1 What's New in This Release

What's New in Siebel Enterprise Integration Manager Administration Guide, Siebel CRM 21.11 Update

The following table lists the changes in this revision of the documentation to support this release of the software.

What's New in Siebel Enterprise Integration Manager Administration Guide, Siebel CRM 21.11 Update

Topic	Description
Using ACT! for Legacy Data Imports	Removed topic. Removed obsolete topic.
<i>Importing LOVs Using EIM</i>	New topic. Added information about importing LOVs using the LOV.ifb file.
<i>Importing LOV and MLOV Data into Base Tables</i>	Modified topic. Updated the information about importing and validating LOV and MLOV data.
<i>Example of Importing and Exporting Hierarchical LOVs</i>	Modified topic. Removed obsolete references to 4776271 (Doc ID) on My Oracle Support.

What's New in Siebel Enterprise Integration Manager Administration Guide, Siebel CRM 20.1 Update

No new features have been added to this guide for this release. This guide has been updated to reflect only product name changes.

What's New in Siebel Enterprise Integration Manager Administration Guide, Siebel CRM 19.1 Update

No new features have been added to this guide for this release. This guide has been updated to reflect only product name changes.

2 Siebel Enterprise Integration Manager: an Overview

Siebel Enterprise Integration Manager: an Overview

This chapter explains how to configure and use Siebel Enterprise Integration Manager.

This chapter includes the following sections:

- *About Siebel Enterprise Integration Manager*
- *EIM Functions*
- *Process Flow Between EIM and Other Databases*
- *Mobile Web Client Requirements*

About Siebel Enterprise Integration Manager

Siebel Enterprise Integration Manager (EIM) is a server component in the Siebel EAI component group that transfers data between the Siebel database and other corporate data sources. This exchange of information is accomplished through intermediary tables called EIM tables. (In earlier releases, EIM tables were known as interface tables.) The EIM tables act as a staging area between the Siebel application database and other data sources.

EIM is your primary method of loading mass quantities of data into the Siebel database. You should use EIM to perform bulk imports, updates, merges, and deletes of data. Examples of each of the main EIM functions (import, export, update, and delete) are provided in *EIM Functions*.

In the Siebel application database, there are application tables (known as base tables), which Siebel applications use. For data to come from other corporate data sources (external databases) into Siebel application tables, the data must go through EIM tables. So the data exchanges between the Siebel database and external databases occurs in two parts:

1. Load data into EIM tables.
2. Run Siebel EIM to import the data from the EIM tables into the Siebel base tables.

Note: While the first part of this data-exchange process involves the intermediary tables that are called EIM tables, only the second part of the process involves the functionality of Siebel EIM.

When data is entered through the Siebel user interface, the application references properties set at the business component object type. However, when data is entered into Siebel base tables through EIM, EIM references properties set at the table object type.

Note: You must use EIM to perform bulk imports, exports, merges, and deletes, because Oracle does *not* support using native SQL to load data directly into Siebel base tables (the tables targeted to receive the data). You should also be aware that EIM translates empty strings into NULL.

EIM Functions

This guide explains how to configure and use Siebel EIM to perform the functions described in this topic. Each function is discussed separately in the chapters referenced.

Import New and Revised Data into Siebel Base Tables

The EIM import function can be used in several different ways:

- When initially implementing a Siebel application, load the Siebel database tables with data and file attachments created by external applications. For example, you can import information about product lines and products from an inventory control database into the Products entity in the Siebel database.
- As part of maintaining the Siebel database, you can use EIM for data archival. This not only provides customers with a Siebel database that is optimally using the resources available to it, but also streamlines the implementation of a corporate data archival strategy.
- As part of maintaining a non-Siebel database, you can update it with information from the Siebel database. For example, you might add new customers to an accounting database from the Siebel database.

See *Importing Data* for a detailed discussion of the import function.

Export Data from Siebel Base Tables

The data contained within a Siebel application is available for transfer to non-Siebel applications by using EIM. When implementing a non-Siebel application, you can export data from the Siebel database tables for use by that application. For example, you can export employee information to a corporate sales commission application. See *Exporting Data* for a detailed discussion of the export function.

Delete Data from Siebel Base Tables

As part of maintaining the Siebel database, you can identify rows to be deleted from a table and its associated child and intersection tables. For example, you might delete an obsolete product line and its associated products. See *Deleting Data* for a detailed discussion of the delete function.

Merge Data in Siebel Base Tables

In response to such external events as corporate mergers, you can merge two or more database rows into a single row. For example, you might merge the Frame, Inc. account information into the Adobe Corp. account. See *Merging Data* for a detailed discussion of the merge function.

Process Flow Between EIM and Other Databases

For each EIM process, you need to complete the following sequence of steps.

1. **Prepare the EIM tables.** For delete, merge, or import operations, the EIM tables require loading with representative data that allows EIM to identify the specific Siebel base table on which to operate. You can use either an SQL ancillary program utility or native SQL to perform this function. The structure of the EIM tables has the required mappings for the primary (or target) base table and other base tables that are serviced by the EIM table. The EIM export processes require minimal preparation of the EIM tables.

When an export operation takes place, the EIM tables are populated with data from the Siebel base tables. Therefore, you can use either an SQL ancillary program or native SQL to transfer data from the Siebel application to a non-Siebel application. For more information, see [Siebel EIM Tables](#).

2. **Edit the EIM configuration file.** An ASCII or Unicode (binary) text file of extension type .IFB that resides in the Siebel Server/admin directory allows you to define the type of EIM processes to be performed: export, delete, merge, or import. For more information, see [EIM Configuration File](#).
3. **Run EIM.** EIM is submitted as a Siebel Server batch component task either from the Administration - Server Management views or from the Server Manager command line interface. For more information, see [Running EIM](#).
4. **Check results.** The EIM component task produces a log file, which provides tracing information about the process. The tracing information produced is variable dependent upon the EIM component task parameters used and the Siebel Server event logging deployed for the EIM component. As always, during testing operations you should check the EIM processes using increased tracing information, and then reduce tracing when the process is deployed to production.

The following image illustrates the process flow between a non-Siebel database and Siebel EIM database as follows:

- A non-Siebel database uses an SQL ancillary program utility to receive or send data to Siebel EIM tables.
- Siebel EIM moves data between Siebel EIM tables and Siebel base tables.

Mobile Web Client Requirements

Due to the complexity of table relationships and Mobile Web Client requirements, you must use EIM to import data into Siebel base tables.

CAUTION: Do not attempt to modify data directly in the physical tables. Oracle does not support performing this activity for the reasons that follow. The logical relationships that exist within the Siebel base tables are many and complex, as governed by the Siebel repository metadata. Direct modification of Siebel base tables is not supported because there is a high risk of data integrity corruption. EIM maintains data integrity and resolves foreign key relationships during the import process. In addition, EIM data inserts, updates, or deletions are routed to mobile users with Siebel Remote local databases or Siebel replicated nodes.

The only exception is when you are migrating the entire Siebel schema from one database to another. In this case, you may select to use a tool provided by the database vendor to migrate the data.

In other rare cases where EIM cannot be used, it may be possible to use Siebel Visual Basic (VB) to insert, update, or delete large amounts of data. For information on VB methods, see *Siebel VB Language Reference*.

For initial data loading, you should consider set-based operations for all EIM processes. To maximize performance, you should also consider running EIM processes in parallel.

For ongoing operations, if you are using Mobile Web Clients within your architecture, you should consider EIM in row-by-row operations for the data that is required of the Mobile Web Clients. Running large EIM processes and set-based operations usually requires performing a database extraction for Mobile Web Clients, if the data being manipulated affects them.

3 Siebel EIM Tables

Siebel EIM Tables

This chapter discusses Siebel EIM tables (also known as interface tables) and how EIM uses them. Siebel EIM tables are intermediate database tables that act as a staging area between the base tables in the Siebel database and other databases. This chapter is organized into the following sections:

- *EIM Tables Overview*
- *EIM Table Columns*
- *EIM Table and Column Mappings*

EIM Tables Overview

Siebel EIM tables are intermediate database tables that act as a staging area between the base tables in the Siebel database and other databases. EIM tables are designed to be simple and straightforward so they can be loaded or read by way of external programs. This section provides an overview of how EIM works with these EIM tables and how table names are derived.

Preparing EIM Tables for Merge, Update, or Import Processes

Before EIM can be used in a merge, update, or import process, a Siebel administrator or a database administrator must populate the EIM tables with data, using any method supported by the database. A Siebel administrator then invokes EIM to process this data. EIM makes multiple passes through the tables to complete the specified process.

Each EIM table usually supports a group of base tables that can be imported or exported in a single batch. Base tables are the tables within the Siebel database that contain your data. Base tables are the final destination of data imported into the Siebel database and the source of data exported from the Siebel database.

Note: If the Siebel administrator is importing into base tables that use the UTC (Universal Time Coordinated) time scale, the Siebel administrator or a database administrator must convert the local time in the data into UTC before loading data into the EIM tables.

EIM Table Naming Conventions

EIM tables in the Siebel database use a three-part naming convention; the syntax is: PREFIX_NAME_SUFFIX. These three parts are described as follows:

- **PREFIX.** All interface tables used by EIM have the prefix EIM_ (such as EIM_ACCOUNT). These EIM tables support Organizations, so they can be used for all EIM processes.

Note: Previous versions of EIM used a different set of EIM (interface) tables, identified by the prefix S_ and the suffix _IF. These tables still appear in the Siebel database, but are inactive. These tables will *not* be included in the Siebel database in future versions. For help activating these tables temporarily, contact your Oracle sales representative for Oracle Advanced Customer Services to request assistance from Oracle's Application Expert Services.
- **NAME.** A unique table name that is generally composed of an abbreviation of an entity type name. If more than one EIM table is required to fully support an entity, a sequential number may be added to the name of each table after the first one.
- **SUFFIX.** A supertype name may be followed by a suffix that indicates the types of data supported by the EIM table or to distinguish it as an EIM table.

For more information, see [Viewing EIM Table Mappings to Base Tables](#).

EIM Table Columns

Running EIM is an iterative process, with each step accomplishing specific tasks and moving toward successful completion of the entire process. To process on a row-by-row basis, EIM uses several columns common to every EIM table. These columns are described in this section.

Several columns are mandatory. Others are conditionally mandatory, depending on the conditions of your import. To determine mandatory columns, use Siebel Tools to view each column in an EIM table and the EIM table's target base table columns.

By following the recommended import sequence, you make sure that the appropriate data dependencies are established.

Note: For import and merge processes, you must populate the ROW_ID, IF_ROW_STAT, and IF_ROW_BATCH_NUM columns in the EIM tables. This also must be done for delete processes when you run DELETE EXACT. For merge processes, you also need to populate the IF_ROW_MERGE_ID column. Do not populate these required columns with spaces because a space does *not* equal a NULL value.

Mandatory Columns for EIM Processing

ROW_ID. For an EIM table row to be eligible for processing, you must initialize its ROW_ID. The ROW_ID, in combination with the value of IF_ROW_BATCH_NUM, must yield a unique value. The ROW_ID values in the EIM tables are *not* the

ROW_ID values that are assigned to the row when it is loaded into the base table. An EIM-generated ROW_ID has a ##-###-### format. A regular ROW_ID that is assigned to the row has a #-## format.

IF_ROW_BATCH_NUM. You must set the values in this column to the same integer, greater than or equal to 0, as an identifying number for all rows to be processed as a batch. The maximum value is 2147483647. Use this column as the first key of any new indexes created on an EIM table.

IF_ROW_MERGE_ID. You can set this column to one of two values:

- NULL. This value identifies the remaining record, or merged-into-row.
- ROW_ID. This value identifies the ROW_ID number in the EIM table where the row will be merged.

Note: This value is the ROW_ID of records in the EIM table, not the base tables.

IF_ROW_STAT. EIM updates this column after processing the row to indicate the status of the record. The IF_ROW_STAT column is not used by EIM when determining which rows to process. When populating the EIM tables, you can set this column to any value except NULL. You can initially set this value to FOR_IMPORT to indicate that the row has not been imported. After processing, if certain rows were not imported due to a data error, you should change:

- IF_ROW_BATCH_NUM value for the rows that require reimporting
- BATCH line in the configuration file

If EIM updates this column to NOT_ALLOWED after processing a row, EIM has attempted to insert a new row but the action is not allowed. In such cases, the INSERT_ROWS parameter may have been set to FALSE.

IF_ROW_STAT_NUM. After processing, this column contains a zero (0) if a row was successfully processed to completion. If processing failed, this column contains the pass number where the pass failed.

Temporary columns. EIM uses temporary columns to manipulate data during processing. For example, EIM might store the ROW_ID value for a Siebel base table in a temporary column. These column names begin with T_ and indicate the table or column for which they are used. Because EIM uses these columns internally during processing, do not manipulate these columns in the EIM tables.

For detailed information about each EIM table, generate a table mapping report, see [Generating EIM Table Mapping Reports](#).

File Attachment Columns

Three EIM table columns must be populated in order to import file attachments. The following information describes these columns and uses the attachment file budget99.doc as an example.

Column	Description	Example
FILE_NAME	This column requires the root filename of the file attachment.	FILE_NAME="budget99"
FILE_EXT	This column requires the extension type of the file attachment (DOC, XLS, or TXT).	FILE_EXT="doc"
FILE_SRC_TYPE	This column requires the value "FILE" or the rows cannot be imported.	FILE_SRC_TYPE="FILE"

You can also use these columns to define hyperlinks, as shown in the following information.

Column	Setting
FILE_NAME	Set to actual URL
FILE_EXT	NULL
FILE_SRC_TYPE	'URL'

Organization Columns

The EIM_ type interface tables use the xxx_BU/xxx_BI column pairs to map organizations. For example, the CON_BU/CON_BI column in the EIM_CONTACT interface table is mapped to the BU_ID column in the S_CONTACT base table.

In order for organizations to be resolved properly, you need to populate the xxx_BU column with the organization name and leave the xxx_BI column empty. Do not populate the xxx_BU column with the organization ROW_ID. EIM looks up the ROW_ID for the organization in xxx_BU and puts it in the corresponding xxx_BI column.

EIM Table and Column Mappings

EIM uses EIM table mappings to map columns from EIM tables to Siebel base tables. Siebel predefined EIM mappings are fixed and cannot be remapped. Using Siebel Tools, you can:

- View EIM table mappings to Siebel base tables
- View interface column mappings to Siebel base table columns
- View Siebel base table mappings to EIM tables
- Print EIM table reports

Some base tables may not be mapped to a corresponding EIM table. In such cases, use Siebel VB to load data into these base tables and create a service request (SR) on My Oracle Support regarding the missing mapping. EIM does not interfere with Siebel VB code because Siebel VB works at the business object layer, and EIM works at the data object layer. You can also use the EIM Table Mapping Wizard to add missing mappings. For more information, see *Configuring Siebel Business Applications*.

For information on using Siebel VB, see *Siebel VB Language Reference*.

Database Extensibility and EIM

If you have licensed Database Extensibility and created extensions, you can use the Column Mapping view to specify mappings to your new fields. Database Extensibility and EIM support mappings between columns in extension tables and EIM tables only if these columns share the same base table. To map EIM table extensions to base table extensions, you must specify which column the extended field will point to in the base table. For more information on Database Extensibility, see *Configuring Siebel Business Applications*.

EIM Table Mappings Provided as Common Parents to Nontarget EIM Table Mappings

Some EIM table mappings (usually to the target base table) are provided only as a common parent to nontarget EIM table mappings. An example of this type of EIM table mapping is mapping from the EIM_OPTY_DTL interface table to the S_OPTY base table. These EIM table mappings have a comment in the Siebel repository, indicating that they do not support inserting or updating data.

In such EIM table mappings, only the user key columns are mapped. Except for updating the primary foreign key columns, EIM does not support inserting and updating rows using these EIM table mappings.

Parameters to Set

For stability of EIM when using these EIM tables, follow the template in the default.ifb file by including the following parameters for the relevant section in the EIM configuration file:

- INSERT ROWS = *optional parent_table*, FALSE
- UPDATE ROWS = *optional parent_table*, FALSE

CAUTION: If you do not include these parameters, the EIM process may fail or some exceptions may occur.

Exception to Recommended Parameter Settings

An exception to using the recommended parameter settings is when you want to update the primary foreign key columns in the parent table. In this case, you do not want to include the following parameter in the EIM configuration file:

UPDATE ROWS = *parent_table*, FALSE

For example, EIM_ACCOUNT1 maps to the user key columns of S_ORG_EXT only. You can use EIM_ACCOUNT1 to update the primary foreign keys in S_ORG_EXT if the explicit primary mappings exist, such as S_ORG_EXT.PR_INDUST_ID, in the explicit primary mapping contained in the table mapping of S_ORG_INDUST. For more information, see [About Explicit Primary Mappings](#).

In this case, you should use the default setting, UPDATE ROWS = S_ORG_EXT, TRUE in the EIM configuration file. If you do not need to update primary foreign keys in S_ORG_EXT, then you should set UPDATE ROWS = S_ORG_EXT, FALSE in the EIM configuration file.

Creating New EIM Table Mappings to Existing Base Tables

You can create new EIM table mappings from an EIM table into a base table if either of the following conditions is true:

- Mappings already exist from the EIM table to the base table.
- The base table is an extension table and mappings already exist from the EIM table to the corresponding base table.

For example, you could create a new column in EIM_ACCNT_DTL and map this either to a new extension column in S_ORG_EXT or to an existing column in the extension table S_ORG_EXT_X. These mappings are defined using Siebel Tools.

If you create an extension column to a base table, then run the EIM Table Mapping Wizard, the Wizard creates the following mappings:

- The mapping for the newly added extension column
- The mappings for all unmapped columns in the base table, including unmapped Siebel base columns

In general, manually creating mappings to an existing Siebel base column in Siebel Tools is not supported. For further information, contact your Oracle sales representative for Oracle Advanced Customer Services to request assistance from Oracle's Application Expert Services.

About Explicit Primary Mappings

The Siebel Data Model uses primary foreign keys (or primaries) to point from a parent base table to a child base table. Primaries enable business logic in the Siebel Data Model, such as identifying the primary position for an account. Moreover, primaries improve performance by eliminating repeating subqueries when data from both the parent table and the primary child table are displayed. If you do not use primaries, then you must execute a new query to identify any child records each time a parent record is displayed.

For more information, see the following sections:

- [Setting Explicit Primary Mappings](#)
- [Setting Explicit Primaries for Many-to-Many Relationships](#)

Setting Explicit Primary Mappings

Primary foreign keys are columns that have names usually beginning with PR_ and are defined as primaries in the data model. If both the parent table and the primary child table of a primary foreign key are mapped to the same EIM table, then you should see an explicit primary mapping for this primary foreign key under the table mapping of the primary child table.

Note: Before you can create an explicit primary mapping, both the parent and the primary child table must be mapped to the same EIM table.

If an explicit primary mapping exists, you can use EIM to set the primary explicitly during import or update by setting the primary flag column in the EIM table. For an example of this, see [Example of Setting Explicit Primary Mappings](#).

Setting Explicit Primaries for Many-to-Many Relationships

The example of setting a primary key in [Example of Setting Explicit Primary Mappings](#) explains how to set an explicit primary for a one-to-many relationship. When setting a primary key for a many-to-many relationship, such as the relationship between Opportunities and Contacts, there is also an intersection table to consider. For an example, see [Example of Setting Explicit Primary Mappings for Many-to-Many Relationships](#).

About Viewing EIM Table Mappings

Before viewing EIM table mappings, you need to make sure your View settings are correct in Siebel Tools so that you can see the appropriate object types in the Object Explorer. Information on viewing EIM table mappings is organized as follows:

- *Verifying Your Object Explorer View Settings*
- *Viewing EIM Table Mappings to Base Tables*
- *Viewing Interface Column Mappings to Base Tables*
- *Viewing Base Table Mappings to EIM Tables*
- *Generating EIM Table Mapping Reports*

Verifying Your Object Explorer View Settings

In order to be able to view all the EIM object types in the Siebel Tools Object Explorer, verify that your settings are correct.

To verify your view settings for the Object Explorer

1. Start Siebel Tools.
2. From the View menu, choose Options.
3. In the Development Tools Options dialog box, click the Object Explorer tab.
4. From the Object Explorer Hierarchy, find the EIM Interface Table object.
The EIM Interface Table may appear enabled, but inactive.
5. Deselect the EIM Interface Table object, then select it again.
The EIM Interface Table object appears enabled, and active.
6. In the Object Explorer Types tab, expand the EIM Interface Table object.
The rest of the EIM object types appear beneath the EIM Interface Table object type.

Viewing EIM Table Mappings to Base Tables

Use Siebel Tools to view EIM table mappings to base tables.

To view EIM table mappings to base tables

1. Start Siebel Tools.
2. In the Object Explorer, click the Types tab.
3. Click EIM Interface Table.
4. In the EIM Tables window, select the EIM table for which you want to view the mappings.
5. In the Object Explorer, expand EIM Interface Table.
6. Click EIM Table Mapping.
The EIM Table Mappings window displays all base table mappings for the selected EIM table.

You can view mappings for all interface columns, but you can only add or modify mappings for extended columns in the base schema to extended columns in the EIM tables.

The following figure shows an example of viewing the EIM table mappings for the EIM_ACCOUNT interface table. In the EIM Table Mappings list applet, you can find information about each base table that has been mapped to the selected EIM table. The Destination Table field contains the physical name of the mapped base table. You can also see which temporary columns (T_*) EIM is using when processing a mapped base table.

EIM Tables						
<div>Extend Apply Activate</div>						
W	Name	Changed	Project	User Name	Alias	
>	EIM_ACCOUNT		EIM Accounts and QL	EIM_ACCOUNT		
	EIM_ACCOUNT1		EIM Accounts and QL	EIM_ACCOUNT1		
	EIM_ACCOUNT2		EIM Accounts and QL	EIM_ACCOUNT2		

EIM Table Mappings						
<div>Map Table Generate Proc Columns</div>						
W	Name	Changed	Destination Table	Second Row	EIM Exists Proc Column	EIM ROW_ID Proc Column
>	S_ACCNT_POSTN		S_ACCNT_POSTN		T_ACCNTPOST_EXS	T_ACCNTPOST_RID
	S_ADDR_ORG		S_ADDR_ORG		T_ADDR_ORG_EXS	T_ADDR_ORG_RID
	S_ORG_BU		S_ORG_BU		T_ORG_BU_EXS	T_ORG_BU_RID
	S_ORG_EXT		S_ORG_EXT		T_ORG_EXT_EXS	T_ORG_EXT_RID
	S_ORG_REL		S_ORG_REL		T_ORG_REL_EXS	T_ORG_REL_RID
	S_PARTY		S_PARTY		T_PARTY_EXS	T_PARTY_RID
	S_PARTY_PER		S_PARTY_PER		T_PARTY_PER_EXS	T_PARTY_PER_RID

Viewing Interface Column Mappings to Base Tables

Use Siebel Tools to view interface column mappings to base table columns.

To view interface column mappings to base tables

1. Complete *Viewing EIM Table Mappings to Base Tables*.
2. In the EIM Table Mappings window, select a base table.
3. In the Object Explorer, expand EIM Table Mapping.
4. Click Attribute Mapping.

The Attribute Mappings window displays column mappings for the selected base table.

The following figure shows an example of viewing column mappings for the S_ADDR_ORG base table. (This example is specific to horizontal Siebel CRM applications.) In the Attribute Mappings list applet, for a selected base table mapping, you can find information about the mapping that has been defined between the EIM table column and the base table column. For example, the following figure shows that the S_ADDR_ORG.ADDR_NAME column has been mapped to the ADDR_ADDR_NAME (EIM_ACCOUNT) interface column.

EIM Table Mappings							
				Map Table		Generate Proc Columns	
	W	Name	Changed	Destination Table	Second Row	EIM Exists Proc Column	EIM ROW_ID Proc Column
		S_ACCNT_POSTN		S_ACCNT_POSTN		T_ACCNTPOST_EXS	T_ACCNTPOST_RID
>		S_ADDR_ORG		S_ADDR_ORG		T_ADDR_ORG_EXS	T_ADDR_ORG_RID
		S_ORG_BU		S_ORG_BU		T_ORG_BU_EXS	T_ORG_BU_RID
		S_ORG_EXT		S_ORG_EXT		T_ORG_EXT_EXS	T_ORG_EXT_RID

Attribute Mappings							
	W	Name	Changed	Interface Table Data Column	Base Table Attribute Column	Export Only	Inactive
>		ACTIVE_FLG		ADDR_ACTIVE_FLG	ACTIVE_FLG		
		ADDR		ADDR_ADDR	ADDR		
		ADDR_LINE_2		ADDR_ADDR_LINE_2	ADDR_LINE_2		
		ADDR_LINE_3		ADDR_ADDR_LINE_3	ADDR_LINE_3		
		ADDR_NAME		ADDR_ADDR_NAME	ADDR_NAME		
		ADDR_NUM		ADDR_ADDR_NUM	ADDR_NUM		
		ADDR_TYPE_CD		ADDR_ADDR_TYPE_CD	ADDR_TYPE_CD		
		BL_ADDR_FLG		ADDR_BL_ADDR_FLG	BL_ADDR_FLG		
		CITY		ADDR_CITY	CITY		
		COMMENTS		ADDR_COMMENTS	COMMENTS		
		COUNTRY		ADDR_COUNTRY	COUNTRY		
		COUNTY		ADDR_COUNTY	COUNTY

Viewing Base Table Mappings to EIM Tables

Use Siebel Tools to view base table mappings to EIM tables.

To search for an EIM table mapping to a specific base table

1. Start Siebel Tools.
2. In the Object Explorer, click the Types tab.
3. Expand EIM Interface Table, and click EIM Table Mapping.
4. Execute a query for a base table mapping, entering the name of the base table in the Destination Table field.

The following figure shows an example of viewing the EIM table mappings for the S_ADDR_ORG base table. (This example is specific to horizontal Siebel CRM applications.) Note that the S_ADDR_ORG base table maps to many EIM tables.

ORACLE

Generating EIM Table Mapping Reports

You can view and produce reports on any and all EIM tables in your repository, or query select EIM tables, including EIM tables that you have added.

CAUTION: In the following procedure, unless you query for specific EIM tables, the default action is to print every EIM table in the repository. Because outputting a report for every EIM table takes a significant amount of time to prepare and print, it is recommended that you perform a query prior to submitting your report request.

Note: To generate and print EIM table mapping reports, you need to have a running instance of Oracle BI Publisher server. For more information, see *Siebel Reports Guide*.

To generate a report for a specific EIM interface table

1. Navigate to Administration - Application screen, then the EIM Tables view.

The EIM Tables list appears.

2. From Menu (the cogwheel icon), select New Query, then specify the name of the specific EIM table.
3. Click Reports on the application toolbar.
 - a. Select EIM Interface Tables Report from the Report Name drop-down list..
 - b. Choose the desired output type, such as PDF or HTML, from the Output Type drop-down list.
 - c. Click Submit to generate the report.

The File Download dialog box appears.

- d. When prompted, click to open, save, or cancel the report.

About the Second Row Property on EIM Table Mapping Objects

The Second Row property is set when a base table is mapped for the second time in an EIM table. If a base table always has data row pairs, it is useful to map the base table twice in an EIM table such that one row in the EIM table will become two different rows in the base table. An example of this is the table mappings of S_INV_LGR_ENTRY in EIM_INV_TXN.

EIM Table Mappings to Base Tables Without User Keys

Some EIM tables contain table mappings to base tables without user keys. When using these EIM tables, you should note the EIM behavior for the relevant process type as described in *Process Issues for Base Tables Without User Keys*.

EIM Tables and Base Tables Without User Keys

The following information lists some examples of EIM tables containing table mappings to base tables without user keys.

EIM Table	Target Base Table Without User Key
EIM_ACCNT_DTL	S_NOTE_ACCNT
EIM_ACCSRCPIDTL	S_NOTE_ACCSRCPI
EIM_ACC_SRC_DTL	S_NOTE_ACC_SRC
EIM_ACT_DTL	S_NOTE_ACT
EIM_ASGN_GRP	S_ASGN_RESULT
EIM_ASSET_DTL	S_NOTE_ASSET
EIM_BASELN_DTL	S_NOTE_BASELINE
EIM_CON_DTL	S_NOTE_CON
EIM_CONSUM_DTL	S_NOTE_CONSUME
EIM_CON_PI_DTL	S_NOTE_CON_PI
EIM_DCP_DTL	S_NOTE_DCP
EIM_DEFECT_DTL	S_NOTE_DEFECT
EIM_INVC_DTL	S_NOTE_INVOICE
EIM_NOTE	S_NOTE
EIM_OPTY_DTL	S_NOTE_OPTY
EIM_ORDER1	S_NOTE_ORDER
EIM_ORDER_ITEM1	S_NOTE_ORDER_IT
EIM_GROUP_DTL	S_NOTE_ORGGROUP
EIM_PRDINT_DTL	S_NOTE_PROD_INT
EIM_PROJECTDTL	S_NOTE_PROJ
EIM_PROJITMDTL	S_NOTE_PROJITEM

EIM Table	Target Base Table Without User Key
EIM_PROJRSRCDTL	S_NOTE_PROJRSRC
EIM_QUOTE_DTL	S_NOTE_QUOTE
EIM_QUO_IT_DTL	S_NOTE_QUOTE_IT
EIM_PDSHIP_DTL	S_NOTE_SHIPMENT
EIM_SR_DTL	S_NOTE_SR
EIM_SRC_DTL	S_NOTE_SRC
EIM_TARGET_DTL	S_NOTE_TARGET
EIM_USR_MSG_DTL	S_NOTE_USR_MSG
EIM_WFM_ACTION	S_ACTION_ARG
EIM_WFM_RULE	S_ESCL_ACTION

Process Issues for Base Tables Without User Keys

This subsection describes issues that you should be aware of when performing EIM processes involving base tables without user keys.

- **Importing Data into Base Tables Without User Keys.** Import works but EIM does not check and prevent duplicate records from being imported into the base tables without user keys. If an import batch is executed repeatedly, the same records are imported repeatedly because EIM cannot check whether the records to be imported already exist in the base table without user keys.
- **Updating Data in Base Tables Without User Keys.** Update on base tables without user keys cannot work, because EIM cannot uniquely identify the record to update.
- **Exporting Data from Base Tables Without User Keys.** Exporting data from base tables without user keys is done the same way as exporting data from base tables with user keys.
- **Deleting Data from Base Tables Without User Keys.** DELETE ALL ROWS and DELETE MATCHES can be used to delete data in target base tables. If a table without a user key is the target table, then delete works as it does for base tables with user keys. In most cases, however, a table without a user key is a secondary table and its data can only be deleted with the table as a child of its parent table.

Note: EIM_NOTE_DEL and EIM_SKLI_DEL are special EIM tables used for deleting from the S_NOTE* and S_*SKILL_IT tables, which do not have the normal U1 user key.

- **Merging Data in Base Tables Without User Keys.** Merge does not work on base tables without user keys.

Deleting EIM Table Rows

When you have successfully imported most of your EIM table rows, you can delete them. However, you might want to leave rows that were not fully imported in order to examine and correct them. If you want to do this, remember that each EIM table imports data into one or more target base tables. For example, EIM_ACCOUNT imports into S_PARTY, S_ORG_EXT, S_ORG_BU, S_PARTY_PER, S_ORG_REL, S_ACCNT_POSTN, S_ADDR_ORG, and S_CTLG_CAT_ORG.

- Each EIM table includes a separate temporary column that contains a status code for each base table into which it has imported data. The names of these columns are contractions of the target base table name. For example, T_ORG_EXT__STA. T_ indicates that this is a temporary column; ORG_EXT is the first three letters of each word in the target base table name (S_ORG_EXT), and __STA indicates that this is the status column. Note that the extension begins with two underscores.
- During import, a row's status column is set to 0 for those tables into which the row was successfully imported. The IF_ROW_STAT is set to IMPORTED if a row is successfully imported into all target base tables, or PARTIALLY IMPORTED if it is successfully imported into at least one target.
 - To delete rows that were successfully imported into all target base tables, you could use the following SQL statement:

```
delete from EIM_ACCOUNT
where (IF_ROW_STAT = 'IMPORTED')
```
 - To delete rows that were successfully imported into specific target base tables, you could use the following SQL statement:

```
delete from EIM_ACCOUNT
where (if_row_stat = 'partially_imported' and
t_org_ext__sta = 0 and t_addorg__sta = 0)
```
 - You can also use ONLY BASE TABLES to limit processing.

Finding Differences in EIM Tables Between Repositories

The Siebel Data Model changes from release to release, and EIM mappings change accordingly. You can use the UTLEIMDIFF utility to find EIM mapping differences between two repositories for a list of EIM tables that you input. The results can be used to help you update your EIM data loading scripts, programs, and so on.

To use the UTLEIMDIFF utility

- Create the view S_EIM_MAP_V in the database.
The database-platform-independent script for creating this view is called create_EIM_MAP_V.sql. This script can be found in the <dbsrvr>\common directory.
- Find the executable UTLEIMDIFF.EXE in the <tools>\bin directory. Use the following switches for the program:

Switch	Entry	Description
/U	[username]	Siebel username

Switch	Entry	Description
/P	[password]	Siebel password
/C	[connect string]	ODBC connect string
/D	[table owner]	Database table owner
/N	“[new Siebel repository]”	Required. Name of the new repository. Note: Enclose the repository name in quotation marks.
/O	“[old Siebel repository]”	Required. Name of the old repository. Note: Enclose the repository name in quotation marks.
/I	[input filename]	This file contains the list of EIM tables to be compared. The default input file (eim_tbl_lst.inp) is in the <tools>\bin directory. You can edit this file.
/M	[report filename]	Required. This is the output report. The default name is eim_diff.txt.
/L	[log filename]	The default name is eim_diff.log.

The program may run for several minutes, depending on the number of tables to be compared.

3. Interpret the three parts of the output file as follows:

- **Part 1 - Interface Table Difference.** Part 1 compares all the EIM tables in the two repositories.
- **Part 2 - Interface Table Mapping Difference.** Part 2 compares the EIM tables listed in the input file.
- **Part 3 - Interface Column Mapping Difference.** Part 3 compares the interface columns for the tables listed in the input file. “UK” means “User Key sequence.” “Req'd” indicates that the column in the base table is required.

The first column of each part is the repository name. If there is an entry in one repository but not the other, then that means that the entry exists in one repository but not the other. If the same entry appears in both repositories, then that means that the entry has been modified.

4 EIM Configuration File

EIM Configuration File

This chapter covers the generic use of EIM configuration files (referred to as .IFB files) and is organized into the following sections:

- *Using the EIM Configuration File to Define a Process*
- *Defining EIM Configuration File Parameters*
- *Sample SQL Scripts*

For specific parameter-level information that affects importing, deleting, merging, and exporting, see the chapters for those functions.

Using the EIM Configuration File to Define a Process

EIM reads a configuration file that specifies the EIM process to perform (import, update, merge, delete, or export) using the appropriate parameters. The EIM configuration file (the default file is default.ifb) is an ASCII text file of extension type .IFB that resides in the Siebel Server/admin directory. Before you can run an EIM process, you must edit the contents of the EIM configuration file to define the processes for EIM to perform.

Note: If you are planning to use Unicode in your implementation, then the EIM configuration file must be saved as a Unicode text file.

EIM then sets the process locale as specified during start up in the command line, the Server Manager graphical user interface (GUI), or the configuration file. You must specify the correct character set, such as Western European or UTF-8, for the target database in one of these locales. For information on locales and character sets, see *Siebel Global Deployment Guide*.

EIM accepts parameter values from three sources:

- The command line entered by the user who invokes the EIM process
- The Siebel Server Manager GUI
- The configuration file specified, or default.ifb if none is specified

Parameter value searches are performed according to a specific hierarchy: command line, component parameter, and configuration file. Command-line parameters thus override component parameters, and component parameters override configuration file parameters.

Note: If the batch number component parameter is set to 0, the batch number in the EIM configuration file (if any) is used. This is the only exception to the parameter hierarchy.

You can define multiple processes in the EIM configuration file and then invoke a specific process using the process parameters discussed later in this chapter. Alternatively, you can create multiple configuration files and specify which one EIM should use.

Defining EIM Configuration File Parameters

The EIM configuration file begins with a header section used to specify global parameters that apply to all process sections defined later in the file. Following the header section, there must be at least one process section with its associated parameters. Some process section parameters are generic for all EIM processes. Other process section parameters are specific to a particular EIM process, such as import.

This chapter describes only the header section and process section parameters that are generic to all EIM processes. For information on process-specific section parameters, see the relevant chapter for each process:

- For an import process, see *Editing the Configuration File for Import Processing*.
- For an export process, see *Editing the Configuration File for Export Processing*.
- For a delete process, see *Editing the Configuration File for Delete Processing*.
- For a merge process, see *Editing the Configuration File for Merge Processing*.

EIM Configuration File Parameters

You can find descriptions of all EIM configuration file parameters in this chapter and the chapters that follow. For information on inheritance rules, see *Inheritance Rules for Configuration Parameters*.

Each parameter is categorized by the specific type of EIM process in which it is used:

- **General Header Parameters.** Header parameters may be used in all EIM processes. See *Header Section Parameters Generic to All EIM Processes* for a list of general header parameters.
- **General Process Parameters.** General process parameters may be used in all EIM processes. See *Process Section Parameters Generic to All EIM Processes* for this list.
- **Import Process Parameters.** Import process parameters apply specifically to an import process. See the tables in *Process Section Parameters Used for Imports* and *Parameters Used for Imports in Both the Header and Process Sections*.
- **Export Process Parameters.** Export process parameters apply specifically to an export process. See *Parameters Used for Exports in Both the Header and Process Sections*.
- **Delete Process Parameters.** Delete process parameters apply specifically to a delete process. See *Parameters Used for Deletes in Both the Header and Process Sections*.
- **Merge Process Parameters.** Merge process parameters apply specifically to a merge process. See *Parameters Used for Merges in Both the Header and Process Sections*.

You may want to refer to the default.ifb configuration file as you read the description of each parameter.

Header Section Parameters Generic to All EIM Processes

Header parameters are necessary at the beginning of the .IFB file. At a minimum, [Siebel Interface Manager] and PROCESS must be specified. The following information provides descriptions of header parameters.

Parameter	Description
CONNECT	The ODBC source name for connecting to the database server.
LOG TRANSACTIONS TO FILE	<p>This parameter must be in the header section and the default value is TRUE. Transactions can be logged in a file or a table. By default, EIM logs transactions into files. Log files are saved in the file system's EIM directory. If you do not want transactions to be logged in files, then setting this parameter to FALSE logs transactions to a table.</p> <p>Note: If this parameter is set to TRUE, you must make sure that the Siebel Server can write to the file system's EIM directory. During installation, the file system directory must be specified using the Uniform Naming Convention (UNC). For more information, see the <i>Siebel Installation Guide</i>.</p>
PASSWORD	<p>The database password for the process to be run. This parameter is inherited for the EIM component from the Siebel Gateway, so it should already be set. However, you can specify this in the .IFB file if you are running EIM from the Siebel application (not the command line) and if you have not already set this value in the EIM Server Component parameters.</p> <p>Note: If you start EIM from the command line, it uses the user name and password you used to log into the srvrmgr. If you start EIM from the Siebel application, EIM looks for the user name and password in the EIM Server Component parameters first, and if they are not specified, EIM then looks in the .IFB file. If EIM cannot find the user name and password in those places, EIM cannot log into the database and it fails. If you do not want your user name and password visible in the .IFB file, then specify them in the EIM Server Component parameters.</p>
PROCESS	Identifies the specific process to run during this invocation of EIM. The named process must be defined in the process section of the .IFB file.
[Siebel Interface Manager]	Header section must use this reserved name.
TABLEOWNER	The database logon name that owns the tables to be operated on; used as the prefix for table names; defined during installation.
USERNAME	<p>The database/employee logon name for the process to be run. This parameter is inherited for the EIM component from the Siebel Gateway, so it should already be set. However, you can specify this in the .IFB file if you are running EIM from the Siebel application (not the command line), and if you have not already set this value in the EIM Server Component parameters.</p> <p>Note: If you start EIM from the command line, it uses the user name and password you used to log into the srvrmgr. If you start EIM from the Siebel application, EIM looks for the user name and password in the EIM Server Component parameters first, and if they are not specified, EIM then looks in the .IFB file. If EIM cannot find the user name and password in those places, EIM cannot log into the database and it fails. If you do not want your user name and password visible in the .IFB file, then specify them in the EIM Server Component parameters.</p>

Process Section Parameters Generic to All EIM Processes

This section contains general process parameters generic to all EIM processes that appear in the process section of the EIM configuration file. The following information provides descriptions of these parameters.

Note: If your configuration file has more than one process section and you want a certain parameter to act on more than one process, you must include the parameter setting within each of the process sections that correspond to the processes on which you intend for the parameter to act.

Parameter	Description
BATCH	<p>Required. Specifies a required batch number for the process to be run. Use this batch number to identify the set of rows to load from the EIM tables for this specific process. This batch number corresponds to the value in the interface column IF_ROW_BATCH_NUM and must be a positive integer between 0 and 2147483647 (no commas). To specify multiple batches, use a range or list of batch numbers.</p> <p>To specify a range of batches, use the first_batch-last_batch format as shown in this example: BATCH=100-120.</p> <p>To list batches, use the comma-delimited format as shown in this example: BATCH=100,103,104. For more information, see Setting Configuration Parameters for Multiple Batches.</p>
COMMIT EACH PASS	<p>Optional. Commit after each EIM pass; default is TRUE.</p> <p>Note: It's best not to use this parameter in delete processes. This is because if a commit occurs after each table or each pass in a delete process, then – in case of errors causing exit from the process – orphan records and dangling references can remain. If the commit occurs for the whole batch, then in case of errors, you can roll back other table deletes.</p>
COMMIT EACH TABLE	<p>Optional. Commit after each base table; default is TRUE.</p> <p>Note: It's best not to use this parameter in delete processes. This is because if a commit occurs after each table or each pass in a delete process, then in case of errors causing exit from the process, orphan records and dangling references can remain. If the commit occurs for the whole batch, then in case of errors, you can roll back other table deletes.</p>
IGNORE BASE TABLES	Optional. Don't process these tables.
INCLUDE	<p>Optional. Subprocess to execute.</p> <p>Note: This parameter can be used only in shell processes. A shell process uses the INCLUDE statement to invoke a sequence of processes in a single run.</p> <p>INCLUDE names a process to be included as part of this process. More than one process can be included in another process. All included processes execute before the process itself.</p>
LOG TRANSACTIONS	<p>Optional. Default value depends on system preference.</p> <p>Use this parameter to control the logging mode. If this parameter is set to TRUE, EIM logs changes when mobile clients sync. If this parameter is set to FALSE, changes aren't logged. In general, when you load data into the HQ database for the first time, this parameter should be set to FALSE.</p> <p>LOG TRANSACTIONS = TRUE operates in row-by-row mode. LOG TRANSACTIONS = FALSE operates in set-based mode.</p>
ONLY BASE TABLES	Optional. Process only base tables.

Parameter	Description
ROLLBACK ON ERROR	Optional. Error rollback behavior; default is FALSE.
SESSION SQL	<p>Optional. Specifies a user-defined SQL statement to be sent to the database server before other SQL statements for this process. This string is sent directly to the database and must be a single SQL statement suitable for immediate processing.</p> <p>You can use the SESSION SQL parameter to set tracing for performance analysis. Only one SESSION SQL parameter can be used in each process section.</p> <p>Note: This parameter cannot be used to insert or update data in Siebel base tables. EIM sends the SQL statement directly to the database and may cause data loss for Siebel Remote and Siebel Replication Manager.</p>
SKIP BU_ID DEFAULT	<p>Optional. Specifies whether the virtual null key is to be skipped for the BU_ID column. The default value is FALSE.</p> <p>Virtual null key sets the BU_ID column value to the default value defined in the repository. To use the default value defined in the repository for the BU_ID column, set this parameter to FALSE (the default). To skip the virtual null key and not use the default value defined in the repository for the BU_ID column, set this parameter to TRUE. This parameter applies to import, delete, and merge processes because the foreign key must be resolved before these processes can run.</p>
TABLE	<p>Required. Specifies the name of an EIM table used in this process. Multiple TABLE parameters may be used to define a process using more than one table.</p> <p>Example:</p> <pre>TYPE = EXPORT BATCH = 101 TABLE = EIM_ACCOUNT EXPORT MATCHES = S_ORG_EXT, (NAME > 'A')</pre> <p>Note: For performance reasons, you should limit the number of tables to export or merge in a single process section to five tables or fewer.</p>
TRANSACTION SQL	Optional. Post-commit SQL statement. Specifies a user-defined SQL statement to be sent to the database before other SQL statements, and immediately after each commit or rollback operation during the process (including subprocesses). For more information about this parameter, see TRANSACTION SQL Parameter .
TYPE	Required. This parameter specifies the type of process being defined (possible values are IMPORT, EXPORT, DELETE, MERGE, SHELL). A shell process uses the INCLUDE statement to invoke a sequence of processes in a single run.
UPDATE STATISTICS	<p>Optional. For DB2 databases only. Controls whether EIM dynamically updates the statistics of EIM tables. The default value is TRUE.</p> <p>For example, if you are running EIM on a DB2 database, the account under which EIM runs must have the DB2 CONTROL table privilege on the EIM tables. The database installer automatically grants this privilege when creating the tables. However, it may be necessary to regrant this privilege if the EIM</p>

Parameter	Description
	<p>tables have been modified or recreated. To regrant the CONTROL privilege, use the script named grantstat.sql in the database installer directory.</p> <p>Note: If you plan to run EIM processes in parallel on a DB2 database, this may cause a deadlock when multiple EIM processes access the same EIM table simultaneously. To avoid this potential problem, set the UPDATE STATISTICS parameter to FALSE.</p>
USE ESSENTIAL INDEX HINTS	Optional. For MS SQL Server and Oracle databases only. The default value is TRUE. This parameter enables a subset of index hints for MS SQL Server.
USE INDEX HINTS	Optional. For Oracle databases only. Controls whether EIM issues optimizer hints to the underlying database to improve performance and throughput. The default value is FALSE.
USING SYNONYMS	Optional. Controls the queries of account synonyms during import processing. When set to FALSE, this parameter saves processing time because queries that look up synonyms are not used. The default value is TRUE.

Inheritance Rules for Configuration Parameters

Some configuration parameters can only be used in a process section of a configuration file, not in the header section. The parameters TYPE and ONLY BASE TABLES are two examples of parameters in this category. Parameters that can be used only in a process section only affect that section, and only the process for which they appear.

Most configuration parameters are used in both the header section and the process section of the configuration file—the parameters USE INDEX HINTS and COMMIT EACH PASS are two examples. These parameters follow the inheritance rules that are listed here, using USE INDEX HINTS as an example:

- If you specify USE INDEX HINTS in a configuration file's header section (that is, in the section [Siebel Interface Manager]), then it will be used for all processes in that configuration file.
- If you specify USE INDEX HINTS in a shell process, then USE INDEX HINTS affects all of the shell's subprocesses when running that shell process.
- If you specify USE INDEX HINTS in a shell process *and* in its subprocess, then the value from the subprocess will override the value from the shell process.
- If you specify USE INDEX HINTS in any other type of EIM process (import, export, delete, or merge), then USE INDEX HINTS will be used only for that process and not for any other processes that might be listed in the configuration file.
- If you specify USE INDEX HINTS in a configuration file's header section (in [Siebel Interface Manager]) *and* in the process section, the value from the process section will override the value from [Siebel Interface Manager].

Setting EIM Configuration Parameters

The table in the topic *Header Section Parameters Generic to All EIM Processes* lists the general configuration parameters that can be set when using EIM.

Keep in mind the following points when working with the EIM configuration file:

- Lines in the default.ifb file that begin with a semicolon (;) are comment lines and are ignored.
- If you are continuing a parameter definition to multiple lines in the .IFB file, make certain that the backslash character (\) is the last character on the line. The backslash character denotes continuation. Do not combine comments (;) with new lines (/) because this format creates difficulties finding a comment in the middle of a line.

CAUTION: When the backslash is followed by a space, EIM interprets the space character as “escaped,” and the new line character then terminates the parameter definition. **This can generate an error message indicating the parameter definition is incomplete.**

If multiple lines have the backslash (continuation) character (\) at the end, this means they are a single parameter line. So, if a semi-colon (comment character) is placed among these lines, EIM ignores the column with the semi-colon and all columns linked through the continuation character.

For example:

```
ONLY BASE COLUMNS = S_PARTY.PARTY_TYPE_CD,\
S_PARTY.PARTY_UID,\
; S_PARTY.ROOT_PARTY_FLG,\
S_CONTACT_FNX.PAR_ROW_ID,\
S_CONTACT_FNX.X_BATCH_ID
```

These statements will cause EIM to comment off S_PARTY.ROOT_PARTY_FLG, S_CONTACT_FNX.PAR_ROW_ID, and S_CONTACT_FNX.X_BATCH_ID.

- PASSWORD and USERNAME values are generally not used for access authentication or as a security measure. EIM acquires access authentication from the component parameters. PASSWORD and USERNAME values in the .IFB file are only used if the parameters are not set at the enterprise or component level.

Setting EIM Configuration File Header Parameters

The first nonblank, noncomment line of the configuration file’s header section must contain the exact information shown:

```
[Siebel Interface Manager]
```

The table in the topic [Header Section Parameters Generic to All EIM Processes](#) lists the other general header parameters to set when using EIM.

Setting EIM Configuration File Process Parameters

This topic describes only the general process parameters, that is, the process parameters that are generic to all EIM processes and that appear in the process section of the EIM configuration file. The process-specific section parameters are described in the chapters that cover each specific EIM process.

The table in [Process Section Parameters Generic to All EIM Processes](#) lists the general process parameters to set when using EIM.

The first nonblank, noncomment line of each process section is a bracketed string that specifies the name of the process. This is the name used in the process argument, or in the run process parameter in the header section. The value between [] (the brackets) can contain alphanumeric characters, spaces, and the following punctuation marks:

```
# _ : - $ % / +
```

There are two types of keywords for process section parameters: required keywords and optional keywords.

Required Keywords for Process Parameters

Of the general configuration parameters listed in *Process Section Parameters Generic to All EIM Processes*, note that the following ones are required when using EIM:

- TYPE
- BATCH
- TABLE

Optional Keywords for Process Parameters

Of the general configuration parameters listed in *Process Section Parameters Generic to All EIM Processes*, note that the following ones are optional when using EIM:

- COMMIT EACH PASS
- COMMIT EACH TABLE
- IGNORE BASE TABLES
- INCLUDE
- LOG TRANSACTIONS
- ONLY BASE TABLES
- ROLLBACK ON ERROR
- SKIP BU_ID DEFAULT
- SESSION SQL
- TRANSACTION SQL
- UPDATE STATISTICS
- USE ESSENTIAL INDEX HINTS
- USE INDEX HINTS
- USING SYNONYMS

TRANSACTION SQL Parameter

This parameter specifies a user-defined SQL statement to be sent to the database before other SQL statements and immediately after each commit or rollback operation during the process (including subprocesses). Although a commit operation is processed first, this statement is emitted (for the first time) immediately after the SESSION SQL parameter. Only one TRANSACTION SQL parameter can be used in each process section.

You must define the rollback of the EIM process by doing either of the following:

- Add the TRANSACTION SQL parameter in the configuration file
- Use the Server Manager to set the Database Rollback Segment Name parameter of the Enterprise Integration Mgr component at the component level

To avoid errors, do not specify the rollback segment:

- When using the siebenv.bat file
- At the task level
- When using both the configuration file and the Server Manager

Note: Do not use the TRANSACTION SQL parameter to insert or update data in Siebel base tables.

To define the rollback segment in the configuration file

- Add a line (as shown in the following example for an Oracle database) to the EIM configuration file.

```
TRANSACTION SQL = "set transaction use rollback segment rb_big"
```

To define the rollback segment using the Server Manager

1. Navigate to Administration - Server Configuration screen, Servers, Components, and then the Parameters view.
2. In the Components list, select Enterprise Integration Mgr.
3. Click the Component Parameters view tab.
4. In the Component Parameters list, select Database Rollback Segment Name.
5. In the Current Value field, type the name of the rollback segment to be used and click Save.

For more information on using the Server Manager, see *Siebel System Administration Guide*.

Setting Extended EIM Configuration Parameters

You can dynamically name and define extended parameters. This section explains how to use extended parameters in the EIM configuration file.

User-Defined Extended Parameters

Use extended parameters to create new parameter names and define values. You can define extended parameters using either the GUI or the command-line interface. User-defined extended parameters use the `$name=value` format inside the EIM configuration file, and the `name=value` format in the GUI or the command-line interface.

The parameter can be a character string consisting of any alphanumeric characters. The underscore symbol (`_`) can also be used.

To define extended parameters using the GUI

1. Navigate to the **Administration - Server Management** screen.
2. From the link bar, click **Jobs**.
3. In the Jobs list, click **New**.
The component job status field changes to Creating.
4. In the Component/Jobs field, click the select button.
5. In the Component/Jobs window, select the **Enterprise Integration Mgr** component, and then click **OK**.
To use a component job template based on EIM for your component job, you must first define the component job template. For information on defining component jobs, see the *Siebel System Administration Guide*.
6. Complete the rest of the fields and click **Save**.
7. In the Job Parameters list, select **New Record** from the menu.
8. In the Name field, click the select button.
9. In the Job Parameters window, select **Extended Parameters**, and then click **OK**.
10. In the Value field, enter the extended parameters using the comma-delimited format `name=value,name=value,as` shown in this example:

ACCT_NAME=COMPAQ,ACCT_NUM=01101,ACCT_CONTACT=John Dove,CONTACT_PHONE=(987)123-4567

11. Click **Save**.
12. In the Component Job form, click the **Submit Job** button.

To define extended parameters using the command-line interface

1. Use the reserved keyword `ExtendedParams` to define the `name=value` format, as shown in this example:

```
ExtendedParams="ACCT_NAME=COMPAQ,ACCT_NUM=01101,ACCT_CONTACT=John
Dove,CONTACT_PHONE=(987)123-4567"
```

Note: You must enter extended parameters in double quotes when using the Server Manager command-line interface.

2. Run EIM to test the extended parameters.

Predefined Extended Parameters

Some extended parameters are predefined in Siebel applications. These parameters also use the `name=value` format. The following information lists these predefined extended parameters.

Parameter	Description	Example
CURRENT_USER	Logon name of current user	<code>CURRENT_USER=Customer1</code>
PASSWORD	Password of current user	<code>PASSWORD=*****</code>
CURRENT_DATETIME	Current date and time information	<code>CURRENT_DATETIME=11/3/98_22:45</code>
ROOT_DIR	Home directory of Siebel Server	<code>ROOT_DIR=Siebel</code>
SIEBEL_FILE_DIR	Siebel file system	<code>SIEBEL_FILE_DIR=Files</code>
LANGUAGE	Language of Siebel Server installation	<code>LANGUAGE=English</code>
TABLE_OWNER	Name of tableowner	<code>TABLE_OWNER=ora22</code>
ODBC_DATA_SOURCE	Connect string for ODBC data source	<code>ODBC_DATA_SOURCE=sun1</code>
MAX_NEST_SUBST	Maximum level of nesting in parameter substitutions. The default value is 10.	<code>MAX_NEST_SUBST=10</code>
NUM_IPTABLE_LOAD_CUTOFF	When this parameter is enabled, EIM loads all schema mappings if the value is less than the number of EIM tables used in the run process. To enable, set the value to a positive number that is less than the number of EIM tables used in the run process. For example, if the EIM process is using one EIM table, then the setting should be <code>NUM_IPTABLE_LOAD_CUTOFF = 0</code> .	<code>NUM_IPTABLE_LOAD_CUTOFF=-1</code>

Parameter	Description	Example
	<p>When disabled, EIM loads only mappings for EIM tables used in the run process. This speeds up the dictionary loading process in EIM. To disable, set the value to -1.</p> <p>This feature is disabled by default.</p> <p>For more information, see <i>Example of Using the NUM_IPTABLE_LOAD_CUTOFF Parameter</i>.</p>	
IfbFileName	Name of the .IFB file where resolved parameters are stored.	IfbFileName=TEST
TraceFlags	Contains logs of various EIM operations. Available TraceFlags include 1, 2, 4, 8, and 32. For descriptions of available TraceFlags, see <i>Trace Flags</i> .	TraceFlags=2

Setting Configuration Parameters for Multiple Batches

To import multiple batches in a single EIM job, follow the guidance in this topic.

Multiple Batches Using a Configuration File (IFB)

- For a single batch: **BATCH = 100**.
- For a continuous sequence: **BATCH = 101-108**.
- For a set of nonsequential batches: **BATCH = 101,103,105**.

Multiple Batches Using the Server Management User Interface

- For a single batch, set the "Batch Number" parameter. For example: **Batch Number: 100**.
- For multiple, sequential batches, specify the range with no spaces: **Batch Number: 101-108**.

It's not possible to directly set a nonsequential set of batches from the user interface. If this is an absolute requirement, you'll need a hybrid of extended properties and IFB file changes, as follows:

- Determine the largest number of nonsequential batches you'll need to load. For purposes of this example, we'll use three.
- In the IFB file, set BATCH as follows: **BATCH = BATCHNUM1,BATCHNUM2,BATCHNUM3**.
- In the user interface, when creating your EIM job, set the extended parameters **BATCHNUM#** to the batches you want, for example:

BATCHNUM1=101,BATCHNUM2=103,BATCHNUM3=105.

Note: Using this approach, you'll need to provide values for each BATCHNUM# variable every time that IFB file is used, but you can provide non-existent batches if you have fewer, such as:

BATCHNUM1=101,BATCHNUM2=999,BATCHNUM3=999.

Sample SQL Scripts

Use the following sample SQL scripts as a starting point for your own scripts. These scripts each provide an example of the data that is necessary when loading account and contact records. Sample scripts are provided for the following RDBMSs:

- *DB2 Sample SQL Script*
- *MS SQL Sample SQL Script*

DB2 Sample SQL Script

```
insert into Siebel.EIM_ACCOUNT

(ROW_ID, IF_ROW_BATCH_NUM, IF_ROW_STAT, PARTY_UID, PARTY_TYPE_CD,
ROOT_PARTY_FLG, PARTY_NAME, NAME, MAIN_PH_NUM, LOC, ACCNT_BU, ACTIVE_FLG,
DISA_CLEANSE_FLG, EVT_LOC_FLG, FCST_ORG_FLG, INT_ORG_FLG, PROSPECT_FLG, PRTNR_FLG,
PRTNR_PUBLISH_FLG, RPLCD_WTH_CMPT_FLG, SKIP_PO_CRDCHK_FLG)

values

('100', '100', 'FOR_IMPORT', 'AUID1', 'ACD1', 'Y', 'Party1', 'Account1',

```

5 Importing Data

Importing Data

Importing data into Siebel base tables is a multistep process that requires significant effort. You must first load data from an external database into the EIM tables. Subsequently, you need to run an EIM process to read the data in these EIM tables and import them into the appropriate Siebel base tables.

This chapter is organized into the following sections:

- *EIM Import Process*
- *Import Data Process Flow*
- *Importing Legacy Data*
- *Updating the Siebel Database*
- *Preparing the EIM Tables for Import Processing*
- *Editing the Configuration File for Import Processing*
- *Special Considerations for Imports*
- *Running an Import Process*
- *Checking Import Results*

EIM Import Process

To import tables of data, EIM performs a sequence of tasks. Each task involves multiple passes; at least one pass is required for each EIM table included in the process. Depending on the type of import process, EIM may repeat several tasks.

This section describes the general tasks that EIM performs to import data into the Siebel database using EIM. To see the general steps that you take when using EIM to import data, see *Import Data Process Flow*.

To import data from EIM tables, EIM performs the following steps:

1. EIM initializes any temporary columns:
 - It compares values in IF_ROW_BATCH_NUM with the batch number provided by the Component task that initiated this import process. For information on IF_ROW_BATCH_NUM, see *Mandatory Columns for EIM Processing*.
 - It sets all temporary columns to NULL and counts the rows to be processed.

Note: If there are rows where required columns contain only blanks, the complete EIM process will fail at this step. Rows will not be imported or updated.
2. EIM applies any DEFAULT_COLUMN and FIXED_COLUMN values defined for this import process. For information on DEFAULT_COLUMN and FIXED_COLUMN, see *Parameters Used for Imports in Both the Header and Process Sections*.

3. EIM applies any filter queries defined for this import process. If a row fails the filter query, EIM eliminates the row from further processing.
4. EIM generates foreign key references for rows with corresponding existing rows in the Siebel base tables. It writes these foreign key values into EIM table temporary columns.

If foreign keys fail for required columns, EIM eliminates these rows from further processing. It also validates bounded picklist values against the List of Values table (S_LST_OF_VAL). For this validation to occur, the List of Values must be specified at the table level, and not just at the business component level. For more information on bounded and unbounded picklists, see *Configuring Siebel Business Applications*.

Note: For bounded picklists, the values must not be marked as Inactive in the S_LST_OF_VAL table.

5. EIM writes the appropriate ROW_ID values in the EIM table rows' temporary columns, for rows with corresponding base table rows. For information on ROW_ID, see *Mandatory Columns for EIM Processing*.
6. EIM creates a ROW_ID with a unique value in the base table for each EIM table row without a corresponding row in the base tables.
7. EIM eliminates rows with invalid values for user keys from further processing.

Note: You can use EIM to update only non-user key columns; EIM does not support modification of existing user key columns. To update user key columns in S_ORG_EXT, S_PROD_INT, S_PROD_EXT, S_PARTY tables use EIM_ORG_EXT_UK, EIM_PROD_INT_UK, EIM_PROD_EXT_UK, and EIM_PARTY_UK. The postfix UK denotes user key.

Note: For more information, see *Fields That Cannot Be Updated*.

It then generates foreign key references for rows without corresponding rows in the Siebel database tables, and writes these foreign key values into EIM table temporary columns:

- If foreign keys fail for required columns, EIM eliminates these rows from further processing.
 - For EIM table rows with data that will reside in multiple destination tables, EIM fails rows with foreign keys that cannot be generated.
8. EIM updates contents of existing base table rows with contents from corresponding EIM table rows that have successfully passed all earlier steps:
 - If any rows contain content that differs from the existing base table row, EIM writes these rows to the Master Transaction Log (if Enable Transaction Logging is enabled).
 - If multiple EIM table rows have the same user primary key for a base table, EIM uses only the first EIM table row to update the base table, and ignores the data in other rows.
 9. EIM inserts any new EIM table rows that have successfully passed all earlier steps in the Siebel database tables:
 - It writes new rows to the Master Transaction Log (if Enable Transaction Logging is enabled).
 - If multiple EIM table rows use the same user primary key for a base table, EIM uses only the first EIM table row to update the base table, and ignores the data in other rows.
 10. EIM updates primary child relationships in the Siebel database tables as necessary. EIM populates all primary child columns with Primary Child Col property set to TRUE. For information on primary child relationships, see *About Explicit Primary Mappings*.

CAUTION: You may want to use the UPDATE ROWS = FALSE statement to preserve existing information. Suppressing updates prevents updating primaries in this step of the import process, so this setting should be used with caution. For more information, see *Suppressing Updates*.

11. Finally, EIM runs optional miscellaneous SQL statements. For more information, see the section on the MISC SQL parameter in *Parameters Used for Imports in Both the Header and Process Sections*.

Import Data Process Flow

This section describes the general process flow that you must follow to import data into the Siebel database using EIM.

Note: Running an import process can be a substantial effort that may require the time of key personnel, as well as significant resources.

1. **Identify and validate the data to be imported.** To perform this task, you must:

- Determine the data to load and whether it already exists in another database. You should review existing data for completeness. For example, the Siebel database may require both an area code and a telephone number, while your existing database may not.
- Determine the number of opportunities, contacts, and accounts you plan to import. This information assists you in estimating the time and resources required to import, process, and store your data.

Note: If the data exists in a database that uses a different character set, the import process does not work properly until you recreate the database.

2. **Identify the column mappings and user key columns of the data to be imported.** To perform this task, you must:

- Identify the mapping between the data and Siebel base columns. For information on Siebel base table columns, see *Siebel Data Model Reference* on My Oracle Support.
- Identify the EIM table columns that map to these base table columns. To view mappings between EIM table columns and base table columns, see *EIM Table and Column Mappings*.
- Identify the user key columns and make sure they are populated uniquely. For information on user key columns, see *Siebel Data Model Reference* on My Oracle Support.

3. **Make sure that your hardware and software environments are ready.** Before you use Siebel EIM tables to import data, the Siebel application must be properly installed.

Work with your Siebel representative and MIS personnel to verify that the required hardware and software resources are available. For information about resource requirements, see *Importing Large Databases*.

4. **Back up your existing database.** Before undertaking any significant change—such as installing a new application, importing data, or upgrading an installed application—you should first perform a comprehensive backup of your database. This facilitates an easy recovery if problems occur.

5. **Copy file attachments to the Siebel Server subdirectory named “input.”** If you want to import file attachments, you can:

- Copy the files to the input subdirectory under the Siebel Server root directory.
- Store file attachments in the location specified in the ATTACHMENT DIRECTORY .IFB file header parameter.

Siebel EIM tables support all file attachment formats, including common file types such as Word documents (.doc), Excel spreadsheets (.xls), and text files (.txt). For information on file attachment columns, see *File Attachment Columns*.

- 6. Load and verify the EIM tables.** Your database administrator can use a database tool provided with your RDBMS (such as SQL*Loader, Bulk Copy Utility, or dbload) to copy data from your existing database to the Siebel EIM tables.

Note: Siebel EIM tables contain several special columns that must be populated before rows can be imported. For more information, see *EIM Table Columns*.

- After the EIM tables are loaded, check the number of loaded rows against your existing database to make sure that the appropriate rows were loaded.
- Check the contents of several rows to make sure that the tables are ready for the import process.

For information on preparing the EIM tables for data import, see *Preparing the EIM Tables for Import Processing*.

- 7. Edit the EIM configuration file (default.ifb).** This file customizes the behavior of EIM by defining the data you will import and identifying the batch number to use.

For information on editing the EIM configuration file for data import, see *Using the EIM Configuration File to Define a Process*.

- 8. Test your import process.** Run a small test batch (perhaps 100 records) to verify that the EIM tables load correctly, and that the correct parameters are set in the configuration file and on the `srvrmgr` command line.

For information on testing your import process, see *Siebel Performance Tuning Guide*.

- 9. Run the import process.** Although your batch sizes depend on the volume of data you must import, consider using multiple smaller batches (1,000 to 5,000 rows) rather than one large batch. Smaller batches place fewer demands on resources. Also, when using smaller batches, the fixing of problems is simpler. If a batch is not imported correctly, it is easier to isolate the condition, correct it, and rerun the batch.

For more information on this step, see *Running an Import Process*.

- 10. Verify results.** EIM provides several diagnostic tools that let you verify the success of import processing. For information on these tools, see *Checking Import Results*.

You must test and run the import process and verify the results for each batch you are importing. If an import process failure occurs, see *Troubleshooting Import Processing Failures* for descriptions of problems that can cause failures.

EIM provides comprehensive status information about each import process. When a process ends, you should review the information as described in *Checking Import Results*.

Importing Legacy Data

This section describes the general concepts and procedures for importing legacy data into the Siebel database using EIM.

Recommended Import Order for Importing Legacy Data

The order in which legacy data is imported is critical to make sure that relationships between dependent data elements are established correctly. Siebel EIM tables do not map one-to-one with Siebel target database tables.

Note: The recommended import order that follows is a general guideline. Your own data import process may require a different order.

To make sure that the necessary data is present to establish relationships between data entities, use the following sequence to import data:

1. Administrative (for example, a List of Values for Currency or Zip Code)
2. Business Unit
3. Positions
4. Accounts
5. Contacts
6. Employees
7. Products
8. Opportunities
9. Personal Accounts
10. Quotes
11. Documents
12. Forecasts
13. Fulfillment
14. Marketing Campaigns
15. CPG Promotion Management
16. CPG Product Movement
17. Service Requests
18. Product Defects
19. Activities and Appointments
20. Notes
21. File Attachments

This import order reflects most import processes. In some cases, the import order for your import process may vary slightly depending on your requirements.

Note: Your Siebel application provides a sample configuration file named default.ifb. You can also use the import sequence in this sample file in your configuration file.

While the import order is most critical when performing the initial import of legacy data, this recommended order should be followed for all subsequent data imports as well.

Note: Some tables cannot be used to import all data necessary for the imported data to be visible in the GUI. For example, the interface table EIM_FCSTOPTYPRD can be used to export forecast data but it cannot be used for importing. The import runs successfully, but the imported data cannot be seen in the GUI because EIM does not populate the table that would make the data visible.

Importing an Initial Batch of Legacy Data

When you are importing an initial batch of legacy data, you need to complete the following procedure.

To import initial batches of data

1. In the EIM table, assign a unique batch number to each batch of data in the IF_ROW_BATCH_NUM column.
2. Disable the Enable Transaction Logging preference.

Note: Typically, initial data loads require transaction logging to be turned off. Siebel Mobile Web Clients will receive their updates during this initial data load.

- a. Navigate to Administration - Siebel Remote screen, then the Remote System Preferences view.
- b. Clear the Enable Transaction Logging system preference.
- c. Click Save.

You can also change the transaction logging preference by changing the LOG TRANSACTIONS parameter in the EIM configuration file. For more information, see *Process Section Parameters Generic to All EIM Processes*.

3. Start an EIM task for each batch number.

For information on running an EIM process, see *Running an Import Process*.

4. Review your import processes by using the log file produced by EIM (EIM_task#.log).

This file contains comprehensive status and diagnostic information about the import processes. By default, this file is located in the Siebel Server log directory.

Importing Large Databases

Before importing a large database, such as a legacy database, you should thoroughly test your import processes. Once the test batches are loaded correctly and any data discrepancies that may affect other batches are resolved, you may want to consider importing large batches for the remaining data. Before doing so, first make sure that the Siebel database is capable of storing the volume of data, and that your resources are adequate to support the processing.

Memory Resources Needed for EIM

To achieve and maintain high performance, the database memory area needs to be large enough to hold most of the frequently accessed data in the cache. Because a very large EIM batch may flush all the data from the cache and cause performance degradation, limit EIM batch sizes so the most frequently accessed data can remain in memory.

Database Resources Needed for EIM

EIM uses database server space for the EIM tables, target base tables, secondary tables, and work areas. To make sure that an import process runs smoothly to completion, you must anticipate and plan for these space requirements. Actual requirements vary based on the RDBMS you are using and the size of the database you are populating. Work with your Siebel representative and database administrator to develop a database blueprint that addresses the following resource requirements:

- **Base tables and indexes.** When establishing appropriate sizes for the Siebel base tables and indexes, consider not only current size, but also reasonable growth. You should plan for future changes that may affect the database, such as organization expansion, new product lines, and company acquisitions. For more information on table sizing, see the documentation for your RDBMS.
- **Secondary tables.** You may be importing data from a single EIM table into multiple destination tables. For each EIM table (except EIM_note), there is a primary, or target, Siebel base table. In addition, there may be one or more secondary tables associated with the target table. Data from the EIM table may ultimately reside in one of these secondary tables.
- **Database manager transaction logging area.** The database manager uses a disk area to log its transactions. If you fail to set an adequately sized logging area for this operation, the database manager halts when the area runs out of space.

- **Transaction rollback areas.** Database resources are temporarily allocated to store intermediate results used to recover the original database state if a transaction is rolled back or aborted. Each RDBMS may use a different implementation. The amount of data processed in a transaction determines the amount of database resources required for rollback areas. Make sure that you allocate sufficient resources, or use smaller batch sizes, to handle the rollback requirements. Your database administrator can configure your database to allocate adequate transaction rollback areas.

After working with small batches to make sure that your import processes run smoothly, you may want to initiate an unattended session in which EIM runs multiple import processes to load a large database.

Updating the Siebel Database

After you have completed the initial import of enterprise data, you can periodically use EIM to update the Siebel database. For example, if you add a new product line, it may be efficient to load the data into your enterprise inventory management database and then import it into the Siebel database. Use the steps described in *Import Data Process Flow*, although the scope of the update import is usually significantly smaller than that of an initial data import.

CAUTION: If you have active mobile Web clients, do not disable the Enable Transaction Logging system preference in the Administration - Siebel Remote screen. If you disable this system preference, the server database and mobile Web client databases will not be synchronized after the import.

By default, when importing information, EIM performs both inserts and updates based on the content of the batch set. EIM first examines the set of information to determine which rows in the batch already exist in the Siebel database:

- Batch rows matching existing base rows are used to update the database.
- Batch rows that do not match base rows are used to perform inserts.

See *INSERT ROWS and UPDATE ROWS Parameters* for further information.

In some circumstances, you may need to suppress inserts and updates. For more information on adjusting parameters to suppress an insert or update, see *Suppressing Data When Updating Existing Databases*.

Note: You can use EIM to update only non-user key columns; EIM does not support modification of existing user key columns. To update user key columns in S_ORG_EXT, S_PROD_INT, S_PROD_EXT, S_PARTY tables use EIM_ORG_EXT_UK, EIM_PROD_INT_UK, EIM_PROD_EXT_UK, and EIM_PARTY_UK. The postfix UK denotes user key. For more information, see *Fields That Cannot Be Updated*.

Updating Siebel Database for Batches with Both an Insert and Update to the Same Record

You may need to update the Siebel database with a batch that contains a record to be inserted as well as an update to that same row. When you use EIM to do this, a record will be inserted, but the update will be flagged as a duplicate.

EIM processes a record once for each batch, so for each record, MIN(ROW_ID) is processed, and the other record is marked as a duplicate (IF_ROW_STAT is set to DUP_RECORD_IN_EIM_TBL for the duplicate record). If you enter the user key of a record with different attributes twice in the EIM table, only the record with the MIN(ROW_ID) will be imported or updated. The duplicate will be ignored.

To avoid this situation, analyze the input records before beginning the EIM task. If you find duplicate records, you can either combine them into one record, or specify a different batch number for the duplicate record so as to process the update in a separate batch. For more information, see *Siebel Performance Tuning Guide*.

Fields That Cannot Be Updated

You cannot update system fields. All Siebel system fields are fields reserved only for use by Oracle for internal Siebel processes. They are not to be populated with customer data.

The following are reserved system fields that cannot be updated:

- CONFLICT_ID
- CREATED
- CREATED_BY
- LAST_UPD
- LAST_UPD_BY
- MODIFICATION_NUM
- ROW_ID
- DB_LAST_UPD
- DB_LAST_UPD_SRC

Preparing the EIM Tables for Import Processing

This section explains how to prepare the EIM tables for a subsequent import into a Siebel database. To import data, EIM reads data in the EIM tables and writes data in the appropriate Siebel base tables by making multiple passes through the EIM tables to:

- Set initial values for some columns in the EIM tables
 - When importing new data, make sure to populate the columns marked Required in the EIM table.
 - When updating existing records you do not need to populate the Required columns, but the user key columns must be populated.

To find which columns are required, and which columns are user keys, generate a table mapping report. See *Generating EIM Table Mapping Reports*.

- Apply filter logic to select rows for importing
- Generate foreign key references and internal values
- Add or update relevant Siebel database rows
- Update each EIM table row to indicate its import status

For general information on EIM tables, see *Siebel EIM Tables*.

Required Initial Values for Special Columns

Each row to be imported must contain the data you want to import and the appropriate values in the following columns:

ROW_ID. This value, in combination with the nonempty contents of IF_ROW_BATCH_NUM, must yield a unique value.

IF_ROW_BATCH_NUM. Set this value to an identifying number for all rows to be processed as a batch.

IF_ROW_STAT. In each row to be imported, set this column to FOR_IMPORT to indicate that the row has not been imported. After processing, if certain rows were not imported due to a data error, do the following:

Change the IF_ROW_BATCH_NUM value in the EIM Interface Table for those rows on which the EIM task (import, update, delete) needs to be executed. This value must correspond to the BATCH value or values provided in the IFB-File.

To identify rows that are not imported, use the following SQL statement:

```
SELECT * from <EIM Interface Table>

where IF_ROW_BATCH_NUM = <BATCH NUMBER USED IN PRECEDING EIM TASK> AND
IF_ROW_STAT <> 'IMPORTED'
```

Note: If a row in the EIM table is successfully imported into the base table, the row's IF_ROW_STAT will be set to 'IMPORTED'. By using "<> 'IMPORTED'", you are only selecting rows that failed the import.

Once you determine which rows have failed, change the batch number for those rows in the EIM table to another batch. For example, if the first run uses batch number 100, and 10 rows failed, run a SQL to update the 10 failed rows to a new batch number, such as batch 101. After the batch number is changed for the failed 10 rows, run EIM the Import operation again, set BATCH = 101 in the ifb file. When you rerun the EIM Import, the operation will pick up the 10 rows under batch 101.

For more information on the BATCH IFB Parameter see the table in *Process Section Parameters Generic to All EIM Processes*.

For more information on special columns, see *EIM Table Columns*.

Required Initial Values for File Attachment Columns

Each file attachment row must contain the filename reference to the files you want to import and the appropriate values in the following columns:

FILE_NAME. Set this column to the root filename of the file attachment.

FILE_EXT. Set this column to the extension type of the file attachment (such as DOC, XLS, or TXT).

FILE_SRC_TYPE. This column must be set to FILE.

For more information on file attachment columns, see *File Attachment Columns*.

Adjusting the Case of Values

EIM supports various case values defined for base table columns in Siebel Tools. EIM adjusts the case value of an EIM table column according to the Force Case property of the corresponding base table column.

Note: The case values supported by EIM are listed in the Force Case property of the Column object in Siebel Tools. Force Case is a protected property that you cannot change.

Prior to importing data into base table columns, EIM also adjusts the case of values in EIM table columns as defined in the list of values. The available case modes include:

- Upper (Makes all letters uppercase)
- Lower (Makes all letters lowercase)
- FirstUpper (Makes the first letter of each word uppercase and leaves other letters unchanged)
- None (Has no effect)

Note: Letters are defined as A through Z (ASCII only). Words are defined as groups of letters separated by spaces (not punctuation).

If a requested case mode is not supported by the database, EIM performs a row-by-row pass through the EIM table to adjust the case of column values and update the row accordingly. If this occurs, you should expect slower import processing.

Note: To change the case mode requires changing read-only properties defined at the table level. For help contact your Oracle sales representative for Oracle Advanced Customer Services to request assistance from Oracle's Application Expert Services.

Editing the Configuration File for Import Processing

This section describes the header and process sections that you need in the EIM configuration file to properly configure EIM for an import process. For general information on the EIM configuration file, see *EIM Configuration File*.

Before import processing begins, you must change the configuration file to support this function. Such changes include:

- Editing the header and process sections and parameters.
- Adjusting settings in the configuration file for various purposes. See *Special Considerations for Imports*.

CAUTION: To prepare for recovery in the event of an unexpected problem, back up your existing database before you begin an import process.

Header Section Parameters Used for Imports

Parameters in the header section generally apply to all types of processes. For a description of the necessary contents in the header section, see *Header Section Parameters Generic to All EIM Processes*.

Process Section Parameters Used for Imports

Parameters in the process section apply only to that specific process and override any corresponding value in the header section for the specific process. This section describes the parameters used in the process section that are specific to an import process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

The following information lists the parameters specific to an import process that appear in the process section of the EIM configuration file. (For the parameters specific to an import process that can appear in both the process section and the header section of the EIM configuration file, see the information in *Parameters Used for Imports in Both the Header and Process Sections*.)

Parameter	Description
COMMIT OPERATIONS	Docking Log row commit frequency; default is 0.
FILTER QUERY	<p>SQL preprocess filter query fragment.</p> <p>Example: FILTER QUERY= (ACCNT_NUM = "1500")</p> <p>This parameter names a query that runs before the import process. The query prescreens certain rows in the import batch, using data values in the EIM tables. Rows that do not meet the filter criteria are eliminated.</p> <p>The query expression should be a self-contained WHERE clause expression (without the WHERE keyword) and should use only unqualified column names from the EIM table or literal values (such as name is not null).</p> <p>By default, the FILTER QUERY parameter is not used.</p>
IGNORE BASE COLUMNS	Specifies base table columns to be ignored by the import process. Use commas to separate column names, which can be qualified with base table names. Required and user key columns cannot be ignored. Use this parameter to improve performance when updating all but a few columns. The default is to not ignore any base table columns.
IGNORE BASE TABLES	Specifies base tables to be ignored by the import process. Use commas to separate table names. Target tables for EIM tables cannot be ignored. The default is to not ignore any base tables. Use this parameter to improve performance when updating all but a few tables. This parameter affects all EIM tables used in the import process.
ONLY BASE COLUMNS	<p>Specifies and restricts base table columns for the import process. Use commas to separate column names, which can be qualified with base table names. Include all user key columns and required columns. Use this parameter to improve performance when updating many rows but few columns. The default is to process all interface columns mapped to the base table.</p> <p>Example: ONLY BASE COLUMNS = S_ORG_EXT.NAME, S_ORG_EXT.LOC, S_ORG_EXT.BU_ID</p>

Parameter	Description
ONLY BASE TABLES	<p>Specifies and restricts selected base tables for the import process. Use commas to separate table names. Target tables for EIM tables must be included. The default is to process all base tables into rows that can be imported from the EIM tables. Use this parameter to improve performance when updating only a few tables. This parameter affects all EIM tables used in the import process.</p> <p>Example: ONLY BASE TABLES = S_CONTACT, S_ORG_EXT</p>
UPDATE ROWS	<p>Optional base table, TRUE/FALSE toggle; default is TRUE.</p> <p>For more information on the UPDATE ROWS parameter, see <i>INSERT ROWS and UPDATE ROWS Parameters</i>.</p>

Note: The ONLY BASE TABLES, IGNORE BASE TABLES, ONLY BASE COLUMNS, and IGNORE BASE COLUMNS parameters can be used to improve EIM performance.

Parameters Used for Imports in Both the Header and Process Sections

The following information describes the parameters that can appear in either the header section or a process section, and are specific to an import process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*. (The information in *Process Section Parameters Used for Imports* lists the parameters specific to an import process that appear in only the process section of the EIM configuration file.)

Parameter	Description
ATTACHMENT DIRECTORY	<p>(Default = SIEBEL_HOME\INPUT) Specifies the directory to be used for importing attachments. Before specifying a directory, make sure the directory exists on a Siebel Server machine and you have read and write access to the directory.</p> <p>Example: ATTACHMENT DIRECTORY = SIEBEL_HOME\INPUT</p>
COMMIT EACH PASS	<p>Specifies whether a separate transaction should be used for each EIM pass through each EIM table. The default value is TRUE, which invokes commits after each pass. This setting helps to reduce the database resources required for the import process and provides a checkpoint to which you can return in the event of unexpected results.</p> <p>Note: COMMIT EACH PASS works cumulatively with COMMIT EACH TABLE. If you set both commit each pass and commit each Table to true, a commit will occur at the end of each pass and at the end of each table.</p>
COMMIT EACH TABLE	<p>Specifies whether a separate transaction should be used for each EIM table. The default value is TRUE, which invokes commits after each table. This setting helps to reduce the database resources required for the import process.</p>

Parameter	Description
	<p>Note: COMMIT EACH TABLE works cumulatively with COMMIT EACH PASS. If you set both commit each pass and commit each Table to true, a commit will occur at the end of each pass <i>and</i> at the end of each table.</p>
COMMIT OPERATIONS	<p>(Import only.) Specifies the number of insert and update operations to be performed before a commit is invoked. The value for this parameter, an integer greater than zero, prevents the transaction rollback space from overflowing when large data sets are imported. The default for COMMIT OPERATIONS is not set; a commit is thus invoked only at the end of the import by default. This setting is ignored if you have turned off Enable Transaction Logging.</p> <p>Note: This parameter is useful only for row-by-row processing (with transaction logging on). It is not used for set-based processing operations.</p>
DEFAULT COLUMN	<p>(Import only) Specifies a default value for an EIM table column. The syntax is column name, value.</p> <p>Example: DEFAULT COLUMN = CURCY_CD , "USD"</p> <p>The given value will be used only if the column is null in the EIM table.</p>
FIXED COLUMN	<p>(Import only.) Specifies the value for an EIM table column. The syntax is the same as for DEFAULT COLUMN.</p> <p>Example: FIXED COLUMN=ORG_CD, "Commercial"</p> <p>The given value will be loaded into the Siebel base table, overriding the value in the EIM table column.</p>
INSERT ROWS	<p>Specifies that nonexistent rows in the EIM table be inserted into the Siebel base table. The default value is TRUE. A table name can be specified with insert rows as the first value, separated by a comma.</p> <p>Example: INSERT ROWS = EIM_ACCOUNT, FALSE</p> <p>If the named table is an EIM table, as in the example, the setting applies to all Siebel base tables imported from this EIM table. If the named table is a Siebel base table, the setting is applied when data is imported from any EIM table.</p> <p>Note: The INSERT ROWS parameter must be set to FALSE for any table with an EIM table that does not have mappings to all its required columns, such as S_ORDER for EIM_ORDER_DTL. In this example, when EIM is not able to resolve the EIM_ORDER_DTL row to an existing S_ORDER record, it attempts to insert it as a new S_ORDER record. Since EIM_ORDER_DTL does not have mappings to all the S_ORDER required columns, the process fails with a "Cannot insert null" error.</p> <p>For more information on the INSERT ROWS parameter, see <i>INSERT ROWS and UPDATE ROWS Parameters</i>.</p>
MISC SQL	<p>Sets specific explicit or implicit primaries, as mentioned in Step 11 in <i>EIM Import Process</i> of the import process. Explicit is when you have specific values to set as primaries. Implicit is when any of a group of values is acceptable. For example, you are importing one account with nine addresses. If any of the addresses is acceptable as being the primary, then set primary to implicit. EIM then selects one of the addresses as primary. If a specific address should be the primary, then set primary to explicit and indicate the primary account by setting its flag column (EIM_ACCOUNT.ACC_PR_ADDR) to Y.</p> <p>Note: MISC SQL is intended for initial data loading only (with DOCKING TRANSACTIONS = FALSE), because when using MISC SQL to set primary child foreign keys, NO transactions are logged for mobile users.</p>

Parameter	Description
	For a list of fields that can be set using the MISC SQL parameter, see <i>MISC SQL Parameter</i> .
NET CHANGE	<p>(Import only.) Specifies the handling of null (non-user key) column values when importing a row that already exists in the Siebel database table.</p> <p>If NET CHANGE = TRUE, the null value will be ignored; otherwise, the column in the base table will be updated with NULL. This parameter is ignored if UPDATE ROWS = FALSE. The default value is TRUE; null attribute values will thus be ignored for existing rows by default.</p> <p>For more information on this parameter, see <i>NET CHANGE Parameter</i>.</p>
ROLLBACK ON ERROR	Specifies whether the current transaction should be rolled back (aborted) when an error, such as an SQL database failure, is encountered. The default value is FALSE. If you set this parameter to TRUE, you should also set COMMIT EACH PASS and COMMIT EACH TABLE to FALSE, and make sure that the database transaction space is large.
TRIM SPACES	(Import only.) Specifies whether the character columns in the EIM tables should have trailing spaces removed before importing. The default value is TRUE.

NET CHANGE Parameter

By default, EIM does not update non-user key columns—that is, columns with a null value. The NET CHANGE parameter specifies the handling of null (non-user key) column values when importing a row that already exists in the Siebel database table. If NET CHANGE = TRUE, the null value will be ignored. If NET CHANGE = FALSE, the column in the base table will be updated with NULL.

Note: NET CHANGE = TRUE does not work for long columns. If you want to update a long column, you must use NET CHANGE = FALSE.

Effect of NET CHANGE = FALSE on IF_ROW_STAT

When NET CHANGE = FALSE, there are three possible outcomes:

- For a null value, EIM updates the base table column to NULL and sets the EIM table's IF_ROW_STAT to IMPORTED.
- For a non-null value that is a duplicate, nothing is done to the base table column and the EIM table's IF_ROW_STAT is set to DUP_RECORD_EXISTS.
- For a non-null value that is not a duplicate, EIM updates the base table column with the value in the EIM table and sets IF_ROW_STAT to IMPORTED.

EIM only updates the non-user key columns with NULL if you set the NET CHANGE parameter to FALSE. Also note that when EIM updates non-user key columns with NULL for the columns that had a non-null value beforehand, then the status of IF_ROW_STAT becomes IMPORTED. This is because EIM has performed the update transaction for this table.

The second case mentioned shows, however, that if a column had a null value beforehand, and EIM has performed the update with all the same records (including this NULL column), then in effect, EIM has ignored this null value and has not performed an update transaction for this NULL column (regardless of whether NET CHANGE is set to FALSE). So in this case, EIM populates IF_ROW_STAT with DUP_RECORD_EXISTS.

If in cases like this you want to update certain columns with NULL, then you can specify the ONLY BASE COLUMNS parameter in the .IFB file.

Example of Using the NET CHANGE Parameter

The following example is part of a sample .IFB file that uses the NET CHANGE parameter:

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD="*****"
PROCESS = IMPORT ACCOUNT
[IMPORT ACCOUNT]
TYPE = IMPORT
BATCH = 1
TABLE = EIM_ACCOUNT
NET CHANGE = FALSE
```

MISC SQL Parameter

The following information lists the EIM tables that can be used with the MISC SQL parameter, as well as the values that can be set. The table lists the values of the MISC SQL parameter when you want to set a field explicitly. If you want to set the field implicitly, replace the letters EXPR (EXplicit PRimary) with IMPR (IMplicit PRimary). Note that all separators for values are underscores.

Table and Primary Child Foreign Key	MISC SQL Parameter Value for Explicit Primary	Corresponding EIM Table	Comments
S_PROJ.PR_OU_ADDR_ID	EXPR_S_PROJ_PR_OU_ADDR_ID	EIM_PROJECT	No implicit primary
S_OPTY.PR_OU_ADDR_ID	EXPR_S_OPTY_PR_OU_ADDR_ID	EIM_OPTY	No implicit primary
S_OPTY.PR_OU_INDUST_ID	EXPR_S_OPTY_PR_OU_INDUST_ID	EIM_OPTY	None
S_CONTACT.PR_HELD_POSTN_ID	EXPR_S_CONTACT_PR_HELD_POSTN_ID	EIM_EMPLOYEE	None
S_CONTACT.PR_USERROLE_ID	EXPR_S_CONTACT_PR_USERROLE_ID	EIM_USER	None
S_CONTACT.PR_OU_ADDR_ID	EXPR_S_CONTACT_PR_OU_ADDR_ID	EIM_CONTACT	None
S_POSTN.PR_POSTN_ADDR_ID	EXPR_S_POSTN_PR_POSTN_ADDR_ID	EIM_POSITION	None
S_POSTN.PR_EMP_ID	EXPR_S_POSTN_PR_EMP_ID	EIM_POSITION	None
S_ORG_EXT.PR_BL_PER_ID	EXPR_S_ORG_EXT_PR_BL_PER_ID	EIM_ACCOUNT	None
S_ORG_EXT.PR_SHIP_PER_ID	EXPR_S_ORG_EXT_PR_SHIP_PER_ID	EIM_ACCOUNT	None

Table and Primary Child Foreign Key	MISC SQL Parameter Value for Explicit Primary	Corresponding EIM Table	Comments
S_CONTACT.PR_AFFL_ID	EXPR_S_CONTACT_PR_AFFL_ID	EIM_CONTACT	None
S_ORG_EXT.PR_BL_PER_ID	EXPR_SIS_S_ORG_EXT_PR_BL_PER_ID	EIM_ACCNT_CUT	None
S_ORG_EXT.PR_SHIP_PER_ID	EXPR_SIS_S_ORG_EXT_PR_SHIP_PER_ID	EIM_ACCNT_CUT	None
S_ORG_EXT.PR_CON_ID	EXPR_S_ORG_EXT_PR_CON_ID	EIM_ACCNT_CUT	None
S_POSTN_CON.PR_ADDR_ID	EXPR_S_POSTN_CON_PR_ADDR_ID	EIM_CONTACT1	None
S_ORG_EXT.PR_BL_PER_ID	EXPR_FINS_S_ORG_EXT_PR_BL_PER_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_SHIP_PER_ID	EXPR_FINS_S_ORG_EXT_PR_SHIP_PER_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_CON_ID	EXPR_FINS_S_ORG_EXT_PR_CON_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_BL_OU_ID	EXPR_S_ORG_EXT_PR_BL_OU_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_SHIP_OU_ID	EXPR_S_ORG_EXT_PR_SHIP_OU_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_PAY_OU_ID	EXPR_S_ORG_EXT_PR_PAY_OU_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_COMPETITOR_ID	EXPR_S_ORG_EXT_PR_COMPETITOR_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_PRTNR_OU_ID	EXPR_S_ORG_EXT_PR_PRTNR_OU_ID	EIM_FN_ACCNT1	None
S_ORG_EXT.PR_EMP_REL_ID	EXPR_FINS_S_ORG_EXT_PR_EMP_REL_ID	EIM_FN_ACCNT1	None
S_ORG_BU.PR_BL_PER_ID	EXPR_S_ORG_BU_PR_BL_PER_ID	EIM_FN_ACCNT1	None
S_ORG_BU.PR_SHIP_PER_ID	EXPR_S_ORG_BU_PR_SHIP_PER_ID	EIM_FN_ACCNT1	None
S_CONTACT.PR_HELD_POSTN_ID	EXPR_FINS_S_CONTACT_PR_HELD_POSTN_ID	EIM_FN_CONTACT1	None

Table and Primary Child Foreign Key	MISC SQL Parameter Value for Explicit Primary	Corresponding EIM Table	Comments
S_ASSET.PR_ASSET_ID	EXPR_S_ASSET_PR_ASSET_ID	EIM_FN_ASSET1	None
S_ORG_GROUP.PR_ADDR_PER_ID	EXPR_S_ORG_GROUP_PR_ADDR_PER_ID	EIM_FN_ORGGRP	None
S_PROD_INT_TNTX.PR_CATEGORY_ID	EXPR_S_PROD_INT_TNTX_PR_CATEGORY_ID	EIM_PRDINT_TNT	None
S_QUOTE_TNTX.PR_ORDER_ID	EXPR_S_QUOTE_TNTX_PR_ORDER_ID	EIM_QUOTE_TNT	None

If you always want to use explicit primaries, follow this syntax:

```
MISC SQL = EXPR_S_CONTACT_PR_OU_ADDR_ID
```

If you always want to use implicit primaries, follow this syntax:

```
MISC SQL = IMPR_S_CONTACT_PR_OU_ADDR_ID
```

The most flexible method is to use explicit primaries on the records for which you have specified a primary, and to automatically use implicit primaries on the records where you have not specified a primary. The following example shows this syntax:

```
MISC SQL = EXPR_S_CONTACT_PR_OU_ADDR_ID, IMPR_S_CONTACT_PR_OU_ADDR_ID
```

For more information on how to use the MISC SQL parameter, see the sample default.ifb file located in the `Siebel Server/admin` directory.

INSERT ROWS and UPDATE ROWS Parameters

The INSERT ROWS and UPDATE ROWS parameters have optional elements of their syntax. For both parameters, the default value is TRUE. To change this for all tables, use this syntax:

```
INSERT ROWS = FALSE
```

To change only one table, specify the table name as follows:

```
UPDATE ROWS = S_CONTACT, FALSE
```

To change multiple tables, specify each table in a separate line, as follows:

```
INSERT ROWS = S_CONTACT, FALSE
INSERT ROWS = S_ADDR_ORG, FALSE
```

If you need the parameter to be FALSE for most tables, and TRUE for only a few, use this method:

```
UPDATE ROWS = FALSE
UPDATE ROWS = S_CONTACT, TRUE
UPDATE ROWS = S_ADDR_ORG, TRUE
```

Running an Import Process

You can run an import process when you have:

- Identified the data for import processing
- Prepared the related EIM tables
- Modified the EIM configuration file accordingly

Run the import process by completing the procedures in *Running EIM*.

Checking Import Results

When an import process ends, you should carefully check the results to verify that data was successfully imported. During each import process, EIM writes comprehensive status and diagnostic information to multiple destinations. This section explains how to use this information to determine the results of the import process and is organized as follows:

- *Viewing a List of Imported Rows*
- *Troubleshooting Import Processing Failures*

Viewing a List of Imported Rows

The first task you should perform to check the results of the import process is to view a list of the imported rows.

To view a list of imported rows

- Query the appropriate EIM tables for rows whose if_row_batch_num equals the batch number for the import.

These columns in each EIM table indicate whether a row was imported successfully, and they identify the pass number on which a row failed. During various passes of import processing, EIM sets the IF_ROW_STAT value to one of the values shown in the following information.

If error flags, SQL trace flags, or trace flags were activated for the EIM process, you can also use the trace file to view the results of the EIM process. For more information on viewing the trace file, see *Viewing the EIM Log File*.

Value	Comment
AMBIGUOUS	There are two rows in the base table that have the same user key but different conflict IDs. EIM cannot distinguish these rows.
DUP_RECORD_EXISTS	The row exactly matches rows that already exist in the destination tables. This error occurs in Step 8 in <i>EIM Import Process</i> . Note that a row may have a duplicate in the target base table, but not in other destination base tables. In this situation, EIM adds the new relation (a child or intersection table) in the other destination base tables, and does not mark the EIM table row as a duplicate.
DUP_RECORD_IN_EIM_TBL	The row was eliminated because it is a duplicate (has the same user key) of another row in the EIM table with the same batch number. In this case, MIN(ROW_ID) is the record processed, and the other records with the same user key are marked as DUP_RECORD_IN_EIM_TBL.

Value	Comment
	Do not confuse DUP_RECORD_IN_EIM_TBL with DUP_RECORD_EXISTS. DUP_RECORD_EXISTS status indicates that the same record already exists in the base table, while DUP_RECORD_IN_EIM_TBL status indicates that there are two or more EIM table records having the same user key values.
FOREIGN_KEY	A required foreign key column in the target table could not be resolved. This error occurs in Step 4 in <i>EIM Import Process</i> .
IMPORTED	The row was successfully processed against all its destination base tables. This status is set after the import has been completed. You can check the import status by using database commands to query the appropriate EIM tables for rows whose IF_ROW_STAT value is not equal to IMPORTED. The result is a list of rows that were not successfully imported.
IMPORT_REJECTED	A user-specified filter query failed for this row. This error occurs in Step 3 in <i>EIM Import Process</i> if the user has specified FILTER QUERY expressions.
IN_PROGRESS	In Step 1 in <i>EIM Import Process</i> , EIM sets IF_ROW_STAT to this initial value for all rows in the batch. If rows still have this status value after EIM exits, a failure occurred that aborted processing for this table.
NON_UNIQUE_UKEYS	The user key was not unique in all the user key specifications on the table.
PARTIALLY_IMPORTED	The row did not fail for the target table (although it may have been a duplicate), but did fail during processing of a secondary base table. This status is set after the import has completed.
PICKLIST_VALUE	A required picklist value in the target table could not be resolved. This error occurs for NULL or invalid bounded picklist values in Step 4 in <i>EIM Import Process</i> .
REQUIRED_COLS	One or more required columns for the target table were NULL. This error occurs for missing user key columns in Step 7 in <i>EIM Import Process</i> , or when inserting new rows in Step 9 in <i>EIM Import Process</i> .
ROLLBACK	EIM encountered an error, such as an SQL database failure, and rolled back the transaction. This status is only used when ROLLBACK ON ERROR = TRUE .
SQL_ERROR	An SQL error occurred during an attempt to import this row. This error occurs for rows processed when Enable Transaction Logging is set to TRUE.

Troubleshooting Import Processing Failures

EIM is designed to import large volumes of data. Most failures are caused by data errors. It is usually faster and easier to correct the data errors and resubmit the corrected rows as part of a subsequent batch than to reprocess an entire batch. EIM does not stop when failures occur.

Failures can occur at several steps during the *EIM Import Process*; each type of failure has a different cause. See the causes listed in the following table.

This section provides guidelines for resolving import processing problems. To resolve the problem, look for it in the list of Symptoms/Error Messages in the following table.

Symptom/Error Message	Diagnostic Steps/Cause	Solution
Step 4 Failures	Step 4 (shown in <i>EIM Import Process</i>) processes foreign keys and bounded picklists. A row fails this step if the foreign key developed from values in the EIM table columns does not correspond to an existing row in the target Siebel database table. For example, a Step 4 failure on ACCNT_NAME indicates that the value in the ACCNT_NAME column of that row did not correspond to an existing name (S_ORG_EXT.NAME) or synonym name (S_ORG_SYN.NAME).	Correct the data errors and resubmit the corrected rows as part of a subsequent batch.
Step 6 Failures	Step 6 (shown in <i>EIM Import Process</i>) failures generally indicate invalid user key values. For example, a contact with a NULL value for the LAST_NAME column will fail because this is a required user key. All user keys are required except MID_NAME for contacts (S_CONTACT.MID_NAME) and LOC (location) for accounts (S_ORG_EXT.LOC).	Correct the data errors and resubmit the corrected rows as part of a subsequent batch.
Step 7 Failures	Step 7 (shown in <i>EIM Import Process</i>) evaluates the foreign key relative to the data being imported (whereas Step 4 as shown in <i>EIM Import Process</i> evaluates it relative to existing data). If the foreign key references a table that is imported from the same EIM table, Step 7 resolves foreign keys into the data to be imported.	Correct the data errors and resubmit the corrected rows as part of a subsequent batch.
Step 8 and Step 9 Failures	Failures for Step 8 (as shown in <i>EIM Import Process</i>) and Step 9 (as shown in <i>EIM Import Process</i>) indicate columns that have NULL values for fields that are required but are not part of the user key.	Correct the data errors and resubmit the corrected rows as part of a subsequent batch.
Data not visible after import	If you find that, after an EIM import, the data is not visible in some views or applets, it is probably because values required for a particular view or applet to display imported data may not have been imported. For example, the Sales Order Line Items applet's product picklist will only display products with S_PROD_INT.SALES_SRVC_FLG value set to N.	To determine which values need to be imported for a particular view or applet, do a client-side spooling and check the SQL conditions when selecting the record.
Unable to edit quotes after import	Users are unable to edit their quotes after importing quote information.	Make sure that the APPROVED_FLG field is set to N or is blank for each quote. Setting APPROVED_FLG to Y makes the quote read only and not editable by the user.

Special Considerations for Imports

There are several issues you should be aware of when running import processes. These issues include the following:

- *Suppressing Data When Updating Existing Databases*

- *Importing Customizable Products*
- *Importing Opportunities and Revenues*
- *Maintaining Denormalized Columns*
- *Importing Marketing Responses*
- *Importing Contacts*
- *Importing Private Contacts*
- *Importing Contacts to Make Them Visible in the Contact List*
- *Troubleshooting the Unique Constraint Error When Importing Accounts or Contacts*
- *Importing Party Records*
- *Importing Solutions*
- *Importing Call Lists and Catalogs*
- *Importing Positions and Employees*
- *Importing Data with Parent and Child Relationships*
- *Importing Industry Codes*
- *Importing File Attachments*
- *Updating File Attachments*
- *Importing Organizations That Contain the BU_ID Column*
- *Importing Accounts Containing Multiple Team Members*
- *Importing Multiline Fields*
- *Importing Exported Rows Into Target and Secondary Tables*
- *Importing International Phone Numbers Using EIM*
- *Importing URL Links into the S_LIT Base Table*
- *Importing LOVs Using EIM*
- *Importing LOV and MLOV Data into Base Tables*
- *EIM Imports and Audit Trail*

Suppressing Data When Updating Existing Databases

By default, when importing information, EIM performs both inserts and updates based on the content of the batch set. However, situations may arise in which you want to perform only inserts or only updates.

Suppressing Inserts

When the batch is a superset of an existing table, you should suppress inserts. For example, you may have a batch set of employee information that includes every individual in your organization. However, your Siebel database contains only members of the sales organization. To ignore batch entries for nonsales personnel in this case, you may want to run the entire batch using this setting to perform updates to existing rows only. If EIM attempts to insert a new row with this setting, the IF_ROW_STAT column is updated to NOT_ALLOWED. This means that EIM has attempted to insert a new row, but the action is not allowed.

To suppress insertions

- Set the INSERT_ROWS parameter in the EIM configuration file to FALSE.

The following example shows how to suppress insertions of unmatched rows from the EIM_ACCOUNT table to the S_ORG_EXT base table.

```
[Import Accounts Details]
TYPE = IMPORT
BATCH = 1
TABLE = EIM_ACCOUNT
INSERT ROWS = S_ORG_EXT, FALSE
```

Suppressing Updates

When the information in your database is already accurate and current, you should suppress updates. For example, opportunities and associated contacts might appear as a batch feed from an external application on a regular basis. You may only be interested in adding new opportunities while preserving the information in existing opportunities. Use the UPDATE ROWS = FALSE statement to preserve existing information.

CAUTION: Because suppressing updates prevents updating primaries in Step 10 in *EIM Import Process*, this setting should be used with caution.

To suppress updates to existing rows

- Set the UPDATE ROWS parameter in the EIM configuration file to FALSE.

The following example shows how to suppress updates to existing rows in the S_ORG_EXT base table.

```
[Import Accounts Details]
TYPE = IMPORT
BATCH = 1
TABLE = S_ACCOUNT_DTLIF
UPDATE ROWS = S_ORG_EXT, FALSE
```

Importing Customizable Products

If your data includes customizable products built in Siebel Product Configurator, you must use XML to load them. Customizable products cannot be loaded using EIM. Customizable products have rules, scripts, and resources associated with them, so in order to migrate customizable products, you must use XML import and export functionality. For information on exporting and importing products, see *Siebel Product Administration Guide*.

Importing Opportunities and Revenues

When importing opportunities and revenues, it is important to note that S_OPTY has some columns that are denormalized from S_REVN: the columns named SUM_*. These columns are not defined as type Denormalized, but nevertheless they need to be maintained as denormalized columns.

Maintaining Denormalized Columns

When updating columns that are the source of denormalized columns in other tables, you must find the records related to the columns being updated and load them as well, in the same batch.

As an example, you are updating the S_SRC table using EIM_SRC. EIM_SRC maps to S_SRC, S_SRC_BU, and S_SRC_POSTN, among others. S_SRC_BU and S_SRC_POSTN both contain the column SRC_NAME, which is denormalized from S_SRC.NAME. So, S_SRC_BU.SRC_NAME and S_SRC_POSTN.SRC_NAME should match S_SRC.NAME.

You have a record in S_SRC, and you want to update its NAME to something else using EIM_SRC. When you load the data of this record with its new NAME into EIM_SRC and then run EIM to update the NAME, EIM does not automatically update the SRC_NAME in the records within S_SRC_BU and S_SRC_POSTN. In order for the EIM engine to update S_SRC_BU.SRC_NAME and S_SRC_POSTN.SRC_NAME with these related records, you must find these related records in S_SRC_BU and S_SRC_POSTN and load them into EIM_SRC as well. The batch number must be the same. Only the user key column data needs to be loaded for these related records.

Importing Marketing Responses

You must populate the CAMP_MEDIA_ID column in the S_COMMUNICATION base table with valid values from the S_SRC_DCP base table in order for the rows to be displayed in the Response views.

Importing Contacts

This topic provides information organized as follows:

- *ASGN_* Flags*
- *S_POSTN_CON.ROW_STATUS Flag*

For more information related to the importing of contacts, see:

- *Importing Private Contacts*
- *Importing Contacts to Make Them Visible in the Contact List*
- *Troubleshooting the Unique Constraint Error When Importing Accounts or Contacts*

ASGN_* Flags

When you import contacts and set positions using EIM, the flags ASGN_MANL_FLG, ASGN_DNRM_FLG, and ASGN_SYS_FLG are set so that the intersection records are not routed to remote users. The Contacts view on the local database will display fewer contacts than the same view for the same user on the server database.

S_POSTN_CON.ROW_STATUS Flag

The column S_POSTN_CON.ROW_STATUS is a flag that can have value Y or N. When a contact is imported with value Y for this column, the contact shows in the user interface with an asterisk [*] in the New column, which means it is a new contact.

Importing Private Contacts

Siebel applications do not support importing private contacts using EIM. The default.ifb file contains a section that sets the CON_PRIV_FLG column to a constant N to make sure that only public contacts are imported. Because EIM does not support importing private contacts, do not change the value of the PRIV_FLG column. Additionally, do not remove this section of the .IFB file. To import contacts, you must have the CON_PRIV_FLG section in the EIM configuration file.

Importing Contacts to Make Them Visible in the Contact List

You need to use EIM_CONTACT to import into S_PARTY, S_CONTACT, and S_POSTN_CON. Make sure S_POSTN_CON.POSTN_ID references valid positions and that there is at least one employee associated with each position. S_POSTN_CON.POSTN_ID is mapped by PC_POSTN_NAME, PC_POSTN_DIVN, PC_POSTN_LOC, and PC_POSTN_BU in EIM_CONTACT. PC_POSTN_BU does not map to S_POSTN.BU_ID and BU_ID is not among the user key columns of S_POSTN. Instead, PC_POSTN_BU together with PC_POSTN_DIVN and PC_POSTN_LOC are used to resolve the S_POSTN.OU_ID, which refers to the divisions the positions belong to.

Divisions are stored in S_ORG_EXT with user key columns NAME, LOC, and BU_ID. For divisions, S_ORG_EXT.BU_ID references Default Organization; therefore, PC_POSTN_BU should be populated with Default Organization.

Troubleshooting the Unique Constraint Error When Importing Accounts or Contacts

This topic documents the causes, diagnostic steps, and solutions for troubleshooting the unique constraint error received when importing data through EIM.

Note: The error message and cause are the same for both contact data import and account data import, but there are separate diagnostic steps and solutions for each type of import data.

To resolve the problem, look for it in the list of Symptoms/Error Messages in the following table.

Symptom/Error Message	Diagnostic Steps/Cause	Solution
<p>When importing Account or Contact data using EIM, the batch fails with the following error:</p> <p>EIM-00107: ODBC (SQL) error.</p> <p>The log file displays an error message similar to the following error shown by an Oracle database:</p> <p>ODBC error 23000: [MERANT] [ODBC</p>	<p>This unique constraint error usually occurs due to inconsistent data in the base tables or incorrect data populated in the interface tables.</p> <p>The inconsistent data may result when two different server tasks, such as Siebel EAI processes and an EIM process, are run at the same time to import the same data.</p> <p>For an example of this, see <i>Example of Troubleshooting the Unique</i></p>	<p>See <i>Example of Troubleshooting the Unique Constraint Error when Importing Accounts or Contacts</i>.</p>

Symptom/Error Message	Diagnostic Steps/Cause	Solution
<p>Oracle 8 driver][Oracle 8]ORA-00001: unique constraint (SIEBEL.S_CONTACT_U1) violated</p> <p>ODBC error 23000: [MERANT][ODBC Oracle 8 driver][Oracle 8]ORA-00001: unique constraint (SIEBEL.S_ORG_EXT_U1) violated</p>	<i>Constraint Error when Importing Accounts or Contacts.</i>	
	Import of EIM contact data into the S_CONTACT table fails with this error. For diagnostic steps, see <i>Example of Troubleshooting the Import of EIM Contact Data into the S_CONTACT Table.</i>	See <i>Example of Troubleshooting the Import of EIM Contact Data into the S_CONTACT Table.</i>
	Import of EIM account data into the S_ORG_EXT table. For diagnostic steps, see <i>Example of Troubleshooting the Import of EIM Account Data into the S_ORG_EXT Table.</i>	See <i>Example of Troubleshooting the Import of EIM Account Data into the S_ORG_EXT Table.</i>

Importing Party Records

There are columns in the S_PARTY table that must be populated when importing party records such as Contacts, Positions, and so on. The following are the required columns, with their possible values:

- **PARTY_TYPE_CD.** Indicates the type of party data that is being imported. The PARTY_TYPE_CD column can have the following values:

Value	Description
Person	For Contact, User, Employee, or Partner.
Organization	For Organization, Division, or Account.
Household	For a Household (or Group). A Household is comprised of a collection of Contacts, independent of Account affiliations.
Position	For an Internal Division Position.
AccessGroup (OR)	For bundling of Party entities. Relates a person to groups indirectly (through Positions, Organizations, Accounts, and so on). An Access Group can have Organizations, Accounts, Positions, and User Lists.
UserList	A User List contains Siebel persons as its members. User Lists are created on an ad-hoc basis, not restricted to the Organizations to which the persons belong or to the Positions they hold.

The PARTY_TYPE_CD column must contain one the values described in this table. No custom values are allowed in the PARTY_TYPE_CD column.

- **PARTY_UID.** PARTY_UID is populated by default through the Siebel upgrade process and the application UI with the ROW_ID of the party record (for example, Contact or Position) that is being created, but you maintain the value for this column. The value does not have to remain identical with the ROW_ID.

With EIM, the PARTY_UID gets populated with the value specified in the EIM table for this column. PARTY_UID may have a calculated value with logic, such as a combination of email and other data. For this reason, PARTY_UID is defined as VARCHAR100.

- **ROOT_PARTY_FLG.** ROOT_PARTY_FLG supports performance for Oracle. The following are possible queries to retrieve high-level Positions, Organizations, or Access Groups. Try using the first query before the second one:
 - **WHERE ROOT_PARTY_FLG='Y'.** ROOT_PARTY_FLG is set to 'Y' for high-level Positions, Organizations, and Access Groups as it applies only to these party subtypes. It is set to 'N' for other party subtypes.
 - **WHERE PAR_PARTY_ID IS NULL.** Oracle cannot use an indexed access path because there are no index entries for NULL, so ROOT_PARTY_FLG was added.

Note: The PAR_PARTY_ID field needs to be populated only when the PARTY_TYPE_CD is set to Organization or Position. For Positions, if the record is a position that is the child of another position, then PAR_PARTY_ID needs to be populated with the ROW_ID of the parent position. In the case of Organizations, this field applies only to internal organizations. Similarly to Positions, the PAR_PARTY_ID needs to be populated with the parent organization if it has one.

Note: Also note that Divisions and Accounts have PARTY_TYPE_CD set to Organization well, but it is not necessary to populate the PAR_PARTY_ID field.

Importing Solutions

The Solution business component has the following Search Specification property: [Solution Item='Y']. For imported records of this type to be visible following an import process, you must import data from the EIM_SOLUTION interface table to the S_RESITEM base table with the value in the SOLUTION_ITEM_FLG column set to 'Y.'

When importing into the S_RESITEM base table, you need to include the following columns in the ONLY BASE COLUMNS parameter in the EIM configuration file:

- FILE_NAME
- FILE_EXT
- FILE_SRC_TYPE

If these columns are not included in the ONLY BASE COLUMNS parameter, a low-level error will be generated.

Another requirement is that the Internal Publish flag (INTR_PUBLISH_FLG) must be set in the parent record for imports to be visible in the Solution/Resolution Documents view.

Importing Call Lists and Catalogs

When importing into the S_CALL_LST and S_CTLG base tables, you need to include the following columns in the ONLY BASE COLUMNS parameter in the EIM configuration file:

- FILE_NAME
- FILE_EXT
- FILE_SRC_TYPE

If these columns are not included in the ONLY BASE COLUMNS parameter, a low-level error will be generated.

Importing Positions and Employees

The Administration - Group views automatically maintain the internal organization hierarchy incrementally as you change your organization's position hierarchy, minimizing transaction volume and therefore improving the performance of Siebel Remote. For more information on using the Administration - Group views for working with positions, see *Siebel Security Guide*.

When using EIM to import or update positions, you must generate reporting relationships after running EIM to maintain organization relationships. If you do not generate reporting relationships, then incomplete or inaccurate data will be displayed in views involving employees or positions. For example, the My Team View will fail to display all positions on the team.

Note: When importing or updating positions, you must check for duplicate reporting relationships. Make sure that no positions report directly to themselves (PAR_POSTN_ID=ROW_ID). Before importing, search for this condition and correct it. If you import a record with this condition, you will get an error when you click Generate Reporting Relationships after the import.

To activate position hierarchy, see [Activating Position Hierarchy](#). To generate reporting relationships, see [Generating Reporting Relationships](#).

Note: EIM does not support importing Multiple Organization Visibility organizations. You cannot import this type of organization using the EIM_ORG_INT interface table or S_ORG_INT base table. EIM does support importing divisions that are not Multiple Organization Visibility Organizations.

To import employees and positions

1. Before importing employees and positions, make sure that the Position and Department columns in the Employee table contain the correct data, as follows:
 - Data from the Hire Date column in the Employee table matches the data from the Emp_Start_Date column in the Position table.
 - Data from the Position Start Date column in the Employee table matches the data from the Position Start Date column in the Position table.
 - Position table contains the logons of all employees.
 - Data from the Employee Hire Date column in the Position table matches the data from the Hire Date column in the Employee table.
2. Import the Employee table.

You should import the Employee table first, because EIM searches for the foreign key of the Position table during its import and update of the Employee table.

Note: If you are importing employees and positions with S_CONTACT.PR_HELD_POSTN_ID and S_POSTN.PR_EMP_ID set as primary columns, import the Position table first. See the following procedure.

3. Import the Position table.
4. If you want to import employees and positions using EIM and you also want to set the following primary columns, then you will have to run the import twice for the EIM_POSITIONS table:
 - S_CONTACT.PR_HELD_POSTN_ID
 - S_POSTN.PR_EMP_ID

For example, to import employees and positions with S_CONTACT.PR_HELD_POSTN_ID and S_POSTN.PR_EMP_ID as primary columns:

- a. Import the Position table using the EIM_POSITION interface table.
- b. Import the Employee table, associate positions, and set the primary held position (S_CONTACT.PR_HELD_POSTN_ID) with the use of the MISC SQL parameter.
- c. Set the primary employee of Position (S_POSTN.PR_EMP_ID) by using the EIM_POSITION table and the MISC SQL parameter.

Activating Position Hierarchy

After importing or merging positions using EIM, or after merging positions through the user interface, it is necessary to generate reporting relationships to populate or rebuild the S_PARTY_RPT_REL. This happens automatically when you insert positions using the user interface.

The Generate Reporting Relationships process needs to be executed after the upgrade process and whenever the denormalized hierarchy structure (S_PARTY_RPT_REL) becomes out of sync with the data in the normalized tables (S_PARTY). As noted in *Siebel Database Upgrade Guide*, tables can become out of sync in the following cases:

- After upgrading, the organizational hierarchy (even if there is only one organization) must be established to maintain appropriate visibility in the views.
- When Siebel Enterprise Integration Manager is used to import or update any of the hierarchies (positions, organizations, or access groups).

Generating Reporting Relationships

If you want to modify your organization structure by importing or updating positions using EIM, you must generate reporting relationships after running EIM to maintain organization relationships. Before generating reporting relationships, you must first activate position hierarchy by completing the procedure in [Activating Position Hierarchy](#).

For best performance, complete all organization changes before generating reporting relationships, because this operation generates a high number of transactions for mobile users. This operation generates reporting relationships for all organizations and divisions regardless of the organization or division you have selected in the GUI. For more information on organization administration, see *Siebel Security Guide*.

Note: If you have mobile users, stop the Transaction Processor before clicking Generate Reporting Relationships. This is necessary because generating the reporting relationships can cause a large number of Siebel Remote transactions to also be generated.

To generate reporting relationships

1. Navigate to the Administration - Group screen, then the Positions view.
2. In the Positions list, click Generate Reporting Relationships.
3. Click OK.

Importing Data with Parent and Child Relationships

Siebel applications support multilevel hierarchies for defining accounts, products, and product lines. For example, a product's bill of materials may involve levels for components, assemblies, and sub-assemblies. Similarly, a parent account may have multiple child accounts for company divisions and wholly-owned subsidiaries. These child accounts may be further organized into subaccounts such as regions and offices.

Siebel applications support an unlimited number of levels within account, product, and product line structures. For a child entity to be successfully imported, its parent must first be successfully imported in a prior batch or in the same batch. For more information, see [Example of Importing and Exporting Hierarchical LOVs](#).

Importing Industry Codes

Siebel applications support the use of Standard Industrial Classification (SIC) codes. For example, a company may want to categorize its customers by industry type using SIC codes. In Siebel applications, the SIC field holds values that map to specific industries. If you want to use SIC codes, you can import data from a third-party database that supports SIC codes using EIM.

Note: SIC codes are valid only for the United States and Canada. If you want to implement industry codes for other countries, you need to create custom industry codes for your company and map these codes accordingly in EIM.

Importing File Attachments

EIM can import file attachments in all formats, including common file types such as Word documents (.doc), Excel spreadsheets (.xls), and text files (.txt). EIM does not place a limit on the number or the total size of files that can be imported.

To import file attachments into Siebel database tables

1. Using Windows Explorer, navigate to the Siebel Server directory.

The default is c:\siebel.

2. Verify that the Siebel directory contains a directory named input.

If the directory does not exist, create it by choosing File, New, and then Folder, and then enter `input`.

3. Copy all file attachments to the input directory.

Siebel EIM tables support all file attachment formats.

4. Populate EIM tables with rows matching the file attachments.
5. Run EIM.

Note: All three file attachment columns (FILE_NAME, FILE_EXT, FILE_SRC_TYPE) must be populated in order to import file attachments. The FILE_SRC_TYPE column must be set to FILE. Although these columns can be listed as nullable in the EIM tables, the import process will return errors if you leave any of these columns as NULL.

Updating File Attachments

You can also update file attachments that have already been imported into the Siebel database.

In order to update file attachments, EIM deletes the old row pointing to the existing file attachment and then imports the new file attachment. After all file attachments have been updated, use the Siebel File System Maintenance Utility named `sfscleanup.exe` (during hours when the network is least laden) to clean the file attachment directory of any unused file attachments.

To update file attachments

1. Update the file attachment by completing the steps in *Importing File Attachments*.
2. Once all file attachments have been updated, run the Siebel File System Maintenance Utility named `sfscleanup.exe` to clean up the file attachment directory.

For information on using `sfscleanup.exe`, see *Siebel System Administration Guide*.

Note: EIM does not support merging of file attachments.

Importing Organizations That Contain the BU_ID Column

Base tables in the Siebel Data Model that are enabled for multiple organizations contain the BU_ID foreign key column. This column points to a business organization defined in the S_BU base table. Examples of such base tables include S_PROD_INT, S_PRI_LST, and S_DOC_AGREE.

Note: For more information on multi-org, see the section on access control in *Siebel Security Guide*.

During the import process, if the value supplied in the EIM table does not resolve to a valid business organization, EIM by default will continue to import the record with the BU_ID set to the default value defined in the base table. If you want EIM to report import failures for such instances, set the parameter SKIP_BU_ID_DEFAULT parameter to TRUE in the .IFB file (the default value for this parameter is FALSE).

If you have not implemented multi-org capability or if you will not be using organizations, then use the Default Organization, a predefined organization in the S_BU base table.

Importing Accounts Containing Multiple Team Members

You can import multiple team members for accounts using EIM_ACCOUNT. Accounts and team members are related through S_ACCNT_POSTN. You can import multiple team members for accounts at the same time and specify the primary positions by setting ACC_PR_POSTN to Y.

Importing Multiline Fields

When importing multiline fields, such as addresses, you should use CHR(13) and CHR(10) for the field to be displayed as a multiline field. Otherwise, the following warning may be displayed in the GUI:

```
You have tried to modify a group of fields that may have more than one value. To
edit or add field values in this group, please open the first field in the group by
clicking on the multivalue field control.
```

Importing Exported Rows Into Target and Secondary Tables

If user keys from the secondary tables are made up of foreign keys referencing the target table and additional user keys of nonrequired columns, note that:

- If you export rows from both target and secondary base tables, one EIM table row will be created for every target table row, and a separate EIM table row will be created for every related secondary table row.
- If you reimport the exported batch rows into both the target and secondary base tables, the exported target table rows will be imported into the secondary table as well. This is because the exported target table rows have NULL values in the secondary table interface columns, and the secondary table's additional user keys allow NULL values to be imported. Additional rows will thus be mistakenly imported into the secondary base table.

To avoid this problem, after exporting the target and secondary base tables rows, you should split the secondary table rows out from the exported batch into another batch, and then import the target and secondary table rows separately.

Importing International Phone Numbers Using EIM

To import international phone numbers, the phone number must be prefixed with a plus (+) sign and the country code. For example, an international phone number with a country code of 44 should have the following format: +44123456789.

Any phone number without a preceding plus sign in the database is treated as a U.S. phone number. This leads to the display of +1 in front of the phone number, and the use of the corresponding PHONE_FORMAT if the regional settings of the client are different.

Importing URL Links into the S_LIT Base Table

To import records as URL links into the S_LIT base table, the FILE_NAME column must not be NULL and the FILE_EXT column must be NULL for URLs.

Importing LOVs Using EIM

Although EIM itself isn't workspace-aware, lists of values (LOVs) are. As described in the *Using Siebel Tools* guide, the way LOVs work in workspaces differs between the design repository (development environment) and the runtime repository. So, each time you load LOVs using EIM, you must manually structure the LOV data to respect the workspace framework and to be consistent with the documented requirements.

In particular, note the following:

- In a design repository (DR), each LOV exists in every integration workspace. For this reason, EIM must create or update an LOV in all instances of the LOV across all integration workspaces, not just a single workspace. For new records, the original record must be active in the target workspace and all copies will be inactive. This is consistent with the UI experience.

Note: If you want the LOVs to be active in all workspaces, set the LOV file variable. If want the LOVs to be Workspace-enabled in all Integration Workspaces, set the LOV file variable to `$WS_INACTIVE_FLG = 'N'`.

- In a runtime repository (RR), any existing instance of the LOV must remain intact while EIM resets the values of the WS_MIN_VER and WS_MAX_VER columns. A newly imported version gets an appropriate WS_MIN_VER value and a WS_MAX_VER gets a value of 10000. To simplify this process and to isolate users from having to understanding the specific details, the following are provided:
 - A stored procedure named LOV_EIM_LOAD, which is automatically created in all environments by the PostInstallDBSetup process. This stored procedure works on all supported database platforms: PostInstallDBSetup detects the correct database-specific version to create.
 - A specialized EIM interface batch file (IFB) named LOV.ifb, which calls the stored procedure as needed.

The LOV.ifb file manages the creation of LOVs across all integration workspaces in the development environment and creates the correct values for WS_MIN_VER and WS_MAX_VER in runtime environments.

When you import LOVs using EIM, you do so by leveraging the LOV.ifb file provided by Oracle, which references the LOV_EIM_LOAD stored procedure. LOV.ifb is provided in the `SIEBSRV_ROOT/admin` directory. This file controls the creation of the original LOV record and also the creation of the LOV record copies in all other integration workspaces.

LOV.ifb File Contents

The structure of the LOV.ifb file is as follows:

```
[Siebel Interface Manager]
USER_NAME = "$TABLE_OWNER"
PASSWORD = "*****"
PROCESS = Import LOV
$SCRATCH_BATCH = 999999 ; Used for temporary processing
$BATCH = 1000 ; The source batch number where the records have been staged in the EIM table
$INT_BATCH = 0 ; The intermediate batch to update the PAR_ROW_ID in base table
$TARGET_REPOSITORY = 'Siebel Repository' ; The target Repository Name
$TARGET_WORKSPACE = 'MAIN' ; The target (primary) Workspace Name. This can be any IWS in DR, but *must* be
'MAIN' in RR environments
$WS_INACTIVE_FLG = 'Y' ; Used for making the LOVs active or inactive in non-primary IWS. Default is
'Inactive', which mimics UI behavior
[Import LOV]
TYPE = SHELL
INCLUDE = List of Value
INCLUDE = List of Value POST RUN
[List of Value]
TYPE = IMPORT
BATCH = $BATCH
; IMPORTANT: Uncomment the appropriate SESSION SQL statement
;ORACLE, DB2390, DB2UDB
;SESSION SQL="CALL $TABLE_OWNER.LOV_EIM_LOAD($TARGET_WORKSPACE,$TARGET_REPOSITORY,'PRE',$BATCH,
$SCRATCH_BATCH,$WS_INACTIVE_FLG)"
;MSSQL
;SESSION SQL="exec $TABLE_OWNER.LOV_EIM_LOAD @AS_WS_NAME=$TARGET_WORKSPACE,@AS_REPOSITORY_NAME=
$TARGET_REPOSITORY,@AS_PROCESS_TYPE='PRE',@AN_SOURCE_BATCH_NO=$BATCH,@AN_TGT_BATCH_NO=
$SCRATCH_BATCH,@AS_WS_INACTIVE_FLG=$WS_INACTIVE_FLG"
TABLE = EIM_LST_OF_VAL
ONLY BASE TABLES = S_LST_OF_VAL
[List of Value POST RUN]
TYPE = IMPORT
BATCH = $SCRATCH_BATCH
; IMPORTANT: Uncomment the appropriate SESSION SQL statement
;ORACLE, DB2390, DB2UDB
;SESSION SQL="CALL $TABLE_OWNER.LOV_EIM_LOAD($TARGET_WORKSPACE,$TARGET_REPOSITORY,'POST',$BATCH,
$SCRATCH_BATCH,$WS_INACTIVE_FLG)"
;MSSQL
;SESSION SQL="exec $TABLE_OWNER.LOV_EIM_LOAD @AS_WS_NAME=$TARGET_WORKSPACE,@AS_REPOSITORY_NAME=
$TARGET_REPOSITORY,@AS_PROCESS_TYPE='POST',@AN_SOURCE_BATCH_NO=$BATCH,@AN_TGT_BATCH_NO=
$SCRATCH_BATCH,@AS_WS_INACTIVE_FLG=$WS_INACTIVE_FLG"
TABLE = EIM_LST_OF_VAL
ONLY BASE TABLES = S_LST_OF_VAL
```

Modify the LOV.ifb File (One-Time Operation)

Note: These steps only need to be performed once, unless you change database platforms.

1. Open the LOV.ifb file for editing in a suitable text editor (for example, Notepad on Windows).
2. Specify the Table Owner name for your database.
This will not change for a given environment, so setting it here eliminates the need to set it every time you run an EIM load for the S_LST_OF_VAL table.
3. Do one of the following:

- Update the PASSWORD entry with the password of the Siebel database table owner.
 - Uncomment the appropriate SESSION SQL statement for your database platform in both sections by removing the semicolon at the start of the line. This is more secure, because you're not storing a password in the file, but you must provide the password manually every time you launch an EIM job.
4. Make sure that the SESSION SQL in each session is correct for your database platform.

Make sure that the third argument is correct in each section as follows:

- The [List of Value] section controls the initial load for EIM, which creates the primary LOV records. The Process Type should be PRE.
 - The [List of Value POST RUN] section makes sure that all secondary records (for example, the record copies in other integration workspaces) are created in the database. The Process Type should be POST. The secondary load is performed immediately after the initial load has completed.
5. Save the file.

Run the EIM Job

1. Populate the EIM_LST_OF_VAL table with the desired records and values, using the database tool of your choice. Make sure that the IF_ROW_BATCH_NUM value is the same for all records.
2. Make sure that the LOV.ifb file you'll use to run the EIM job is populated with the appropriate values, as follows:

Variable	Description	Example Values
\$BATCH	Matches the IF_ROW_BATCH_NUM used to populate the EIM table. This can be the same every time or you can start with a value and increment for each batch. Using a different batch number each time lets you leave old batches in the EIM table in case there's ever a need to re-run the batch or determine later in which batch a particular LOV was added.	1000
\$SCRATCH_BATCH	<p>This is a temporary batch number used to populate integration workspaces and handle other management tasks related to LOVs and Workspaces as described above.</p> <p>Note: This value can't be the same as \$BATCH. Any existing content in the EIM table that has that IF_ROW_BATCH_NUM value will be deleted during the process. In general, leaving the default value is easiest and safest to avoid inadvertently deleting any other content from the EIM_LST_OF_VAL table.</p>	999999
\$TARGET_REPOSITORY	The name of your repository in the target environment. In most cases, this is "Siebel	Siebel Repository

Variable	Description	Example Values
	Repository” and this can usually be left as is unless a specific circumstance requires changing it.	
\$TARGET_WORKSPACE	<p>This is the primary workspace into which you'd like to import LOVs.</p> <ul style="list-style-type: none"> In the design repository, this is the initial integration workspace where the LOVs will be created. The LOVs will be marked as active in this workspace (WS_INACTIVE_FLG = N). In the runtime repository, this must be “MAIN”, as that's the only workspace. 	<p>MAIN</p> <p>int_myrelease</p>
\$WS_INACTIVE_FLG	<p>Indicates whether the secondary LOVs created in other integration workspaces should be active or inactive after they're loaded.</p> <ul style="list-style-type: none"> The default value is “Y”, meaning that they will be inactive. This is consistent with creating LOVs in the user interface, in which copies are inactive until an active version is delivered or there's a rebase from a parent where the LOV has been activated. A value of “N” can be used to indicate that all instances of the imported LOVs should be active in all integration workspaces. <p>Note: This variable is applicable only to design repository environments; runtime repository environments only have one workspace.</p>	Y/N

- Run the EIM job in the normal way, specifying the LOV.ifb file that you edited. For more information about running EIM jobs in general, see *Running EIM*.
- Clear the LOV cache (in the LOV Administration view) to force the Object Managers to get the new LOVs.

For more information about how LOVs work in workspaces in Siebel Web Tools or Siebel Tools, see the *Using Siebel Tools* guide.

For more information about working with LOVs in the Siebel application user interface, see the *Siebel Applications Administration Guide*.

For more information about performing repository migrations, see the *Siebel Database Upgrade Guide*.

Importing LOV and MLOV Data into Base Tables

When importing data into base tables, such as S_ORG_EXT or S_CONTACT, any column that is LOV-bounded in the target base table must be populated with the Display Value in the corresponding column in the EIM table, whether into an LOV column or a multilingual LOV (MLOV) column, you must populate the table column with the display value of a specific language.

The difference between the LOV and MLOV cases is the following:

- When importing into an LOV column, EIM puts the display value directly into the column.
- When importing into an MLOV column, EIM translates MLOV values during the import process. The EIM engine looks up the Language Independent Code (LIC) of the display value in the EIM table column and populates the LIC into the MLOV column.

By default, EIM runs in the same language as that of the Siebel Server installation. For example, if the Siebel Server installation is in German, then the LANGUAGE parameter setting defaults to German. You might import an Account Status of "Aktiv" (English equivalent: Active) into the Account table using EIM, in which case the following takes place:

- If the column is not MLOV-enabled, then the EIM table loaded with "Aktiv" places that value, "Aktiv", into the Account base table.
- If the column is MLOV-enabled, then the EIM first translates from German to the Language-Independent Code (LIC) for "Aktiv" ("Active") and places that LIC value into the Account base table.

Note: You must always populate EIM table columns that are mapped to LOV bounded base table columns with values that correspond to S_LST_OF_VAL.VAL, even when MLOV are used.

When importing data LOV data from EIM tables into base tables, you might encounter the following error message in your trace file:

```
[ERR00] Interface table:
[ERR00] S_XXXX_XMIF (Interface for XXXX Built-In M:1 Extension Table)
[ERR00] -----
[ERR00]
[ERR00] Base table:
[ERR00] S_XXXX_XM (Account M:1 Extension)
[ERR00] -----
[ERR00] TYPE (Type)
[ERR00] This column contains a bounded picklist value and the value given does not
[ERR00] correspond to a value in the list-of-values table for the given picklist
type.
```

This error message indicates that either a picklist has not been created for this column (TYPE) or the value in your EIM table for this column does not correspond to one of the values in the LOVs available for the corresponding LOV Type. To resolve this issue, you need to make sure that:

- An LOV Type with associated LOVs already exists for this column.
- The value you are importing for this column corresponds to one of the values associated to that LOV Type.

The following procedure explains how to import data into an LOV-enabled column, using the LOV Bounded Column S_ORG_EXT.ACCNT_TYPE_CD (which stores the Account Type Code) as an example.

To import data into an LOV-enabled column

1. Determine the LOV Type for the column in the S_ORG_EXT table, as follows:

- Search for the table S_ORG_EXT.
- Expand the Object Explorer to the Column object and query for the column that stores the LOV data (ACCT_TYPE_CD).
- Identify the LOV Type for the column (CUT_ACCOUNT_TYPE).

Note: For a column to be LOV bounded, it must have an LOV Type and the LOV Bounded attribute must be TRUE. For a column to be MLOV-enabled, additional attributes must be set: Translate Flag must be set to Y and Translation Table Name must be defined as S_LST_OF_VAL.

2. Navigate to the List of Values View in the Siebel client and query for that LOV Type (CUT_ACCOUNT_TYPE).

A list of all Display Values and LICs is presented. Note that EIM runs in a specific language and requires the display values that match that language. For example, if EIM runs in German, then all the values you load into the EIM table for this column must use the DEU display values. The LICs are never used for loading data into base tables via EIM.

3. Load the EIM table, as follows:

- a. Populate the appropriate EIM table (for example, EIM_ACCNT_CUT) with the account data and set the values in the column mapped to the base column (EIM_ACCNT_CUT.AC_ACCNT_TYPE_CD) to one of the display values identified in the previous step. As noted previously, you cannot use LICs here (unless they happen to match the defined Display Value).
- b. Execute the EIM job.

EIM Imports and Audit Trail

If the use of Audit Trail is a requirement in your Siebel implementation, set the following two system preferences to true. (Preferences are available in the Administration - Application screen, System Preferences view.)

- **EnableAuditing.** Controls auditing for the system.
- **EnableEimAuditing.** Controls auditing for EIM.

These preferences are false by default.

Note: This section applies only to import of data and for information on Deleting data with EIM.

6 Exporting Data

Exporting Data

This chapter explains how to export data from the Siebel base tables into the EIM tables. This chapter is organized into the following sections:

- *Overview of EIM Export Processing*
- *EIM Export Process*
- *Preparing the EIM Tables for Export Processing*
- *Editing the Configuration File for Export Processing*
- *Running an Export Process*
- *Checking Export Results*

Overview of EIM Export Processing

To export data, EIM reads the data in the Siebel database tables and places the information in the appropriate EIM tables. You can then copy data from the EIM tables into another database. The export process generally populates the applicable EIM table with a row for every Siebel base table row encountered. As a consequence, where EIM tables have mappings to multiple Siebel base tables, one export operation can generate multiple rows within the EIM table governing the rows encountered within the Siebel base tables.

During its multiple passes through the EIM tables, EIM performs the following tasks:

- EIM initializes the EIM tables for export.
- It applies filter logic to select rows for exporting.
- EIM updates EIM table rows to indicate the export status.

EIM then provides comprehensive status information about each export process. When the process ends, you should review this information. See *EIM Export Process* for more details on how EIM functions in the export process.

The following tasks comprise an EIM export process:

- *Preparing the EIM Tables for Export Processing*
- *Editing the Configuration File for Export Processing*
- *Running an Export Process*
- *Checking Export Results*
- *Extracting Data from the EIM Tables*

Upon completion of the EIM process, your database administrator can access the EIM tables and extract the data for use in a non-Siebel application.

EIM Export Process

To export tables of data, EIM performs a sequence of tasks. Each task involves multiple passes; at least one pass is required for each EIM table included in the process.

To export data to EIM tables, EIM performs the following steps:

1. EIM initializes EIM tables for export.

If clear interface Table in the configuration file is true, all rows with the specified batch number are deleted. Otherwise, a warning is issued if rows already exist with the specified batch number. The default configuration file is default.ifb.

2. It uses export parameter expressions in the configuration file to locate and export table rows:

- If export all rows is true, ignore any export matches parameters and export all rows.
- If export all rows is false, use export matches parameters to locate specific rows.

Set if_row_stat to exported for rows that are successfully exported.

3. For parent tables, EIM locates child table rows and exports them to their corresponding EIM tables.

Note: Transaction logging does not occur during export operations because Siebel base table values are not modified.

Preparing the EIM Tables for Export Processing

Unlike other Open Interfaces processes, an export process requires minimal preparation of the EIM tables. During the first step of export processing, EIM inspects each EIM table involved in the process. If EIM finds a row whose if_row_batch_num matches the batch number for this export process, it does one of the following:

- Clear the row if the CLEAR INTERFACE TABLES parameter is set to TRUE in the EIM configuration file
- Issue a warning if the CLEAR INTERFACE TABLES parameter is set to FALSE in the EIM configuration file

For information on the CLEAR INTERFACE TABLES parameter, see *Parameters Used for Exports in Both the Header and Process Sections*.

Checking Existing Rows Batch Numbers

Before you initiate an export process, you should verify that rows do not contain an if_row_batch_num matching the batch number you plan to use. If such rows do exist, you should either make sure that they do not contain data you need to preserve, or change the batch number for the export process. In each row that you are exporting, you may also want to set the IF_ROW_STAT column to FOR_EXPORT.

Preserved Column Values

The values for the LAST_UPD and CREATED columns in the EIM tables always contain the values for the LAST_UPD and CREATED columns from the target base table. For example, if you use the EIM_CONTACT interface table to export data from the S_CONTACT and S_ADDR_PER base tables, the values of the EIM_CONTACT.LAST_UPD and EIM_CONTACT.CREATED columns contain the data from the S_CONTACT.LAST_UPD and S_CONTACT.CREATED columns, respectively.

EIM Tables Not Supported for Export Processes

Due to the complexity of the associated base tables, EIM export processes to the following interface tables are not supported:

- EIM_ACCSRCPIDTL
- EIM_CRSE_TSTRUN
- EIM_IC_CALC
- EIM_IC_PERF_HST
- EIM_MDF

For more information on special columns, see [EIM Table Columns](#). For general information on EIM tables, see [Siebel EIM Tables](#).

Editing the Configuration File for Export Processing

This section describes the header and process sections that you need in the EIM configuration file to properly configure EIM for an export process. For general information on the EIM configuration file, see [EIM Configuration File](#).

Before export processing begins, you must change the configuration file to support this function. Such changes include:

- Editing the configuration file header and process sections using the parameters specific to export processes. For general information on the EIM configuration file, see [EIM Configuration File](#).
- Altering configuration file settings for the following purposes:
 - [Exporting All Data Rows](#)
 - [Exporting Selected Data Rows](#)
 - [Exporting Recursive Relationships](#)
 - [Exporting LOV and MLOV Data](#)

Header Section Parameters Used for Exports

Parameters in the header section generally apply to all types of processes. For a description of the necessary contents in the header section, see [Header Section Parameters Generic to All EIM Processes](#).

Process Section Parameters Used for Exports

Parameters in the process section apply only to that specific process and override any corresponding value in the header section for the specific process. This section describes the parameters used in the process section that are specific to an export process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

To export data, you must define at least one process with type = export. The following example contains lines that may be used in the EIM configuration file to define an export process from the S_PARTY table and its extension tables.

```
[Export Accounts]
TYPE = EXPORT
BATCH = 2
TABLE = EIM_ACCOUNT
EXPORT ALL ROWS = TRUE
```

Note: For performance reasons, you should limit the number of tables to export in a single process section to five or less.

Parameters Used for Exports in Both the Header and Process Sections

The following table describes the parameters that can appear in either the header section or a process section, and are specific to an export process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

Parameter	Description
ATTACHMENT DIRECTORY	<p>(Default is SIEBEL_HOME\OUTPUT) Specifies the directory to be used for exporting attachments. Before specifying a directory, make sure the directory exists on a Siebel Server machine and you have read and write access to it. Example:</p> <p>ATTACHMENT DIRECTORY = SIEBEL_HOME\OUTPUT (for Windows)</p> <p>ATTACHMENT DIRECTORY = "SIEBEL_HOME/OUTPUT" (for UNIX)</p> <p>If the export of an attachment fails, the export process continues and EIM writes a message in the trace file.</p>
CLEAR INTERFACE TABLE	Specifies whether existing rows in the EIM table for the given batch number should be deleted. The default value is TRUE.
EXPORT ALL ROWS	Specifies that all rows in the target base table and secondary tables are to be exported. The default value is FALSE. Existing values in the EIM table and export matches expressions are ignored. For all columns to export using an EIM table (both data from the base table and data from related child tables), you need to make sure this parameter is set to TRUE (you may need to add this line if it does not currently exist) in the .IFB file.

Parameter	Description
	Note: Rows from child tables of related child tables are not exported until they have been mapped.
EXPORT MATCHES	<p>WHERE clause fragment. Example:</p> <pre>EXPORT MATCHES = (NAME LIKE "GEN%")</pre> <p>For more information on the EXPORT MATCHES parameter, see EXPORT MATCHES Parameter.</p>

EXPORT MATCHES Parameter

The EXPORT MATCHES parameter specifies a where clause expression for filtering base table rows. The value is in two parts: the Siebel EIM table name and the filter expression that goes against the target base table. The expression is applied against the target base table for the EIM table.

The expression is a self-contained where clause expression (without the where) and should use only literal values or unqualified column names from the base table. There must also be a space separating the operator from the operand.

Note: Complex SQL WHERE clauses like subqueries are not supported.

EXPORT MATCHES can be used only against a target base table, or against a non-target base table that is an extension table of S_PARTY when the target table is S_PARTY. For more information, see the following.

The syntax to use with the EXPORT MATCHES parameter depends on whether the target base table is S_PARTY or not.

Note: The column names included in the criteria (that is, in “(...criteria...)” syntax) must be columns from the target base table or the table that is specified for the EXPORT MATCHES parameter.

Syntax for EXPORT MATCHES with S_PARTY as the Target Base Table

The syntax shown in this topic is for use with the EXPORT MATCHES parameter if the EIM table's target table is S_PARTY. Allowed syntax includes the following:

```
EXPORT MATCHES = S_PARTY, (...criteria...)
EXPORT MATCHES = <non-target base table name of Siebel Extension type>,
(...criteria...)
```

Note: When using the EXPORT MATCHES parameter against a non-target base table, you must still include the target table in the export.

The following syntax is *not* allowed:

```
EXPORT MATCHES = <EIM table name>, (...criteria...)
EXPORT MATCHES = (...criteria...)
```

Syntax for EXPORT MATCHES with Target Base Tables Other Than S_PARTY

The syntax shown here is for use with the EXPORT MATCHES parameter if the EIM table's target table is not S_PARTY. Allowed syntax includes the following:

```
EXPORT MATCHES = <EIM table name>, (...criteria...)
EXPORT MATCHES = <target base table name>, (...criteria...)
```

```
EXPORT MATCHES = (...criteria...)
```

The following syntax is *not* allowed:

```
EXPORT MATCHES = <non-target base table name>, (...criteria...)
```

To check whether a base table is of Siebel extension type

1. In Siebel Tools, navigate to the Table control and query a table name.

Check the Type property value. If the Type property value contains 'Extension (Siebel),' then the table is a Siebel extension type table.

Exporting All Data Rows

To export all rows from the tables that are mapped in an EIM table, set the export all rows parameter for the file to true in the specific export batch section of the EIM configuration file. The following example contains lines that may be used in the EIM configuration file to export all data rows from the accounts table.

```
[Export Accounts]
TYPE = EXPORT
BATCH = 2
TABLE = EIM_ACCOUNT
EXPORT ALL ROWS = TRUE
```

Prior to exporting, make sure that your database administrator has allocated enough space for the EIM table into which data will be exported.

Exporting Selected Data Rows

To export selected rows from base tables, set the export all rows parameter as follows:

```
EXPORT ALL ROWS = FALSE
```

Specify one or more export matches expressions to define the rows you want exported in this batch.

Exporting Recursive Relationships

Siebel applications support multilevel hierarchies for defining accounts, products, and product lines. For example, a product's bill of materials may involve levels for components, assemblies, and sub-assemblies. Similarly, a parent account may have multiple child accounts for company divisions and wholly owned subsidiaries. These child accounts may be further organized into subaccounts such as regions and offices. Siebel applications support an unlimited number of levels within account, product, and product line structures.

Exporting LOV and MLOV Data

When exporting List of Values (LOV) data, whether from an LOV column or a multilingual LOV (MLOV) column, the EIM engine populates the EIM table column with the display value of a specific language. The difference between the two cases is the following:

- When exporting from an LOV column, the EIM engine exports the display value stored in the column.
- When exporting from an MLOV column, EIM translates MLOV values during the export process. You do not need to populate the EIM table columns prior to the export. The EIM engine looks up the language-specific display value for the Language Independent Code (LIC) stored in the MLOV column, and puts the display value in the EIM table column.

Note: If you are exporting from an MLOV, you must set the LIC parameter to the appropriate language first. EIM exports the display value for the language specified.

For more information on how EIM processes LOV and MLOV data, see *Importing LOV and MLOV Data into Base Tables*.

Running an Export Process

You may run an export process once you have:

- Identified the data for export processing
- Prepared the related EIM tables
- Modified the EIM configuration file accordingly

Run the export process by completing the procedures in *Running EIM*.

If you are exporting data that pertains to organizations and divisions, it may be necessary to run additional SQL statements against the EIM table to complete the export of names from the S_BU base table (used for organizations).

To populate the BU columns from the S_BU base table

1. In the Admin directory within the Siebel Server root directory, open the file named `eim_export_lookup_bu_name.sql`.
2. Locate the appropriate SQL statement for the base table that you are exporting.
3. Modify this SQL statement if necessary and run it against the EIM table to populate the BU columns from the S_BU base table.

Checking Export Results

When an export process ends, you should carefully check the results to verify that data was successfully exported. During each export process, EIM writes comprehensive status and diagnostic information to several destinations.

Viewing a List of Exported Rows

You can verify export results by checking a list of exported rows, as described in the following procedure.

To view a list of exported rows

- Query the appropriate EIM tables for rows whose `if_row_batch_num` equals the batch number for the export.

The value of `if_row_stat` should be exported.

If error flags, SQL trace flags, or trace flags were activated for the EIM process, you can also use the trace file to view the results of the EIM process. For more information on viewing the trace file, see [Viewing the EIM Log File](#).

Extracting Data from the EIM Tables

Upon completion of an export process, the database administrator can use appropriate tools (such as native SQL) to extract data from the EIM tables for subsequent use by an external application. The following examples illustrate when to perform this process:

- If you have exported employee information for transfer to a human resources application.
- If you want to load customer information for a specific accounting application. Begin by exporting your customer information from the Siebel database.

7 Deleting Data

Deleting Data

This chapter covers the process of deleting selected data from the Siebel database. This chapter is organized into the following sections:

- *EIM Delete Process*
- *Preparing the EIM Tables for Delete Processing*
- *Editing the Configuration File for Delete Processing*
- *Running a Delete Process*
- *Checking Delete Results*

Note: It is solely your responsibility to decide what data can, should, or might be deleted and what data should, or must be deleted, and any other regulatory requirements that might apply to you, or the data.

EIM Delete Process

EIM reads information from the EIM tables and the EIM configuration file to identify rows to delete from the Siebel base tables.

During its multiple passes through the EIM tables, EIM performs the following tasks:

- EIM initializes the EIM tables for deletion.
- It applies filter logic to do one of the following:
 - Select rows for deleting
 - Insert EIM tables rows that correspond to matching base table rows
 - Select rows with matching user keys in the EIM tables
- EIM updates other tables with rows containing foreign keys that point to newly deleted rows.

EIM provides comprehensive status information about each delete process. When the process ends, you should review this information. For further details, see the following.

The EIM delete function requires you to perform the following tasks:

- *Preparing the EIM Tables for Delete Processing*
- *Editing the Configuration File for Delete Processing*
- *Running a Delete Process*
- *Checking Delete Results*

The delete process performed by EIM is called a *cascade delete*. When a cascade delete is performed, all of the contents of a data structure, including all of its substructures, are deleted. In other words, the data deleted is not restricted to the base tables mapped to the EIM table that you specified in the delete process, but all child records as well. To delete data,

EIM performs a sequence of tasks. Each task involves multiple passes; at least one pass is required for each EIM table included in the process. You should be very careful and specific when specifying delete criteria. For example, using the criteria “DELETE MATCHES = S_PARTY, (CREATED > xxxxx)” causes all records of S_PARTY that match this criteria to be deleted from the database.

Deletion Methods Supported

EIM uses a combination of EIM table row contents and configuration file parameter values to determine the method for selecting rows to be deleted. The following methods are supported:

- Delete rows in a Siebel base table with user key values specified in the corresponding EIM table.
- Delete rows in the base table where the contents of a named column match those specified by a where clause expression in the configuration file.
- Delete all rows in the base table regardless of EIM table row contents or configuration file where clause expressions.

CAUTION: Do not use EIM to delete organizations. Using EIM to delete data from the Products base tables is also not recommended and can lead to inadvertent data integrity loss.

Delete Process Flow

Preparing for an EIM delete process requires a thorough understanding of the parameter settings that specify delete criteria. You should be very careful and specific when setting delete-criteria parameters to avoid unintentional data loss. The EIM parameters mentioned in the following process flow are discussed in depth in *Parameters Used for Deletes in Both the Header and Process Sections*.

To delete data, EIM performs the following steps.

1. EIM initializes EIM tables for delete.

If clear interface Table in the configuration file is true, all rows with the specified batch number are deleted. clear interface Table must be false for a delete process that uses EIM table values to identify rows for deletion.

2. EIM deletes rows.
 - a. If the DELETE EXACT parameter in the configuration file is set to TRUE, EIM deletes the rows from the table that match the user key defined in the EIM table.
 - b. If the DELETE MATCHES parameter in the configuration file is set to a base table, EIM deletes the rows from the target base table that match the predicate specified in the parameter.
 - c. If the DELETE ALL ROWS parameter in the configuration file is set to TRUE, EIM deletes all rows from the target base table.

For information on configuration file parameters to use in a delete process, see *Parameters Used for Deletes in Both the Header and Process Sections*.

3. EIM sets IF_ROW_STAT to DELETED for rows that are successfully processed.

- When a foreign key column that references the deleted record is a required one, the record with the foreign key is deleted. Otherwise, the foreign key column is cleared.

Note: If the record to be deleted is a parent, the child records are affected as described in this procedure. However, if a non-required foreign key is part of the user key and clearing it will create a conflict, then the record will be deleted.

- EIM deletion of a parent row causes cascade deletion of child rows only if the foreign key column in the child table is a mandatory column. Otherwise a cascade clear is performed.

Note: Because the delete process affects the contents of base tables, transaction logging should be in effect during delete operations if you have active mobile Web clients, so that the appropriate transactions are captured for later docking.

Preparing the EIM Tables for Delete Processing

This section provides assistance in loading the EIM tables with data used to control deletion of rows from Siebel base tables.

You must make sure that each EIM table row to be processed contains both data that correctly identifies the exact base table rows to delete and the appropriate values in the following columns.

ROW_ID. This value in combination with the nonempty contents of IF_ROW_BATCH_NUM must yield a unique value.

IF_ROW_BATCH_NUM. Set this to an identifying number for all EIM table rows to be processed as a batch.

IF_ROW_STAT. In each row to be deleted, set this column to FOR_DELETE to indicate that the row has not been deleted. After processing, if certain rows were not deleted due to a data error:

- Change the IF_ROW_BATCH_NUM value for the rows that require redeleting.
- Change the BATCH NUMBER line in the configuration file.

It is not possible to delete rows that have the same primary user key and different conflict IDs using EIM, because EIM relies on user keys to identify rows in base tables. If there are two rows in the base table that have the same user key but different conflict IDs, EIM cannot distinguish these rows. In such case, the IF_ROW_STAT field of the row in the EIM table will be marked as AMBIGUOUS.

Note: When you are deleting records based on user keys, specify the parameter DELETE EXACT in the .IFB file.

For more information on special columns, see *EIM Table Columns*. For general information on EIM tables, see *Siebel EIM Tables*.

Editing the Configuration File for Delete Processing

This section describes the header and process sections that you need in the EIM configuration file to properly configure EIM for a delete process. It also discusses the parameters in the configuration file that must be adjusted for the delete process. For general information on the EIM configuration file, see *EIM Configuration File*.

Before delete processing begins, you must change the configuration file to support this function. Such changes include:

- Editing the header and process sections and parameters
- Adjusting settings in the configuration file for the following purposes:
 - *Deleting All Data Rows*
 - *Deleting Data Rows Identified by User Key Values*
 - *Deleting from Base Tables Other Than the Target Base Table*
 - *Deleting Rows from Extension Tables*
 - *Deleting File Attachments*
 - *Handling Aborts of EIM Delete Processing*

Header Section Parameters Used for Deletes

Parameters in the header section generally apply to all types of processes. For a description of the necessary contents in the header section, see *Header Section Parameters Generic to All EIM Processes*.

Process Section Parameters Used for Deletes

Parameters in the process section apply only to that specific process and override any corresponding value in the header section for the specific process. This section describes the parameters used in the process section that are specific to a delete process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

To delete data, you must define at least one process with TYPE = DELETE.

If the process is defined with TYPE = DELETE, the DELETE ROWS parameter will be automatically set to TRUE. In some cases, you may not want to delete data from a nontarget base table as a result of cascade action. In this case, use the DELETE ROWS parameter to prevent deletion of rows from a specified table. The following example contains lines that can be used in the EIM configuration file to define a delete process for the accounts table while preventing rows from being deleted in the S_ADDR_ORG table.

```
[Delete Accounts]
TYPE = DELETE
BATCH = 200
TABLE = EIM_ACCOUNT
DELETE ROWS = S_ADDR_ORG, FALSE
DELETE EXACT = TRUE
ONLY BASE TABLES = S_ORG_EXT
```

Parameters Used for Deletes in Both the Header and Process Sections

This section describes the parameters that can appear in either the header section or a process section and are specific to a delete process. For generic parameters that can be used in all EIM processes, see [Header Section Parameters Generic to All EIM Processes](#) and [Process Section Parameters Generic to All EIM Processes](#).

The following table provides descriptions of the parameters that can appear in the header and process sections of the EIM configuration file, and which are specific to delete processes.

Parameter	Description
CASCADE DELETE ONLY	(Default = FALSE). Set this parameter to TRUE to delete child records with nullable foreign keys when the parent record is deleted. If FALSE, then when EIM deletes a parent record, it sets the foreign keys of the child records to NULL.
CLEAR INTERFACE TABLE	This parameter specifies whether existing rows in the EIM table for the given batch number should be deleted. Valid values are true (the default unless DELETE EXACT = TRUE) and false (the default if DELETE EXACT = FALSE).
DELETE ALL ROWS	Used for deleting all rows in table; default is FALSE. Note: Use this parameter with caution. For more information on this parameter, see DELETE ALL ROWS Parameter .
DELETE EXACT	Delete using user key matching algorithm with rows in EIM table; default is FALSE. For more information on this parameter, see DELETE EXACT Parameter .
DELETE SKIP PRIMARY	This parameter specifies whether EIM should perform a cascade update to the primary child column. The default value is TRUE.
DELETE MATCHES	SQL WHERE fragment deletion criteria. Example: DELETE MATCHES = EIM_ACCOUNT, (NAME LIKE "TST_ACCT%").
DELETE ROWS	This parameter specifies whether rows from the target base table can be deleted. Valid values are TRUE (the default) and FALSE. This parameter can prevent deletions from one table while allowing them in others. For example, the following parameter setting prevents deletion of rows from the S_ADDR_ORG table: <pre>DELETE ROWS=S_ADDR_ORG, FALSE</pre> Note: Use the FALSE setting for DELETE ROWS carefully. Inappropriate use can result in dangling foreign key pointers.
IGNORE BASE COLUMNS	Specifies base table columns to be ignored by the import process. Use commas to separate column names, which can be qualified with base table names. Required and user key columns cannot be

Parameter	Description
	ignored. Use this parameter to improve performance when updating all but a few columns. The default is to not ignore any base table columns.
UPDATE ROWS	<p>Specifies whether foreign key references can be updated. This parameter can be used to prevent the updating of foreign key references with a setting of FALSE. The default value is TRUE, which affects all tables. To affect only specific tables, you can specify a table name. For example:</p> <pre>UPDATE ROWS = S_CONTACT, TRUE</pre> <p>The UPDATE ROWS parameter also prevents updates in one table while allowing them in others. If this parameter is set to FALSE, EIM does not update rows in the specified base table. If you need to specify multiple tables, use one UPDATE ROWS statement for each table.</p> <p>Note: Use the FALSE setting for UPDATE ROWS carefully.</p> <p>Inappropriate use can result in dangling foreign key pointers.</p>

Note: You must use one of the following delete parameters described in this section: DELETE EXACT, DELETE MATCHES, or DELETE ALL ROWS.

DELETE EXACT Parameter

This parameter specifies the base table rows to delete by using user key values specified in the EIM table. By default, delete exact = false. If DELETE EXACT is set to TRUE, you must use the ONLY BASE TABLES parameter in conjunction with this parameter to identify the base tables.

Note: Do not use ONLY BASE TABLES with the target base table and nontarget base tables, because the EIM table record cannot specify just one record to be deleted.

Although this parameter can be used to delete rows from both target and nontarget base tables, use the delete exact parameter to delete only nontarget base tables *containing user keys*. Rows in nontarget base tables that do not contain user keys will not be deleted. For example, you cannot use the DELETE EXACT parameter to update the S_ACTION_ARG table and the S_ESCL_ACTION table because there are no user keys defined for these tables.

As another example, you can use DELETE EXACT to delete any of the nontarget base tables such as S_ADDR_PER and S_ACCNT_POSTN using the EIM_ACCOUNT table. In this case, the EIM_ACCOUNT table would need to be loaded with records that would singularly identify the S_ACCNT_POSTN or the S_ADDR_PER record to be deleted.

To use the DELETE EXACT parameter to delete data from base tables other than the target base table, specify the user key columns only for a single base table for each row in the EIM table. When specifying rows for exact deletion, make sure any columns not necessary to specify the row to be deleted are NULL to avoid problems with deleting from the wrong base table. EIM tries to enforce this behavior by requiring other user key columns to be NULL. If a row cannot be identified as clearly referring to a row in a single base table, that row will fail to be deleted.

Deleting from Base Tables Other Than the Target Base Table explains how to delete data from base tables other than the target base table using the DELETE EXACT parameter with the following scenario as an example. In this example, EIM_ACCOUNT is mapped to base tables including S_ORG_EXT, S_ORG_PROD, and S_ORG_INDUST. You should delete data only from S_ORG_PROD, and you should not delete data from S_ORG_EXT or any other base tables.

DELETE MATCHES Parameter

This parameter specifies a WHERE clause expression for filtering base table rows. The value is in two parts: the Siebel base table name and the filter expression that goes against the target base table. An example would be:

```
DELETE MATCHES = S_ORG_EXT, (LAST_UPD > '2000-06-22' AND LAST_UPD < '2000-06-23')
```

The expression is a self-contained WHERE clause expression (without the WHERE) and should use only literal values or column names (optionally prefixed with the base table name). There must also be a space separating the operator from the operand in this expression (a space must be added between > and '). When deleting rows for a specific date, you should use date ranges as shown in the example instead of setting the date equal to a specific date. By default, DELETE MATCHES expressions are not used.

This parameter will only write the user keys values of the deleted target table rows to the EIM table columns. It will not write values of nonuser keys columns or nontarget table rows column values to the EIM table. The deleted rows cannot be reimported using the EIM table rows written by the EIM delete process, because they will not contain all the original information.

Only use this parameter to delete rows from target base tables. Rows will be deleted from the target base table even if the DELETE ROWS parameter is set to FALSE for that table.

CAUTION: Do not use the DELETE MATCHES parameter to delete rows from S_PARTY based tables. For example, using the criteria "DELETE MATCHES = S_PARTY, (CREATED > xxxxx)" will cause all records of S_PARTY that matches this criteria to be deleted from the database.

DELETE ALL ROWS Parameter

This parameter specifies that all rows in the target base table are to be deleted. Valid values are true and false (the default). Existing values in the EIM table and delete matches expressions are ignored.

This parameter will only write the user keys values of the deleted target table rows to the EIM table columns. It will not write values of nonuser keys columns or nontarget table rows column values to the EIM table. The deleted rows cannot be reimported using the EIM table rows written by the EIM delete process, because they will not contain all the original information.

CAUTION: Use the DELETE ALL ROWS = TRUE setting with extreme caution. It will delete all rows in the named base table including any seed data. Do not remove unnecessary seed data by deleting all rows from the S_LST_OF_VAL base table. If you do so, you will not be able to reimport "clean" data and you will be forced to rebuild the seed data or restore from backup. To selectively delete rows, use the DELETE EXACT or DELETE MATCHES expressions.

Deleting All Data Rows

If you want to delete all data rows in a target base table, you must perform the following procedure. Typically, this would only be performed in a test environment.

To delete all rows in a target base table

- Set the DELETE ALL ROWS parameter in the EIM configuration file to TRUE; its default value is FALSE.

The following example contains lines that can be used in the EIM configuration file to delete all rows from the accounts table:

```
[Delete Accounts]
TYPE = DELETE
BATCH = 200
TABLE = EIM_ACCOUNT
DELETE ALL ROWS = TRUE
```

CAUTION: Use the DELETE ALL ROWS = TRUE setting with extreme caution. It will indeed delete all rows in the target base table.

Deleting Data Rows Identified by User Key Values

You must complete the following procedure to delete rows identified by user key values.

To delete rows with user key values appearing in the EIM tables

1. Set the DELETE EXACT parameter in the EIM configuration file to TRUE; its default value is FALSE.
2. Add the ONLY BASE TABLES parameter and set this parameter to the name of the base table you want to delete.

The following example contains lines that can be used in the EIM configuration file to delete rows with user key values in the EIM tables from the Accounts table:

```
TYPE = DELETE
BATCH = 200
TABLE = EIM_ACCOUNT
DELETE EXACT = TRUE
ONLY BASE TABLES = S_ACCNT_POSTN
```

Note: Although you can use the DELETE EXACT parameter to delete rows from both target and nontarget base table, you should only use it to delete nontarget base tables that contain user keys. Rows in nontarget base tables that do not contain user keys will not be deleted.

Rows from the following tables do not have primary user keys and thus cannot be deleted using this parameter:

- Notes
- Territory Items
- Fulfillment Items

Deleting from Base Tables Other Than the Target Base Table

To use the DELETE EXACT parameter to delete data from base tables other than the target base table, specify the user key columns only for a single base table for each row in the EIM table. When specifying rows for exact deletion, make sure any columns that are not necessary to specify the row to be deleted are NULL to avoid problems with deleting from the wrong base table. EIM tries to enforce this behavior by requiring other user key columns to be NULL. If a row cannot be identified as clearly referring to a row in a single base table that row will fail to be deleted.

The following procedure explains how to delete data from base tables other than the target base table using the DELETE EXACT parameter with the following scenario as an example. In this example, EIM_ACCOUNT is mapped to base tables including S_ORG_EXT, S_ORG_PROD, and S_ORG_INDUST. If you want to delete data only from S_ORG_PROD, and not delete data from S_ORG_EXT or any other base tables, complete the following procedure.

To delete data from base tables other than the target base table

1. Populate the following columns in the EIM table (such as user keys for the S_ORG_PROD table and all the special interface columns):

- ACCNT_NAME
- ACCNT_LOC
- INS_PROD_NAME
- INS_PROD_VENDR
- INS_PROD_VENDR_LOC
- INS_DT, ROW_ID
- IF_ROW_BATCH_NUM
- IF_ROW_STAT
- ROW_ID

2. Add or modify the following process section in your .IFB file:

TYPE = DELETE

BATCH = *<number used to populate IF_ROW_BATCH_NUM column>*

TABLE = EIM_ACCOUNT

ONLY BASE TABLES = S_ORG_PROD

DELETE EXACT=TRUE

3. Run EIM.

This deletes all rows from the S_ORG_PROD table that have user keys that match the rows in your EIM table.

Deleting Rows from Extension Tables

You cannot delete a row from one-to-one extension tables (*_X type) without removing its parent row. For example, to remove a row from S_CONTACT_X, you must remove the parent row from S_CONTACT.

If you have to delete data in an extension column, update it with NULL by setting NET CHANGE = FALSE in the configuration file, and if necessary, use ONLY BASE COLUMNS.

Deleting File Attachments

You can also delete file attachments that have previously been imported into the Siebel database.

In order to delete file attachments, EIM deletes the row pointing to the file attachment. After all file attachments have been deleted, use the Siebel File System Maintenance Utility named `sfscleanup.exe` during hours when the network is least laden to clean the file attachment directory of any unused file attachments.

To delete file attachments

1. Run an EIM delete process for all file attachments that you want to delete.
2. After all file attachments have been deleted, run the Siebel File System Maintenance Utility named `sfscleanup.exe` to clean up the file attachment directory.
For information on using `sfscleanup.exe`, see *Siebel System Administration Guide*.

Handling Aborts of EIM Delete Processing

If an EIM delete process is aborted, base tables associated with deleted rows may not be updated. Orphans rows may be created because foreign keys may not have been updated. This may cause critical data integrity issues.

To avoid this problem, you should set the following parameters in the `.IFB` file to make sure that the EIM delete process performs only one commit and rollback when aborted:

COMMIT EACH TABLE = FALSE

COMMIT EACH PASS = FALSE

ROLLBACK ON ERROR = TRUE

Running a Delete Process

You may run a delete process after you have:

- Identified the data for delete processing
- Prepared the related EIM tables
- Modified the EIM configuration file accordingly

Run the delete process by completing the procedures in *Running EIM*.

Checking Delete Results

When a delete process ends, you should carefully check the results to verify that data was successfully deleted. During each process, EIM writes comprehensive status and diagnostic information to several destinations.

EIM uses a special column named `T_DELETED_ROW_ID` in the EIM tables. EIM writes the `ROW_ID` of each deleted base table row to this column.

To view a list of deleted base table rows

- Query the appropriate EIM table for rows whose `IF_ROW_BATCH_NUM` equals the batch number for the delete.

The value of T_DELETED_ROW_ID identifies deleted rows.

If error flags, SQL trace flags, or trace flags were activated for the EIM process, you can also use the trace file to view the results of the EIM process. For more information on viewing the trace file, see [Viewing the EIM Log File](#).

EIM Deletes and Audit Trail

When EIM is used to delete base table records, any corresponding Audit Trail table (S_AUDIT_ITEM) records associated with those base table records will also be deleted, even when S_AUDIT_ITEM is not explicitly defined on the EIM Interface Table Repository Object.

For example, when deleting an Employee record using EIM_EMPLOYEE, Audit Trail records related to that Employee, such as those on Account, Contact, or other objects that Employee may have touched are also deleted.

If this behaviour is not desired for a given EIM DELETE operation, add the statement DELETE ROWS=S_AUDIT_ITEM, FALSE to the IFB configuration file used by that EIM job.

8 Merging Data

Merging Data

This chapter covers the process of merging data into the Siebel database. This chapter is organized into the following sections:

- *Overview of EIM Merge Processing*
- *EIM Merge Process*
- *Preparing the EIM Tables for Merge Processing*
- *Editing the Configuration File for Merge Processing*
- *Running a Merge Process*
- *Checking Merge Results*

Overview of EIM Merge Processing

EIM uses a combination of EIM table row contents and configuration file parameter values to control the merge process. A merge process deletes one or more existing rows from the base table and makes sure that intersecting table rows are adjusted to refer to the remaining rows. Data from the record you select as the remaining record is preserved. Data from the other records is lost. If there are other records associated with the records you merge, those records (with the exception of duplicates) are associated with the remaining record.

Duplicate child records of the deleted rows will have CONFLICT_ID updated during the merge process. For example, when merging two Accounts (parent), the user keys of the Contacts (child) will be compared, and if the same Contact belongs to both Accounts, the Contact of the deleted Account will have its CONFLICT_ID updated.

You can only merge records that have primary user keys. Because records in the following tables do not have primary user keys, these records cannot be merged:

- Notes
- Territory Items
- Fulfillment Items

CAUTION: Using EIM to merge data in the Products and Positions base tables is not recommended and can lead to inadvertent data integrity loss.

It is not possible to merge rows that have the same primary user key and different conflict IDs using EIM, because EIM relies on user keys to identify rows in base tables. If there are two rows in the base table that have the same user key but different conflict IDs, EIM cannot distinguish between these rows. In such cases, the IF_ROW_STAT field of the row in the EIM table will be marked as AMBIGUOUS.

EIM can only be used to merge rows from target base tables and not secondary tables. For example, the target base table for EIM_ASSET is S_ASSET. EIM can only be used to merge two or more S_ASSET rows into single S_ASSET rows. You cannot use EIM to merge two or more S_ASSET_CON rows into single S_ASSET_CON rows.

EIM Merge Process

During its multiple passes through the EIM tables, EIM completes the following tasks within a merge process:

- Initialize the EIM tables for merge.
- Select for merge the rows with matching user keys in the EIM tables.
- Merge child rows into the replacement rows. EIM then deletes rows from the target base table that are specified in the EIM table.
 - For deleted rows, EIM sets T_MERGED_ROW_ID to the ROW_ID of the row that was merged into (the remaining row).
 - EIM sets T_DELETED_ROW_ID to the ROW_ID of the deleted base table row.
- Update child rows containing foreign keys that point to newly deleted rows. For base tables that have foreign keys in newly deleted rows, EIM updates the foreign keys to point to remaining rows (depending on the value for update rows in the configuration file).

EIM provides comprehensive status information about each merge process. When the process ends, you should review this information. For more information, see [Checking Merge Results](#).

Each task involves multiple passes; at least one pass is required for each EIM table included in the process.

Note: Because the merge process affects the contents of base tables, transaction logging should be enabled during merge operations if you have active mobile Web clients, so that the appropriate transactions are captured for later synchronization. For more information, see [Enabling Transaction Logging for Merge Processing](#).

Running through the EIM merge process requires that you perform the following steps, which are discussed in the remaining sections of this chapter:

1. [Preparing the EIM Tables for Merge Processing](#).
2. [Editing the Configuration File for Merge Processing](#).
3. [Running a Merge Process](#).
4. [Checking Merge Results](#).

Preparing the EIM Tables for Merge Processing

This section provides assistance in loading the EIM tables with data used to control the process of merging rows in Siebel applications base tables. Your database administrator can use the loading tool provided by your database.

You must make sure that each EIM table row to be processed contains the appropriate values in the following columns. The following table shows a merge example for special columns.

IF_ROW_BATCH_NUM	NAME	ROW_ID	IF_ROW_MERGE_ID
1	IBM	100	NULL
1	IBM Japan	101	100

IF_ROW_BATCH_NUM	NAME	ROW_ID	IF_ROW_MERGE_ID
1	IBM Europe	102	100

IF_ROW_BATCH_NUM. Set this to an identifying number for all EIM table rows to be processed as a batch.

ROW_ID. This value in combination with the nonempty contents of IF_ROW_BATCH_NUM must yield a unique value.

IF_ROW_MERGE_ID. Set this value to one of two values. For an EIM table row whose ROW_ID and IF_ROW_BATCH_NUM columns identify the remaining or merged-into row, set this value to NULL. For EIM table rows whose ROW_ID and IF_ROW_BATCH_NUM columns identify a row to be merged (and subsequently deleted), set this value to the ROW_ID where this row will be merged. Upon completion of the merge process, the first row remains and the remaining rows are deleted. All child and intersection table rows that previously pointed to ROW_IDs 101 and 102 now point to 100.

IF_ROW_STAT. In each row to be merged, set this column to FOR_MERGE to indicate that the row has not been merged. After processing, if certain rows were not merged due to a data error, you should change:

- IF_ROW_BATCH_NUM value for the rows that require remerging.
- BATCH NUMBER line in the configuration file.

Note: In addition to populating these columns, user key information for each row to be merged must be loaded into the EIM table.

If you do not correctly populate all the user key columns, the merge process will fail and the IF_ROW_STAT column in the EIM table will be set to the value NO_SUCH_RECORD. This indicates that EIM cannot find the appropriate rows to merge using the specified user keys.

For more information on special columns, see *EIM Table Columns*. For general information on EIM tables, see *Siebel EIM Tables*.

Editing the Configuration File for Merge Processing

This section describes the header and process sections that you need in the EIM configuration file to properly configure EIM for a merge process. For general information on the EIM configuration file, see *EIM Configuration File*.

Before merge processing begins, you must change the configuration file to support this function. Such changes include:

- Editing the header and process sections and parameters
- Adjusting settings in the configuration file in the following ways:
 - *Updating Affected Rows*
 - *Avoiding Aborts of EIM Merge Processing*
 - *Enabling Transaction Logging for Merge Processing*
 - *Specifying Remaining Records for Merge Processes*

Header Section Parameters Used for Merges

Parameters in the header section generally apply to all types of processes. For a description of the necessary contents in this section, see *Header Section Parameters Generic to All EIM Processes*.

Process Section Parameters Used for Merges

Parameters in the process section apply only to that specific process and override any corresponding value in the header section for the specific process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

To merge data, you must define at least one process with type = merge. The following example contains lines that can be used in the EIM configuration file to define a merge process for the Accounts table.

```
[Merge Accounts]
TYPE = MERGE
BATCH = 1
TABLE = EIM_ACCOUNT
UPDATE ROWS = TRUE
```

Note: For performance reasons, you should limit the number of tables to merge in a single process section to five or less.

Parameters Used for Merges in Both the Header and Process Sections

The following information describes the parameters that can appear in either the header section or a process section, and are specific to a merge process. For generic parameters that can be used in all EIM processes, see *Process Section Parameters Generic to All EIM Processes*.

Parameter	Description
SET BASED LOGGING	<p>Specifies whether set-based logging is enabled. The default value is TRUE.</p> <p>Note: EIM will ignore this parameter if Enable Transaction Logging is unchecked in the Remote System Preferences view of the Administration - Siebel Remote screen.</p> <p>For more information on this parameter, see <i>SET BASED LOGGING Parameter</i>.</p>
UPDATE ROWS	<p>Specifies whether the foreign key (or keys) that reference the merged rows in the named table need to be adjusted. Valid values are TRUE (the default) and FALSE.</p> <p>Note: Use the <code>UPDATE ROWS = Table_Name, FALSE</code> setting carefully. Inappropriate use can result in dangling foreign key pointers.</p>

SET BASED LOGGING Parameter

When set-based logging is enabled, a separate log entry is generated for all rows in each table affected by EIM. This allows greater performance improvement because EIM can perform the operations as set operations in SQL, without resorting to row-by-row processing to support the transaction log. Set-based transaction logging is most useful when a table is read-only to mobile Web clients. Set-based logging is always the default for merge. The SET BASED LOGGING parameter must be set to FALSE to allow transaction logging for merge.

Updating Affected Rows

During a merge operation, a specific base table may have some rows deleted and others updated. You can use the UPDATE ROWS parameter to prevent updates to one base table while allowing updates to another. By default, UPDATE ROWS = TRUE.

Avoiding Aborts of EIM Merge Processing

If an EIM merge process is aborted, base tables associated with merged rows may not be updated. Orphan rows may be created because foreign keys may not have been updated. This may cause critical data integrity issues.

To avoid this problem, set the following parameters in the .IFB file so the EIM merge process performs only one commit or rollback when aborted:

COMMIT EACH TABLE = FALSE

COMMIT EACH PASS = FALSE

ROLLBACK ON ERROR = TRUE

Enabling Transaction Logging for Merge Processing

To enable transaction logging for an EIM merge process, set the following parameters in the .IFB file so the EIM merge process runs in ongoing (row-by-row) mode:

LOG TRANSACTIONS= TRUE

SET BASED LOGGING = FALSE

For information on the LOG TRANSACTIONS parameter, see *Optional Keywords for Process Parameters*. For information on the SET BASED LOGGING parameter, see *Process Section Parameters Used for Merges*.

Specifying Remaining Records for Merge Processes

In a merge process, data from the record you select as the remaining record is preserved, while data from the other records is lost. Do not specify the same record as both the remaining record and the record to be deleted, or it will be deleted. You should also make sure that a record is specified as a remaining record only once in a batch.

Note: EIM behavior, whether executed from the GUI or through an EIM run, does not merge data in the base record. It simply repoints the foreign keys in the dependent child records. This applies to all columns in the base table. This could lead to unintended data loss in an extension column. For more information, see *Example of Running a Merge with Custom Columns*.

Running a Merge Process

You can run a merge process after you have:

- Identified the data for merge processing
- Prepared the related EIM tables
- Modified the EIM configuration file accordingly

Run the merge process by completing the procedures in *Running EIM*.

Checking Merge Results

When a merge process ends, you should carefully check the results to verify that data was successfully merged. During each process, EIM writes comprehensive status and diagnostic information to several destinations.

During a merge process, EIM writes the following values to two special columns in the EIM tables:

- T_DELETED_ROW_ID contains the ROW_ID of the deleted base table row.
- T_MERGED_ROW_ID contains the ROW_ID of the remaining base table row.

To view the results of a merge

1. Query the appropriate EIM table for rows whose IF_ROW_BATCH_NUM equals the batch number for the merge process.
2. Inspect the values of T_DELETED_ROW_ID and T_MERGED_ROW_ID.

If error flags, SQL trace flags, or trace flags were activated for the EIM process, you can also use the trace file to view the results of the EIM process. For more information on viewing the trace file, see *Viewing the EIM Log File*.

9 Running EIM

Running EIM

This chapter covers how to run an EIM process and check the results. This chapter is organized into the following sections:

- *Preparing to Run an EIM Process*
- *Running an EIM Process*
- *Viewing the EIM Log File*
- *Optimizing EIM Performance*

Preparing to Run an EIM Process

You can run an EIM process (import, export, delete, or merge) once you have:

- Identified the data for EIM processing
- Prepared the related EIM tables
- Modified the EIM configuration file accordingly

You can start an EIM process by running a server task for the Enterprise Integration Manager component. You can run the server task using either the GUI or the command-line interface. For more information on running server tasks, see *Siebel System Administration Guide*.

Running an EIM Process

On each pass, EIM processes one EIM table and performs a particular action on all rows in that table for that batch. Most passes affect only the EIM table's temporary columns; for example, resolving foreign keys. There are two methods for running an EIM process:

- *Running an EIM Process Using the Graphical User Interface*
- *Running an EIM Process Using the Command-Line Interface*

Running an EIM Process Using the Graphical User Interface

The most common method for starting an EIM server task is to use the graphical user interface (GUI). When performing this procedure, be aware that passes in Step 8 in *EIM Import Process* (update), Step 9 in *EIM Import Process* (insert), and Step 10 in *EIM Import Process* (primary keys) affect the base tables. All steps are performed for all columns used in the import process.

CAUTION: If you are running EIM on a DB2 database, then set the database configuration parameters as described in the *Siebel Installation Guide*, or EIM will not run successfully. You should also run the `updatestats.sql` script (located in `dbserver_home\db2`) each time before running EIM, or performance issues may be encountered when loading the dictionary. For more information, see *Siebel Performance Tuning Guide*.

To run an EIM process using the GUI

1. Navigate to the Administration-Server Management screen, and then Jobs view.
2. In the Jobs list, click New.

The component job status field changes to Creating.

3. In the Component/Job field, click the Select button.

The Component/Jobs pick applet appears.

4. From the Find drop-down list, select Name, and perform the following query: Enterprise Integration Mgr, then click OK.

If you want to use a component job template based on EIM for your component request, you must first define the component job template. For information on defining component job templates, see *Siebel System Administration Guide*.

5. In the Job Detail view, enter data in other appropriate fields as described in the table that follows.

Field	Description
Scheduled Start	The scheduled start date and time of the component job.
Expiration	The date at which the component job is no longer valid.
Requested Server	Set if you want to target a server component on a specific Siebel Server.
Request Key	Set if you want to target a component or repeating component job to a specific instance of the server component identified by the request key. In all other situations, keep this field blank.
Delete Interval	Set with Delete Unit field, this field determines the length of time before the component job is deleted. If not updated, this field defaults to 1.
Delete Unit	Set with Delete Interval field, this field determines the length of time before the component job is deleted. If not updated, this field defaults to Weeks.
Retry on Error	Check this box to retry the component job in case of error.
Sleep Time	This field is available when the Retry on Error check box is true and determines the amount of time before the component job is retried.

Field	Description
Number of Retries	This field is available when the Retry on Error check box is true and determines the number of times the component job is retried.

6. Click the menu button, and then click Save Record.
7. In the Job Parameters list, add or change any component job parameters for the EIM process:
 - a. Click the New button.
 - b. In the Name field, click the Select button.

The Job Parameters dialog box appears. The parameters that appear in the Job Parameters dialog box vary depending on the server component you selected in Step 3.

- c. Select a parameter in the Component Parameters dialog box, and modify its value.
 - d. Click the menu button and then click Save Record.
8. In the Jobs list, click the Submit Job button.

The Status field changes from Creating to Queued.

CAUTION: EIM is a multistep process. Once the EIM process is running, do not stop or pause the task. Otherwise, some steps may not roll back correctly.

Running an EIM Process Using the Command-Line Interface

You can also start the EIM server task through the command-line interface. For example, if you are using a UNIX operating system or if you have experienced the EIM server task being QUEUED when the job was submitted by the GUI, use the command-line interface to run an EIM process.

To run an EIM process using the command-line interface

1. Start the `svrmgr` program in the command-line interface.

For information on `svrmgr` program, see *Siebel System Administration Guide* .

2. Execute a start task command or a run task command on the Enterprise Integration Mgr component. Be sure to specify the configuration file with the config parameter.

Note: You cannot use the Uniform Naming Convention (UNC) in the Server Manager command-line interface when specifying the configuration file.

If you do not specify a configuration file, the default.ifb configuration file will be used. If you put the .IFB file you want to use in a directory other than the default directory (<SiebSrvr\Admin> folder), you will need to specify the path to the .IFB file when you start the EIM component.

The following example shows how to use the run task command to start an import process:

```
run task for component eim with config=import.ifb
```

For more information on the start task command and the run task command, see *Siebel System Administration Guide*.

CAUTION: EIM is a multistep process. *When the EIM process is running, do not interrupt the task.* Otherwise, some steps may not roll back correctly.

The following example shows how to use the run task command to start an import process that uses a different LOV language than the default setting of the EIM LOV language parameter:

```
run task for component eim with config=import.ifb, LovLang=ESN
```

Viewing the EIM Log File

In the Task Info Log view, you can view information about the results of an EIM process by drilling down in an EIM server task that has completed. This information is also provided in the EIM log file within the `siebel server\log` directory. The log consists of three general sections:

- **Startup messages.** This section pertains to dictionary loading, parameter loading, and .IFB file parsing.
- **Run-time messages.** This section shows the begin and end times for each process.
- **Row-count summary of each process.** This section shows the number of rows updated in each table.

If error flags, SQL trace flags, or trace flags were activated for the EIM process, the EIM log file will also contain the results of each flag. For more information on trace flags and error flags, see *Using Trace Flags, SQL Trace Flags, and Error Flags*.

Further information on the EIM log file is provided as follows:

- *Using Trace Flags, SQL Trace Flags, and Error Flags*
- *Setting Event Logging from the Graphical User Interface*
- *Setting Event Logging from the Command-Line Interface*
- *Trace Flag Settings*

To view EIM log file information in the Task Info Log

1. Navigate to Administration - Server Management screen, then the Tasks view.

2. In the Tasks list, select the task for the EIM process.
3. Click the Log tab.

The log for the selected task is displayed in the Log list.

Note: You can also view this information by opening the EIM log file in the `siebel server\log` directory.

Using Trace Flags, SQL Trace Flags, and Error Flags

You can activate trace flags and error flags to log transactions. This topic covers the following types of flags:

- **Error flags.** See *Error Flags*.
- **SQL Trace flags.** See *SQL Trace Flags*.
- **Trace flags.** See *Trace Flags*.

Note: Activating flags will have a direct effect on performance. Typically, activating flags should only be done when testing EIM processes. Avoid activating flags in a production environment unless absolutely necessary.

Recommended settings for error flags, SQL trace flags, and trace flags include the following:

- **To display errors and unused foreign keys.** Start with the following setting combination. The setting Trace Flag=1 provides a summary (after each batch) of the elapsed time in EIM steps 10 and 11.

Setting	Value
Error Flag	1
SQL Trace Flag	1
Trace Flag	1

- **To determine SQL performance.** The following setting combination produces a log file with SQL statements including the elapsed time for each statement.

Setting	Value
Error Flag	1
SQL Trace Flag	8
Trace Flag	3

- **To determine optimal batch size and monitor performance in a particular step.** The following setting combination produces a log file showing the elapsed time for each EIM step.

Setting	Value
Error Flag	0
SQL Trace Flag	0
Trace Flag	1

Error Flags

To activate error flags, you must complete Step 7 in *Running an EIM Process Using the Graphical User Interface* when running an EIM process. Setting the Error Flags parameter to 1 produces a detailed explanation of rows that were not successfully processed.

There are a variety of reasons why rows might not be processed. The following sample shows an excerpt from an EIM Error Flag 1 trace. The log begins with a header that describes an export failure that occurred during Step 2, Pass 101.

```
2001-04-04 03:47:59 4/4/01 3:47 Warning: No rows in S_ORG_EXT matched by expressions
for export.
2001-04-04 03:47:59 Process [Export Old Accounts] had all rows fail
2001-04-04 03:47:59 on EIM_ACCOUNT for ] 2001 in step 2, pass 101:
2001-04-04 03:47:59 No base table rows matched expressions. (severity 5)
2001-04-04 03:47:59 Base table:
2001-04-04 03:47:59 S_ORG_EXT (Account)
2001-04-04 03:47:59 The match expressions specified for exporting rows through this
interface table
2001-04-04 03:47:59 did not match any of the rows currently in the target base table.
2001-04-04 03:47:59 Since there were no matches for the given match expressions,
processing for
2001-04-04 03:47:59 this interface table was discontinued. However, processing of
other interface
2001-04-04 03:47:59 tables will continue.
2001-04-04 03:47:59 Recorded 1 group of failures.
```

SQL Trace Flags

To activate SQL trace flags, you must complete Step 7 in *Running an EIM Process Using the Graphical User Interface* when running an EIM process.

Setting the SQL Trace Flags parameter to 8 creates a log of all SQL statements that make up the EIM task. The lower values for SQL Debug Flags (1, 2, and 4) are used for logging at the ODBC level.

Trace Flags

Trace flags contain logs of various EIM operations. To activate trace flags, you must complete Step 7 in *Running an EIM Process Using the Graphical User Interface* when running an EIM process. Also set event logging for the EIM component, as described in *Setting Event Logging from the Graphical User Interface*.

Trace flags are bit-based. Available trace flags include 1, 2, 4, 8, and 32. To activate multiple trace flags, set the Trace Flags parameter to the sum of individual trace flag numbers. For example, to log trace flags 2 and 4, set the Trace Flags parameter to 6.

Setting Event Logging from the Graphical User Interface

You can set event logging for the EIM component using the Administration - Server Configuration views in the Siebel client.

Note: You can also set event logging using the SrvrMgr command line. See *Setting Event Logging from the Command-Line Interface*.

To set event logging for the EIM component from the GUI

1. Navigate to the Administration - Server Configuration screen, Servers, Components, and then the Events view.
2. In the Components list, select Enterprise Integration Manager as the component.
3. Click the Events tab to view all the configurable event types for the selected component.
The log level is set to a default value of 1.
4. Perform a query and enter the specified log level for each of the following event types:

Event Type	Log Level Value
EIM SQL	4
SQL Summary	4
Task Configuration	4
EIM Trace	3

Note: The event types EIM Debug, EIM Error, and EIM System Stats exist for compatibility with previous versions of the Siebel application. Do not change the default value for these parameters.

It is not necessary to restart the Siebel Server to apply the event type log level changes. The changed settings are active in the next EIM task executed.

For more information on event logging administration, see *Siebel System Monitoring and Diagnostics Guide*.

Setting Event Logging from the Command-Line Interface

You can also set event logging for the EIM component from the Server Manager command line.

To set event logging for the EIM component from the command line

- Use the following commands:

```
change evtloglvl SQLSummary=4 for component eim
change evtloglvl EIMSQL=4 for component eim
change evtloglvl TaskConfig=4 for component eim
change evtloglvl EIMTrace=3 for component eim
```

Other necessary commands for activating tracing levels are the following:

- **When running the EIM task.** Specify the following parameters:

```
Srvrmgr> run task for component eim with config=<configfile.ifb>, TraceFLags=1,
ErrorFlags=1, SQLFlags=8
```

- **To view existing event log levels for the EIM component.** Use the following command:

```
Srvrmgr> list evtloglvl for component eim
```

Trace Flag Settings

This topic provides Trace Flag setting information as follows:

- [Trace Flag 1](#)
- [Trace Flag 2](#)
- [Trace Flag 4](#)
- [Trace Flag 8](#)
- [Trace Flag 32](#)

Trace Flag 1

Setting the Trace Flags parameter to 1 creates a step-oriented log of the task. This can be used to determine the amount of time EIM spends on each step of the EIM task, or for each EIM table processed. The following sample shows an EIM Trace Flag 1 output:

```
Initializing
Loading configuration file imacct.ifb 0s
Opening server database ora_dev 6s
Loading Siebel dictionary 15s
Initializing 21s
Import Accounts 14
Importing EIM_ACCOUNT
Step 1: initializing IF Table 0s
Step 4: resolving foreign keys S_ORG_EXT 0s
Step 5: locating existing row S_ORG_EXT 0s
Step 7: finding new foreign keys 4s
Step 9: inserting new rows S_ORG_EXT 2s
Importing EIM_ACCOUNT 15s
Updating primaries
Step 10: updating primary keys S_ORG_EXT 3s
Updating primaries 3s
Import Accounts 14 18s
```

Trace Flag 2

Setting the Trace Flags parameter to 2 creates a file log that traces all substitutions of user parameters. The following example shows an EIM Trace Flag 2 output:

```
[TRC01] Parameter Set << AFTER RESOLUTION >>
[TRC01] UserParams = IFTABLE=EIM_ACCOUNT
[TRC01] [0] $IFTABLE = EIM_ACCOUNT
[TRC01] [1] $CURRENT_USER = wgong
[TRC01] [2] $CURRENT_DATETIME = 4/6/01 13:17
[TRC01] [Siebel Integration Manager]
[TRC01] log transactions = false
[TRC01] $COLUMN_VALUE = 'EIM ins_acct Test%'
[TRC01] [ins_acct_shell]
[TRC01] TYPE = SHELL
[TRC01] INCLUDE = del_acct
[TRC01] INCLUDE = ins_acct
[TRC01] [del_acct]
[TRC01] SESSIONSQL = DELETE FROM DEV50.EIM_ACCOUNT WHERE IF_ROW_BATCH_NUM=21
[TRC01] TYPE = DELETE
[TRC01] BATCH = 20
[TRC01] TABLE = EIM_ACCOUNT
[TRC01] $COLUMN_NAME = NAME
[TRC01] DELETE MATCHES = EIM_ACCOUNT,(NAME LIKE 'EIM ins_acct Test%')
[TRC01] [ins_acct]
[TRC01] SESSIONSQL = INSERT INTO DEV50.EIM_ACCOUNT (IF_ROW_STAT, ROW_ID,
IF_ROW_BATCH_NUM, ACCNT_NAME, ACCNT_LOC) SELECT 'X', ROW_ID, 21, 'EIM ins_acct Test
' || ROW_ID, 'Loc' FROM DEV50.S_SYS_PREF
[TRC01] TYPE = IMPORT
[TRC01] BATCH = 21
[TRC01] TABLE = EIM_ACCOUNT
```

Trace Flag 4

Setting the Trace Flags parameter to 4 creates a file log that traces all user-key overrides. The following example shows an EIM Flag 4 output for a user key override to the EIM_ACCOUNT table:

```
[TRC02] -----
[TRC02] ***** IF TABLE <EIM_ACCOUNT> uses USER_KEY_COL *****
[TRC02] Action: No Move & Insert
[TRC02] overriding UK Index (S_TERR_ITEM_U1) at position (0)
[TRC02] ##### Destination TABLE (S_TERR_ITEM) index vector: [S_TERR_ITEM_U1]
[TRC02] --- Column (T_TERITE_OUID) index vector: [S_TERR_ITEM_U1]
[TRC02] --- Column (T_TERITE_TERID) index vector: [S_TERR_ITEM_U1]
[TRC02] -----
```

Trace Flag 8

Setting the Trace Flags parameter to 8 creates a file log that traces all Interface Mapping warnings. The following example shows an EIM Flag 8 output for an Interface Mapping warning between the EIM_ACCOUNT and S_TERR_ITEM tables:

```
[TRC03] -----
[TRC03] IF table EIM_ACCOUNT destination S_TERR_ITEM
[TRC03] IF column EIM_ACCOUNT.T_TERITE_TERID:
[TRC03] imports to: S_TERR_ITEM.TERR_ID
[TRC03] exports from: S_TERR_ITEM.TERR_ID
[TRC03] Column NAME of join isn't in table!
[TRC03] Missing join to user key NAME
[TRC03] -----
```

Trace Flag 32

Setting the Trace Flags parameter to 32 creates a file log that traces all file attachment status. The trace file contains four labels, three of which are used to trace file attachment processes as described in the following table.

Label	Description
Attachment Imported	Indicates whether the file attachment was encoded, compressed, and copied to the Siebel file server with the new name.
Attachment (Old) Deleted	This label applies only to updates and indicates whether an existing file was replaced and deleted.
Attachment Not Found	Indicates that the file attachment cannot be found in the input directory.

The following sample shows an EIM Flag 32 output for an opportunity file attachment:

```
[TRC32] Attachment Imported: E:\V50\output\openpost.doc ->
\\BALTO\SIEBFILE\ORADEV50\S_OPTY_ATT_10+413+1_10-41R-0.saf
[TRC32] Attachment (Old) Deleted: \\BALTO\SIEBFILE\ORADEV50\S_OPTY_ATT_10+413+1_10-
40Y-0.saf
[TRC32] Attachment Not Found: E:\V50\output\openpost.doc
[TRC32] Attachment Identical: E:\V50\output\openpost.doc IDENTICAL TO
\\BALTO\SIEBFILE\ORADEV50\S_OPTY_ATT_10+413+1_10-41R-0.saf
```

Optimizing EIM Performance

There are several ways you can improve EIM run-time performance. The best practices suggested in this section optimize EIM performance. For additional information on improving the performance of EIM, see *Siebel Performance Tuning Guide*.

Table Optimization for EIM

This section discusses ways that you can optimize tables for EIM processing.

Configuration Parameters

Limit base tables and columns to be processed. Four EIM parameters can help improve performance by limiting the affected tables and columns:

- ONLY BASE TABLES
- IGNORE BASE TABLES
- ONLY BASE COLUMNS
- IGNORE BASE COLUMNS

The ONLY BASE COLUMNS parameter is critical for the performance of an EIM process updating a few columns in many rows.

Note: Do not use the IGNORE BASE COLUMNS parameter for merge processes or export processes. This parameter should only be used for import processes and delete processes.

For other suggestions involving parameter settings, see *Parameter Settings Optimization for EIM*.

Indexes

Verify that all indexes exist for the tables involved. In most implementations, the tables and corresponding indexes in the following list tend to be the most heavily used and should be separated across devices. In general, the following indexes should be on different physical devices from the tables on which they are created.

- S_ACCNT_POSTN
- S_OPTY
- S_ADDR_ORG
- S_OPTY_POSTN
- S_CONTACT
- S_POSTN_CON
- S_DOCK_TXN_LOG
- S_PARTY_RPT_RE
- S_SRV_REQ
- S_EVT_ACT
- S_OPTY
- S_ORG_EXT

For organizations that plan to use EIM extensively, you should put your key EIM tables (based on your unique business requirements) on different devices from the Siebel base tables, because all tables are accessed simultaneously during EIM operations.

You can speed up deletes and merges involving S_ORG_EXT by adding an index to one or more columns. For more information, see *Siebel Performance Tuning Guide*.

Maintenance of EIM Tables

Perform regular table maintenance on EIM tables. Frequent insert or delete operations on EIM tables can cause fragmentation in the table. Ask your database administrator to detect and correct fragmentation in the EIM tables.

Always delete batches from EIM tables upon completion. Leaving old batches in the EIM table wastes space and can adversely affect performance. For other suggestions on working with batches, see *Limiting the Number of Records and Rows for Merge Processes*.

Batch Processing Optimization for EIM

This section suggests ways in which you can optimize EIM batch processing. Try using different batch sizes. Large batch sizes are often not efficient. For import and delete processes that use the DELETE EXACT parameter, use approximately 20,000 rows in a single batch.

Limiting the Number of Records and Rows for Merge Processes

You can improve performance by limiting the number of records in a batch. For information, see *Siebel Performance Tuning Guide*.

Using Batch Ranges

Try using batch ranges (BATCH = x–y). This allows you to run with smaller batch sizes and avoid the startup overhead on each batch. The maximum number of batches that you can run in an EIM process is 1,000.

For IBM DB2, load a few batches of data into the EIM table and run EIM for just one of these batches. This primes the statistics in the DB2 catalogs. Afterward, do not update statistics on the EIM tables, and run EIM with the parameter UPDATE STATISTICS = FALSE in the .IFB file. This helps achieve consistent performance results when running EIM. See *Parameter Settings Optimization for EIM* for other suggestions about parameters.

Run-Time Optimization for EIM

This section describes the ways you can optimize EIM performance at run time.

Parallel Processing

Run independent EIM jobs in parallel. Two or more EIM processes can be started simultaneously by using the Siebel Server Manager.

A special setup is not required to run EIM processes in parallel. For parallel processing, the following conditions must be met:

- No duplicate unique keys between runs for inserts.
- No duplicate updates or deletes between runs.
- No lock escalations on either EIM tables or target tables can be tolerated. Set LOCKLIST and MAXLOCKS as high as necessary to prevent this.

Note: If you run EIM jobs in parallel on the same base tables, you might encounter unique constraint errors if you have the same values for the unique index fields in batches being processed by two different EIM jobs.

CAUTION: Running EIM processes in parallel on a DB2 database may cause a deadlock when multiple EIM processes access the same EIM table simultaneously. To avoid this potential problem, set the UPDATE STATISTICS parameter to FALSE in the EIM configuration file. The UPDATE STATISTICS parameter is applicable only for DB2. For other suggestions, see *Parameter Settings Optimization for EIM*.

For more information on parallel processing, see *Siebel Performance Tuning Guide*.

Transaction Logging

Consider disabling the Enable Transaction Logging system preference in the Administration - Siebel Remote screen during the EIM run. Switching off transaction logging improves performance; however, this benefit must be balanced with the need for mobile users to reextract afterward. To disable transaction logging, complete Step 2 in *Importing an Initial Batch of Legacy Data*.

Parameter Settings Optimization for EIM

This section discusses ways that you can optimize EIM performance through parameter settings.

USING SYNONYMS Parameter for Optimizing EIM

Ignore account synonyms. Set the USING SYNONYMS parameter to FALSE in the .IFB file to indicate that account synonyms can be ignored during processing. This logical operator indicates to EIM that account synonyms do not require processing during import, thus reducing the amount of processing. Do not set the USING SYNONYMS parameter to FALSE if you plan to use multiple addresses for accounts. Otherwise, EIM will not attach addresses to the appropriate accounts. You can use EIM_ACCOUNT to import accounts with multiple addresses and then specify the primary address for an account by setting ACC_PR_ADDR to Y.

Trace Flag Settings for Optimizing EIM

Generate a task log to identify slow-running steps and queries by using Trace Flags. To use Trace Flags, set Error Flags=1, Trace Flags=1, and SQL Trace Flags=8. Rerun the batch and use the resulting task log to determine which steps and queries are running especially slowly. For additional information on trace flag settings, see [Trace Flag Settings](#).

Database Server Optimization for EIM

The overall performance of EIM is largely dependent on the overall performance of the database server. To achieve optimal database server performance, it is critical that the tables and indexes in the database be arranged across available disk devices in a manner that evenly distributes the processing load.

The mechanism for distributing database objects varies by RDBMS, depending on the manner in which storage space is allocated. Most databases have the ability to assign a given object to be created on a specific disk.

A redundant array of independent disks (or RAID) can provide large amounts of I/O throughput and capacity, while appearing to the operating system and RDBMS as a single large disk (or multiple disks, as desired, for manageability).

The use of RAID can greatly simplify the database layout process by providing an abstraction layer over the physical disks while achieving high performance. Regardless of the RDBMS you implement and your chosen disk arrangement, be sure that you properly distribute the following types of database objects:

- Database log or archive files.
- Temporary workspace used by the database.

By following these suggestions, you should be able to improve the performance of the database server.

10 EIM: Examples of Common Usage

EIM: Examples of Common Usage

This chapter provides examples that illustrate the Siebel EIM processes. The information is organized as follows:

- *EIM Import Process Examples*
- *EIM Merge Process Example*
- *EIM Delete Process Examples*
- *Examples of Resolving Foreign Keys*
- *Other Examples*

EIM Import Process Examples

This section provides examples that can be applied to your running of import processes.

Example of Importing from Multiple EIM Tables in a Single .IFB File

You use shell processes to import multiple EIM tables in a single .IFB file. In the sample .IFB file that follows, first EIM_CONTACT is imported, then EIM_ACCOUNT is imported.

```
[Siebel Interface Manager]
PROCESS = Import Contacts and Accounts
[Import Contacts and Accounts]
TYPE = SHELL
INCLUDE = "Import Contacts"
INCLUDE = "Import Accounts"
[Import Contacts]
TYPE = IMPORT
TABLE = EIM_CONTACT
BATCH = 100
[Import Accounts]
TYPE = IMPORT
TABLE = EIM_ACCOUNT
BATCH = 200
```

Example of Updating a Table in a One-to-One Relationship with Its Parent

To update a table that has a one-to-one relationship with its parent table, make sure that the EIM table has only one record matching the user key of the target table.

For example, to update column values in S_ORG_EXT_X using EIM_ACCNT_DTL, there can be only one record in EIM_ACCNT_DTL that matches the user key of the S_ORG_EXT_X table. If more than one record with the same user key is inserted into this EIM table, then EIM might select the wrong record for update, and update IF_ROW_STAT with DUP_RECORD_EXISTS for the rest of the records.

Example of Updating Columns When There Are Two Records with the Same User Key in a Single Batch

EIM does not update columns in the following scenario: you have two records with same user key in the same batch, but with different nonuser keys to be updated.

This cannot be done because there is no way for EIM—which runs set-based operations—to know which record updates which of the non-user keys in one batch. EIM chooses the row with MIN(ROW_ID) and marks the other rows as duplicates.

To perform this kind of update, for which you are updating a record more than twice, you must run two different batches.

Example of Updating Columns When There Are Two Non-Target Base Tables Mapped to One EIM Table

If there are two non-target base tables mapped to one EIM table and one of the non-target base tables has a foreign key pointing to the other one, the data in the same row of the EIM table cannot be inserted into these two tables in one batch or one session. In cases like this, run EIM twice.

The reason is that, in Step 4 in *EIM Import Process*, the non-target parent base table is queried to resolve the foreign key of the non-target child base table, but the new row in the parent table has not been inserted.

Take for example, the EIM_CONTACT mapping. You cannot insert the data in one EIM_CONTACT row into S_PARTY, S_CONTACT, S_ADDR_PER, and S_CON_ADDR simultaneously, because the foreign key of the non-target child base table S_CON_ADDR is pointing to the non-target parent table S_ADDR_PER.

In the first run, a new row will be created in S_PARTY, S_CONTACT, S_ADDR_PER. In the second run, a new row will be inserted in S_CON_ADDR.

Example of Importing Primary Keys

In order to import a primary column, you must populate the following interface columns:

- These interface columns:
 - ROW_ID
 - IF_ROW_BATCH_NUM
 - IF_ROW_STAT
- The interface columns that map to the user key columns of the EIM table's target base table

- The interface columns that map to the user key columns of the primary column's base table
- The primary flag interface column that maps to the primary base column
- The interface columns that map to the primary's intersection table

The intersection row must exist before setting the primary. If you want to import the intersection row and set it as the primary at the same time, you must also populate the interface columns that map to the intersection table's required columns.

For example, If you want to update the S_ORG_EXT.PR_POSTN_ID primary column with the EIM_ACCOUNT interface table, you must populate the following:

- The interface columns:
 - ROW_ID
 - IF_ROW_BATCH_NUM
 - IF_ROW_STAT
- The interface columns that map to the user keys of the S_PARTY table (EIM_ACCOUNT's target base table):
 - PARTY_UID
 - PARTY_TYPE_CD
- The interface columns that map to the user keys of the S_ORG_EXT table:
 - NAME
 - LOC
 - ACCNT_BU
- The primary flag interface column that maps to S_ORG_EXT.PR_POSTN_ID:
 - ACC_PR_POSTN
- The interface columns that map to the S_ACCNT_POSTN table (S_ORG_EXT.PR_POSTN_ID primary's intersection table):
 - NAME
 - LOC
 - ACCNT_BU
 - POSTN_NAME
 - POSTN_DIVN
 - POSTN_LOC
 - POSTN_BU

Note: You can find the S_ORG_EXT.PR_POSTN_ID primary's intersection table using Siebel Tools. In Table, query and select S_ORG_EXT > Column, then query and select PR_POSTN_ID > Primary Inter Table Name property value.

The following are .IFB settings that you can use when running an EIM task that populates an EIM table to update a S_ORG_EXT row's PR_POSTN_ID primary position to reference the S_POSTN row:

[Siebel Interface Manager]

```

USER NAME = "SADMIN"
PASSWORD = "*****"
RUN PROCESS = Update S_ORG_EXT.PR_POSTN_ID
[Update S_ORG_EXT.PR_POSTN_ID]
TYPE = IMPORT
BATCH = 1
TABLE = EIM_ACCOUNT
ONLY BASE TABLES = S_PARTY, S_ORG_EXT, S_ACCNT_POSTN
INSERT ROWS = S_PARTY, FALSE
UPDATE ROWS = S_PARTY, FALSE
INSERT ROWS = S_ORG_EXT, FALSE
ONLY BASE COLUMNS = S_PARTY.PARTY_UID, \
S_PARTY.PARTY_TYPE_CD, \
S_ORG_EXT.NAME, \
S_ORG_EXT.LOC, \
S_ORG_EXT.BU_ID, \
S_ORG_EXT.PR_POSTN_ID, \
S_ACCNT_POSTN.OU_EXT_ID, \
S_ACCNT_POSTN.POSITION_ID

```

There are some cases that require you to include the MISC SQL parameter to set the primaries. For more information, see [MISC SQL Parameter](#).

Example of Setting a Primary

As one example of setting a primary, you can populate the PR_PROD_LN_ID column in the S_PROD_INT base table by completing the following procedure:

To populate the PR_PROD_LN_ID column in the S_PROD_INT base table

1. Populate the S_PROD_INT base table using the EIM_PROD_INT interface table.
2. Populate the S_PROD_LN base table using the EIM_PROD_LN interface table.
3. Populate S_PROD_LN_PROD using EIM_PROD_INT1 and specifying the primary product lines by setting PROD_PR_PROD_LN to Y.

Visibility of Fields: Example of Importing Party Objects

Loading of party objects affects visibility of fields. You should be aware that, in most cases, an organization table should be populated along with the party object table.

For example, when a user clicks the Account field to open the MVG applet in the Contact form applet, the Account field disappears and returns to a null value after the EIM process is run.

This is because there is an association between Contacts and Accounts that is stored in the intersection table S_PARTY_PER. So to establish this relationship, you should fill in the columns for only the S_PARTY, S_CONTACT, and S_PARTY_PER table.

Visibility of Fields: Example of Importing Accounts

To view all accounts, the data must be inserted into the S_PARTY, S_ACCNT_POSTN, S_ORG_EXT, and S_ORG_BU tables, as well as other relevant tables. S_ORG_BU must be populated for visibility in the All Accounts view.

To insert the data into the required tables, you can use the EIM_ACCOUNT interface table. Make sure the values in the OU_NUM and MASTER_OU_ID columns of the S_ORG_EXT base table are populated.

The EIM_ACCOUNT and EIM_ORG_BU interface tables are mapped to S_ORG_BU. You can use EIM_ACCOUNT and EIM_ORG_BU to populate S_ORG_BU.

MASTER_OU_ID in S_ORG_EXT must be populated for visibility in any of the Accounts views. If S_ORG_EXT.MASTER_OU_ID is not populated, the imported accounts will be visible only in the Accounts/Orgs view in the Data Administration screen. The imported accounts will not be visible in the Accounts view in the Data Administration screen, or any other view including My Accounts, All Accounts, and All Accounts Across Organizations.

Note: When loading account addresses, make sure to set an explicit primary. The default setting is implicit, which means that primaries are not set until a record is retrieved in the application. This can cause queries, such as on the State field, to return incomplete or inconsistent data. For more information, see [About Explicit Primary Mappings](#).

The sample .IFB file that follows can be used for importing accounts. The account visibility depends on S_ORG_BU to resolve the organization and S_ACCT_POSTN for the position.

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = Import Account
[Import Account]
TYPE = IMPORT
BATCH = 555
TABLE = EIM_ACCOUNT
ONLY BASE TABLES = S_PARTY, S_ACCNT_POSTN, S_ORG_EXT, S_ORG_BU
DEFAULT COLUMN = ACCNT_FLG, "Y"
DEFAULT COLUMN = ACTIVE_FLG, "Y"
DEFAULT COLUMN = BUYING_GROUP_FLG, "N"
DEFAULT COLUMN = CG_DEDN_AUTH_FLG, "Y"
DEFAULT COLUMN = CG_SVP_A_LOCK_FLG, "N"
DEFAULT COLUMN = CG_SVP_LOCK_FLG, "N"
DEFAULT COLUMN = CG_SVP_SKIP_FLG, "N"
DEFAULT COLUMN = CL_SITE_FLG, "N"
DEFAULT COLUMN = DISA_CLEANSE_FLG, "N"
DEFAULT COLUMN = EVT_LOC_FLG, "N"
DEFAULT COLUMN = FCST_ORG_FLG, "N"
DEFAULT COLUMN = FUND_ELIG_FLG, "N"
DEFAULT COLUMN = INCL_FLG, "N"
DEFAULT COLUMN = INT_ORG_FLG, "N"
DEFAULT COLUMN = PLAN_GROUP_FLG, "N"
DEFAULT COLUMN = PROSPECT_FLG, "N"
DEFAULT COLUMN = PRTRN_FLG, "N"
DEFAULT COLUMN = PRTRN_PUBLISH_FLG, "N"
DEFAULT COLUMN = RPLCD_WTH_CMPT_FLG, "N"
DEFAULT COLUMN = SKIP_PO_CRDCHK_FLG, "N"
```

Visibility of Fields: Example of Importing Contacts

This example provides a sample .IFB file for importing contacts. The contact visibility depends on S_CONTACT_BU to resolve the organization and S_POSTN_CON for the position.

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = Import Contact
[Import Contact]
```

```

TYPE = SHELL
INCLUDE = "Import Contact Informationen"
INCLUDE = "Import POSTN_CON Informationen"
[Import Contact Informationen]
TYPE = IMPORT
TABLE= EIM_CONTACT
BATCH = 555
ONLY BASE TABLES = S_PARTY, S_CONTACT, S_CONTACT_BU
DEFAULT COLUMN = CON_ACTIVE_FLG, "Y"
DEFAULT COLUMN = CON_DISACLEANSEFLG, "N"

DEFAULT COLUMN = CON_PTSHPKKEYCONFLG, "N"
DEFAULT COLUMN = CON_SENDSURVEY_FLG, "N"
DEFAULT COLUMN = CON_SPEAKER_FLG, "N"
DEFAULT COLUMN = CON_SUPPRESSEMAILF, "N"
DEFAULT COLUMN = CON_SUPPRESSFAXFLG, "N"
[Import POSTN_CON Informationen]
TYPE = IMPORT
TABLE= EIM_CONTACT1
BATCH = 555
ONLY BASE TABLES = S_PARTY, S_CONTACT, S_POSTN_CON

```

Visibility of Fields: Example of Importing Employees

This example provides a sample .JFB file for importing employees. The employee visibility depends on S_CONTACT_BU to resolve the organization, S_POSTN_CON for the position, S_PER_RESP for responsibility, and S_PARTY_PER for the relationship between the S_PARTY and S_CONTACT.

```

[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = Import New Employee
[IMPORT New Employee]
TYPE = SHELL
INCLUDE = "Import Employee"
INCLUDE = "Import Contact"
INCLUDE = "Import Contact1"
[Import Employee]
TYPE = IMPORT
BATCH = 666
TABLE = EIM_EMPLOYEE
ONLY BASE TABLES = S_PARTY, S_CONTACT, S_EMP_PER, S_PARTY_PER, S_PER_RESP, S_USER
; For S-contact
DEFAULT COLUMN = CON_ACTIVE_FLG, "Y"
DEFAULT COLUMN = CON_DISACLEANSEFLG, "N"
DEFAULT COLUMN = CON_EMAILSRUPD_FLG, "N"
DEFAULT COLUMN = CON_DISPIMGAUTHFLG, "N"

ASSET_ID,  
BU_ID
```

Example of Troubleshooting the Import of Extension Columns

Use the guidelines that follow to troubleshoot an import failure that occurs when extension columns are added to some Siebel tables and the EIM import task failed to populate data to these columns.

To troubleshoot the import of extension columns

1. Delete the diccache.dat file from the <siebel server>\bin directory and test the EIM task again.

EIM will rebuild this file from the information in the repository if the file does not exist.

2. Run the DBCHK utility to make sure the EIM table in the repository is in synch with the EIM table in the database. For example, use the following command:

```
dbchk /u SADMIN /p <*****> /t <table owner> /r "Siebel Repository"  
/l dbchk.log /d /s <ODBC data source> <interface table name>
```

For information on running the DBCHK utility, see [Checking the Repository](#).

- a. If the repository is not in synch with the database, log in to Siebel Tools, and in the Table object, select the EIM table records.
 - b. Click the Apply and Activate buttons to apply and activate all changes on the EIM table to the database.
 - c. Run the DBCHK utility again.
3. Follow the instructions to set event logging in [Viewing the EIM Log File](#) and run the EIM task.

This generates a detailed EIM log file. Review the log file to see whether there are any errors causing the import failure.

4. If the extension column is:
 - o A foreign key or primary column, its mapping should only be created through the EIM Table Mapping Wizard, or by Oracle's Application Expert Services.
 - o A foreign key column, its foreign key mapping can be created by running the EIM Table Mapping Wizard on the base table of the extension column.
 - o A primary column for a M:M relationship (that is, an EIM table is defined in the extension primary column's Primary Inter Table property), its EIM Explicit Primary Mapping can be created by running the EIM Table Mapping Wizard on the intersection table.
 - o A primary column for a 1:M relationship (that is, no EIM table is defined in the extension primary column's Primary Inter Table property), its EIM Explicit Primary Mapping can be created by running the EIM Table Mapping Wizard on the primary child table (as defined in the extension primary column's Primary Child Table property).

5. Check the mappings for the extension columns.

- a. Log in to Siebel Tools.
- b. Navigate to the EIM Interface Table object and query to select the interface table EIM Table Mapping.

If the extension column is:

- Not a foreign key or primary column, it should only have an Attribute Mapping under its base table's EIM Table Mapping.
- A foreign key column, it should not have any Attribute Mapping defined. It should have a Foreign Key Mapping.
- A primary column, it should not have any Attribute Mapping or Foreign Key Mapping defined.

If the extension primary column is:

- For a M:M relationship, it should have an EIM Explicit Primary Mapping under its intersection table's EIM Table Mapping.
- For a 1:M relationship, it should have an EIM Explicit Primary Mapping under its primary child table's EIM Table Mapping.

Checking the Repository

Step 2 in *Example of Troubleshooting the Import of Extension Columns* asks you to run the DBCHCK utility to make sure the EIM table in the repository is in synch with the EIM table in the database.

Both the DBCHCK and DICTUTL utilities are run from the DOS prompt in the `siebsrvr\bin\` directory. DBCHCK verifies that the physical schema is in synch with the repository. DICTUTL verifies that all dock objects and rule definitions are correct.

To check the repository using DBCHCK and DICTUTL

1. Run the `siebenv.bat` file to make sure that the Siebel application environment variables are set correctly.

Note: There should be no quotes around the parameters in `siebenv.bat`.

2. Make sure there are no quotes around the value to which SIEBEL_REPOSITORY is set.

If this value is set incorrectly, you will encounter error messages.

3. Run the DBCHCK utility to verify that the physical schema is in synch with the repository. A typical command to run DBCHCK and generate a log file is the following:

```
Prompt>dbchck /S <ODBC_DATASOURCE> /U <USERNAME> /P <PASSWORD> /T <TABLE_OWNER>
/R <REPOSITORY> /L <LOGFILE> /D <CHECK_AGAINST_DICTIONARY> /A <ALL_TABLES>
```

- a. Use the `/A` option to specify whether you are running the DBCHCK against all tables; use a Boolean 'Y' (no quotation marks) to specify that you are.
- b. To view all of the options for DBCHCK, run DBCHCK at the DOS prompt without any options.

This provides all the options that can be used in conjunction with DBCHCK. The following are some of the common options used in conjunction with DBCHCK:

Option	Description
/S	Specifies the ODBC source to use for the database.

Option	Description
/U	Specifies the username to log in to the database.
/P	Specifies the user password to log in to the database.
/T	Specifies the username of the table owner.
/R	Specifies the repository name for the dictionary.
/L	Specifies the log file name for errors.
/D	Checks tables against the dictionary only.
/A	Checks all Siebel tables in the database.

- c. Check the <LOGFILE> for unacceptable errors.

Unacceptable errors may occur if data types are mismatched. Acceptable errors may occur if a schema object (such as a table or an index) is intentionally external to the repository.

4. Run DICTUTL to verify that all dock objects and rule definitions are correct. A typical command to run DICTUTL and generate a log file is the following:

```
Prompt>dictutl /C <ODBC_DATASOURCE> /U <USERNAME> /P <PASSWORD> /D <TABLEOWNER>
/N <REPOSITORY_NAME> /A <IGNORE_DICTIONARY_CACHE> y > LOGFILE.log
```

Further command options are explained as follows:

Option	Description
/A	Y means ignore the dictionary cache.
> LOGFILE.log	LOGFILE is the log file that you designate for DICTUTL.

5. Review the LOGFILE.log file to check for errors.

Example of Troubleshooting the Unique Constraint Error when Importing Accounts or Contacts

This example provides further detail to complement *Troubleshooting the Unique Constraint Error When Importing Accounts or Contacts*.

The unique constraint error when inserting records using EIM is usually due to inconsistent data in the base tables or incorrect data populated in the interface tables. The inconsistent data may result when two different server tasks, such as Siebel EAI processes and EIM processes, are run at the same time to import the same data.

For example, you populate the EIM_ACCOUNT table with a new record to be added to the S_PARTY table. Uniqueness for the S_PARTY table is based on the S_PARTY_U1 index. However, the associated record in the S_ORG_EXT table that EIM will create may be found to be a duplicate of an existing record in the S_ORG_EXT table, because uniqueness for the S_ORG_EXT table is based on the S_ORG_EXT_U1 index. This duplicate record may have been created by another process, such as an EAI process or a process initiated through the user interface.

Because the S_ORG_EXT table is considered a 1:1 extension table of the S_PARTY table, EIM only checks if there is an existing S_ORG_EXT record that references the S_PARTY row in the PAR_ROW_ID column. In this case, no record is returned since the S_PARTY record is a new one. As a result, the S_ORG_EXT_U1 index is violated when EIM tries to insert the record into the S_ORG_EXT table. This incomplete EIM job then creates new S_PARTY rows without the associated S_ORG_EXT rows.

The PARTY_UID column is part of the user key for the S_PARTY table and is used by the EIM process to identify if an account or contact record is a new record or an existing record.

The S_PARTY.PARTY_UID is a user-definable key and can have any of the following values:

- If contact or account data is being migrated from a system external to Siebel, then the PARTY_UID column can be any user-defined key value or contact or account key in the external system.
- If the contact record is created using the Siebel Web Client, then S_PARTY.PARTY_UID is set to the value in S_PARTY.ROW_ID by default.
- If the account record is created using the Siebel Web Client, then S_PARTY.PARTY_UID is set to the same value in S_PARTY.ROW_ID by default.

The remainder of this topic is divided into two parts which detail diagnostics steps for each of the following two scenarios:

- **Contact data import.** See *Example of Troubleshooting the Import of EIM Contact Data into the S_CONTACT Table*.
- **Account data import.** See *Example of Troubleshooting the Import of EIM Account Data into the S_ORG_EXT Table*.

Example of Troubleshooting the Import of EIM Contact Data into the S_CONTACT Table

Use the guidelines that follow to check data consistency in the Siebel tables for contact record import.

To diagnose the unique constraint error for an import of contact data

1. For all contact records, verify that the value in S_PARTY.ROW_ID is set to the same value in S_CONTACT.ROW_ID and S_CONTACT.PAR_ROW_ID. If a record exists in S_PARTY, then a matching record should also exist in S_CONTACT. Run the following two SQL queries to validate the data in these tables:

a. Query against S_CONTACT:

```
SELECT ROW_ID FROM S_CONTACT WHERE PAR_ROW_ID <> ROW_ID
```

This statement should return zero rows.

b. Query against S_PARTY:

```
SELECT PARTY_UID, NAME FROM
S_PARTY P1
WHERE PARTY_TYPE_CD = 'Person' AND
NOT EXISTS
(SELECT * FROM S_CONTACT O1
WHERE O1.PAR_ROW_ID = P1.ROW_ID)
```

This statement should return zero rows.

2. For all contact records, make sure that the corresponding S_PARTY.PARTY_TYPE_CD is set to 'Person'. Use the following SQL statement to validate that this is set correctly:

```
SELECT ROW_ID FROM S_PARTY T1
WHERE EXISTS (SELECT * FROM S_CONTACT T2 WHERE T1.ROW_ID = T2.PAR_ROW_ID)
AND T1.PARTY_TYPE_CD <> 'Person'
```

This statement should return zero rows.

3. Populate the exact PARTY_UID value in the EIM_CONTACT table as is in the base table. For example, if a record is created through the Siebel Client UI, then make sure that the value in S_PARTY.PARTY_UID is the same as the value in S_PARTY.ROW_ID. For these records, populate S_PARTY.ROW_ID into EIM_CONTACT.PARTY_UID.

The following SQL query checks for any mismatch in the PARTY_UID values between the EIM_CONTACT and S_PARTY tables:

```
SELECT PARTY_UID FROM EIM_CONTACT T1 WHERE T1.PARTY_TYPE_CD = 'Person' AND
NOT EXISTS (SELECT * FROM S_PARTY T2 WHERE T1.PARTY_UID = T2.PARTY_UID)
```

This statement should return zero rows.

4. Values in the EIM_CONTACT.PARTY_UID column should be unique in an EIM batch. Use the following SQL statement to verify that there are no duplicate values in this column:

```
SELECT PARTY_UID, COUNT(*) FROM EIM_CONTACT
WHERE IF_ROW_BATCH_NUM = <eim batch#>
GROUP BY PARTY_UID
HAVING COUNT(*) > 1
```

This statement should return zero rows. If any rows are returned, duplicate values in the PARTY_UID column exist within the same batch. The duplicate rows should be removed from this batch.

Solution

If an EIM batch has records created in an external system, but records created through the Siebel Client UI also exist, make sure that the correct PARTY_UID values are populated in the EIM_CONTACT table. For example, for externally generated contacts, EIM_CONTACT.PARTY_UID will have a user-defined value from the external system. For contact records that were created using the Siebel Client UI, make sure that the value in EIM_CONTACT.PARTY_UID is set to the value in S_PARTY.ROW_ID.

If externally generated PARTY_UID values are incorrectly populated into contact records created through the Siebel Client UI, where the value in S_PARTY.PARTY_UID equals the value in S_PARTY.ROW_ID, EIM treats these records as new and tries to insert these records into the S_CONTACT table. Because the PARTY_UID value already exists in S_CONTACT, the EIM process fails with the unique constraint violation error for the S_CONTACT table.

If an EIM batch contains both contact records with user-defined PARTY_UID values and records created through the Siebel Client UI, the following solutions can be used to make sure this error does not occur:

- **Option 1.** Configure your Siebel application so that for records generated through the Siebel Client UI, S_PARTY.PARTY_UID matches the format used when loading data into the EIM_CONTACT table.
- **Option 2.** If you have user-defined PARTY_UID values in the S_PARTY table, then before running the EIM process, run the SQL statements that follow to identify any records that exist where an EIM_CONTACT.PARTY_UID value does not match an existing S_PARTY.PARTY_UID value. If records like this exist, then update the EIM_CONTACT table with the correct PARTY_UID value that matches a value in S_PARTY.PARTY_UID.

The following SQL statement can be used to identify such records in EIM table:

```
SELECT PARTY_UID FROM EIM_CONTACT T1 WHERE T1.PARTY_TYPE_CD = 'Person' AND
NOT EXISTS (SELECT * FROM S_PARTY T2 WHERE T1.PARTY_UID = T2.PARTY_UID)
```

If this query does not return any records, then run the following query to find duplicate records:

```
SELECT CON_PERSON_UID FROM EIM_CONTACT T1 WHERE T1.PARTY_TYPE_CD = 'Person' AND
NOT EXISTS (SELECT * FROM S_CONTACT T2 WHERE T1.CON_PERSON_UID = T2.PERSON_UID)
```

Populate the correct values for PARTY_UID in the EIM_CONTACT table matching the base table S_PARTY.PARTY_UID for such records.

Example of Troubleshooting the Import of EIM Account Data into the S_ORG_EXT Table

The examples shown in this topic use the EIM_ACCOUNT interface table. You can replace EIM_ACCOUNT with the appropriate EIM table for importing contact data as needed.

Use the guidelines that follow to check data consistency in the Siebel tables for account record import.

To diagnose the unique constraint error for an import of account data

1. For all account records, verify that the value S_PARTY.ROW_ID is set to the same value in S_ORG_EXT.ROW_ID and S_ORG_EXT.PAR_ROW_ID. If a record exists in S_PARTY, then a corresponding record should also exist in S_ORG_EXT. Run the two SQL queries that follow to validate the data in these tables.

- a. Query against S_ORG_EXT:

```
SELECT ROW_ID FROM S_ORG_EXT WHERE PAR_ROW_ID <> ROW_ID
```

This statement should return zero rows.

- b. Query against S_PARTY:

```
SELECT PARTY_UID, NAME FROM
S_PARTY P1
WHERE PARTY_TYPE_CD = 'Organization' AND
NOT EXISTS
```

```
(SELECT * FROM S_ORG_EXT O1
WHERE O1.PAR_ROW_ID = P1.ROW_ID)
```

This statement should return zero rows.

2. For all account records, make sure that the corresponding S_PARTY.PARTY_TYPE_CD is set to 'Organization'. Use the following SQL statement to validate that this is set correctly:

```
SELECT ROW_ID FROM S_PARTY T1
WHERE EXISTS (SELECT * FROM S_ORG_EXT T2 WHERE T1.ROW_ID = T2.PAR_ROW_ID)
AND T1.PARTY_TYPE_CD <> 'Organization'
```

This statement should return zero rows.

3. Populate the exact PARTY_UID value in the EIM_ACCOUNT table as is in the base table. For example, if a record is created in the Siebel Client UI, make sure that the value in S_PARTY.PARTY_UID is the same as the value in S_PARTY.ROW_ID. For these records, populate S_PARTY.ROW_ID into EIM_ACCOUNT.PARTY_UID.

The following SQL statement checks for any mismatch in the PARTY_UID values between the EIM_ACCOUNT and S_ORG_EXT tables:

```
SELECT PARTY_UID FROM EIM_ACCOUNT T1 WHERE T1.PARTY_TYPE_CD = 'Organization' AND
NOT EXISTS (SELECT * FROM S_PARTY T2 WHERE T1.PARTY_UID = T2.PARTY_UID)
```

This statement should return zero rows.

4. Values in the EIM_ACCOUNT.PARTY_UID column should be unique in an EIM batch. Use the following SQL statement to verify that there are no duplicate values in this column:

```
SELECT PARTY_UID, COUNT(*) FROM EIM_ACCOUNT
WHERE IF_ROW_BATCH_NUM = <EIM Batch Number>
GROUP BY PARTY_UID
HAVING COUNT(*) > 1
```

This statement should return zero rows. If any rows are returned, duplicate values in the PARTY_UID column exist within the same batch. The duplicate rows should be removed from this batch.

Solution

If an EIM batch has records created in both the external system and through the Siebel Client UI, make sure that the correct PARTY_UID values are populated in the EIM_ACCOUNT table. For example, for externally generated accounts, EIM_ACCOUNT.PARTY_UID column will have a user-defined value, but for account records created using the Siebel Client UI, the value in EIM_ACCOUNT.PARTY_UID is set to the value in S_PARTY.ROW_ID for the Account.

If externally generated PARTY_UID values are incorrectly populated for account records created using the Siebel Client UI, where the value in S_PARTY.PARTY_UID equals the value in S_PARTY.ROW_ID, EIM treats these records as new records and tries to insert these records into the S_ORG_EXT table. Because the PARTY_UID value already exists in S_ORG_EXT, the EIM process fails with the unique constraint violation error for the S_ORG_EXT table.

If an EIM batch contains both account records with user-defined PARTY_UID and records created through the Siebel Client UI, the two solutions that follow can be used to make sure this error does not occur.

- **Option 1.** Configure your Siebel application so that for records generated through the Siebel Client UI, S_PART.PARTY_UID matches the format you use when loading data into the EIM_ACCOUNT table.
- **Option 2.** If you have user-defined PARTY_UID values in the S_PARTY table, then before running the EIM process, run the following SQL statements to identify any records that exist where an EIM_ACCOUNT.PARTY_UID value does not match with an existing S_PARTY.PARTY_UID value. If records like

this exist, then update the EIM_ACCOUNT table with the correct PARTY_UID value that matches a value in S_PARTY.PARTY_UID.

The following SQL statement can be used to identify such records in the EIM table:

```
SELECT PARTY_UID FROM EIM_ACCOUNT T1 WHERE T1.PARTY_TYPE_CD = 'Organization' AND
NOT EXISTS (SELECT * FROM S_PARTY T2 WHERE T1.PARTY_UID = T2.PARTY_UID)
```

To correct the data, populate the appropriate values for PARTY_UID in the EIM_ACCOUNT table matching the base table S_PARTY.PARTY_UID for such records.

Example of Importing and Exporting Hierarchical LOVs

You can migrate a hierarchical list of values from one Siebel CRM environment to another, as shown in this example.

To migrate a hierarchical list of values

1. Run an EIM export task using the following .IFB settings:

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = Export LOV
[Export LOV]
TYPE = SHELL
INCLUDE = "Export LOV_TYPE"
INCLUDE = "Export LOV_REPLICATION_LEVEL"
INCLUDE = "Export LOVs_Parent"
INCLUDE = "Export LOVs_Child"
USE INDEX HINTS = TRUE
[Export LOV_TYPE]
TYPE = EXPORT
BATCH = 1
TABLE = EIM_LST_OF_VAL
EXPORT MATCHES = (TYPE = 'LOV_TYPE' and \
VAL <> 'LOV_TYPE' and \
VAL <> 'REPLICATION_LEVEL')
USE INDEX HINTS = TRUE
[Export LOV_REPLICATION_LEVEL]
TYPE = EXPORT
BATCH = 2
TABLE = EIM_LST_OF_VAL
EXPORT MATCHES = (TYPE = 'REPLICATION_LEVEL' and \
VAL <> 'All')
USE INDEX HINTS = TRUE
[Export LOVs_Parent]
TYPE = EXPORT
BATCH = 3
TABLE = EIM_LST_OF_VAL
EXPORT MATCHES = (TYPE <> 'LOV_TYPE' and \
PAR_ROW_ID IS NULL and \
ROW_ID NOT IN ('0-1EOTJ', '0-1EOTR', \
'0-1EOTT', '0-1EOTX', '0-1EOTZ', \
'0-1EOUB', '0-1EOUF', '0-1EOUH', \
'0-1EOUJ', '0-1EOUL', '0-1EOUN', \
'0-1EOUR', '0-2SRAZ', '0-3EM3U', \
'0-3EM3Y', '0-3EM42', '0-3G4D0', \
'0-3G4D2', '0-3GBNN', '0-3GFJQ', \
'0-3GFJV', '0-3K8OB', '0-3LEF9', \
```

```
'0-3LG6Z', '0-3RL6J', '0-3YWL5', \
'0-3YWLD', '0-40X27', '0-6ECJG', \
'04-AZLJB', '04-AZLJD', '04-AZLJF', \
'04-AZLJH', '04-BFOLX', '04-BFOLZ', \
'04-BFOM1', '04-BFOM3', '04-BFOM7', \
'04-BFOM9', '04-BFOMO', '04-BKLND', \
'04-BKLNN', '04-CYI2Z', '04-CYI32', \
'04-CYI34'))
USE INDEX HINTS = TRUE
[Export LOVs_Child]
TYPE = EXPORT
BATCH = 4
TABLE = EIM_LST_OF_VAL
EXPORT MATCHES = (TYPE <> 'LOV_TYPE' and \
PAR_ROW_ID IS NOT NULL and \
ROW_ID NOT IN ('0-6DCE7', '04-AQ79M', \
'04-AQ79O', '04-AQ79Q'))
USE INDEX HINTS = TRUE
```

2. Run the SQL statement that follows to populate the EIM_LST_OF_VAL.PAR_BI and other EIM_LST_OF_VAL.*_BU interface columns.

Note: This SQL statement can be found in < siebel server root >\Admin\eim_export_lookup_bu_name.sql. Locate the SQL for EIM_LST_OF_VAL.

```
update EIM_LST_OF_VAL IT
set IT.BITMAP_LIT_BU = (select min(OI.NAME) from S_BU OI where OI.ROW_ID =
IT.BITMAP_LIT_BI)
, IT.LOV_BU = (select min(OI.NAME) from S_BU OI where OI.ROW_ID = IT.LOV_BI)
, IT.LOV_VIS_BU = (select min(OI.NAME) from S_BU OI where OI.ROW_ID =
IT.LOV_VIS_BI)
, IT.PAR_BU = (select min(OI.NAME) from S_BU OI where OI.ROW_ID = IT.PAR_BI);
```

3. Make sure the target environment's EIM_LST_OF_VAL interface table is empty, then move the exported data from the source environment's EIM_LST_OF_VAL interface table to the target environment's EIM_LST_OF_VAL interface table.
4. At the target environment, verify the existence of the three list of values records that follow before proceeding to Step 5.

Type	Display Value	Replication Level
LOV_TYPE	LOV_TYPE	All
LOV_TYPE	REPLICATION_LEVEL	All
REPLICATION_LEVEL	All	All

- a. If these records do not exist, then create them in the Siebel client by going to the Administration - Application screen, then the LOV Explorer view.

5. Run the following SQL at the target environment's database:

```
UPDATE EIM_LST_OF_VAL A
SET A.IF_ROW_BATCH_NUM = 5
WHERE NOT EXISTS (SELECT 'x'
FROM EIM_LST_OF_VAL B
WHERE B.LOV_TYPE = A.PAR_TYPE
```

```
AND B.LOV_VAL = A.PAR_VAL
AND B.LOV_LANG_ID = A.PAR_LANG_ID
AND (B.LOV_SUB_TYPE = A.PAR_SUB_TYPE
OR (B.LOV_SUB_TYPE IS NULL
AND A.PAR_SUB_TYPE IS NULL))
AND B.LOV_BU = A.PAR_BU
AND B.IF_ROW_BATCH_NUM <= 3)
AND A.IF_ROW_BATCH_NUM = 4;
```

6. If the SQL listed in Step 5 has updated zero records, proceed to Step 7. Otherwise, run the following SQL at the target environment's database and repeat Step 6 until the SQL has updated zero records:

```
UPDATE EIM_LST_OF_VAL A
SET A.IF_ROW_BATCH_NUM = <see Note A row in the following table>
WHERE NOT EXISTS (SELECT 'x'
FROM EIM_LST_OF_VAL B
WHERE B.LOV_TYPE = A.PAR_TYPE
AND B.LOV_VAL = A.PAR_VAL
AND B.LOV_LANG_ID = A.PAR_LANG_ID
AND (B.LOV_SUB_TYPE = A.PAR_SUB_TYPE
OR (B.LOV_SUB_TYPE IS NULL
AND A.PAR_SUB_TYPE IS NULL))
AND B.LOV_BU = A.PAR_BU
AND B.IF_ROW_BATCH_NUM = <see Note B row in the following table>
AND A.IF_ROW_BATCH_NUM = <see Note C row in the following table>);
```

Note	Value
A	Next new batch number; that is, 6 for the first time you run, 7 for the second time you run, and so on.
B	Last batch number; that is, 4 for the first time you run, 5 for the second time you run, and so on.
C	Last batch number; that is, 5 for the first time you run, 6 for the second time you run, and so on.

7. Run the following SQL at the target environment's database:

```
UPDATE EIM_LST_OF_VAL
SET IF_ROW_BATCH_NUM = <next new batch number>
WHERE LOV_VIS_BU IS NOT NULL;
```

8. Run an EIM import task at the target environment using the following parameters:

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = Import LOV
[Import LOV]
TYPE = IMPORT
BATCH = 1-<last batch number as specified in step 7>
TABLE = EIM_LST_OF_VAL
USE INDEX HINTS = TRUE
```

9. Migrate the S_LOV_REL rows using the EIM_LOV_REL interface table.

EIM Merge Process Example

This section provides an example you might find useful when merging custom columns.

Example of Running a Merge with Custom Columns

In this example, you run a merge that includes two account records with the same location (LOC), and a string of information in the old record that must be copied into the new record. The two records have different values for Name because the account had a name change. The information contained in the records that result from the merge is as follows:

Record	LOC	Name	X_CUSTOM_COLUMN
Old record	1	A	top-tier account
Remaining	1	B	None

When these two accounts are merged, the information in the old record's custom column is lost and the custom column in the remaining record appears blank.

Note: EIM behavior, whether executed from the GUI or through an EIM run, does not merge data in the base record. It simply repoints the foreign keys in the dependent child records. This applies to all columns in the base table. This could lead to unintended data loss in an extension column.

EIM Delete Process Examples

This section provides usage examples that can be applied to your running of delete processes.

Example: Using DELETE MATCHES to Delete Data from S_PARTY Extension Tables

If the EIM table's target table is S_PARTY:

The syntax is as follows:

```
DELETE MATCHES = S_PARTY, [...criteria...]  
DELETE MATCHES = [non-target base tables name of Siebel Extension type],  
[...criteria...]
```

In this example, you want to delete an existing account. This account's data is as follows:

```
S_PARTY: PARTY_TYPE_CD='Organization', PARTY_UID='1-28XIF'  
S_ORG_EXT: LOC='San Mateo', NAME='TEST', BU_ID=' 0-R9NH'
```

If you would like to apply criteria against the S_PARTY table, you can use the following session in the .IFB file:

```
[Delete Account]
TYPE = DELETE
BATCH = 100
TABLE = EIM_ACCOUNT
DELETE MATCHES = S_PARTY, (PARTY_UID = '1-28XIF')
```

Or if you would like to apply criteria against the S_ORG_EXT table, you can use the following session in the .IFB file:

```
[Delete Account]
TYPE = DELETE
BATCH = 100
TABLE = EIM_ACCOUNT
DELETE MATCHES = S_ORG_EXT, (NAME = 'TEST')
```

Both methods achieve the same result. But in this example, it is easier to use criteria against S_ORG_EXT, since you know which account you want to delete.

Note: When S_PARTY is the target base table, you cannot use the EIM table name or neglect the target base table name in DELETE MATCHES expressions.

Example: Using DELETE MATCHES to Delete Data from non-S_PARTY Extension Tables

If the EIM table's target table is not S_PARTY:

```
DELETE MATCHES = [EIM table name], [...criteria...]
DELETE MATCHES = [target base table name], [...criteria...]
DELETE MATCHES = [...criteria...]
```

For example, if you want to delete all activities created by employee SADMIN, you go to the S_EVT_ACT table and find all the records with the following:

```
OWNER_LOGIN='SADMIN'
```

You can use the following session in your .IFB file:

```
[Delete Activity]
TYPE = DELETE
BATCH = 100
TABLE = EIM_ACTIVITY
DELETE MATCHES = <Table>, (OWNER_LOGIN = 'SADMIN')
```

<Table> can be replaced by EIM_ACTIVITY or S_EVT_ACT, or it can be remain empty.

Example of Using DELETE EXACT

The DELETE EXACT parameter is used to delete rows in a Siebel base table with user key values specified in the corresponding EIM table. In this case, the corresponding EIM table has to be populated.

In this example, you want to delete an existing account. This account's user key data is as follows:

```
S_PARTY: PARTY_TYPE_CD='Organization', PARTY_UID='1-28XIF'
```

```
S_ORG_EXT: LOC='San Mateo', NAME='TEST', BU_ID=' 0-R9NH'
```

To delete an existing account

1. Choose the EIM_ACCOUNT table and populate this table as follows:

```
EIM_ACCOUNT.LOC ='San Mateo'  
EIM_ACCOUNT.NAME ='TEST'  
EIM_ACCOUNT.ACCNT_BU ='Default Organization' (corresponding to BU_ID=' 0-R9NH')
```

2. Populate the other required columns of the EIM_ACCOUNT table, such as IF_ROW_BATCH_NUM.
3. Run the EIM delete process.

The following is an excerpt from a sample .IFB file:

```
[Delete Account]  
TYPE = DELETE  
BATCH = 300  
TABLE = EIM_ACCOUNT  
ONLY BASE TABLES = S_ORG_EXT  
DELETE EXACT=TRUE
```

To delete an existing account using S_PARTY's user key to populate the EIM_ACCOUNT table

1. Choose the EIM_ACCOUNT table and populate this table as follows:

```
EIM_ACCOUNT : PARTY_TYPE_CD='Organization' and PARTY_UID='1-28XIF'
```

2. Populate the other required columns of the EIM_ACCOUNT table, such as IF_ROW_BATCH_NUM.
3. Run the EIM delete process.

The following is an excerpt from a sample .IFB file:

```
[Delete Account]  
TYPE = DELETE  
BATCH = 300  
TABLE = EIM_ACCOUNT  
ONLY BASE TABLES = S_PARTY  
DELETE EXACT=TRUE
```

The examples shown in the previous tasks achieve the same result.

Note the following about using DELETE EXACT:

- In the .IFB file, you must specify ONLY BASE TABLES, so that only this data will be deleted.
- Only one base table can be specified in the ONLY BASE TABLES parameter. Otherwise, unexpected SQL statements will be generated
- If you want to delete data in two or more tables, you must specify two or more sessions in your .IFB file, since you can only specify one table in each session.

The following are the differences between DELETE EXACT and DELETE MATCHES:

- DELETE MATCHES does not require data population of an EIM table, while DELETE EXACT does. So DELETE MATCHES is easier to use when the deleting criterion is simple.
- DELETE MATCHES does not work well with complicated deleting criterion, because you do not get the chance to check whether you are mistakenly deleting the correct data. With DELETE EXACT, you can always check the data in the EIM table before you start the EIM delete process.

- DELETE MATCHES can only be used when the deleting criterion is against a target base table (or against its extension table if the target base table is S_PARTY), and when only one base table is involved. However, with DELETE EXACT, you can always use EIM or SQL statements to export the user key data from the base table to the EIM table, and then cleanse the data. As long as the corresponding user key columns in the EIM table can be populated, DELETE EXACT can be used to delete the data in the base table.

To find the target base table of an EIM table

1. In Siebel Tools, navigate to EIM Interface Table control, and query the EIM table name.
2. Check the Target Table property to find the target base table name.

Example of Deleting Specific Positions from Accounts

To delete specific positions from an account, you must populate the interface table EIM_ACCOUNT with an SQL script in addition to making modifications to the .IFB file. This is because DELETE MATCHES does not work for nonbase tables.

You can use the following sample .IFB file:

```
[Siebel Interface Manager]
USER NAME = "SADMIN"
PASSWORD = "*****"
PROCESS = DELETE
[DELETE]
TYPE = SHELL
INCLUDE = "Delete Accounts Main"
[Delete Accounts Main]
TYPE = DELETE
BATCH = 1
TABLE = EIM_ACCOUNT
ONLY BASE TABLES = S_ACCNT_POSTN
DELETE EXACT = TRUE
```

Examples of Resolving Foreign Keys

The examples in this section illustrate ways of dealing with foreign keys that do not resolve to existing values.

Example 1: Resolving the Foreign Key Value

EIM reports the low-severity error that follows when the foreign key value in the base table does not match the value in the EIM table.

Note: This error example is based on the Siebel version 7.7 data model.

```
EIM_SRV_REQ
-----
CAT_CTLG_BI
CAT_CTLG_TYPE_CD
CAT_CTLG_NAME
CAT_CTLG_VER_NUM
CAT_CTLG_CAT_ENDDT
CAT_CTLG_CAT_NAME
```

```
Base table:
S_CTLG_CAT_SR
-----
CTLG_CAT_ID
```

This is a foreign key value in the base table and the values in the interface table did not resolve to existing values. Verify that the IF columns correspond to existing base table rows. This failure caused the rows to be eliminated from further processing for this secondary base table. However, processing of the rows WILL continue for other destination base tables.

To resolve the foreign key value, you must find the user key columns in the foreign key table. Based on multiple columns, user keys are used to uniquely identify rows within tables for EIM processing.

The following information lists the user key attributes and base table columns for the EIM_SRV_REQ interface column discussed in this example.

EIM_SRV_REQ Column	User Key Attribute	Base Table Column
CAT_CTLG_BU	CTLG_ID/BU_ID/NAME	S_BU.NAME
CAT_CTLG_TYPE_CD	CTLG_ID/CTLG_TYPE_CD	S_CTLG.CTLG_TYPE_CD
CAT_CTLG_NAME	CTLG_ID/NAME	S_CTLG.NAME
CAT_CTLG_VER_NUM	CTLG_ID/VERSION_NUM	S_CTLG.VERSION_NUM
CAT_CTLG_CAT_ENDDT	EFF_END_DT	S_CTLG_CAT.EFF_END_DT
CAT_CTLG_CAT_NAME	NAME	S_CTLG_CAT.NAME

The following example task shows how the user key plays a role to identify the base column for corresponding EIM columns for the described scenario.

To resolve the foreign key value

- Identify the foreign key table to which S_CTLG_CAT_SR.CTLG_CAT_ID points.
 - In Siebel Tools, in the Object Explorer list, go to the Table object and query for the S_CTLG_CAT_SR table.
 - Navigate to the Column object and query for the CTLG_CAT_ID column.
 - Verify that the foreign key table value is S_CTLG_CAT.
- Find the user key columns defined in the S_CTLG_CAT table.
 - In Siebel Tools, in the Object Explorer list, go to the Table object and query for the S_CTLG_CAT table.
 - Navigate to the User Key object and select the U1 index (S_CTLG_CAT_U1).
 - Navigate to the User Key Column object and verify that the User Key columns for S_CTLG_CAT are CTLG_ID (FK), EFF_END_DT, and NAME.
- In Siebel Tools, identify the foreign key table to which S_CTLG_CAT.CTLG_ID points: S_CTLG
- Find the user key columns defined in the S_CTLG table: BU_ID (FK), CTLG_TYPE_CD, NAME, and VERSION_NUM
- Identify the foreign key table to which S_CTLG.BU_ID points: S_BU

6. Find the user key columns defined in the S_BU table using Siebel Tools: NAME
7. Based on the previous results, populate the following interface columns as listed in the following table to resolve the S_CTLG_CAT_SR.CTLG_CAT.ID foreign key.

Interface Column Name	Instructions
CAT_CTLG_BU	Populate with S_BU.NAME value from Step 6.
CAT_CTLG_TYPE_CD	Populate with S_CTLG.CTLG_TYPE_CD value from Step 4.
CAT_CTLG_NAME	Populate with S_CTLG.NAME value from Step 4.
CAT_CTLG_VER_NUM	Populate with S_CTLG.VERSION_NUM value from Step 4.
CAT_CTLG_CAT_ENDDT	Populate with S_CTLG_CAT.EFF_END_DT value from Step 2c.
CAT_CTLG_CAT_NAME	Populate with S_CTLG_CAT.NAME value from Step 2.

Example 2: Resolving the Foreign Key for Position Division

The table S_ORG_EXT is used to store the Account records and the internal Division records. The user key of S_ORG_EXT consists of the columns NAME, LOC, and BU_ID. For Division records, BU_ID always references Default Organization.

During an EIM run, in order to identify the foreign key S_POSTN.OU_ID, EIM needs information about the user key columns of S_ORG_EXT. The foreign key S_POSTN.OU_ID points to Division records in S_ORG_EXT. So the division's NAME, LOC, and Default Organization should be used to resolve the OU_ID.

Note: S_POSTN also has a foreign key BU_ID which may or may not reference Default Organization. This BU_ID is not to be confused with the BU_ID in the user key of S_ORG_EXT. Do not use it together with the division's NAME and LOC to resolve S_POSTN.OU_ID; doing this can result in failure if the BU_ID references organizations other than Default Organization.

Example 3: Resolving the Foreign Key Using a Special User Key

A typical example of using a special user key (rather than the normal U1 user key) to resolve foreign keys is the use of the special user key S_ADDR_PER:Communications in the resolution of foreign keys to S_ADDR_PER. This special user key contains only the column ADDR_NAME, in contrast to (ADDR_NAME, PER_ID) in the U1 user key.

The mapping of S_ORDER.BL_ADDR_ID in EIM_ORDER, for example, uses the special user key S_ADDR_PER:Communications instead of the U1 user key. Mappings of all foreign keys to S_ADDR_PER use this special user key instead of the U1 user key.

Other Examples

The following examples in this topic illustrate various ways of working with EIM: setting explicit primary mappings, improving EIM performance, defining foreign key column values, implementing a multi-org hierarchy, adding a position to a party table, and using the EIM_ASSET interface table.

Example of Setting Explicit Primary Mappings

After importing a Contact using EIM_CONTACT, you can use EIM_CONTACT3 to import the Contact's personal email addresses into S_PER_COMM_ADDR. You can explicitly set the primary email address by populating the primary flag column CON_PR_EMAIL_ADDR with Y.

The following table shows an example of setting the primary email address for Contact "CON100" to "John.Smith@hotmail.com."

PARTY_UID	PARTY_TYPE_CD	CON_PERSON_UID	CON_PRIV_FLG	CON_BU	ADDR_COMMEDIUM_CD	ADDR_ADDR	CON_PR_EMAIL_ADDR
CON100	Person	CON100	N	Default Organization	Email	JSmith@yahoo.com	Not applicable
CON100	Person	CON100	N	Default Organization	Email	JSmith@hotmail.com	Y
CON100	Person	CON100	N	Default Organization	Email	JSmith@gmail.com	Not applicable

If an explicit primary mapping is not used or not used properly—such as no address or more than one address flagged as the primary email address—then EIM ignores this explicit primary mapping and sets the primary implicitly.

Example of Setting Explicit Primary Mappings for Many-to-Many Relationships

Example of Setting Explicit Primary Mappings explains how to set an explicit primary for a one-to-many relationship. When setting a primary key for a many-to-many relationship, such as the relationship between Opportunities and Contacts, there is an intersection table to consider.

As an example, you can work with the primary S_OPTY.PR_CON_ID. First you import into S_CONTACT using EIM_CONTACT. Then you use EIM_OPTY to import into S_OPTY and the intersection table S_OPTY_CON, and explicitly set the primary S_OPTY.PR_CON_ID during this process.

The column definitions for one-to-many primaries are different from those of many-to-many primaries. In the case of a one-to-many primary, such as S_CONTACT.PR_EMAIL_ADDR_ID, the foreign key table and the primary child table are both defined as S_PER_COMM_ADDR, and the primary intersection table is empty. In the case of a many-to-many primary, such as S_OPTY.PR_CON_ID, the foreign key table is S_CONTACT, and both the primary child table and the primary intersection table are defined as S_OPTY_CON. The explicit primary mapping for S_OPTY.PR_CON_ID is under the table mapping of its primary child table, that is, S_OPTY_CON. It could be easy to mistake S_CONTACT as the primary child table for S_OPTY.PR_CON_ID and this could lead you to look for an explicit primary mapping. This explicit primary mapping would not be found, however, because S_CONTACT is not mapped in EIM_OPTY.

Example of Creating Mappings for Extension Columns

For an example of how to map extension columns, see the section on the EIM Table Mapping Wizard in *Configuring Siebel Business Applications*.

Example of Improving Performance by Dropping Indexes

Often, especially for initial EIM loads, you can improve EIM performance by determining that there are indexes present which are not being used for a particular EIM process. By pinpointing the unnecessary indexes, and by dropping them for the duration of an EIM run, you can achieve performance improvements. For an example of this, see *Siebel Performance Tuning Guide*.

Foreign Key Column Values: NO MATCH ROW ID versus NULL versus a Valid ROW_ID

There are three possible values that EIM can define for primary columns (foreign key columns) when it processes a batch:

- **NO MATCH ROW ID.** EIM sets the foreign key columns to NO MATCH ROW ID if the primary value cannot be found when EIM processes Step 10 in *EIM Import Process*. EIM does this because the primary key is missing in the linked table. The following are special considerations regarding NO MATCH ROW ID:
 - **S_CONTACT.** The export function will update the BU_ID on the S_CONTACT table to NO MATCH ROW ID when there is no record existing in the S_CONTACT_BU table for a given contact. To avoid this, every contact should have a corresponding record in the S_CONTACT_BU table.
 - **S_PRI_LST_BU.** The S_PRI_LST_BU table must be loaded to avoid having the UI set S_PRI_LST.BU_ID to NO MATCH ROW ID.
- **NULL.** If the foreign key columns allow a NULL value in the parent table, EIM carries the NULL value.
- **A valid ROW_ID.** If a valid ROW_ID is not defined, EIM uses the value in the primary column to determine the ROW_ID.

Example of Using the NUM_IPTABLE_LOAD_CUTOFF Parameter

When the NUM_IPTABLE_LOAD_CUTOFF parameter is enabled, EIM loads all schema mappings if the value is less than the number of EIM tables used in the run process. To enable this parameter, set the value to a positive number that is less than the number of EIM tables used in the run process. For example, if the EIM process is using one EIM table, then the setting should be NUM_IPTABLE_LOAD_CUTOFF = 0.

When this parameter is disabled, EIM loads only mappings for the EIM tables used in the run process. This speeds up the dictionary loading process in EIM. To disable this parameter, set the value to -1.

Note: NUM_IPTABLE_LOAD_CUTOFF is disabled by default.

EIM does not necessarily look at all of the EIM tables in the IFB file. EIM counts only the number of EIM tables being used in the running process.

For example, in the .IFB file that follows, there are three EIM tables: EIM_ACCOUNT, EIM_CONTACT, and EIM_OPTY. But there are only two EIM tables (EIM_ACCOUNT, EIM_CONTACT) for the process to be run (Import Objects). So with a NUM_IPTABLE_LOAD_CUTOFF value of 2, EIM does not load all of the schema mappings. If you want EIM to load all of the schema mappings in this example, set the NUM_IPTABLE_LOAD_CUTOFF value to 1 (or 0).

By setting the parameter to 2 in this example, you are disabling it because the number is equal to, not less than, the number of EIM tables used in the run process.

Sample .IFB file:

```
[Siebel Interface Manager]
PROCESS = Import Objects
[Import Objects]
TYPE = SHELL
INCLUDE = Import Accounts
INCLUDE = Import Contacts
[Import Accounts]
TYPE = IMPORT
BATCH = 100
TABLE = EIM_ACCOUNT
[Import Contacts]
TYPE = IMPORT
BATCH = 100
TABLE = EIM_CONTACT
[Export Opty]
TYPE = Export
BATCH = 100
TABLE = EIM_OPTY
```

Example: Transaction Logging with Row-by-row Processing versus Set-based Processing

Transaction logging is enabled and disabled from within the Remote System Preferences view in the Administration - Siebel Remote screen. The preference is called Enable Transaction Logging. You can also adjust the transaction logging system preference setting by changing the LOG_TRANSACTIONS parameter in the EIM configuration file. For more information, see *Process Section Parameters Generic to All EIM Processes*.

LOG TRANSACTIONS and SET BASED LOGGING Parameters

EIM performs row-by-row (RBR) transaction logging when LOG TRANSACTIONS is set to TRUE and SET BASED LOGGING is set to FALSE in the .IFB file. In row-by-row logging mode, EIM fetches all the data to the client.

Most of the time, SET BASED LOGGING is not explicitly set. When SET BASED LOGGING is not explicitly set, the Enable Transaction Logging system preference in the Administration - Siebel Remote screen is used to determine the processing method.

When Enable Transaction Logging is disabled, all operations (insert, update, and delete) are performed in set-based mode. If you explicitly set LOG TRANSACTIONS = FALSE in the .IFB file, then EIM does not log any transactions into the Master Transaction Log table.

When Enable Transaction Logging is enabled, all inserts and deletes are performed in set-based mode, while updates are performed in RBR mode. When Enable Transaction Logging is checked, EIM logs transactions into either the .DX files or the S_DOCK_TXN_LOG table, depending on the setting for LOG TRANSACTIONS TO FILE in the .IFB file.

When SET BASED LOGGING is explicitly set, EIM uses the value of this parameter to determine the processing mode. When SET BASED LOGGING is TRUE, all operations (insert, update, delete) are performed in set-based mode. When SET BASED LOGGING is FALSE, all operations are performed in RBR mode. For import and delete processes, it is not recommended that the SET BASED LOGGING parameter be set to TRUE because in most cases, there is no reason to set this parameter explicitly. For merge processes, SET BASED LOGGING must be set to FALSE for transaction logging to work properly.

To log every transaction separately, EIM changes its operation mode to RBR.

Logging Locations for LOG TRANSACTIONS and LOG TRANSACTIONS TO FILE

With RBR processing, data is logged according to one of three scenarios:

1. EIM logs transactions into S_DOCK_TXN_LOG table or .DX files if:
 - Remote System Preference Enable Transaction Logging is checked
 - LOG TRANSACTIONS = TRUE in the .IFB file (default)
 - LOG TRANSACTIONS TO FILE = TRUE in the .IFB file (default)

If LOG TRANSACTIONS = TRUE and LOG TRANSACTIONS TO FILE = TRUE (which are the default values), EIM logs a transaction into the .DX files, which are stored in <SiebelFileSystem\eim> folder. EIM creates the "marker" transaction in the S_DOCK_TXN_LOG table.

S_DOCK_TXN_LOG.LOG_DATA1 (or LOG_DATA_2, 3, 4) stores the name and the location of the .DX file as in the following example:

```
N128*d:\15051sia\FS\eim\1-CP-1.dx
```

In this example, 1-CP-1.dx is the name of the .DX file and it is located in the \\15051sia\FS\eim folder.

Once the data is created in the .DX file and the marker transactions have been created in the S_DOCK_TXN_LOG table, Transaction Processor (TxnProc) captures the .DX files from the \eim folder and brings them into the TxnProc folder for Transaction Router (TxnRouter) to process.

2. EIM logs transactions into the S_DOCK_TXN_LOG table, and eventually, TxnProc or TxnMerge creates the .DX file in the <SiebSrvr\Docking\TxnProc> folder if:
 - LOG TRANSACTIONS = TRUE in the .IFB file (default)
 - LOG TRANSACTIONS TO FILE = FALSE in the .IFB file
3. EIM does not log any transactions into the S_DOCK_TXN_LOG table or in the .DX file if:
 - LOG TRANSACTIONS = FALSE in the .IFB file

This is the case regardless of what value is defined for LOG TRANSACTIONS TO FILE.

The LOG TRANSACTIONS parameter is explicitly used to control whether changes made by EIM to the Siebel database should be visible to remote clients (by logging transactions for use by the Docking Manager, which synchronizes the Siebel database with remote clients).

When to Use Row-by-Row Processing

For import and delete processes, you should let EIM determine which mode to use. EIM will use the method with the best performance for the functionality requested. For initial data loading, you can disable transaction logging for improved performance (EIM will use set-based mode for all operations). For ongoing operations with Mobile Web Clients, transaction logging should be enabled (EIM will choose set-based logging for inserts and deletes, and RBR for updates).

For merge processes with transaction logging enabled, you must explicitly set EIM to run in RBR mode in order for transaction logging to work properly.

The following are examples of cases when RBR logging should be used:

- Running an EIM import task using the COMMIT OPERATIONS parameter.

Note: COMMIT OPERATIONS is useful only for RBR logging.

- Running an EIM merge task. To enable transaction logging for an EIM merge process, the EIM merge process runs in ongoing (row-by-row) mode.

Advantages and Disadvantages of Using RBR Logging

Advantages of RBR logging include the following:

- Since EIM inserts all the information (data as well as column info) into the S_DOCK_TXN_LOG table, in cases for which mobile clients bring about synchronization problems, RBR logging is beneficial in making troubleshooting easier.
- The row-by-row mode is required for logging update transactions. If the SET BASED LOGGING parameter is not set, then EIM runs in RBR for update operations when transaction logging is enabled. RBR is also required for merge processes when transaction logging is enabled.

Note: When running merge processes with transaction logging, SET BASED LOGGING = FALSE is required. If EIM performs a merge with set-based logging instead of RBR, transactions are not written to S_DOCK_TXN_LOG even though TRANSACTION LOGGING is set to TRUE. The merge works correctly, but remote clients cannot get the transactions and are out of synch as a result.

A disadvantage of RBR logging is that RBR logging affects performance, especially with large imports and deletes.

Example of Implementing a Multi-Organization Hierarchy

If you use multi-org, this means that a single record is shared across multiple organizations. For overview information on multi-org, see the section on access control in *Siebel Security Guide*.

In this example, you are adding a new organization to convert a single-org to a multi-org. The process of converting a single-org to a multi-org involves adding the additional organization and its related structure, adding positions, and then associating the data to the new organization.

Note: Some data, such as Accounts, has a many-to-many relationship to organizations, while other data, such as Contacts and Service Requests do not.

To convert from single-org to multi-org

1. Add a new organization (New Org) into the Organization table.
2. Assign records to the new organization.
You can assign records through the GUI or using EIM.
For example, assign an Employee record (Emp1). The Employee records are stored in the S_CONTACT table. There is a many-to-many relationship between the employee and the organization, so the intersection table S_CONTACT_BU holds the relationship between the organization and the employee.
You add a new record in the S_CONTACT_BU intersection table to hold the relationship between New Org and Emp1. Now Emp1 is available to both the original organization and New Org.
3. Verify that you can see the record in both organizations.

Example of Adding a Position to a Party Table

This example shows how positions are added to party tables, such as Account, Contact, and Employee. You are adding positions to the Account table.

You can use the EIM_ACCOUNT table to populate S_ACCNT_POSTN, which is an intersection table between Accounts and Position.

In the S_ACCNT_POSTN table, you provide information about the position you are trying to add (POSITION_ID) and the account you are trying to associate with the position (OU_EXT_ID).

In the EIM_ACCOUNT table, you provide information about the account.

To populate the EIM table, you must always include the target base table: in this case, S_PARTY. Since EIM_ACCOUNT is for account information, S_PARTY should also be filled with account information. So you set the S_PARTY.PARTY_TYPE_CD = 'Organization' since Account belongs to the Organization type. (PARTY_TYPE_CD = 'Person' is only used for Contact, User, Employee, or Partner.)

The .IFB file looks like this:

```
[Add Position]
TYPE = IMPORT
BATCH = 2002
TABLE = EIM_ACCOUNT
```

```
ONLY BASE TABLES = S_PARTY, S_ACCNT_POSTN  
INSERT ROWS = S_PARTY, FALSE  
INSERT ROWS = S_ORG_EXT, FALSE  
INSERT ROWS = S_ACCNT_POSTN, TRUE  
UPDATE ROWS = S_ACCNT_POSTN, TRUE
```

Example of Using the EIM_ASSET Interface Table

The following information shows an example of how to populate the EIM_ASSET interface table for an import process in order to properly display product and part number information in the Oracle's Siebel application's Asset Management - Assets View.

Field to Populate	Description
OWNER_ACCNT_BU	The organization of which the account is part.
OWNER_ACCNT_LOC	The account site for the related asset.
OWNER_ACCNT_NAME	The account's actual name.
AST_ASSET_NUM	The product's serial number.
AST_PROD_BU	Can be specified as "Default Organization" if necessary.
AST_PROD_NAME	The product's actual name.
