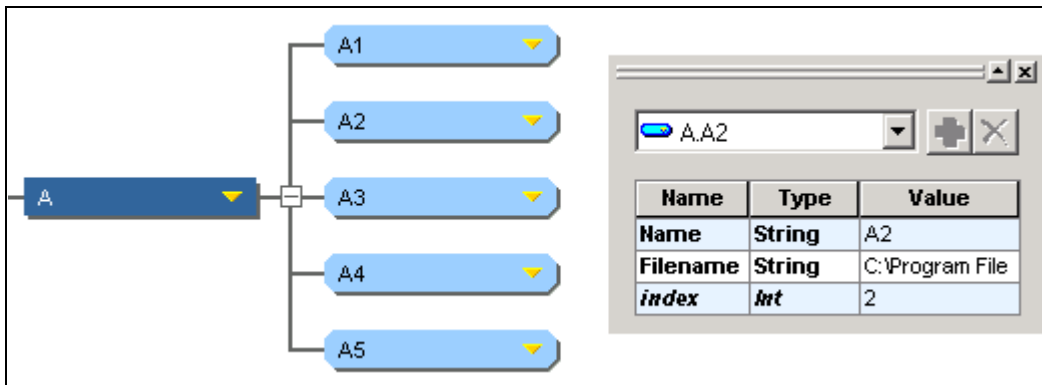

`\samples\Configurator\SampleSolutions\GetQuantity_UDF\classes`

The `getQuantity()` function has two arguments:

- An integer representing an integer attribute value on the specific domain member holding the desired quantity.
- The Selection Point/attribute name combination for the Selection Point containing the domain member holding the desired quantity.

In order for the function to evaluate properly, the target domain member must have an attribute value equal to the same value of the first argument.

In the figure below, the domain member A2 has an attribute called *index* with an integer value of 2. If you wished to obtain the quantity of the A2 domain member, the first argument in the `getQuantity()` function would be 2.

Partial Structure View and expression Properties Editor for domain member A2

Note. Set the return type for `getQuantity()` to *Numeric*. The expression in the figure below, named GQ2 in the sample model, will return the quantity selected on the A2 domain member.

Expression editor for getQuantity()

Setting Up getQuantity()

To demonstrate getQuantity(), you must first place it and the model files in the appropriate directories.

To install the function:

1. Stop the PeopleSoft Advanced Configurator Server if it is running.
2. Create a \classes folder that resides within the \Web-inf folder of your PeopleSoft Advanced Configurator installation. For example:

```
C:\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-Inf
```

3. Copy the getQuantityFunction.class file to the \classes folder just created.
4. Locate UserFunctions.xml on the Configurator CD:

```
\samples\Configurator\SampleSolutions\GetQuantity_UDF\WEB-INF\config
```

5. Do *one* of the following:

If no user-defined functions have been installed in your PeopleSoft Advanced Configurator environment, you can copy the entire UserFunctions.xml file into the config folder, located typically in:

```
C:\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\config
```

If user-defined functions are already installed in your PeopleSoft Advanced Configurator environment, open the UserFunctions.xml file from the CD and copy and paste the following text to your existing UserFunctions.xml file between the <FUNCTION_LIST> tags:

```
<FUNCTION NAME="getQuantity" CATEGORY="user" RETURN_TYPE="float"
CLASS="GetQuantityFunction"
DEFAULT_ARGUMENT_TYPE="integer"
DEFAULT_ARGUMENT_NAME="getQuantity-var"
MIN_ARGUMENTS="2" MAX_ARGUMENTS="2"/>
```

6. Locate the getQuantity sample model on the Configurator CD in:

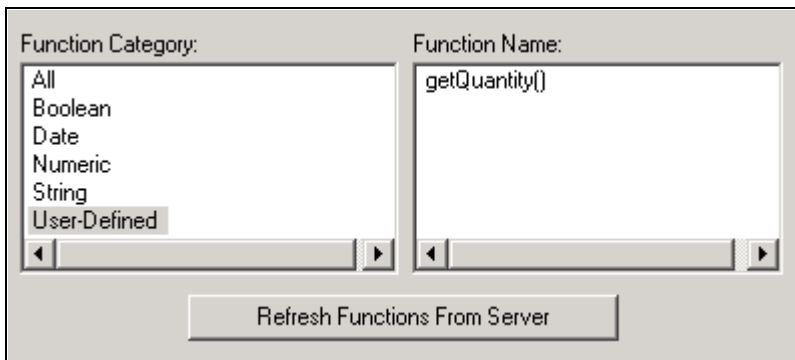

```
\samples\Configurator\SampleSolutions\GetQuantity_UDF\model
```

- Copy the getQuantity folder and its contents to:

```
C:\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\Web-inf\classes
```

Note. Do not place the getQuantity folder and its contents in a subfolder.

- Start the PeopleSoft Advanced Configurator Server.
- Start the Visual Modeler and open the getQuantity sample model you just copied.
- Select Project, Settings to verify that the model is pointing at the correct hostname for your Configurator Server.
- Open any expression (for example, GQ2) by double-clicking on one in the Components windows.
- Click on the Refresh Functions From Server button. The Visual Modeler will connect to the Configurator Server, read the UserFunctions.xml file, and update the list of user-defined functions available for modeling.
- Click on the compile icon in the toolbar of the Visual Modeler. Verify that the model was compiled successfully by viewing its name in the Visual Modeler message window, as shown:

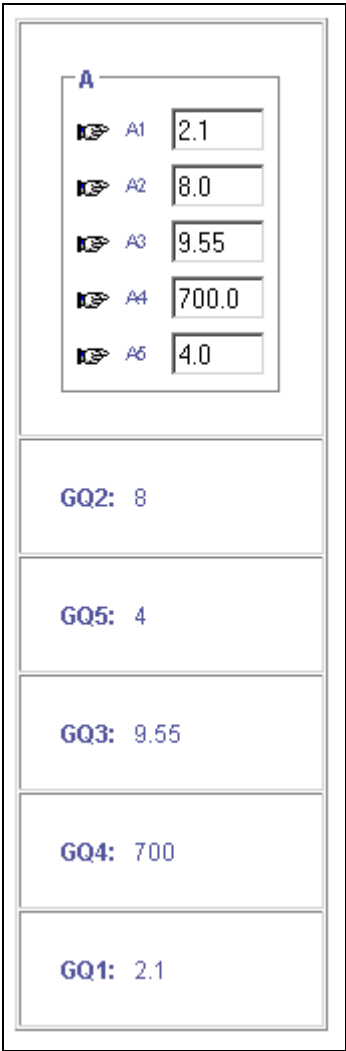

Updated function list

Viewing getQuantity() Behavior

This section discusses how to run the GetQuantity model so as to observe results from the getQuantity() function.

To see the runtime behavior of getQuantity(), compile and run the getQuantity() sample model by clicking the Compile and run the model icon in the toolbar of the Visual Modeler. Enter quantity values for each domain member on the selection point and click the Submit button. Note that the G1-G5 expressions return the quantity values entered. Also note that the GQ2 expression returns the quantity value of A2, as it was used in the examples above.

Model Tester showing getQuantity() runtime behavior

Appendix C

Advanced Configurator Form Controls

This appendix provides the specific code for the form controls supported by Advanced Configurator for use in developing custom user interfaces:

- Single-Select Group Form Control
- Multi-Select Group Form Control
- Single-Select List Form Control (Drop-Down)
- Multi-Select List Form Control
- Single-Select Table Form Control
- Multi-Select Table Form Control
- Single-Select Image Table
- Application Why Help
- Form Control Why Help
- Text Input Form Control
- Numeric Data Form Control
- Extern Entry

Single-Select Group Form Control

The following JSP code generates a single-select group form control in HTML:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_CAPTION, <Caption>);
    params.put(PARAM_GENERATENONEMODE, <Generate None Mode>);
    params.put(PARAM_GENERATENONETEXT, <Generate None Text>);
    generateSingleSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

Note. The form control template filenames are in mixed case, such as SingleSelectGroup.jsp. For the deployments running on Solaris systems, make sure the characters of the filename match correctly (case-sensitive) with the template filenames.

The following is the HTML output of the previous JSP code:

```
<FONT COLOR="ctrlStateFontColor">Caption</FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<IMG ALT="ControlItemStateTag" BORDER="0" SRC="ControlItemStateImage">
<INPUT TYPE="radio" NAME="Control ID" VALUE="$NADA"><FONT COLOR="...">GenerateNone
Text   </FONT><BR>
<IMG ALT="- " BORDER="0" SRC="itemStateImag">
<INPUT TYPE="radio" NAME="Control ID" VALUE="ControlItemName~State">><FONT COLOR=>
"...">
```

Multi-Select Group Form Control

The following JSP code creates a multiple-select group form control in HTML.

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_CAPTION, <Caption>);
    generateMultiSelectGroup(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

The following is the HTML output of the previous JSP code:

```
<FONT COLOR="ctrlStateFontColor">Caption</FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<IMG ALT="ControlItemStateTag" BORDER="0" SRC="ControlItemStateImag">
<INPUT TYPE="checkbox" NAME="Control ID" VALUE="ControlItemName~State">><FONT=>
COLOR="...">
ControlItemName DeltaPrice</FONT><BR>
```

Single-Select Table Form Control

The following JSP code creates a single-select table form control in HTML:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_CAPTIONIMAGE, <Caption Image>);
    params.put(PARAM_COLUMNHEADINGS, <Column Headings>);
    params.put(PARAM_GENERATENONEMODE, <Generate None Mode>);
    params.put(PARAM_GENERATENONETEXT, <Generate None Text>);
    generateSingleSelectTable(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endsan -->

```

The following is the HTML output of the previous JSP code.

```

<FONT COLOR="ctrlStateFontColor"> Caption </FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<TABLE>
  <TR>
    <TH></TH>
    <TH>ColumnHeadingItem</TH>
    ...
  </TR>
  <TR>
    <TD><IMG ALT="itemStateTag" SRC="itemStateImage">
      <INPUT TYPE="radio" NAME="Control ID" VALUE="$NADA">
    </TD>
    <TD><FONT COLOR="ctrlItemStateFontColor">GenerateNoneText</FONT>
    </TD>
  </TR>
  <TR>
    <TD><IMG ALT="-" BORDER="0" SRC="itemStateImage">

    <TD><FONT COLOR="ctrlItemStateFontColor">ControlItemAttribute
      </FONT>
    </TD>
    ...
  </TR>
  ...
</TABLE>

```

Multi-Select List Form Control

The following JSP code creates a multiple-select list form control in HTML.

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_CAPTION, <Caption>);
    generateMultiSelectList(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

The following is the HTML output of the previous JSP code.

```

<FONT COLOR="ctrlStateFontColor"> Caption </FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<SELECT NAME="Control ID " MULTIPLE >
<OPTION VALUE="$NADA">GenerateNoneText
<OPTION VALUE="ControlItemName~State" >StateTag ControlItemName DeltaPrice

```

Single-Select List Form Control

The following JSP code creates a single-select list form control in HTML:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_CONTROLSIZE, <Control Size>);
    params.put(PARAM_CAPTION, <Caption> );
    params.put(PARAM_GENERATENONEMODE, <Generate None Mode>);
    params.put(PARAM_GENERATENONETEXT, <Generate None Text>);
    generateSingleSelectList(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

The following is the HTML output of the previous JSP code.

```

<FONT COLOR="ctrlStateFontColor"> Caption </FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<SELECT NAME="Control ID ">
<OPTION VALUE="$NADA">GenerateNoneText
<OPTION VALUE="ControlItemName~State" >StateTag ControlItemName DeltaPrice

```

Multi-Select Table Form Control

The following JSP code creates a multiple-select table form control in HTML:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_ATTRIBUTES, <Attributes>);
    params.put(PARAM_CONTROLID, <Control ID>);
    params.put(PARAM_COLUMNHEADINGS, <Column Headings>);
    params.put(PARAM_CAPTION, <Caption>);
    generateMultiSelectTable(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

The following is the HTML output of the previous JSP code:

```

<FONT COLOR="ctrlStateFontColor"> Caption </FONT>
<IMG BORDER="0" SRC="ctrlStateImage"><BR>
<TABLE>
  <TR>
    <TH></TH>
    <TH>ColumnHeadingItem</TH>
    ...
  </TR>
  <TR>
    <TD><IMG ALT="itemStateTag" BORDER="0" SRC="itemStateImage">
      <INPUT TYPE="checkbox" NAME="Control ID"
        VALUE="ControlItemName~ItemState " >
    </TD>
    <TD><FONT COLOR="ctrlItemStateFontColor">ControlItemAttribute
      </FONT>
    </TD>
    ...
  </TR>
  ...
</TABLE>

```

Single-Select Image

Pass parameters to the template, and create a single-select image on the model's Web page as follows:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
    if (params != null)
    {
        params.clear();
        params.put(PARAM_OBJECTNAME, <Object Name>);
        params.put(PARAM_DOMAINMEMBERNAME, <Domain Member Name>);

        params.put(PARAM_IMAGEATTRIBUTE, <Image Attribute>);
        //or
        //params.put(PARAM_IMAGENAME, <Image Name>);

        //optional image parameters
        params.put(PARAM_IMAGEPATH, <Image Path>);
        params.put(PARAM_IMAGEWIDTH, <Image Width>);
        params.put(PARAM_IMAGEHEIGHT, <Image Height>);
        params.put(PARAM_IMAGESTATES, <Image States>);
        params.put(PARAM_MOUSEOVERIMAGES, <Mouseover Images>);
        params.put(PARAM_ALTTEXTATTRIBUTE, <Alt Text Attribute>);
        params.put(PARAM_ALTTEXT, <Alt Text>);
        params.put(PARAM_ADDITIONALATTRIBUTES, <Additional Attributes>);
        params.put(PARAM_AUTOSUBMIT, <Autosubmit>);

        //optional callback parameters
        params.put(PARAM_CREATECALLBACK, <Create Callback>);
        params.put(PARAM_SELECTCALLBACK, <Select Callback>);
        params.put(PARAM_UNSELECTCALLBACK, <Unselect Callback>);
        params.put(PARAM_MOUSEOVERCALLBACK, <Mouseover Callback>);
        params.put(PARAM_MOUSEOUTCALLBACK, <Mouseout Callback>);
        params.put(PARAM_AUTOSUBMITCALLBACK, <Autosubmit Callback>);

        generateSingleSelectImage(params, request, out);
    }
    %>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

Single-Select Image Table

Pass parameters to the template and create a single-select image table on the model's Web page as follows:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
    if (params != null)
    {
        params.clear();
        params.put(PARAM_OBJECTNAME, <Object Name>);

        params.put(PARAM_CAPTION, <Caption>);
        //or
        //params.put(PARAM_CAPTIONIMAGE, <Caption Image>);

        params.put(PARAM_IMAGEATTRIBUTE, <Image Attribute>);

        //optional standard Advisor parameters
        params.put(PARAM_SORT, <Sort>);
        params.put(PARAM_FILTERELIMINATEDITEMS, <Caption Image>);
        params.put(PARAM_FILTERELIMINATIONLEVEL_LOWER, <Lower E Level>);
        params.put(PARAM_FILTERELIMINATIONLEVEL_UPPER, <Upper E Level>);
        params.put(PARAM_COMPARATOR, <Comparator>);

        //optional image parameters
        params.put(PARAM_IMAGEPATH, <Image Path>);
        params.put(PARAM_IMAGEWIDTH, <Image Width>);
        params.put(PARAM_IMAGEHEIGHT, <Image Height>);
        params.put(PARAM_IMAGESTATES, <Image States>);
        params.put(PARAM_MOUSEOVERIMAGES, <Mouseover Images>);
        params.put(PARAM_ALTTTEXTATTRIBUTE, <Alt Text Attribute>);
        params.put(PARAM_ADDITIONALATTRIBUTES, <Additional Attributes>);
        params.put(PARAM_AUTOSUBMIT, <Autosubmit>);

        //optional callback parameters
        params.put(PARAM_CREATECALLBACK, <Create Callback>);
        params.put(PARAM_SELECTCALLBACK, <Select Callback>);
        params.put(PARAM_UNSELECTCALLBACK, <Unselect Callback>);
        params.put(PARAM_MOUSEOVERCALLBACK, <Mouseover Callback>);
        params.put(PARAM_MOUSEOUTCALLBACK, <Mouseout Callback>);
        params.put(PARAM_AUTOSUBMITCALLBACK, <Autosubmit Callback>);

        //optional table parameters
        params.put(PARAM_COLUMNS, <Columns>);
        params.put(PARAM_ROWS, <Rows>);
        params.put(PARAM_BORDER, <Border>);
        params.put(PARAM_CELLSPACING, <Cell Spacing>);
        params.put(PARAM_CELLPPADDING, <Cell Padding>);

        generateSingleSelectImageTable(params, request, out);
    }
    %>
<!-- METADATA TYPE="CalicoControl" endsan -->

```

Application Why Help

The following JSP code creates the application why help in HTML:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_CAPTION, <Caption>);
    generateApplicationWhyHelp(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

The Caption parameter value is the string to be displayed as the caption for the violations. The Caption Image is the image to be displayed as the caption for the violations. Specify either Caption or Caption Image but not both.

Note. There are no required parameters for the Application Why Help form control template.

The following is the HTML output of the previous JSP code:

```

Caption
<LI>ViolationItem 1
<LI>ViolationItem 2

```

Form Control Why Help

The following JSP code creates the Form Control Why Help in HTML:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
  if (params != null)
  {
    params.clear();
    params.put(PARAM_OBJECTNAME, <Object Name>);
    params.put(PARAM_CAPTION, <Caption>);
    generateControlWhyHelp(params, request, out);
  }
%>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

Note. PARAM_OBJECTNAME is the only required parameter for the Control Why Help form control template.

The following is the HTML output of the previous JSP code:

```

Caption
<LI>ViolationItem 1
<LI>ViolationItem 2
...

```

Text Input Form Control

Pass parameters to the template, and create the text input text box on the model's Web page as follows:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
    if (params != null)
    {
        params.clear();
        params.put(PARAM_OBJECTNAME, <Object Name>);

        params.put(PARAM_CAPTION, <Caption>);
        //or
        //params.put(PARAM_CAPTIONIMAGE, <Caption Image>);

        // optional parameters
        params.put(PARAM_TEXTINPUTDEFAULT, <Default Entry>);
        params.put(PARAM_ENTRYSIZE, <Entry Size>);

        generateTextInput(params, request, out);
    }
    %>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

Numeric Data Form Control

The following JSP code creates a numeric data control on the model's web page:

```
<!-- METADATA TYPE="CalicoControl" startspan-->
<%
    if (params != null)
    {
        params.clear();
        params.put(PARAM_OBJECTNAME, <Object Name>);

        params.put(PARAM_CAPTION, <Caption>);
        //or you could use
        //params.put(PARAM_CAPTIONIMAGE, <Caption Image>);
        // but not both caption parameters.

        generateNumericData(params, request, out);
    }
    %>
<!-- METADATA TYPE="CalicoControl" endspan -->
```

The following is the HTML output of the previous JSP code:

Caption : Numeric Data

Extern Entry

Use the following to pass parameters to the template, and to create the extern entry text box on the model's Web page:

```

<!-- METADATA TYPE="CalicoControl" startspan-->
<%
    if (params != null)
    {
        params.clear();
        params.put(PARAM_OBJECTNAME, <Object Name>);
        params.put(PARAM_CONTROLID, <Control ID>);

        params.put(PARAM_CAPTION, <Caption>);
        //or
        //params.put(PARAM_CAPTIONIMAGE, <Caption Image>);

        // optional parameters
        params.put(PARAM_FLOATENTRY, <Float Entry>);
        params.put(PARAM_DATE, <Date Entry>); params.put(PARAM_INTEGER, <Integer=>
Entry>); params.put(PARAM_BOOLEAN, <Boolean Entry>); params.put(PARAM_=>
STRINGENTRY, <String Entry>); params.put(PARAM_ENTRYSIZE, <Entry Size>);

        generateExternEntry(params, request, out);
    }
    %>
<!-- METADATA TYPE="CalicoControl" endspan -->

```

Appendix D

Compound Model Properties File

Before you can test or deploy a compound model, you must specify its operating properties in CalicoNA.properties. This file is located in \\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\solutions\CompoundSample.

This appendix provides an explanation of the properties and the text of the file.

Properties Description

This section explains each property and the values expected as they appear in the file. A complete, non-annotated version of the file follows.

```
# Auto Save On Session Timeout (true/false)
calico.session.autosave=false
```

If set to true, this property will save any configurations that are open when the session times out. It is recommended that you consider all the ramifications of this behavior before setting the flag to true.

```
# Solution info
calico.solution.name=TelcoDemo
calico.solution.version=1-2
calico.solution.description=Component Modeling Demo
calico.solution.allowNew=true
```

These properties are read and displayed by the solutions list servlet.

```
calico.page.restore=
```

See [and Chapter 22, "Understanding the Runtime System," Restore Policy, page 329.](#)

This property is reserved for features to be added in a future release. Leave it at its default value.

```
# Compound Structure File
calico.compoundstructure.name=TelcoDemo
calico.compoundstructure.version=1-0
calico.compoundstructure.restore.policy=1
```

These properties define the Compound Structure Document used when using compound configurations. Default is the TelcoDemo (TelcoSample) sample compound model.

```
# Resource Bundle Names
calico.resourcebundle.name=NAResourceBundle
calico.verify.resourcebundle.name=NAVerifyResourceBundle
```

These properties define the resource bundles for the sample pages and the error messages resulting from exceptions thrown during verification.

```
# Default Date Format
calico.default.date.format=MMM d, yyyy 'at' hh:mm aaa
```

This property defines the date format used by deltas in the sample pages.

```
# Database
calico.na.db=true
```

This property is reserved for functions to be added in a future release. Leave it at its default value.

```
# Images
calico.na.image.violation=/calico/images/violation.gif
calico.na.image.noviolation=/calico/images/no_violation.gif
calico.na.image.add=/calico/images/add_icon.gifcalico.na.image.delete=/calico→
/images/delete_icon.gif
calico.na.image.sort=/calico/images/sort_icon.gif
```

These properties specify the images used by the compound configuration sample pages.

```
# Edit Component Entry Points (Relative To Document Root)
Hub=/solutions/CompoundSample/hub/hub.jsp
Node=/solutions/CompoundSample/node/node.jsp
Circuit=/solutions/CompoundSample/circuit/circuit.jsp
```

These properties define the entry points to each model used in compound configuration. Note that all reference the root directory of the web server, and are not relative to the compound configuration manager page or directory.

```
# Network Advisor Application Pages (Relative To Document Root)
calico.page.manager=/solutions/CompoundSample/CalicoNAManager.jsp
```

This property defines the manager page to be used in compound configuration.

```
CalicoNAAddComp=/calico/CalicoNAAddComp.jsp
CalicoNAAddConn=/calico/CalicoNAAddConn.jsp
CalicoNAChangeId=/calico/CalicoNAIdentification.jsp
CalicoNADeleteComp=/calico/CalicoNADeleteComp.jsp
CalicoNADeleteConfig=/calico/CalicoNADeleteConfig.jsp
CalicoNADeleteConn=/calico/CalicoNADeleteConn.jsp
CalicoNAEditComp=/calico/CalicoNAEditComp.jsp
CalicoNAEditConn=/calico/CalicoNAEditConn.jsp
CalicoNAError=/calico/CalicoNAError.jsp
CalicoNALoadConfig=/calico/CalicoNALoadConfig.jsp
CalicoNASaveConfig=/calico/CalicoNASaveConfig.jsp
CalicoNAVerify=/calico/CalicoNAVerify.jsp
CalicoNAVViewBOM=/calico/CalicoNABOM.jsp
CalicoNAVViewDeltaDetail=/calico/CalicoNAVViewDeltaDetail.jsp
CalicoNAVViewDeltas=/calico/CalicoNAVViewDeltas.jsp
```

These properties define the page to be used with each action in compound configuration. When the Manager page finds any of these actions in the request, it will redirect the request to the appropriate page.

File Text

The following is the unannotated text of the CalicoNA.properties file.

```
# PeopleSoft Configurator Compound Modeling Properties

# Auto Save On Session Timeout (true/false)
calico.session.autosave=false

# Solution info
calico.solution.name=TelcoDemo

```

Appendix E

Node-Circuit-Hub Service

This appendix describes a sample complex product (communications services) offering that includes node, circuits, and hubs, and gives you the XML representation of its compound structure definition.

Description of Services

The following bulleted items describe the sample product offering.

Node

In the sample model, a Node:

- Can be created.
- Is configured.
- Can stand alone.
- Can be connected to a single Circuit.

Hub

In the sample model, a Hub:

- Can be created.
- Is configured.
- Can stand alone.
- Can be connected to, at most, 24 Circuits.

Circuit

In the sample model, a Circuit:

- Can be created.
- Is configured.

Connections

In the sample model, applicable conditions for a Connection are:

- Must be connected to at least one Node or Hub.
- Can have at most two connections.
- The one or two connections can be to either Nodes or Hubs.
 - Node-Circuit
 - Hub-Circuit
 - Node-Circuit-Node
 - Node-Circuit-Hub or Hub-Circuit-Node
 - Hub-Circuit-Hub
- When a Circuit is connected to either a Node or a Hub, the following data relationship exists:
 - The PortSpeedSelection from the first Node or Hub should be applied to the Ext_PortSpeedSelection_A on the Circuit.
 - The PortSpeedSelection from the second Node or Hub should be applied to the Ext_PortSpeedSelection_B on the Circuit.
 - The ProtocolSelection from the first Node or Hub should be applied to the Ext_ProtocolSelection_A on the Circuit.
 - The ProtocolSelection from the second Node or Hub should be applied to the Ext_ProtocolSelection_B on the Circuit.
- When Circuits are connected to a Hub, a collection containing the portSpeed value from each Circuit should be applied to the Ext_PortSpeeds variable on the Hub.

XML Representation of Compound Structure Definition

The following XML represents the compound structure definition for the sample services offering. Compound models use the XML schema at run time to control operation, and to verify the structure of a compound configuration instance. It is located in

```
\bea\wlserver_10.3.1\config\CalicoDomain\applications\CalicoApp\solutions\Compound⇒
Sample
```

```

<CompoundStructure name="TelcoDemo" version="1-0">
  <comment>This is a sample compound structure that represents the current=>
Network Advisor 1.0 TelcoDemo, plus additional
functionality available with Network Advisor 3.5.  Specifically, this sample adds=>
in a hub component.</comment>
  <Components>

Appendix F

PCIF

The PeopleSoft Advanced Configurator Interchange Format, or PCIF, is an XML format that can be used to generate PeopleSoft Visual Modeler models from an outside data source. PCIF encapsulates all the functionality that is available to a Configurator modeler.

This appendix describes the elements and ordering of the PCIF document so that you can create an XML file that describes your model data in the format understood by the Configurator Visual Modeler.

Included with the installation of PeopleSoft Visual Modeler is the file PCIF.dtd, which describes the structure of PCIF documents and acts as the validator for them.

In order to successfully describe and validate the outside data, the contents of the PCIF document must be ordered so that the Visual Modeler can recognize the elements. To some extent, the DTD enforces this ordering; however, for some objects, particularly CLASS elements, the PCIF writer must maintain a hierarchical ordering to ensure that the document can be imported correctly. Order is explained in greater detail in the individual element sections below.

The information in this appendix assumes that you are familiar with the concepts inherent to the PeopleSoft Configurator, the Visual Modeler, and XML. Some elements' descriptions reference a "target model." The target model is the Visual Modeler model into which PCIF is being imported. The target model does not have to be empty; in fact, a modeler can use a PCIF document to update models with newer data, as the Visual Modeler gives the modeler the option of overwriting objects that have the same name as those defined in an imported PCIF document.

This document is arranged in the order that one might find XML elements in a PCIF document, starting with the topmost element (a MODEL).

Note. It is strongly recommended that any PCIF document created by an application other than the Visual Modeler has the document type declaration:

```
<!DOCTYPE MODEL PUBLIC "PeopleSoft Configurator Model" "PCIF.dtd">
```

This document type declaration should be made before the root element MODEL. Using this document type declaration ensures that when the PCIF document is imported into the Visual Modeler, it will be validated against the DTD, thereby preventing errors in the model due to badly formed PCIF.

MODEL Element

The MODEL element is the root element of a model in the PCIF representation.

Attributes:

Name	Type	Required?	Description
VERSION	CDATA	Yes	The version of PCIF implemented. This document describes PCIF version 1.0.
NAME	CDATA	Yes	The name of the model. On import, this attribute will be overridden by the name of the model importing it.
MODEL_VERSION	CDATA	Yes	The version of the model itself (as would be specified in the Visual Modeler's Project Settings dialog box). On import, this attribute will be overridden by the version of the model importing it.

Subelements:

Name	How Many?	Description
DATABASE_REFERENCE	0 or more	A reference to an external data source.
CLASS	0 or more	A class. Classes must be defined in hierarchical order, that is, a parent class must be defined before its subclasses. If any classes have SQL queries, their respective DATABASE_REFERENCES should have already been defined.
SELECTION_POINT	0 or more	Selection points must be defined on classes that exist in the target model or have been previously defined in this PCIF document. If a leaf class does not have a selection point defined, the Visual Modeler optionally can autogenerate a selection point for that class.
EXPRESSION	0 or more	An expression.
NOT_COMPATIBLE	0 or more	A non-compatibility constraint.
COMPATIBLE	0 or more	A compatibility constraint.
REQUIRED	0 or more	A requires constraint.

Name	How Many?	Description
DYNAMIC_DEFAULT	0 or more	A dynamic default.
ELIMINATION	0 or more	An elimination constraint.
COMPARISON	0 or more	A comparison constraint.
RESOURCE_CONSTRAINT	0 or more	A resource balancing constraint.
SUMMATION	0 or more	A summation.

DATABASE_REFERENCE Element

Attributes:

Name	Type	Required?	Description
ALIAS	CDATA	Yes	The name by which this database will be referenced in the Visual Modeler.
DATA_SOURCE	CDATA	Yes	The name of the underlying ODBC and JDBC data source.
LOGIN_ID	CDATA	Yes	The login name for the data source.
PASSWORD	CDATA	Yes	The password for the data source. If the Visual Modeler has created the PCIF file, this password will be encrypted using the Visual Modeler's password encryption scheme. For security reasons, an encrypted password can only be read and written by the Visual Modeler.

Name	Type	Required?	Description
PASSWORD_ENCRYPTED	Boolean	Yes	A flag that tells the Visual Modeler if the password specified in the PASSWORD attribute has been encrypted. If an application other than the Visual Modeler is creating a PCIF document, this attribute should always be set to FALSE, and the password should be unencrypted.

Subelements: None.

CLASS Element

Classes must be defined in a hierarchical manner; that is, parent classes must be defined in a MODEL before the child classes are defined. Furthermore, attributes that are referenced in a class' domain members or SQL query should be defined on the class or on one of its parent classes.

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the class. Each individual class must have a unique name; if a duplicate name is found in the model, and the class of that name has the same parent class, then the Visual Modeler can optionally overwrite the existing class with the class defined in the PCIF. If the class's name in PCIF is "RootClass", any attributes defined on this class will be added to the Root Class.
PARENT	CDATA	Yes	The parent class of this class. If not specified, the class will be a child of the Root Class by default.

Subelements:

Name	How Many?	Description
CLASS_ATTRIBUTE	0 or more	An attribute defined on this class. There should never be attribute conflicts with a parent class; that is, if an attribute is defined on a parent class, no attribute by that name should be defined on any child class.
DOMAIN_MEMBER	0 or more	A domain member. Classes should not have both a SQL query and domain members; the two are mutually exclusive. Classes that are parent classes (they have subclasses) should not have domain members.
STANDARD_QUERY	0 or 1	A standard SQL query that defines an database from which this class should get its domain members. If a STANDARD_QUERY is defined on a CLASS, that CLASS should not have any DOMAIN_MEMBER elements, and it should not have an ADVANCED_QUERY element.
ADVANCED_QUERY	0 or 1	An advanced SQL query that defines an database from which this class should get its domain members. If an ADVANCED_QUERY is defined on a CLASS, that CLASS should not have any DOMAIN_MEMBER elements, and it should not have an STANDARD_QUERY element.
REFRESH_INTERVAL	0 or more	A rule that defines how often this class will refresh those attributes which have been marked for scheduled data refreshes. Should only be present if STANDARD_QUERY or ADVANCED_QUERY is defined. Multiple REFRESH_INTERVALs will effectively be "anded" together, so all of them will apply.

Name	How Many?	Description
SELECTION_POINT_ATTRIBUTE	0 or more	A selection point level attribute defined on this class. There should never be attribute conflicts with a parent class or with selection points defined on this class or its subclasses; that is, if a selection point level attribute is defined here, a selection point level attribute of that name should not be defined on the parent class, subclasses, or selection points of this class. Furthermore, no domain member level attributes of that name should be defined on the parent class or subclasses of this class.

CLASS_ATTRIBUTE Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the attribute. This attribute name should not have been defined on an parent of the class it's currently being defined on.
TYPE	Choice of {Date, String, Boolean, Int, Float}	Yes	The type of this attribute.

Subelements:

Name	How Many?	Description
DEFAULT_VALUE	0 or 1	The default value of this attribute.

DEFAULT_VALUE Element

Attributes: None.

Subelements: None.

The DEFAULT_VALUE element contains #PCDATA , which holds the default value of a CLASS_ATTRIBUTE. If the CLASS_ATTRIBUTE is of type Date, the default value should be formatted as an ISO-standard time, such as 2002-09-17T00:00:00.000000+06:00.

If the CLASS_ATTRIBUTE is of type Float, the default value should be formatted as a floating point number, such as 1.328.

If the CLASS_ATTRIBUTE is of type Integer, the default value should be formatted as an integer number, such as 13.

If the CLASS_ATTRIBUTE is of type Boolean, the default value should be formatted as a boolean with the first letter capitalized, such as True or False.

DOMAIN_MEMBER Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the domain member. If this domain member already exists in the target model, properties from the PCIF domain member will overwrite those in the target model.

Subelements:

Name	How Many?	Description
DEFAULT_VALUE	0 or 1	The default value of this attribute.

DM_ATTRIBUTE Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the attribute for which this domain member is providing a value.

Subelements:

None.

The DM_ATTRIBUTE element contains #PCDATA, which holds a value. If the CLASS_ATTRIBUTE to which this DM_ATTRIBUTE is referring is of type Date, the default value should be formatted as an ISO-standard time, such as 2002-09-17T00:00:00.000000+06:00.

If the CLASS_ATTRIBUTE is of type Float, the default value should be formatted as a floating point number, such as 1.328.

If the CLASS_ATTRIBUTE is of type Integer, the default value should be formatted as an integer number, such as 13.

If the CLASS_ATTRIBUTE is of type Boolean, the default value should be formatted as a boolean with the first letter capitalized, such as True or False.

STANDARD_QUERY Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
DATA_SOURCE	CDATA	Yes	A reference to the ALIAS of a DATABASE_REFERENCE.
DISTINCT	Boolean	Yes	Flag that decides whether the query retrieves distinct results.

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
PRIMARY_TABLE	1	The primary WHERE clause and domain member mappings.
SECONDARY_TABLE	0 or more	JOIN clauses and secondary domain member mappings.

PRIMARY_TABLE Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
TABLE	CDATA	Yes	The table in the database where this query will be retrieving its data.

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
COLUMN	0 or more	The mappings of database table columns to domain member attributes.
WHERE	0 or 1	The query's where clause. An empty clause will select all the specified columns of the table unconditionally.

COLUMN Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the column coming from the database table.
KEY	Boolean	Yes	Flag that decides whether this column will be a domain member key. Exactly one column should have this attribute set to TRUE.
ATTRIBUTE_NAME	CDATA	Yes	The domain member attribute into which this column's data will be stored.

Subelements: None

WHERE Element

Attributes: None

Subelements: None.

Contains #PCDATA which acts as the WHERE clause for a standard SQL query.

SECONDARY_TABLE Element

Attributes:

Name	Type	Required?	Description
TABLE	CDATA	Yes	The table in the database where this query will be retrieving its data.

Subelements:

Name	How Many?	Description
COLUMN	0 or more	The mappings of database table columns to domain member attributes.
JOIN	0 or 1	The query's join clause. An empty clause will join all the specified columns of the table unconditionally.

JOIN Element

Attributes: None.

Subelements: None.

Contains #PCDATA which acts as the JOIN clause for a standard SQL query.

ADVANCED_QUERY Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
DATA_SOURCE	CDATA	Yes	A reference to the ALIAS of a DATABASE_REFERENCE.
ASSUME_SORTED	Boolean	No	Flag that indicates whether the ViM should assume the data from this query is already sorted in the order the modeler requires

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
COLUMN	0 or more	The mappings of database table columns to domain member attributes.
QUERY_TEXT	0 or 1	The text of the SQL query.

QUERY_TEXT Element

Attributes: None.

Subelements: None.

Contains #PCDATA, which acts as the text of an SQL query.

SELECTION_POINT Element

Attributes:

Name	Type	Required ?	Description
NAME	CDATA	Yes	The name of the selection point. Each individual selection point must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing selection point with the selection point defined in the PCIF.
CLASS	CDATA	Yes	The name of the class this selection point refers to. This class must have been defined either in the target model or earlier in the PCIF document.
DEFAULT_QUANTITY	CDATA	No	The default quantity to use for all domain members in this selection point. Cannot be specified if DEFAULT_QUANTITY_EXPRESSION is specified.
DEFAULT_QUANTITY_POLICY	CDATA	No	The quantity policy to use with defaults applied to all domain members in the selection point. Only valid if DEFAULT_QUANTITY or DEFAULT_QUANTITY_EXPRESSION is specified.
DEFAULT_QUANTITY_EXPRESSION	CDATA	No	The expression that defines the default quantity to use for all domain members in this selection point. Cannot be specified if DEFAULT_QUANTITY is specified.
QUANTITY	Boolean	No	Flag that defines whether this selection point has quantity. Defaults to false.
QUANTITY_ATTRIBUTE	CDATA	No	Domain member attribute from which to gather default quantity data.
QUANTITY_ATTRIBUTE_POLICY	CDATA	No	Quantity policy to use with defaults gathered from domain member attributes. Only valid when QUANTITY_ATTRIBUTE is specified.

Name	Type	Required ?	Description
MULTISELECT	Boolean	No	Flag that defines whether this selection point is multiselect. Defaults to false.
OPTIONAL	Boolean	No	Flag that defines whether this selection point is optional. Defaults to false.
USE_MIN_MAX	Boolean	No	Flag that defines whether this selection point uses the min and max quantity constraints. Defaults to false.

Subelements:

Name	How Many?	Description
STATIC_DEFAULTS	0 or 1	The set of static defaults for this selection point.
SELECTION_POINT_MIN_QTY_SETTINGS	0 or 1	The minimum quantity settings for the selection point. This subelement should only be defined if USE_MIN_MAX is true.
SELECTION_POINT_MAX_QTY_SETTINGS	0 or 1	The maximum quantity settings for the selection point. This subelement should only be defined if USE_MIN_MAX is true.
DOMAIN_MEMBER_MIN_QTY_SETTINGS	0 or 1	The minimum quantity settings for domain members on this selection point. This subelement should only be defined if both USE_MIN_MAX and QUANTITY are true.
DOMAIN_MEMBER_MAX_QTY_SETTINGS	0 or 1	The maximum quantity settings for domain members on this selection point. This subelement should only be defined if both USE_MIN_MAX and QUANTITY are true.

Name	How Many?	Description
SELECTION_POINT_ATTRIBUTE	0 or more	A selection point level attribute defined on this selection point. There should never be attribute conflicts with the class on which this selection point is defined; that is, if a selection point level attribute is defined here, a selection point level attribute of that name should not be defined this selection point's class or any of its parent classes. Furthermore, no domain member level attributes of that name should be defined on this selection point's class or any of its parent classes.

STATIC_DEFAULTS Element

Attributes: None

Subelements:

Name	How Many?	Description
STATIC_DEFAULT	0 or more	A static default.

STATIC_DEFAULT Element

Attributes:

Name	Type	Required?	Description
DOMAIN_MEMBER	CDATA	Yes	The domain member that is to be defaulted.
QUANTITY	CDATA	No	The quantity that should be used with this default. Should be an integer number. Should not be defined if QUANTITY_EXPRESSION is defined.
QUANTITY_EXPRESSION	CDATA	No	The expression that should be used to find the quantity for this default. Should not be defined if QUANTITY is defined.

Name	Type	Required?	Description
QUANTITY_POLICY	CDATA	No	The quantity policy that should be used with this default. Should be one of {IGNORE, MIN, MAX, SUM}. IGNORE corresponds to a quantity policy of "Overridable."

Subelements: None

SELECTION_POINT_MIN_QTY_SETTINGS Element

Attributes:

Name	Type	Required?	Description
SOURCE	Choice of {QUANTITY, EXPRESSION, SQL_QUERY}	Yes	The source of the number that will be the minimum number of selections on the selection point.
QUANTITY	CDATA	No	The absolute quantity that will act as the minimum selections. Should only be specified if SOURCE is QUANTITY. Should be an integer.
EXPRESSION	CDATA	No	The expression that will act as the minimum selections. Should only be specified if SOURCE is EXPRESSION.
SQL_QUERY	CDATA	No	The SQL query that will gather the data to act as the minimum selections. Should only be specified if SOURCE is SQL_QUERY.
DATABASE	CDATA	No	The ALIAS of the database that the SQL query will act on. Should be defined in the target model or in the PCIF earlier as a DATABASE_REFERENCE. Should only be specified if SOURCE is SQL_QUERY.

Subelements:

Name	How Many?	Description
EXPLANATION	0 or 1	The explanation that will appear if this constraint is violated.

DOMAIN_MEMBER_MIN_QTY_SETTINGS Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
SOURCE	Choice of { QUANTITY, EXPRESSION, ATTRIBUTE }	Yes	The source of the number that will be the minimum number of selections for each domain member.
QUANTITY	CDATA	No	The absolute quantity that will act as the minimum quantity. Should only be specified if SOURCE is QUANTITY. Should be an integer.
EXPRESSION	CDATA	No	The expression that will act as the minimum quantity. Should only be specified if SOURCE is EXPRESSION.
ATTRIBUTE	CDATA	No	The attribute that will contain the data to act as the minimum quantity. Should only be specified if SOURCE is ATTRIBUTE. The attribute should already have been defined on the selection point's class or one of its parent classes.

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
EXPLANATION	0 or 1	The explanation that will appear if this constraint is violated.

DOMAIN_MEMBER_MAX_QTY_SETTINGS Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
SOURCE	Choice of { QUANTITY, EXPRESSION, ATTRIBUTE }	Yes	The source of the number that will be the maximum number of selections for each domain member.

Name	Type	Required?	Description
QUANTITY	CDATA	No	The absolute quantity that will act as the maximum quantity. Should only be specified if SOURCE is QUANTITY. Should be either an integer or the word "UNBOUNDED".
EXPRESSION	CDATA	No	The expression that will act as the maximum quantity. Should only be specified if SOURCE is EXPRESSION.
ATTRIBUTE	CDATA	No	The attribute that will contain the data to act as the maximum quantity. Should only be specified if SOURCE is ATTRIBUTE. The attribute should already have been defined on the selection point's class or one of its parent classes.

Subelements:

Name	How Many?	Description
EXPLANATION	0 or 1	The explanation that will appear if this constraint is violated.

DYNAMIC_DEFAULT Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the dynamic default. Each individual dynamic default must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing dynamic default with the dynamic default defined in the PCIF. If a constraint of a different type exists in the model, the ViM will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
FORMAT	Choice of {Internal, DBTable, SQLQuery}	No	Specifies whether this constraint stores its row data internally (to CMS files), stores them to a database table, or retrieves them from a SQL Query.

Name	Type	Required?	Description
DATA_SOURCE	CDATA	No	Specifies from which database this constraint should store or retrieve its data. Must be a reference to a database name previously defined in the PCIF file as a DATABASE_REFERENCE, or to a database already defined in the destination model. The DATA_SOURCE attribute must be present if FORMAT is DBTable or SQLQuery.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.
ARGUMENT	1 or more	An argument that displays as a column on the left hand side.
RHS_ARGUMENT	1 or more	An argument that displays as a column on the right hand side.
ROW	1 or more	A row that defines a set of values that are incompatible.
CONSTRAINT_QUERY	0 or 1	The SQL query information for this constraint. Should only be specified if the FORMAT attribute is set to SQLQuery.

EXPLANATION Element

Attributes: None.

Subelements: None.

Contains #PCDATA with the text of an explanation.

EXPRESSION Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the expression. Each individual expression must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing expression with the expression defined in the PCIF.
TYPE	Choice of {Numeric, Boolean, Date, String}	Yes	The return type of the expression.
COMMENT	CDATA	No	A comment on the expression.

Subelements: None.

Contains #PCDATA which represents the text of the expression itself.

NOT_COMPATIBLE Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the non-compatibility constraint. Each individual non-compatibility must have a unique name; if a duplicate name is found in the model, then the ViM can optionally overwrite the existing non-compatibility with the non-compatibility defined in the PCIF. If a constraint of a different type exists in the model, the ViM will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
FORMAT	Choice of {Internal, DBTable, SQLQuery}	No	Specifies whether this constraint stores its row data internally (to CMS files), stores them to a database table, or retrieves them from a SQL Query.

Name	Type	Required?	Description
DATA_SOURCE	CDATA	No	Specifies from which database this constraint should store or retrieve its data. Must be a reference to a database name previously defined in the PCIF file as a DATABASE_REFERENCE, or to a database already defined in the destination model. The DATA_SOURCE attribute must be present if FORMAT is DBTable or SQLQuery.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.
ARGUMENT	1 or more	An argument that displays as a column on the left hand side.
RHS_ARGUMENT	0 or more	An argument that displays as a column on the right hand side.
ROW	0 or more	A row that defines a set of values that are incompatible.
CONSTRAINT_QUERY	0 or 1	The SQL query information for this constraint. Should only be specified if the FORMAT attribute is set to SQLQuery.

EXTERN Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name by which this extern will be referenced in the Visual Modeler.
DEFAULT_VALUE	CDATA	No	The default value of this extern.
REQUIRED	Boolean	No	Flag indicating whether a value must be provided for this extern at runtime in order for the configuration to be valid.

Name	Type	Required?	Description
TYPE	Choice of {Date, String, Boolean, Int, Float}	Yes	The data type of this extern.

Subelements: None

EFFECTIVITY Element

Attributes: None

Subelements:

Name	How Many?	Description
EFFECTIVEDATE	1 or more	The effectivity dates.

EFFECTIVEDATE Element

Attributes:

Name	Type	Required?	Description
EFFECTIVE_FROM	CDATA	Yes	The date effectivity begins. Should be in ISO-time format, for example 2002-09-17T00:00:00.000000+06:00. Should be a date before EFFECTIVE_TO.
EFFECTIVE_TO	CDATA	Yes	The date effectivity ends. Should be in ISO-time format, for example 2002-09-17T00:00:00.000000+06:00. Should be a date after EFFECTIVE_FROM.
COMMENT	CDATA	No	A comment on these effective dates.

Subelements:

Name	How Many?	Description
EFFECTIVEDATE	1 or more	The effectivity dates.

COMMENT Element

Attributes: None.

Subelements: None.

Contains #PCDATA with the text of a comment.

ARGUMENT Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
LEVEL	CDATA	No	The level of this argument. Should be an integer. Defaults to 1.
CLASS	CDATA	No	The class this argument refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
SELECTION_POINT	CDATA	No	The selection point this argument refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
PROPERTY	CDATA	No	The property (also known as an attribute) that this argument refers to.
EXPRESSION	CDATA	No	The expression that this argument refers to.
COMPLETE	Boolean	No	Flag indicating whether the set of expression comparisons in the column denoted by this argument forms a complete range. Only valid if the EXPRESSION attribute is specified.

Subelements: None

RHS_ARGUMENT Element

Attributes:

Name	Type	Required?	Description
LEVEL	CDATA	No	The level of this argument. Should be an integer. Defaults to 1.
CLASS	CDATA	No	The class this argument refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
SELECTION_POINT	CDATA	No	The selection point this argument refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
PROPERTY	CDATA	No	The property (also known as an attribute) that this argument refers to.

Subelements: None

ROW Element

Attributes: None

Subelements:

Name	How Many?	Description
VALUE	0 or more	A single value in a column of a table constraint. If this SET is on the left hand side, there should be only one VALUE. If it is on the right hand side, there can be multiple VALUES.

There should be exactly as many SET elements in a ROW as there are ARGUMENTs plus RHS_ARGUMENTs. For instance, if there are two ARGUMENTs and three RHS_ARGUMENTs, there should be five SET elements in each ROW.

SET Element

Attributes: None

Subelements:

Name	How Many?	Description
DEFAULT_VALUE	0 or 1	The default value of this attribute.

VALUE Element

Attributes: None.

Subelements: None.

Contains #PCDATA that references a domain member name or attribute value.

The CONSTRAINT_QUERY Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
SEPARATOR_CHARACTER	CDATA	No	If this SQL query will return multiple values per row, this is the character that separates each individual value. Should be exactly one character long.
QUANTITY_SEPARATOR	CDATA	No	If this SQL query will return values with quantities and quantity policies, this is the character that will separate the policy, the quantity, and the value. Should be exactly one character long.

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
SQL_CLAUSE	Exactly 1	The SQL clause for this constraint.

SQL_CLAUSE Element

Attributes: None.

Subelements: None.

Contains #PCDATA that is a complete SQL clause.

COMPATIBLE Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the compatibility constraint. Each individual compatibility must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing compatibility with the compatibility defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
FORMAT	Choice of (Internal, DBTable, SQLQuery)	No	Specifies whether this constraint stores its row data internally (to CMS files) or to a database table, or retrieves them from a SQL Query.
DATA_SOURCE	CDATA	No	Specifies the database that this constraint is to use to store or retrieve its data. Must be a reference to a database name previously defined in the PCIF file as a DATABASE_REFERENCE, or to a database already defined in the destination model. The DATA_SOURCE attribute must be present if FORMAT is DBTable or SQLQuery.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint..
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.
ARGUMENT	1 or more	An argument that displays as a column on the left hand side.
RHS_ARGUMENT	0 or more	An argument that displays as a column on the right hand side.
ROW	0 or more	A row that defines a set of values that are incompatible.
CONSTRAINT_QUERY	0 or 1	The SQL query information for this constraint. Should only be specified if the format attribute is set to SQLQuery.

REQUIRED Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the required constraint. Each individual required must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing required with the required defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
FORMAT	Choice of (Internal, DBTable, SQLQuery)	No	Specifies whether this constraint stores its row data internally (to CMS files) or to a database table, or retrieves them from a SQL Query.
DATA_SOURCE	CDATA	No	Specifies the database that this constraint is to use to store or retrieve its data. Must be a reference to a database name previously defined in the PCIF file as a DATABASE_REFERENCE, or to a database already defined in the destination model. The DATA_SOURCE attribute must be present if FORMAT is DBTable or SQLQuery.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.
ARGUMENT	1 or more	An argument that displays as a column on the left hand side.
RHS_ARGUMENT	1 or more	An argument that displays as a column on the right hand side.

Name	How Many?	Description
ROW	0 or more	A row that defines a set of values that are incompatible.
CONSTRAINT_QUERY	0 or 1	The SQL query information for this constraint. Should only be specified if the format attribute is set to SQLQuery.

ELIMINATION Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the elimination constraint. Each individual elimination must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing elimination with the elimination defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
LEVEL	CDATA	No	The level of this constraint. Defaults to 1.
ALLOW	Choice of {NONE, ALL, GREATEST, LEAST, FIRST, LAST, EARLIEST, LATEST}	No	The set of values the elimination will allow.
SELECTION_POINT	CDATA	No	The selection point this elimination applies to.
TARGET_ATTRIBUTE	CDATA	No	The attribute this elimination acts upon. Should be a valid attribute of the SELECTION_POINT specified earlier.

Name	Type	Required?	Description
COMPARATOR	Choice of {NEQ, GEQ, LEQ, LT, GT, EQ, CONTAINS, DOES_NOT_CONTAIN, STARTS_WITH, ENDS_WITH, STARTS, ENDS, IS_CONTAINED_IN, IS_NOT_CONTAINED_IN}	Yes	The comparator that will be used in the elimination.
COMPARISON_EXPRESSION	CDATA	No	The expression that the target attribute will be compared to. Should be of the same type as the TARGET_ATTRIBUTE. Should not be specified if COMPARISON_CONSTANT is specified.
COMPARISON_CONSTANT	CDATA	No	The constant that the target attribute will be compared to. Should be of the same type as the TARGET_ATTRIBUTE. Should not be specified if COMPARISON_EXPRESSION is specified.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The name of the comparison constraint. Each individual comparison must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing comparison with the comparison defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.

COMPARISON Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the comparison constraint. Each individual comparison must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing comparison with the comparison defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.
LEVEL	CDATA	No	The level of this constraint. Defaults to 1.
LEFT_EXPRESSION	CDATA	No	The expression on the left hand side of the comparison.
COMPARATOR	Choice of {NEQ, GEQ, LEQ, LT, GT, EQ, CONTAINS, DOES_NOT_CONTAIN, STARTS_WITH, ENDS_WITH, STARTS, ENDS, IS_CONTAINED_IN, IS_NOT_CONTAINED_IN}	No	The comparator that will be used in the elimination.
RIGHT_EXPRESSION	CDATA	No	The expression on the right hand side of the comparison. Should be of the same type as the LEFT_EXPRESSION. Should not be specified if RIGHT_CONSTANT is specified.
RIGHT_CONSTANT	CDATA	No	The constant on the right hand side of the comparison. Should be of the same type as the LEFT_EXPRESSION. Should not be specified if RIGHT_EXPRESSION is specified.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.

RESOURCE_CONSTRAINT Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the resource constraint. Each individual resource constraint must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing resource constraint with the resource constraint defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the constraint is enabled. Defaults to TRUE.

Subelements:

Name	How Many?	Description
EFFECTIVITY	0 or 1	The effectivity dates for this constraint.
COMMENT	0 or 1	A comment on this constraint.
EXPLANATION	0 or 1	An explanation that is shown if this constraint is violated.
RESOURCE_PROVIDERS	Exactly 1	The resource providers.
RESOURCE_CONSUMERS	Exactly 1	The resource consumers.

RESOURCE_PROVIDERS Element

Attributes: None

Subelements:

Name	How Many?	Description
ATTRIBUTE	0 or more	The attributes that provide resources.

ATTRIBUTE Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
CLASS	CDATA	Yes	The class this attribute refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
SELECTION_POINT	CDATA	No	The selection point this attribute refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
PROPERTY	CDATA	Yes	The property (also known as an attribute) that this attribute refers to.

Subelements: None

RESOURCE_CONSUMERS Element

Attributes: None

Subelements:

<i>Name</i>	<i>How Many?</i>	<i>Description</i>
ATTRIBUTE	0 or more	The attributes that consume resources.

SELECTION_POINT_ATTRIBUTE Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
NAME	CDATA	Yes	The name of the selection point level attribute. This attribute name should not have been defined on an parent of the class or selection point it's currently being defined on.
TYPE	Choice of {Date, String, Boolean, Int, Float}	Yes	The type of this attribute.

Subelements:

Name	How Many?	Description
DEFAULT_VALUE	0 or 1	The default value of this attribute.

SUMMATION Element

Attributes:

Name	Type	Required?	Description
NAME	CDATA	Yes	The name of the summation. Each individual summation must have a unique name; if a duplicate name is found in the model, then the Visual Modeler can optionally overwrite the existing summation with the summation defined in the PCIF. If a constraint of a different type exists in the model, the Visual Modeler will not import this constraint.
ENABLED	Boolean	No	Flag that specifies whether the summation is enabled. Defaults to TRUE.

Subelements:

Name	How Many?	Description
COMMENT	0 or 1	A comment on this constraint.
SUMMANDS	Exactly 1	The attributes to be summed.
TOTAL_ATTRIBUTE	Exactly 1	The attribute where the sum will be stored.

SUMMANDS Element

Attributes: None

Subelements:

Name	How Many?	Description
ATTRIBUTE	0 or more	The attributes that are to be summed.

TOTAL_ATTRIBUTE Element

Attributes:

<i>Name</i>	<i>Type</i>	<i>Required?</i>	<i>Description</i>
CLASS	CDATA	No	The class this attribute refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
SELECTION_POINT	CDATA	No	The selection point this attribute refers to. Either the CLASS or the SELECTION_POINT must be specified, but not both.
PROPERTY	CDATA	Yes	The property (also known as an attribute) that this attribute refers to.

Subelements: None

Appendix G

Element-Attribute Trees

XML may be viewed as a tree of elements, with some elements having attributes. This appendix presents COP XML as element-attribute trees, and has these sections:

- Complete COP XML
- Configurator XML Interface

Complete COP XML

The COP DTD defines which XML elements and attributes may be used for:

- Configurations saved in XML, and restored from XML by the COP.
- XML requests sent to, and XML responses received from the COP, and translated by the COPXMLServlet—the Configurator XML interface.

The next two trees present the complete COP XML, including those elements and attributes that are not part of the Configurator XML interface.

Without Attributes

This tree presents the complete COP XML without attributes:

```

Configurator XML Interface

The Configurator XML interface uses only some of the elements and attributes of the COP DTD. The next two trees present only those elements and attributes that the COPXMLServlet translates into HTTP POST requests, and responses.

Request

This tree has those COP XML elements and attributes that are used in a request.

```

CONFIGURATION MODEL_ID LOCALE MODEL_VERSION COMPILE_VERSION TOTAL_PRICE

Glossary

File set	<ul style="list-style-type: none">• <i>Model files</i>, which reside on the production Configuration server.• <i>User Interface (UI)</i> files, either the PeopleSoft Advanced Configurator HTML Pages and a UI specification, or custom HTML pages based on JavaServer Pages™ (JSP) technology.• (Optional) Java class files for custom functions.
Component model	The cross-constrained models comprising a compound model are called component models.
Compound model	A group of related component models that contain decision points and expressions that constrain, or are constrained by, the values of one or more decision points in other models.
Configurable component	<p>Each component model is associated with one or more configurable components. These components represent those parts of a complex product that are themselves separately configurable. They are to the compound model what selection points are to the component model.</p> <p>Using configurable components, you can specify what kinds of components (defined by a component model) can be included in the compound model, how they can be connected, and which information from each component is passed to each of the other component models. Each configurable component is associated with one and only one component model. However, each component model can be associated with more than one configurable component.</p>
Connection point	The object that defines the connection between the selection points of two component models. Connection points synchronize selections.
Defaults	Decision points in component models offer the option of setting the values that appear when the page first appears. Similarly, you can set default values for decision points generated by a compound model's configurable components. These will override the static default values set in the associated component model.
Directional, nondirectional relationship	Compatibility, requirement, and dynamic default constraints have an optional notion of direction.
Multi-select control	<p>A control that supports zero or more selections, determined by the "Multi Sel" or Use Min/Max properties. If the control is expressed as a drop-down list, the selection <i>None</i> is always added so that the control can be initialized without picks. If the control is expressed as check boxes, <i>None</i> is unnecessary, as the user can de-select selections.</p> <p>See Chapter 6, "Specifying Quantities on Selection Points," Setting Default Selections and Quantities, page 124.</p>

Optional control, required control	Two properties control whether a selection on the corresponding selection point is required for the configuration to be verified correct. You can use one or the other as needed. It is determined by setting either the Optional property to <i>False</i> , or the Use Min/Max property to <i>True</i> with a "Min" value greater than 0.
Relationships	<p>In compound modeling, you can pass values from one component model to the selection points in another component model. You can use these values in constraints, creating "external constraints." These external constraints constrain the selection point of one component model against the selection point of another component model, and require your user to configure components so that they can connect to one another.</p> <p>Required relationships in a compound model are those that must be met or the configuration is not valid. You can have the Configurator check for such relationships by specifying them for each configurable component.</p>
Single-select control	A control that supports only one selection (radio buttons), specified either when the "Multi Sel" property is set to "False," or when "Use Min/Max" is True with a "Min" value of 0. If either of these properties is set to False, a selection named "None" will be automatically added as a selection item.
Solution	In online configuration, a <i>Solution</i> is the set of files and information specifically created to solve a product configuration problem. To implement a Solution based on Advanced Configurator, you must create some or all of these files, depending on the requirements of your configuration problem and whether or not the Solution integrates with other PeopleSoft CRM applications.
Solution Installer	An installer database (MSI file) produced by the Packaging Tool that contains the files needed by a PeopleSoft configuration application to run independently of the enterprise server on a local machine.
Solution Package	The set of filenames for the files that you want included in the Solution Installer intended for distribution to the mobile user. The Package has the extension .cci and contains filenames and references for those files.
