Chapter 6 Oracle JDBC for Rdb Pool Server

3.3 Oracle JDBC for Rdb Pool Server
3.3.1 Starting a Pool Server
3.3.2 Pool Server Operation

3.4 Oracle JDBC for Rdb Manager Server
3.4.1 Utilizing a Manager Server
3.4.2 Starting a Manager Server
3.4.3 Adding a Remote Manager Server Configuration Entry
3.4.4 Using the Controller to Start Remote Servers
3.4.5 Manager Server Operations

Chapter 4 Server Configuration

4.1 Server Configuration Options
4.2 Multi-Process Server Configuration Options
4.3 Pool Server Configuration Options
4.4 Manager Server Configuration Options

5.4 Using Self-Signed Certificates for Testing

Chapter 6 Oracle JDBC for Rdb Controller

6.1 Running the Controller
6.1.2 Controller Command Line

6.2 Connecting to Servers
6.2.1 Connect Command
6.2.2 Implicit Connection

6.3 Control Password

6.4 Multicast Polling

6.5 Server Matching
6.5.1 type match
6.5.2 name match
6.5.3 port match
6.5.4 stat match
6.5.5 node match
6.5.6 vers match
6.5.7 Handling Servers From Prior Releases

6.6 Server Operations
6.6.1 Closing Servers
6.6.2 Opening Servers
6.6.3 Showing Servers
6.6.4 Starting Servers
6.6.5 Stopping Servers
6.6.6 Watching Servers
6.6.7 Watching Events
6.6.8 Polling Servers
6.6.9 Poll Subcommands
6.6.10 Showing Executors
6.6.11 Showing Server Pool

6.7 Client Operations
6.7.1 Showing Clients
6.7.2 Stopping Clients

6.8 Other Commands
6.8.1 Digest
6.8.2 Obfuscate

Chapter 7 Oracle SQL/Services and Oracle JDBC for Rdb Servers

7.1 JDBC Dispatcher
7.1.1 Creating an Oracle SQL/Services JDBC Dispatcher
7.1.2 Associating an Oracle SQL/Services JDBC Dispatcher to a Server
7.1.3 Legacy Behaviour – Using the PORT_ID
7.1.4 Starting a JDBC Dispatcher
7.1.5 Stopping a JDBC Dispatcher

7.2 Command Procedures used by Oracle SQL/Services
7.2.1 JDBC Dispatcher Setup Procedure

7.3 Using Pool Servers

Chapter 8 Performance

8.1 Performance Features
8.2 FetchSize
8.3 Lockwait and Maxtries
8.3.1 Lockwait precedence

8.4 Inactivity timeouts
8.4.1 Client connection timeout
8.4.2 Server Inactivity Timeout

8.5 SQL Statement Cache
8.5.1 Caching Statement Handles

8.6 Results Cache

Chapter 9 Event Logging and Notification
Preface

Purpose of This Manual

The Oracle JDBC for Rdb User Guide describes concepts, features and usage of the Oracle JDBC for Rdb drivers and servers. This user guide covers Oracle JDBC for Rdb for OpenVMS on both Alpha and Integrity Servers.

Intended Audience

This document is intended for users responsible for:

- System management
- Database administration
- Application programming

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Document Structure

This document consists of the following chapters:

<table>
<thead>
<tr>
<th>Chapter 1</th>
<th>Introduction.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 2</td>
<td>Describes the Oracle JDBC for Rdb drivers.</td>
</tr>
<tr>
<td>Chapter 3</td>
<td>Describes the Oracle JDBC for Rdb servers.</td>
</tr>
<tr>
<td>Chapter 4</td>
<td>Describes details on how to configure Oracle JDBC for Rdb servers.</td>
</tr>
<tr>
<td>Chapter 5</td>
<td>Describes details on how to use SSL with Oracle JDBC for Rdb.</td>
</tr>
<tr>
<td>Chapter 6</td>
<td>Describes how to use the Oracle JDBC for Rdb controller.</td>
</tr>
<tr>
<td>Chapter 7</td>
<td>Describes how to use Oracle JDBC for Rdb with Oracle SQL/Services.</td>
</tr>
<tr>
<td>Chapter 8</td>
<td>Describes performance features that are available.</td>
</tr>
<tr>
<td>Chapter 9</td>
<td>Describes Event Notification and Logging.</td>
</tr>
<tr>
<td>Chapter 10</td>
<td>Describes other features that are available.</td>
</tr>
<tr>
<td>Chapter 11</td>
<td>Describes the JDBC extensions available for use with Oracle Rdb.</td>
</tr>
<tr>
<td>Chapter 12</td>
<td>Shows general examples and data type compatibilities.</td>
</tr>
</tbody>
</table>

Conventions

Oracle JDBC for Rdb is often referred to as JDBC.

Oracle Rdb is often referred to as Rdb.

Hewlett-Packard Company is often referred to as HP.

The following conventions are used in this document:

<table>
<thead>
<tr>
<th>word</th>
<th>A lowercase word in a format example indicates a syntax element that you supply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>{ }</td>
<td>Brackets enclose optional clauses from which you can choose one or none.</td>
</tr>
<tr>
<td>...</td>
<td>A horizontal ellipsis means you can repeat the previous item.</td>
</tr>
<tr>
<td>. .</td>
<td>A vertical ellipsis in an example means that information not directly related to the example has been omitted.</td>
</tr>
</tbody>
</table>

Release Specific Information

Certain features require specific versions of JDBC. These features are highlighted by a banner similar to the following:

Since release 7.3.4.0.0

Note: Only new features or changed behavior seen since (and including) release 7.3.1.0.0 are highlighted.

Conventions in Code Examples

Code examples illustrate SQL or other command-line statements. They are displayed in a monospace (fixed-width) font and separated from normal text as shown in this example:

```
SELECT last_name FROM employees WHERE last_name = 'TOLIVER';
```
Chapter 1

Introduction

Oracle provides the following Oracle JDBC for Rdb drivers:

- Oracle JDBC for Rdb native driver for client-side use with an Oracle Rdb installation
- Oracle JDBC for Rdb thin driver, a 100 percent pure Java driver for client-side use without an Oracle Rdb installation. This is particularly useful with applets.

The Oracle JDBC for Rdb drivers provide the same basic functionality. They both support the following standards and features:

- Minimum JDK 1.5 / JDBC 3.0
- Same syntax and APIs

Starting with Oracle JDBC for Rdb Release 7.3.5.0.0, the installation of JDBC on INTEGRITY system will install varianted version of the native and thin drivers. These JAR files are built to run in conjunction with a minimum JAVA version and provide support for JDBC features as shown in the following table:

<table>
<thead>
<tr>
<th>Driver JAR file</th>
<th>Minimum version of JAVA required</th>
<th>JDBC supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDBNATIVEV5.JAR and RDBTHINV5.JAR</td>
<td>JDK 1.5</td>
<td>JDBC 3.0, as released in JDK 1.4</td>
</tr>
<tr>
<td>RDBNATIVEV6.JAR and RDBTHINV6.JAR</td>
<td>JAVA SE 6</td>
<td>JDBC 4.0 as released in JAVA SE 6</td>
</tr>
<tr>
<td>RDBNATIVEV8.JAR and RDBTHINV8.JAR</td>
<td>JAVA SE 8</td>
<td>JDBC 4.2 as released in JAVA SE 8</td>
</tr>
</tbody>
</table>

In keeping with prior versions, the installation procedure will also install non-versioned variants of the driver JAR files:

- RDBNATIVE.JAR
- RDBTHIN.JAR

These driver are identical to the JDK 1.5 varianted JAR files.

The Oracle JDBC for Rdb drivers implement standard Sun Microsystems java.sql interfaces. It is assumed that the reader of these notes is already familiar with Java and JDBC.

General information on Java may be found at http://www.oracle.com/technetwork/java/index.html

General information on JDBC may be found at http://www.oracle.com/technetwork/java/index-142838.html

Documentation for HP's Java for OpenVMS system may be found at the following web sites:

http://www.compaq.com/java/documentation/index.html - Java 2

In conjunction with the Oracle JDBC for Rdb thin driver, Oracle provides the following Oracle JDBC for Rdb servers:

- Oracle Rdb thin server
- Oracle Rdb multi-process server
- Oracle Rdb Pool server

The Oracle JDBC for Rdb servers carry out remote database access operations on behalf of the Oracle JDBC for Rdb thin driver.

Management of the Oracle JDBC for Rdb servers may be carried out using the Oracle JDBC for Rdb controller, the Oracle Rdb Connectivity Management gui or the Oracle SQL/Services manager.

Contents
Chapter 2
Oracle JDBC for Rdb Drivers

There are two types of Oracle JDBC for Rdb drivers:

- Oracle JDBC for Rdb native driver
- Oracle JDBC for Rdb thin driver

The following sections discuss these two diver types as well how to connect to Oracle Rdb databases and use System Properties when using the drivers:

- Connection Options
- Oracle JDBC for Rdb System Properties

2.1 Oracle JDBC for Rdb Native Driver

The Oracle JDBC for Rdb native driver is a Type II driver intended for use with client-server Java applications.

The native driver, written in a combination of Java and C, converts JDBC invocations to calls to SQLMOD modules, using native methods to call C-entry points.

When you use the native driver, the driver connects directly to the Oracle Rdb database system using SQLMOD. If you are not using Rdb Remote Access then there are no network connections involved. This means that the native driver is potentially the fastest JDBC access method available within the Oracle JDBC for Rdb drivers.

Because the driver uses SQLMOD libraries to carry out Oracle Rdb access, the driver can only be used on a client machine if Oracle Rdb has been setup on that machine and the appropriate Oracle Rdb and SQL shared images are available. In addition, it is necessary for the driver to dynamically load a shared image to use with its Java JNI interface. Thus this driver is not suitable for use with applications that require Java applets.

2.1.1 URL Specification Used with the Oracle JDBC for Rdb Native Driver

When you use the JDBC DriverManager to connect to an Oracle Rdb database using the native driver the following connection URL format should be used:

Format
jdbc:rdbNative:<database_specification><connect_switches>

Elements
The format elements are described in the following table:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;database_specification&gt;</td>
<td>Is the full file specification of the Rdb database that you wish to connect.</td>
</tr>
<tr>
<td>&lt;connect_switches&gt;</td>
<td>These optional switches may be used to specify certain settings that should be established when the database connection is made. See Connection Options for more details.</td>
</tr>
</tbody>
</table>

Remarks
The <database_specification> should be a valid OpenVMS file specification or logical name.

Example
To connect to MY_DB_DIR:PERSONNEL:

```java
Connection conn = DriverManager.getConnection(  
    "jdbc:rdbNative:my_db_dir:personnel", user, pass);
```

2.1.2 Class Used with the Oracle JDBC for Rdb Native Driver

The Rdb native driver can be found in the following class:

```java
oracle.rdb.jdbc.rdbNative.Driver
```

2.1.3 Oracle JDBC for Rdb Native Driver jar files

The Oracle JDBC for Rdb driver classes may be found in the Rdb native driver jar file.

Prior to Oracle JDBC for Rdb release 7.3.5.0.0 only one Rdb native driver jar file was available to use:

```java
rdbNative.jar
```

Starting with release 7.3.5.0.0 you have the choice of three variants of the Rdb native driver jar:
These jars provide JDBC and JAVA version specific variants of the driver classes:

<table>
<thead>
<tr>
<th>Driver JAR file</th>
<th>Minimum version of JAVA required</th>
<th>JDBC supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDBNATIVEV5.JAR</td>
<td>JDK 1.5</td>
<td>JDBC 3.0, as released in JDK 1.4</td>
</tr>
<tr>
<td>RDBNATIVEV6.JAR</td>
<td>JAVA SE 6</td>
<td>JDBC 4.0 as released in JAVA SE 6</td>
</tr>
<tr>
<td>RDBNATIVEV8.JAR</td>
<td>JAVA SE 8</td>
<td>JDBC 4.2 as released in JAVA SE 8</td>
</tr>
</tbody>
</table>

To allow compatibility with prior versions, the file rdbNative.jar is also installed with the JDBC installation. This jar is identical to the rdbNativeV5.jar file.

These jar files are available in the rdb$jdbc_home directory created during JDBC installation. They are also available in the Window MSI installation file provided during Oracle JDBC for Rdb installation.

2.2 Oracle JDBC for Rdb Thin Driver

The Oracle JDBC for Rdb thin driver is a 100 percent pure Java, Type IV driver. Because it is written entirely in Java, this driver is platform-independent. It does not require any additional Oracle software on the client side.

For use with applets, the thin driver can be downloaded into a browser along with the Java applet being run. The HTTP protocol is stateless, but the thin driver is not. The initial HTTP request to download the applet and the thin driver is stateless. Once the thin driver establishes the database connection, the communication between the browser and the database is stateful and in a two-tier configuration.

The thin driver allows a direct connection to any Oracle Rdb database via an Oracle JDBC for Rdb server using TCP/IP on Java sockets.

Note:
When the thin driver is used with an applet, the client browser must have the capability to support Java sockets.

2.2.1 URL Specification Used With the Oracle Rdb Thin Driver

When you use the JDBC DriverManager to connect to an Oracle Rdb database using the thin driver the following connection URL format should be used:

**Format**

```
jdbc:rdbThin://<node>:<port>/<database_specification><connect_options>
```

**Elements**
The format elements are described in the following table:

<table>
<thead>
<tr>
<th>Table 2.2-1 RdbThin Format Elements</th>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&lt;node&gt;</td>
<td>Is the node name or IP address of the node that the Rdb JDBC server you wish to connect to is running.</td>
</tr>
<tr>
<td></td>
<td>&lt;port&gt;</td>
<td>Is the port the Rdb thin server you wish to connect to is listening.</td>
</tr>
<tr>
<td></td>
<td>&lt;database_specification&gt;</td>
<td>Is the full file specification of the Rdb database that you wish to connect.</td>
</tr>
<tr>
<td></td>
<td>&lt;connect_options&gt;</td>
<td>These optional switches may be used to specify certain settings that should be established when the database connection is made. See <a href="#">Connection Options</a> for more details.</td>
</tr>
</tbody>
</table>

**Example**
To connect using the thin driver via an Oracle Rdb thin server to MY_DB_DIR:PERSONNEL on node BRAVO using port 1701:

```
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1701/my_db_dir:personnel", user, pass);
```

**Note:**
The `<database_specification>` should be a valid OpenVMS-style file specification or logical name, for example:
When you use an Oracle Rdb thin driver connection, any logical names and relative directory specifications used in the database specification must be valid for the account and directory from which the Oracle Rdb thin server was started.

### 2.2.2 Class Used With the Oracle JDBC for Rdb Thin Driver

The Rdb thin driver can be found in the following class:

```java
oracle.rdb.jdbc.rdbThin.Driver
```

### 2.2.3 Oracle JDBC for Rdb Thin Driver jar files

The Oracle JDBC for Rdb thin driver classes may be found in the Rdb thin driver jar file.

Prior to Oracle JDBC for Rdb release 7.3.5.0.0 only one Rdb thin driver jar file was available to use:

```
rdbThin.jar
```

Starting with release 7.3.5.0.0, on INTEGRITY systems you have the choice of three variants of the Rdb thin driver jar:

- `rdbThinV5.jar`
- `rdbThinV6.jar`
- `rdbThinV8.jar`

These jars provide JDBC and JAVA version specific variants of the driver classes:

<table>
<thead>
<tr>
<th>Driver JAR file</th>
<th>Minimum version of JAVA required</th>
<th>JDBC supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDBTHINV5.JAR</td>
<td>JDK 1.5</td>
<td>JDBC 3.0, as released in JDK 1.4</td>
</tr>
<tr>
<td>RDBTHINV6.JAR</td>
<td>JAVA SE 6</td>
<td>JDBC 4.0 as released in JAVA SE 6</td>
</tr>
<tr>
<td>RDBTHINV8.JAR</td>
<td>JAVA SE 8</td>
<td>JDBC 4.2 as released in JAVA SE 8</td>
</tr>
</tbody>
</table>

To allow compatibility with prior versions, the non-varianted file `rdbThin.jar` is also installed with the JDBC installation. This jar is identical to the `rdbThinV5.jar` file.

These jar files are available in the `rdb$jdbc_home` directory. They are also available in the Window MSI installation file provided during Oracle JDBC for Rdb installation.

### 2.3 Connection Options

The Oracle JDBC for Rdb drivers recognize a number of options that may be added to the connection string to specify certain default behavior and settings to be established when the connection is made.

Connection options may be either added directly to a connection URL using the `@` character as a separator, or as property values in the properties block that may be passed to the `DriverManager.getConnection()` method.

#### Format

(In connection URL only)

```
@<option_name>=<value>
```

#### Options

The connections options that may be used are described in the following table:

<table>
<thead>
<tr>
<th>Option Name</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alias</td>
<td>string</td>
<td>null</td>
<td>Sets the alias for this database attach. This option is used only when attaching to a second database within the same Connection. See <a href="#">Attaching to Multiple Databases in the Same Connection</a> for more details.</td>
</tr>
<tr>
<td>app</td>
<td>string</td>
<td>null</td>
<td>Sets the application name using this connection. This optional switch may be used to help identify application use of JDBC connections. The application name, if provided, will be displayed in the JDBC server logs and in the display of client information when using the controller <code>show clients</code> command.</td>
</tr>
<tr>
<td>Option Name</td>
<td>Type</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cli.idleTimeout</td>
<td>decimal or hex</td>
<td>0</td>
<td>Sets the maximum time (in milliseconds) this client connection may be idle. If no operation is carried out using this connection within the time specified, the connection will be forcibly disconnected. The value 0 means unlimited idle time allowed. See Client connection timeout for more details.</td>
</tr>
<tr>
<td>concurrentThread</td>
<td>true or false</td>
<td>false</td>
<td>Sets the maximum number of times the main process will attempt to establish handshake with its associated executor sub-process.</td>
</tr>
<tr>
<td>handshakeTries</td>
<td>decimal or hex</td>
<td>500</td>
<td>Sets the time (in milliseconds) between handshake tries attempted between the main process and its associated executor sub-process.</td>
</tr>
<tr>
<td>handshakeWait</td>
<td>decimal or hex</td>
<td>10</td>
<td>Sets the time (in milliseconds) between handshake tries attempted between the main process and its associated executor sub-process.</td>
</tr>
<tr>
<td>lockwait</td>
<td>decimal or hex</td>
<td>-1</td>
<td>Sets the lockwait (in seconds) for transactions. The value –1 means that the server will wait indefinitely for the lock. See Lockwait and Maxtries for more details.</td>
</tr>
<tr>
<td>multiProcess</td>
<td>true or false or detached or spawn</td>
<td>false</td>
<td>If true a new executor process will be created for this connection. If the value detached is specified a separate detached process will be used for the executor. If the value spawn is specified, a sub-process is used. This is the same as specifying the value true. See Executor Sub-process used with the Rdb Native driver for more details.</td>
</tr>
<tr>
<td>networkKeepalive</td>
<td>true or false</td>
<td>false</td>
<td>Sets the maximum time (in milliseconds) this client connection will wait on the completion of a read or write on the network. If the read or write does not complete within the designated time an exception will be raised.</td>
</tr>
</tbody>
</table>

**Options:**
- **true**
- **false**
- **detached**
- **spawn**
- **decimal or hex**
- **integer**
- **0**
- **Since release 7.3.5.1.0**
- **Since release 7.3.4.2.3**
<table>
<thead>

</tbody>
</table>

**DatabaseMetaDat** calls should be “Rdb” rather than “Oracle Rdb”. The default is false, i.e. “Oracle Rdb” will be returned as the database product name.

This option may be required to be set to true for use with applications that may incorrectly assume that the database is an Oracle DBMS database due to the word “Oracle” being present in the product name.
<table>
<thead>
<tr>
<th>option_name</th>
<th>value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>useHints</td>
<td>true or false</td>
<td>true</td>
<td>If true, the optional JDBC hint methods will be observed. If false, the optional JDBC hint methods will be silently ignored. See JDBC Hint Methods for more details.</td>
</tr>
<tr>
<td>useQueryHeader</td>
<td>true or false or character set name</td>
<td>false</td>
<td>Since release 7.3.3.0.0 If true or a valid character set name, JDBC will use the RDBSRELATION_HEADER column of the RDB$RELATION_FIELDS system table information to derive the Remarks property for the table columns returned in the DatabaseMetaData.getColumns() method. If false (the default) the Remarks field will be derived from the RDB$DESCRIPTION column of RDBSRELATION_FIELDS. If a character set name is used and is valid that character set will be used when converting the contents of the query header segmented string. The character set name provided must be a valid character set name as found in the Supported Character Sets table of the Rdb SQL Reference Manual. If a character name is provided but is not valid the query header value will be converted assuming DEC_MCS encoding.</td>
</tr>
<tr>
<td>user or username</td>
<td>Database user name</td>
<td>none</td>
<td>The username to use when attaching to the database.</td>
</tr>
</tbody>
</table>

### Example

To connect using the thin driver via an Oracle JDBC for Rdb server to MY_DB_DIR:PERS on node BRAVO using port 1755 and enabling full trace logging for this connection:

```java
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://bravo:1755/my_db_dir:pers@tracelevel=-1",
    user, pass);
```

Alternatively, these options may be placed in a properties block:

```java
Properties info = new Properties();
info.put("user", user);
info.put("password", password);
info.put("tracelevel", traceLevel);
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://bravo:1755/my_db_dir:pers", info);
```

### 2.3.1 Oracle Rdb Second Password

**Since release 7.3.4.2.0**

Starting with Oracle Rdb release 7.3.2, Oracle Rdb allows you to specify a second password on the database attach and connect statements. This password must be provided at the same time the database password is provided. Oracle Rdb uses both passwords to authorize the database attach request.

If a second password is required, you must provide it during the JDBC connection request. The connection attribute "password2" may be used to provide this information. This password may be in plain text or obfuscated text created using the Controller Obfuscate command.

**Note:**

If the plain text password contains the "@" character, the obfuscated form of the password must be used, otherwise JDBC may fail to parse the connection string correctly.

**Example**

```java
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://bravo:1755/my_db_dir:pers?password2=obfuscated_password", info);
```
Preferably, the password should be obfuscated:

```
jdbc:rdbThin://bravo:1755/my_db_dir:pers@password2=##01249C19B8226825E92313CBC2AB
```

Alternatively, these options may be placed in a properties block:

```
Properties info = new Properties();
info.put("user", user);
info.put("password", password);
info.put("password2", password2);
info.put("tracelevel", traceLevel);
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1755/my_db_dir:pers",
info);
```

Note:

If you specify a second password in the JDBC connection but the version of the Oracle Rdb database is earlier than release 7.3.2., the following exception will be returned on the connection request:

```
%SQL
-F
-DBENVSYNERR, Syntax error in database environment specification
```

### 2.3.2 Timezones and Oracle Rdb Date/time Values

When working with date/time data in client applications, especially when the data has to be displayed or entered in textual format, it is important to know in which timezone the data should be interpreted. This is especially important where applications need to work with data originating from more than one timezone.

Although a number of Java classes and their methods may accept timezone information as a direct parameter, many use the default Java VM timezone information when interpreting date time information.

This default timezone may be set by the client using one or more of the following techniques:

- `-Duser.timezone` on the Java command line or
- The Java `TimeZone.setDefault()` method or
- The appropriate Operating System timezone setter such as `SYS$MANAGER:UTC$TIME_SETUP.COM` on OpenVMS or
- `timezone` JDBC connection attribute (since release 7.3.4.2.2 JDBC)

(See your Java documentation for information on setting timezones and the `TimeZone` class.)

Although timezone information is not stored in the Rdb database, the timezone information obtained from the host system on which the database resides is used by Rdb to carry out the conversion of date/time values to the internal numeric format that this data is actually stored as within the database.

In general the timezone used by Rdb is the timezone of the host system where the database resides i.e. the timezone that has been set by using OpenVMS tools such as `SYS$MANAGER:UTC$TIME_SETUP.COM`.

During the processing of date/time data to and from the Rdb database JDBC needs to correctly convert between the Java internal datetime format and the Oracle Rdb datetime forms. To do this JDBC must take into account the timezone under which the Rdb data is considered to be stored.

JDBC uses the client application default timezone (as discovered using `TimeZone.getDefault()`) to carry out these conversions. JDBC assumes that the client’s timezone setting matches the database data timezone.

If the timezones do not match, the data/time values may not be converted correctly during insertion or retrieval, and may not be correctly interpreted by other applications such as interactive SQL. Thus it is important when accessing Rdb data, that the timezone setting at the time of the execution of update or query statements correctly match the timezone of the underlying Rdb data.

To ensure that time data is handled correctly you may have to set your client application environment default timezone using one of the methods cited above.

Client applications may also require interpreting datetimes using timezones other than the one associated with the Rdb data, i.e. the default timezone required for the application might not match the Rdb database timezone.
Beginning with release 7.3.4.2.2 client applications may tell JDBC within which timezone the Rdb data should be interpreted irrespective of the default timezone of the application. See the section Sessiontimezone Connection Attribute for more details.

2.3.3 Timezone Connection Attribute

Since release 7.3.4.2.2

Oracle JDBC for Rdb allows you to specify the timezone to use when formatting and interpreting date/time strings. By default JDBC will use the current Java session timezone when carrying out date/time formatting operations. This can be overridden for each connection the JDBC client makes.

The connection attribute timezone may be used to provide this information. The timezone names used are the standard Java timezone IDs. See java.util.TimeZone#getAvailableIDs() for more details.

Note:
This change in timezone is local to the JDBC client; the JDBC server timezone setting is not changed using this configuration option.

Example 1

Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1755/my_db_dir:pers"+"@timezone=Europe/Paris", user, pass);

Use the "@timezone" option if you wish the Java default timezone to be changed.

By changing the Java default timezone all datetime formatting operations carried out within the current Java session may be affected. This timezone change will also apply to all JDBC connections made within this session that have not had their timezone explicitly set by using a timezone configuration option.

See Connection Options for more information.

2.3.4 Sessiontimezone Connection Attribute

Since release 7.3.4.2.2

Client applications may inform JDBC of the timezone under which date/time data within the Rdb database should be interpreted. This timezone information is used to correctly carryout data conversions between Rdb and the Java subsystem. (See Timezones and Oracle Rdb Date/time Values for information about this data conversion).

By default, on the client, JDBC uses the Java TimeZone.getDefault() method to obtain the application’s default timezone, and uses this timezone during data conversions.

If this timezone is not the same as one used for the Rdb data, you may use the @sessiontimezone connection parameter to correctly set the appropriate timezone for conversions, for example:

Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1755/my_db_dir:pers"+"@sessiontimezone=Europe/Paris", user, pass);

Use the "@sessiontimezone" option if you wish to change the timezone used to convert datetime values between Rdb and Java for this connection only. This will change how JDBC will convert datetime values for that connection but will not change the Java session default timezone.

This timezone is only used for data conversion and does not affect the Java VM default timezone on either the client or the server.
2.3.4.1 Setting sessiontimezone Application Wide

If you wish to set the sessiontimezone for all Oracle JDBC for Rdb connections made by your application, you can use the following Java command line system properties.

$java -Doracle.rdb.jdbc.sessiontimezone=GMT my_application

or

$java -Drdb.timezone=GMT my_application

2.3.5 ConcurrentThread Connection Attribute

Since release 7.3.5.1.0

Although JDBC is thread-safe when concurrent threads use separate connections, a number of optimization features introduced into JDBC drivers over the last few releases may cause threading issues when concurrent threads are using the same JDBC connection.

Concurrent thread access of a single JDBC connection may fail with a number of symptoms including Access Violations and prematurely closed connections.

Third-party or client applications using JDBC drivers may carry out concurrent threading on connections to optimize data retrieval. When these applications are used with Oracle JDBC for Rdb drivers, it is possible that operations may fail due to threading issues.

If your application intends to carry out concurrent thread operations on the same JDBC connection, the concurrentThread connection attribute may be used to inform JDBC of this fact.

When set to true, this attribute will cause JDBC drivers to disable some of the enhancements to statement preparation and record retrieval that are normally carried out but that are not thread-safe if interrupted by another thread using the same connection object.

See Connection Options for more information.
Oracle JDBC for Rdb servers are the server-side components that services JDBC requests issued by applications using the Oracle Rdb thin driver.

There are four types of Oracle JDBC for Rdb servers:

- Oracle JDBC for Rdb thin server
- Oracle JDBC for Rdb Multi-Process server
- Oracle JDBC for Rdb Pool server
- Oracle JDBC for Rdb Manager Server

Each server is multi-threaded, able to handle multiple client requests at the same time.

Oracle JDBC for Rdb servers should be installed and invoked on each node from which you wish to serve Oracle Rdb databases.

The Oracle JDBC for Rdb thin driver communicates with the Oracle JDBC for Rdb servers using Java sockets over TCP/IP.

Any of the servers, with the exception of the Oracle JDBC for Rdb manager server, may be used by thin clients to connect to Rdb databases. The Oracle JDBC for Rdb manager server cannot be used for thin client access, it is a special server that may be used to aid in the management of your JDBC server environment.

The following sections provide information about each of the server types and the various ways you may start-up a server on your system.

Note: In order to start Oracle JDBC for Rdb servers you will require certain access to the Oracle JDBC for Rdb directories and files. See File and Directory access Requirements for more details.

3.1 Oracle JDBC for Rdb Thin Server

The Oracle JDBC for Rdb thin server is a server-side component that services JDBC requests issued by applications using the Oracle Rdb thin driver.

The standard thin server is multi-threaded, able to handle multiple client requests at the same time. Because the server is maintained as a single OpenVMS process, database access for each of the threads is synchronized.

A thin server is installed and invoked on each node from which you wish to serve Oracle Rdb databases. Oracle Rdb must be already installed and running on these nodes.

The server communicates with the Oracle Rdb thin driver using Java sockets over TCP/IP with the default Port ID 1701.

3.1.1 Starting a Thin Server

A thin server may be started by using the appropriate start statement within the controller, as an Oracle SQL/Services JDBC dispatcher or directly from the operating system command line.

3.1.1.1 Starting a Thin Server from the Oracle JDBC for Rdb Controller

A thin server may be started from the controller by referencing a thin server definition in an XML-formatted configuration file. See Starting Servers within Oracle JDBC for Rdb Controller for more details.

Example

Given the following server section in the XML-formatted configuration file mycfg.xml:

```
<server name="serv1" type="RdbThinSrv" url="/\localhost:1707/" logfile="myLogs:.serv1.log" />
```

the following command may be used to start this server from within the controller:

```
rdbthincontrol> start server serv1
```

Alternatively the controller may be used in command mode to start a server:

```
$ java -jar rdbthincontrol.jar -cfg mycfg.xml -name serv1 -startserver
```

3.1.1.2 Starting a Thin Server from Oracle SQL/Services

A thin server may be started from the Oracle SQL/Services manager.

Using the Oracle SQL/Services manager, you must first establish a connection to the SQL/Service server. Once connected you may then start a JDBC dispatcher.
3.1.1.3 Starting a Thin Server from the Command Line

Instead of placing a number of options on the command line, you may wish to create a server definition within an XML-formatted configuration file and then start the server using its server name. The server type for this server definition must be set to RdbThinSrv for a standard thin server.

Format

```java
$ java -jar rdbthinsrv.jar [<-option>]
```

Elements

See Server Configuration Options for a list of valid `<-option>`. Remember that on the DCL command line, each configuration option must have a hyphen (-) prepended to it.

Remarks

By default, the server is assumed to be of type RdbThinSrv, a standard thin server.

Example 1

```java
$ java -jar rdbthinsrv.jar -port 1707
```

Example 2

Given the following server section in the XML-formatted configuration file `mycfg.xml`:

```xml
<server name="serv1" type="RdbThinSrv" url="/localhost:1707/" logfile="myLogs:serv1.log" />
```

the following method may be used to start this thin server:

```java
$ java -jar rdbthinsrv.jar -cfg mycfg.xml -name serv1
```

3.2 Oracle JDBC for Rdb Multi-Process Server

The Oracle JDBC for Rdb multi-process server is a server-side component that processes requests from the Oracle JDBC for Rdb thin driver using small memory footprint sub-processes to carry out the requested operations on the Oracle Rdb database.

A multi-process server is multi-threaded and may handle multiple concurrent clients allocating each client its own subprocess for database access, thus allowing better concurrency and availability.

The majority of the multi-process server operations are carried out in a client thread context within the main server process, handing off control to the client’s allocated subprocess only when direct Oracle Rdb database operations are required. Each client has its own OpenVMS subprocess, thus concurrency is improved, as the server does not need to synchronize database operations.

By default, the allocated subprocess is terminated on client disconnect. Executors may also be retained for re-use after client disconnect by specifying a positive `maxFreeExecutors` configuration option.

An idle timeout value may be placed on executors to request the server to close down a free executor after a predefined amount of time of non-use, even if the number of free executors is less than the `maxFreeExecutors` limit. If the specified idle time elapses, the executor will be a candidate for termination if the number of free executors is greater than the `minFreeExecutors`.

A multi-process server is installed and invoked on each node from which you wish to serve Oracle Rdb databases. Oracle Rdb must be already installed and running on these nodes.

The server communicates with the thin driver using Java sockets over TCP/IP with the default Port ID 1701.

3.2.1 Starting a Multi-Process Server

A multi-process server may be invoked by using the appropriate start statement within the controller, or directly from the operating system command line.

Example

```
$run sys$system:SQLSRV_MANAGE72 SQLSRV> connect server;
Connecting to server
Connected
SQLSRV> start disp JDBC_MPDISP;
```

See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.
3.2.1.1 Starting a Multi-Process Server from the Controller

A multi-process server may be started from the controller by referencing a multi-process server definition in an XML-formatted configuration file.

See Starting Servers within Oracle JDBC for Rdb Controller for more details.

Example 1

Given the following server section in the XML-formatted configuration file mycfg.xml:

```xml
<server
  name="Mpserv1"
  type="RdbThinSrvMP"
  url="/localhost:1799/"
  logfile="myLogs:serv1.log"
/>
```

the following command may be used to start this server from within the controller:

```
rdbthincontrol> start server Mpserv1
```

Example 2

Given the same configuration file as shown above, the controller may be used in command mode to start a server:

```
$ java -jar rdbthincontrol.jar -cfg mycfg.xml -
  -name Mpserv1 -startserver
```

3.2.1.2 Starting a Multi-Process Server from Oracle SQL/Services

A multi-process server may be started from Oracle SQL/Services manager.

Using the Oracle SQL/Services manager, you must first establish a connection to the SQL/Service server. Once connected you may then start a JDBC dispatcher.

Before you can start a JDBC dispatcher, you must first create its definition in the Oracle SQL/Services environment.

See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.

Example

```
$ run sys$system:SQLSRV_MANAGE72
SQLSRV> connect server;
Connecting to server
Connected
SQLSRV> start disp JDBC_MPDISP;
SQLSRV>
```

See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.

3.2.1.3 Starting a Multi-Process Server from the Command Line

You may invoke a multi-process server from the OpenVMS command line.

Format

```
$ java -jar rdbthinsrv.jar [<-option>…]
```

Elements

See Server Configuration Options for a list of valid <-option>s. Remember that on the DCL command line, each configuration option must have a hyphen (-) pre-pended to it.

Remarks

Both the thin server and multi-process server are started using the same rdbthinsrv.jar file. It is the server type that determines the style of server that will be started.

By default, the server is assumed to be of type RdbThinSrv, a standard thin server. To start a multi-process server, the server type must be set to RdbThinSrvMP.

Alternatively, the developer may wish to create a server definition within an XML-formatted configuration file and then start the server using its server name. Again the server type must be set to RdbThinSrvMP.

On the DCL command line you must use double quotes to preserve the case-sensitive type name.

Example 1

```
$ java -jar rdbthinsrv.jar -port 1755 -type "RdbThinSrvMP"
```

Example 2

Given the following server section in the XML-formatted configuration file mycfg.xml:

```xml
<server
  name="Mpserv1"
  type="RdbThinSrvMP"
  url="/localhost:1799/"
  sharedmem="102400"
  logfile="myLogs:serv1.log"
/>
```
the following method may be used to start this multi-process server:

```
$ java -jar rdbthinsrv.jar -cfg mycfg.xml -name Mpserv1
```

### 3.2.2 Shared Memory Usage

The multi-process server needs to allocate shared global memory for communication with its executors, the size of which you may specify using the `sharedmem` server configuration option.

The default allocation for shared memory is 1024 KB and is only adequate for one or two executors.

A rule of thumb that can be used is to allow 1024 KB for each concurrent executor you expect to be running in conjunction with the server, but this will depend on the complexity of the queries, the number of columns involved and the size of the data area that will have to be created to hold the data returned to the executor by Rdb.

### 3.2.3 Pre-started Executors

With a multi-process server you may also specify the number of executor process that may be pre-started when the server starts running, by specifying a positive `prestartedExecutors` configuration option.

This is particularly useful if your system takes a while to start OpenVMS processes and sub-processes due to system load.

In addition you can also specify the maximum number of free executor process that may be kept around while the server is running by specifying a positive `maxFreeExecutors` configuration option.

By pre-starting executor processes you may reduce the overall elapsed time it takes for a client to make its initial database connection, but keep in mind that free executors, although they may not have database connections active, may still have OpenVMS system resources allocated.

### 3.2.4 Executor Naming

Each executor started up on a single system requires a unique process name on that system. By default, a name will be created for the executor based on the name of the server that started it and a hexadecimal value that represents the instance of the executor process with relation to the server.

By default, the name of the executor subprocess has the following format:

**Format**

First seven (7) characters of server name + eight (8) character hexadecimal id.

**Remarks**

Names of executors are not case-sensitive.

The first seven (7) characters of the names of multi-process servers started up within the same system should be unique irrespective of character casing; otherwise, executor process names may clash.

**Example 1**

RDBTHNS0000220

The format of the executor names may be changed by using the `srv.execPrefix` configuration option:

**Format**

```
srv.execPrefix + up to eight (8) character hexadecimal id.
```

**Remarks**

If the `srv.execPrefix` configuration option is specified for a multi-process server, all executors for that server will have this name prefix. The server will try to provide a unique name for each executor instance by appending to the given prefix as many characters of the hexadecimal numeric id of the executor that will still keep the executor name within the Process name sized expected by OpenVMS.

See [XML Formatted Configuration File](#) for more details on server definitions.

**Example 2**

Given the `srv.execPrefix` of "MY_EXECUTOR_" the fourth executor will be named:

MY_EXECUTOR_004

**Note:**

The longer the prefix, the smaller the number of characters that may be used to provide uniqueness, so consideration should be given to the number of concurrent executors that you expect a server to maintain when specify a customized executor name prefix.
3.2.5 Executor Process Startup

By default the multi-process server will create a subprocess for each executor it allocates and starts. OpenVMS command procedures are used during this subprocess creation. Information about these command procedures may be found in the Server Command Procedures and On Start Commands sections of this document.

If a persona is specified for the server (see Persona for more information) or if the srv.usecreprc configuration attribute is set to true, the server will use the OpenVMS CREPRC system service to start the process as detached.

If a persona is not specified and the srv.usecreprc is set to false then the Java System.exec() method will be used instead which will start a subprocess.

Note:
Some OpenVMS quotas are shared across the entire process subtree (i.e. shared between the server process and its subprocesses), thus it is possible that the increasing the number of concurrent executors available for a server may exceed process or system quotas and some executors may fail to start correctly. (See your OpenVMS documentation on process and system level quota limits.)

If shared process level quotas are found to be an issue then consider using the srv.usecreprc configuration attribute to tell the MP server to use detached process for the executors. As the executor will run within its own detached process the operating system should allocate a separate set of process quotas to it.

If the server environment, or the JDBC directories are not appropriately setup, errors may occur during the startup of the executor process. See File and Directory access Requirements for more details on JDBC directories access requirements.

The steps taken during the startup of an executor process depend on whether or not persona or srv.usecreprc are used with the server.

3.2.5.1 Executor Start-up Steps

Since release 7.3.4.1.2

Without Persona and when srv.usecreprc is false

If persona is not used and srv.usecreprc is set to false the following steps are carried out by the server to start an executor:

1. An executor name based on the server name is generated for the new process; see Executor Naming for more details.
2. An attached process is created using the System.exec() method.
3. The command procedure designated by the srv.execStartup option for the multi-process server is executed. If this option has not been specified for the server nor for the DEFAULT server in the configuration file, then RDB$JDBC_HOME:RDBJDBC_STARTEXEC.COM is used. See Server Startup Command Procedure.
4. If the srv.onExecStartCmd option is present for this server or for the DEFAULT server then this command is executed. This is generally used to setup server and site specific environments. See srv.onExecStartCmd.
5. The executor image pointed to by the logical name RDBJDBEXEC is executed.
6. The executor and server establish communications channels using global shared memory.

With Persona or when srv.usecreprc is true

If persona is used or srv.usecreprc is set to true:

1. An executor name based on the server name is generated for the new process; see Executor Naming for more details.
2. Process quotas are determined for the executor process based on the current quotas of the executing server.
3. A termination mailbox is setup for the executor process and read issued.
4. CREPRC is used to create a process and SYS$SYSTEM:LOGINOUT.EXE is executed.
5. Steps 3 thru 6 as described in the previous list above.

3.2.5.2 Executor Process Start-up Problems

If a problem occurs during executor subprocess creation, the status codes relating to the problem will be written to the server log, for example:

Java.sql.SQLException: Unable to start process,
The status code shown is a VMS status code or an Rdb specific status code; see your OpenVMS and Oracle Rdb documentation for more information on this status code.

The substatus indicates more information about the problem found. The following table lists the substatus values and their meanings.

<table>
<thead>
<tr>
<th>Substatus</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>No more memory, check your quotas.</td>
</tr>
<tr>
<td>13</td>
<td>Unable to create command procedure in rdb$jdbc_com: directory, either insufficient privilege or access denied or there already exists an earlier version of the file with the same name but created by another user.</td>
</tr>
<tr>
<td>19</td>
<td>Problem in pathname pointed to by rdb$jdbc_com logical name, invalid device specified.</td>
</tr>
<tr>
<td>20</td>
<td>Problem in pathname pointed to by rdb$jdbc_com logical name, invalid directory specified.</td>
</tr>
<tr>
<td>24</td>
<td>Too many files open by server already, check your quotas.</td>
</tr>
<tr>
<td>28</td>
<td>Disk full, check the disk pointed to by rdb$jdbc_com.</td>
</tr>
<tr>
<td>30</td>
<td>Disk or directory is write-protected, check the disk/directory pointed to by rdb$jdbc_com.</td>
</tr>
<tr>
<td>65530</td>
<td>Process terminated prematurely.</td>
</tr>
<tr>
<td>65531</td>
<td>Problem reading termination mailbox.</td>
</tr>
<tr>
<td>65532</td>
<td>Problem during call to CREPRC.</td>
</tr>
<tr>
<td>65533</td>
<td>Problem getting information about termination mailbox.</td>
</tr>
<tr>
<td>65534</td>
<td>Problem creating termination mailbox.</td>
</tr>
</tbody>
</table>

Note:
It is important that the server process has appropriate access rights to the directories specified by JDBC$RDB_HOME, RDB$JDBC_COM and RDB$JDBC_LOGS logical names, see File and Directory access Requirements for more details.

### 3.2.6 Executor Maintenance

The multi-process server maintains a list of executor processes that it has started to allow it to do basic housekeeping on these processes.

At process start up, the server will attempt to create the number of executors specified in the server configuration parameter prestartedExecutors. Once started, these executors will be placed in the server’s free executor list.

Executors may be either free, meaning that currently no client is using it, or occupied, meaning that the executor has been allocated to a client.

When an executor is freed, for example, when the occupying connection disconnects, the server has to decide if it should be kept in its free executor list, or alternatively, closed down. The server configuration parameter maxFreeExecutors specifies the maximum number of free executors to keep around.

If the server has a positive, non-zero value for its configuration parameter minFreeExecutors, depending on the executor reuse scheme specified for the server, it may attempt to prestart enough executors to meet the minimum free executor limit specified. The server may check the minimum executor level whenever an executor is allocated from the free list, returned to the free list, or periodically if lost executor sweeping is enabled.

The server may also periodically check to see if any executors in its free list have been free for longer than the specified srv.execTimeout. Executors that have exceeded this limit will be candidates for termination. However, if the number of free executors is less than or equal to the server configuration parameter minFreeExecutors, the idle executor will not be terminated.

### 3.2.7 Lost Executor Sweep

The server may periodically check occupied executors to ensure that they are still viable.

If an executor process has been terminated unexpectedly, or appears to be unresponsive, the server will try to ensure that the executors OpenVMS process is terminated correctly and the client connection will be flagged as lost. The next time the client attempts to carry out an action, a lost connection exception will be returned to them.

The server configuration parameter srv.lostExecSweep controls how often the server will do its executor viability checks.

The server may also use the lost executor sweep to ensure that the required minimum number of free executors are available, see Executor Reuse for more details.

### 3.2.8 Executor Balancing

Since release 7.3.2.0.0

By default, the multi-process server uses a first-in/first-out (FIFO) scan of its free executor list to select the next executor process to allocate to the new connection request.
The way the free executor list is scanned to select the next executor process may be changed to suit your requirements; this is called executor balancing.

Executor balancing specifies the order in which the multi-process server should select the next candidate from the free executor list and may be changed by specifying a value for the `srv.execBalance` configuration attribute for that server.

The `srv.execBalance` configuration attribute will accept either a numeric value or the appropriate keyword as shown in the table below. Keywords are not case sensitive.

The following table shows the possible balance values recognized by the multi-process server:

<table>
<thead>
<tr>
<th>Value</th>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Default or FIFO</td>
<td>Use a FIFO to select the next free executor. This is the default balancing style.</td>
</tr>
<tr>
<td>1</td>
<td>MostMemory</td>
<td>Select the executor that has the most memory already allocated to it. This is determined by checking the PAGEFILE count for the executor process.</td>
</tr>
<tr>
<td>2</td>
<td>LeastMemory</td>
<td>Select the executor that has the least memory already allocated to it. This is determined by checking the PAGEFILE count for the executor process.</td>
</tr>
<tr>
<td>3</td>
<td>Oldest</td>
<td>Select the executor that has spent the most amount of time in the current free list.</td>
</tr>
<tr>
<td>4</td>
<td>Youngest</td>
<td>Select the executor that has spent the least amount of time in the current free list.</td>
</tr>
</tbody>
</table>

### 3.2.9 Executor Reuse

By default, the multi-process server will reuse executors when they are free, however, the server’s reuse of executors may be changed to suit your application and environmental requirements.

The `srv.execReuse` configuration attribute is used to set the type of executor reuse the server should carry out.

The following table shows the possible executor reuse values recognized by the multi-process server:

<table>
<thead>
<tr>
<th>Value</th>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Serial</td>
<td>Reuse executors. The scope of executor use is a single server connection request. This is the default reuse type.</td>
</tr>
<tr>
<td>1</td>
<td>Preemptive</td>
<td>Reuse executors. The scope of executor use is a single server connection request. Whenever an executor is allocated to a connection, and the number of free executors is below the minimum number set by <code>minFreeExecutors</code>, another executor will be started concurrently to replace the one used. If the lost executor sweeper is active, the number of free executors will be checked on each sweep cycle. If the number of free executors is below the minimum number set by <code>minFreeExecutors</code>, executors will be started until the required minimum number of executors are present.</td>
</tr>
<tr>
<td>-1</td>
<td>None</td>
<td>Do not reuse executors. On disconnect, the executor will be destroyed, and if the number of free executors is below the minimum number set by <code>minFreeExecutors</code>, another executor will be started to replace the one destroyed.</td>
</tr>
<tr>
<td>-2</td>
<td>Fresh</td>
<td>Do not reuse executors. On disconnect, the executor will be destroyed, and if the number of free executors is below the minimum number set by <code>minFreeExecutors</code>, another executor will be started to replace the one destroyed. If the lost executor sweeper is active, the number of free executors will be checked on each sweep cycle. If the number of free executors is below the minimum number set by <code>minFreeExecutors</code>, executors will be started until the required minimum number of executors are present.</td>
</tr>
<tr>
<td>-3</td>
<td>Fresh_Preemptive</td>
<td>Do not reuse executors.</td>
</tr>
</tbody>
</table>
Whenever an executor is allocated to a connection, and the number of free executors is below the minimum number set by minFreeExecutors, another executor will be started concurrently to replace the one used.

On disconnect, the executor will be destroyed, and if the number of free executors is below the minimum number set by minFreeExecutors, another executor will be started to replace the one destroyed.

If the lost executor sweeper is active, the number of free executors will be checked on each sweep cycle. If the number of free executors is below the minimum number set by minFreeExecutors, executors will be started until the required minimum number of executors are present.

The `srv.execReuse` configuration attribute will accept either a numeric value or the appropriate keyword as shown in the table above. Keywords are not case sensitive.

The different types of executor reuse are described in the following sections.

### 3.2.9.2 Executor Reuse “Serial”

When a client disconnects, the executor used for the connection will be returned to the server’s free list to be reused later. This is termed “serial” reuse and is the default reuse behaviour.

Before returning the executor to the free list, the multi-process server also checks the number of free executors currently in the free list. If there are already more free executors than the `maxFreeExecutors` server configuration attribute, the executor process will be terminated instead of being returned to the free list.

If the executor reuse is set to serial, the server with disregard any `minFreeExecutors` configuration attribute set.

### 3.2.9.3 Executor Reuse “Preemptive”

If the `srv.execReuse` configuration attribute is set to “preemptive”, the MP server will attempt to retain a minimum number of free executors as set by `minFreeExecutors`.

As executors are allocated to connections, if the number of free executors is below the `minFreeExecutors` value, the server will concurrently start a new executor to replace the allocated one.

If executor processes are prematurely terminated by any means and the lost executor sweeper is active, the server will attempt to restart enough executors to maintain the required minimum number.

Before returning the executor to the free list, the multi-process server also checks the number of free executors currently in the free list. If there are already more free executors than the `maxFreeExecutors` server configuration attribute, the executor process will be terminated instead of being returned to the free list.

### 3.2.9.4 Executor Reuse “None”

There may be situations where you require pre-started and available executor processes, for example, to reduce the initial connection time, but require that a fresh OpenVMS process be used for each new connection.

In these situation it is required that the executor process be pre-started prior to the connection request, but be terminated after the connection has been released.

The `srv.execReuse` configuration attribute used in conjunction with the `minFreeExecutors` configuration attribute allows you to setup this type of configuration.

Setting the `srv.execReuse` configuration attribute to “none”, tells the MP server to terminate each executor after the client has disconnected from it. At this time, if the current number of free executors is less than the server's `minFreeExecutors` configuration attribute, and less than `maxFreeExecutors`, the server will prestart new executor processes until the `minFreeExecutors` number of free executor process is reached.

Note:

If the executor reuse is “none”, idle executors are not placed back on the free list and the associated OpenVMS processes will be terminated.

### 3.2.9.5 Executor Reuse “Fresh”

If the `srv.execReuse` configuration attribute is set to “fresh”, the MP server will terminate each executor after the client has disconnected from it. At this time, if the current number of free executors is less than the server's `minFreeExecutors` configuration attribute, and less than `maxFreeExecutors`, the server will prestart new executor processes until the `minFreeExecutors` number of free executor process is reached.

In addition, if the lost executor sweeper is active, the number of free executors will be checked on each sweep cycle. If the number of free executors is below the minimum number set by
3.2.9.6 Executor Reuse “Fresh_Preemptive”

If the `srv.execReuse` configuration attribute is set to “fresh_preemptive”, the MP server will terminate each executor after the client has disconnected from it. At this time, if the current number of free executors is less than the server's `minFreeExecutors` configuration attribute, and less than `maxFreeExecutors`, the server will prestart new executor processes until the `minFreeExecutors` number of free executor process is reached.

As executors are allocated to connections, if the number of free executors is below the `minFreeExecutors` value, the server will concurrently start a new executor to replace the allocated one.

If executor processes are prematurely terminated by any means and the lost executor sweeper is active, the server will attempt to restart enough executors to maintain the required minimum number.

### Contents

#### 3.3 Oracle JDBC for Rdb Pool Server

The Oracle JDBC for Rdb Pool server is a server-side component that accepts connection requests from the thin driver and redirects the requests to the next available Oracle JDBC for Rdb server for processing.

Using the Pool server you can designate a single Port ID that can be used by client-side applications to connect to the next available server. The Pool server selects the next available server from a table of candidate servers in a round-robin fashion.

Once the connection request has been redirected, the thin driver and the designated server communicate directly with each other; the Pool server is no longer involved with that connection.

A Pool server is installed and invoked on each node from which you wish to direct the access to Oracle JDBC for Rdb servers. Oracle Rdb need not be present on these nodes, as the Pool server does not communicate directly with Oracle Rdb.

The Pool server and its pooled servers do not need to be on the same node, but they must be able to communicate with each other over TCP/IP. Firewalls and other network security devices may interfere with this communication.

The Pool server communicates with the thin driver using Java sockets over TCP/IP with the default Port ID 1702.

**Note:**

The Pool server carries out server pooling NOT connection pooling. Connections are created in each connection request and are not reusable.

#### 3.3.1 Starting a Pool Server

A Pool server must be invoked on each node on which you wish to provide server redirection. The Pool server does not need to be on the same node as its pooled servers.

A Pool server may be invoked by using the appropriate start statement within the controller, as an Oracle SQL/Services JDBC dispatcher or directly from the operating system command line.

##### 3.3.1.1 Starting a Pool Server from the Controller

A Pool server may be started from the controller by referencing a Pool server definition in an XML-formatted configuration file. See [Starting Servers](#) within Oracle JDBC for Rdb Controller for more details.

**Example**

Given the following server section in the XML-formatted configuration file `mycfg.xml`:

```
<server
   name="mypoolserver"
   type="RdbThinSrvPool"
   url="/localhost:1702/" >
   <pooledServer name="srv1forRdb"/>
   <pooledServer name="srv2forRdb"/>
   <pooledServer name="srvMPforRdb"/>
</server>
```

the following command may be used to start this server from within the controller:

```
rdbthincontrol> start server mypoolserver
```

Alternatively the controller may be used in command mode to start a server:

```
$ java –jar rdbthincontrol.jar –cfg mycfg.xml –
   –name mypoolserver –startserver
```
3.3.1.2 Starting a Pool Server from Oracle SQL/Services

A Pool server may be started from the Oracle SQL/Services manager:

Using the Oracle SQL/Services manager, you must first establish a connection to the SQL/Service server. Once connected you may then start a JDBC dispatcher.

Before you can start a JDBC dispatcher, you must first create its definition in the Oracle SQL/Services environment. See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.

Example

```
$run sys$system:SQLSRV_MANAGE72
SQLSRV> connect server;
Connecting to server
Connected
SQLSRV> start disp JDBC_DISP;
```

See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.

3.3.1.3 Starting a Pool Server from the Command Line

You may invoke a Pool server from the OpenVMS command line.

Format

```
$ java –jar rdbthinsrvpool.jar [-option ]
```

See Pool Server Configuration Options for a list of valid options. Each option must have a hyphen (–) prepended to it.

Example

```
$ java –jar rdbthinsrvpool.jar –cfg mycfg.xml –name mypoolserver
```

3.3.2 Pool Server Operation

Once started, by default, the Pool server will scan the list of pooled servers in a round-robin fashion to select the next available server. See the section Pool Balancing on how this scan order may be changed to suit your needs.

You can start and stop the servers in the pool at anytime. If a server is not available, then the Pool server will bypass it. The Pool server also has the ability to automatically start up one or more pooled servers when the Pool server itself starts up.

During Pool server startup, a check is made on each server within its pool to see if the pooled server has the `autoStart` option enabled. If `autoStart` is enabled, then the command procedure pointed to by the `srv.startup` option of that pooled server will be executed. See Server Command Procedures for more details.

While the Pool server is running, it will periodically check to see that each pooled server within its pool of servers with `autoRestart` option enabled is still running. If `autoRestart` is enabled for a non-running pooled server, the command procedure pointed to by the `srv.startup` option of that pooled server will be executed to restart the server.

You can use the `srv.keepAliveTimer` option on Pool server start-up to specify the time between checks for non-running `autoRestart` servers. See Pool Server Configuration Options for more details.

If the Pool server is shutdown using the controller or the Oracle SQL/Services manager, then during server shutdown all pooled servers within the pool that were started by the pool server will also be shut down.

However, if the Pool server is terminated forcibly by stopping or deleting the OpenVMS process, it will not be able to carry out an orderly shutdown, in which case its pooled servers will not be shutdown automatically.

3.3.2.1 Pool Server redirection and failSAFE IP

During connection redirection by the Pool server, the IP of the chosen pooled server will be returned to the thin driver so that it may redirect the client’s connection request to that chosen server. As the DNS node name conversions may differ on the client and server node, the Pool server will implicitly convert any named nodes to IP addresses before returning the resultant IP to the thin driver.

The conversion to IP addresses may limit the failover to a standby address carried out by failSAFE IP. failSAFE IP is an optional service provided by TCP/IP Services on OpenVMS to allow IP addresses to fail over when nodes fail.

You may specify that the Pool server should not carry out the translation of named nodes to IP addresses during the connection redirection. This will then maintain the “logical” nature of the named IP and thus allowing failSAFE IP to correctly redirect to a standby node. See srv.useLogicalIPs in Pool Server Configuration Options for more details.

3.3.2.2 Server Pool Balancing
By default, the pool server uses a round-robin scan of the pool to select the next candidate pooled server for allocation. The order in which the pool server scans the pool may be changed by specifying a value for the `srv.balance` configuration attribute for that pool server.

The `srv.balance` configuration attribute will accept either a numeric value or the appropriate keyword as shown in the table below. Keywords are not case sensitive.

The following table shows the possible balance values recognized by the pool server:

<table>
<thead>
<tr>
<th>Value</th>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Default</td>
<td>Use a round-robin to select the next server from the pool. This is the default balancing style.</td>
</tr>
<tr>
<td>1</td>
<td>Memory</td>
<td>Select the server that has the least percentage of its total global shared memory allocation currently in use.</td>
</tr>
<tr>
<td>2</td>
<td>Users</td>
<td>Select the server that has the least number of users currently connected. The servers are searched using round-robin. If the server has no clients currently connected it will be selected, otherwise the first server encountered with the least number of current clients will be selected.</td>
</tr>
<tr>
<td>4</td>
<td>Executors</td>
<td>Select the server that has the greatest number of free executors. This is only applicable to multi-process pooled servers. Pooled servers that are not multi-process are deemed to have zero(0) free executors.</td>
</tr>
<tr>
<td>8</td>
<td>FreeExecutors</td>
<td>Using round-robin, select the server that has at least 1 free executor. If no server is found to have a free executor then the next server is selected using round-robin.</td>
</tr>
<tr>
<td>16</td>
<td>Usage</td>
<td>Select the server that has the greatest number of free client slots available. The number of free slots is determined by subtracting the current number of clients connected from the maximum number of clients allowed (<code>maxClients</code>). The first server found by a round-robin search to have no clients currently connected will be selected irrespective of its <code>maxClients</code> setting. Servers that have no <code>maxClients</code> limit will be selected as primary candidates, in which case the server with the least number of current clients will be selected.</td>
</tr>
<tr>
<td>32</td>
<td>PoolOrder</td>
<td>Since release 7.3.4.0.5</td>
</tr>
</tbody>
</table>

3.4 Oracle JDBC for Rdb Manager Server

The Oracle JDBC for Rdb manager server is a server-side component that services JDBC management requests.

The manager server is multi-threaded, able to handle multiple management requests at the same time.

A manager server cannot be used to access databases. Its purpose is to provide a management capability on nodes that may be remote to where the controller application is running. Its main function is to handle starting of JDBC servers on remote nodes.

A manager server is installed and invoked on each node on which you wish to remotely start JDBC servers. Oracle Rdb needs to be installed and running on these nodes, if you wish to remotely start a JDBC server that will access a local Rdb database.
The server communicates with management applications using Java sockets over TCP/IP with the default Port ID 2060.

### 3.4.1 Utilizing a Manager Server

The main purpose of the manager server is to provide a mechanism that will allow JDBC servers to be started up on nodes remote to the one the controlling application is running.

The manager server can also be used to automatically start servers on its local host and to periodically check to ensure each server is operational. If the manager server finds a failed server it can attempt to restart that server. See Manager Server Operations for more details.

Although any JDBC server running on your network may be stopped by the controller as long as the controller has the appropriate server control password for that server, and has network access to that node, the invocation or startup of a JDBC server using the controller is limited to the local node on which the controller application is running.

This is because an OpenVMS process has to be started for the server to run within, which is more difficult when the node on which the process is to be started is remote to the invoking application.

Oracle JDBC for Rdb does not use features such as Java RMI to invoke remote events as this may introduce greater security risks on your network. Thus, without any additional components, the controller can only start server processes locally.

In order to provide a controlled mechanism to start remote server processes, Oracle JDBC for Rdb introduced the manager server.

Although the manager server itself needs to be started on the remote node, which is a necessary bootstrapping step, once it is started it can service requests from the remote controller application to startup new JDBC server instances.

The manager server will only respond to management requests made from application that have connected as control users, that is, the application must know the manager server’s control password to connect successfully to it.

To utilize a manager server for remote server startup, the following steps are required:

1. Startup an instance of a manager server on the remote node you wish to later start JDBC servers on. See Starting a Manager Server for more details.
2. Add a manager server entry to the local configuration file that you will be using with the controller.
3. Request the controller to start the remote server.

### 3.4.2 Starting a Manager Server

A manager server may be started by using the appropriate start statement within the controller, as an Oracle SQL/Services JDBC dispatcher or directly from the operating system command line.

The configuration file used to start the manager server should also contain server definitions for all JDBC servers that you wish to be able to start remotely using this manager server, otherwise the DEFAULT server definition found in this configuration file will be used.

### 3.4.2.1 Starting a Manager Server from the Oracle JDBC for Rdb Controller

A manager server may be started from the controller by referencing a manager server definition in an XML-formatted configuration file. See Starting Servers within Oracle JDBC for Rdb Controller for more details.

**Example**

Given the following server section in the XML-formatted configuration file mycfg.xml:

```xml
<server
  name="manserv1"
  type="RdbManSrv"
  url="/\localhost:2060/"
  logfile="myLogs\manserv1.log"
/>
```

the following command may be used to start this server from within the controller:

```
rdbthincontrol> start server serv1
```

Alternatively the controller may be used in command mode to start a server:

```
$ java -jar rdbthincontrol.jar -cfg mycfg.xml -
  -name serv1 -startserver
```

### 3.4.2.2 Starting a Manager Server from Oracle SQL/Services

A manager server may be started from the Oracle SQL/Services manager.

Using the Oracle SQL/Services manager, you must first establish a connection to the SQL/Service server. Once connected you may then start a JDBC dispatcher.
Before you can start a JDBC dispatcher, you must first create its definition in the Oracle SQL/Services environment. See Oracle SQL/Services and Oracle JDBC for Rdb Servers for more details.

Example

```sql
$run sys$system:SQLSRV_MANAGE72
SQLSRV> connect server;
Connecting to server
Connected
SQLSRV> start disp JDBC_MANDISP;
```

### 3.4.2.3 Starting a Manager Server from the Command Line

You may invoke a manager server from the OpenVMS command line.

Instead of placing a number of options on the command line, you may wish to create a server definition within an XML-formatted configuration file and then start the server using its server name.

The server type for this server definition must be set to RdbManSrv for a manager server.

Manager servers are invoked using the `rdbmansrv.jar`.

#### Format

```
$ java -jar rdbmansrv.jar [<-option>]
```

#### Elements

See Server Configuration Options for a list of valid `<option>`s. Remember that on the DCL command line, each configuration option must have a hyphen (−) prepended to it.

#### Remarks

By default, the server is assumed to be of type RdbManSrv.

See XML formatted Configuration File for more details on server definitions within configuration files.

Example 1

```sh
$ java -jar rdbmansrv.jar -port 2666
```

Example 2

Given the following server section in the XML-formatted configuration file `mymancfg.xml`:

```xml
<server
    name="manserv1"
    url="//localhost:2060/"
    logfile="myLogs:manserv1.log"
/>
```

the following method may be used to start this manager server:

```sh
$ java -jar rdbmansrv.jar -cfg mymancfg.xml -name manserv1
```

### 3.4.3 Adding a Remote Manager Server Configuration Entry

In order for the controller to know where manager servers can be found, you have to add one or more entries to your controller configuration file specifying the name, and url of the manager server or servers.

Once defined, this information will be used by the controller to connect to the appropriate manager server and request that the designated remote server should be started.

The manager server entry need only contain the name, and url of the manager server.

```xml
<server
    name="manserv1"
    url="/myremotenode.adir.com:2060/"
/>
```

Once defined you may then use the controller to start remote servers on the same node the manager server is running.

See Using the Controller to Start Remote Servers for more details.

### 3.4.4 Using the Controller to Start Remote Servers.

If a remote node has a manager server currently running you can start a JDBC server on that node by utilizing the VIA qualifier of the controller start command.
The name of the server you wish to start will be sent to the manager server, which in turn will lookup that name within the server definitions of its own configuration file to determine the server characteristics to use. It will then use these characteristics to startup that server on behalf of the controller.

Example 1
Assuming the local controller configuration file `mycfg.xml` contains the following server definition:

```xml
<server
    name="manserv1"
    url="/myremotenode.adir.com:2060/
/>
```

And that the remote manager server was started on node `myremotenode.adir.com` using a configuration file that included the following server definitions:

```xml
<server
    name="manserv1"
    type="RdbManSrv"
    url="/localhost:2060/"
    controlpass="MYCONTROL"
/>
<server
    name="mysrv1"
    type="RdbThinSrv"
    url="/localhost:1701/"
/>
```

The following local command will start up a thin server called `mysrv1` listening on port 1701 on node `myremotenode.adir.com`:

```bash
$java -jar rdb$jdbc_home:rdbthincontrol.jar -cfg mycfg.xml rdbthincontrol> start server mysrv1 via manserv1 jones MYCONTROL
```

Example 2
If you have a session control password in the configuration file that is the same as the control password of the manager server then you do not need to give the control password on the command line.

Assuming the local controller configuration file `mycfg.xml` contains the following session and server definitions:

```xml
<session
    name="DEFAULT"
    controlUser="jones"
    controlPass="MYCONTROL" />
<server
    name="manserv1"
    url="/myremotenode.adir.com:2060/"
/>
```

And given the same remote configuration file used for the remote manager server setup as shown in Example 1, the following local command will start up a thin server called `mysrv1` listening on port 1701 on node `myremotenode.adir.com`:

```bash
$java -jar rdb$jdbc_home:rdbthincontrol.jar -cfg mycfg.xml rdbthincontrol> start server mysrv1 via manserv1
```

Oracle recommends not to store password in your configuration file, however if you choose to store them then an obfuscated form should be used. You may use the obfuscate function within the Controller application to generate an obfuscated password that is suitable to use with the controlpass property. See Password Obfuscation in Server Configuration Files for more details.

3.4.5 Manager Server Operations

Once started, by default, the manager server will scan the list of servers found in its configuration file to determine if any require starting.

During the manager server startup, a check is made on each server definition within its configuration file to locate any servers that have `autoStart` option enabled. For each server that has an URL indicating that it should run on the same host on which the manager server is running, and that has `autoStart` enabled, the manager server will attempt to start that server using the command procedure pointed to by the `srv.startup` option for that server. See Server Command Procedures for more details.

While the manager server is running, it will periodically check to see that each server found in its configuration file that has an URL indicating that it should run on the same host on which the manager server is running, that has the `autoRestart` option enabled, is still running. If `autoRestart` is
You can use the `srv.keepAliveTimer` option on manager server start-up to specify the time between checks for non-running autoRestart servers. See Manager Server Configuration Options for more details.

You may also use the `srv.keepAliveWait` option on manager server start-up to specify the time the manager server will wait for a newly started server to respond that it has started successfully. See Manager Server Configuration Options for more details.

If the manager server is shutdown, any servers it has started will continue to run. You may use the controller to stop these servers if required.

## Chapter 4
### Server Configuration

There are a number of configuration options that apply to Oracle JDBC for Rdb servers that may be used as command line options or as server options inside a configuration file. See Configuration Files for more details on how to use these options within a configuration file.

The following sections detail the configuration options and files:
- Server Configuration Options
- Multi-Process Server Configuration Options
- Pool Server Configuration Options
- Manager Server Configuration Options
- Configuration Files

### 4.1 Server Configuration Options

The following server configuration options may be used on the command line or in configuration files in conjunction with standard thin servers:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>anonymous</td>
<td>false</td>
<td>If specified <code>true</code>, tells the server to allow anonymous connections, that is, connections where the user and password are not specified. Depending on how the Oracle Rdb database has been set up, Oracle Rdb may allow connection to the database without a username being explicitly specified, in which case the characteristics of the authorization account of the server invoker will be used by Oracle Rdb to determine database access. This switch may be used in conjunction with the <code>password</code> and <code>user</code> configuration options to provide default authorization on connections. By default, anonymous connections are disabled and the client must specify a valid username and password combination to access the Rdb database.</td>
</tr>
<tr>
<td>allowAccessToCL</td>
<td>false</td>
<td>If specified <code>true</code>, indicates that users may be allowed access to Command Line operations on the system on which the server is executing. This option should only be used within an XML formatted configuration file. See Access to the Command Line for more details.</td>
</tr>
<tr>
<td>allowAccessToRoot</td>
<td>false</td>
<td><strong>Since release 7.3.4.0.0</strong> If specified, indicates that users may be allowed access to the server root. Server root access is required to carry out operations such as CREATE and DROP databases. If the specified value is <code>true</code>, all users will have the ability to connect to the server root. If the specified value is &quot;priv&quot;, only</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>privileged users will have the ability to connect to the server root.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>This option should only be used within an XML formatted configuration file. See Access to the Server Root for more details.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>By default, server root access is disabled.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>allowCreateDatabase</td>
<td>false</td>
<td>Since release 7.3.4.0.0 If specified, indicates that the server will allow appropriate users the ability to create new Rdb databases. If the specified value is true, all users will have the ability to create new database if allowed by OpenVMS and Rdb. If the specified value is “priv”, only privileged users will have the ability to create new databases. See Create and Drop Database for more details. By default, create database is prohibited.</td>
</tr>
<tr>
<td>allowDropDatabase</td>
<td>false</td>
<td>Since release 7.3.4.0.0 If specified, indicates that the server will allow appropriate users the ability to drop existing Rdb databases. If the specified value is true, all users will have the ability to drop databases if allowed by OpenVMS and Rdb. If the specified value is “priv”, only privileged users will have the ability to drop databases. See Create and Drop Database for more details. By default, drop database is prohibited.</td>
</tr>
<tr>
<td>allowShowDatabases</td>
<td>false</td>
<td>If specified true, indicates that the server will respond to user requests for a list of databases that are known to the server. The list of known named databases is specified in the Database section of the configuration file. See Named Databases for more details.</td>
</tr>
<tr>
<td>autorestart</td>
<td>false</td>
<td>If specified true, indicates to any Pool server that may include this server in its pool of servers to automatically restart this pooled server. See Oracle JDBC for Rdb Pool Server for more details. Manager servers may also restart servers that have this option enabled. See Oracle JDBC for Rdb Manager Server for more details. This option is only valid in an XML formatted Configuration File.</td>
</tr>
<tr>
<td>autostart</td>
<td>false</td>
<td>If specified true, indicates to any Pool server that may include this server in its pool of servers to automatically start up this pooled server. See Pool Server Operation for more details. Manager servers may also start servers that have this option enabled. See Oracle JDBC for Rdb Manager Server for more details. This option is only valid in an XML formatted Configuration File.</td>
</tr>
<tr>
<td>b or buffersize</td>
<td>send_buffer_size</td>
<td>Provides a hint to the server on sizing of the underlying network I/O buffers. Increasing buffer size can increase the performance of network I/O for high-volume connection, while decreasing it can help reduce the backlog of incoming data.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>bypass</td>
<td>false</td>
<td>If specified true, that if the privilege is available, bypass will be an allowable privilege for the server process. Rdb checks this privilege to determine the access rights to databases and database objects. If enabled, all validated users connected to databases via this server instance will be considered to have bypass privilege. The default is false where the bypass privilege is disabled for the server by default. Validated users who already possess the bypass privilege will still have bypass available. See BYPASS Privileges for more details.</td>
</tr>
<tr>
<td>cfg or configfile file specification</td>
<td>none</td>
<td>The file specification of a configuration file where server attributes may be found. Attributes set in this configuration file may be overridden by setting the same attribute at the command line level. If the file extension is XML, the configuration parameters are held in a XML format. See Configuration Files for more details. By default no configuration file is used.</td>
</tr>
<tr>
<td>cli.idleTimeout timeout</td>
<td>0</td>
<td>Sets the maximum time, in milliseconds, a client connection may be idle. If no operation is carried out using this connection within the time specified, the connection will be forcibly disconnected. A value of zero (0) means unlimited idle time allowed. See Client connection timeout for more details.</td>
</tr>
<tr>
<td>controlpass control_password</td>
<td>none</td>
<td>Specifies the password that control users must use to be able to issue control commands on this server instance. This password may be either plain text or an obfuscated password value. See Control Password for more information on this password.</td>
</tr>
<tr>
<td>fs or fetchsize default_fetch_size</td>
<td>100</td>
<td>Specifies the default fetchsize to use. The fetchsize provides a hint to the server indicating the number of records to retrieve and send back to the client at the one time. Increasing the fetchsize may improve the network performance by reducing the average network overhead per record retrieved.</td>
</tr>
<tr>
<td>lockwait lock_wait</td>
<td>-1</td>
<td>Specifies the maximum number of seconds to wait on getting a record lock. This switch, used in conjunction with mastries and trywait, specifies how often and how long to try to get a lock on a locked object before issuing a locked object exception. A value of minus one (-1) means wait indefinitely.</td>
</tr>
<tr>
<td>log or logfile file specification</td>
<td>console</td>
<td>Specifies the file specification of the log file for this server. If trace is enabled, the trace messages will be written to this file instead of the console. By default, trace messages will be written to the console.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>maxclients</td>
<td>max_num_of_clients</td>
<td>Specifies the maximum number of concurrent clients this server instance may handle.</td>
</tr>
<tr>
<td></td>
<td>-1</td>
<td>A value of minus one (-1) means allow an unlimited number of clients.</td>
</tr>
<tr>
<td>maxtries</td>
<td>max_num_of_lock_attempts</td>
<td>Specifies the maximum number of times to try to get a record lock.</td>
</tr>
<tr>
<td></td>
<td>10</td>
<td>This switch, used in conjunction with lockwait and trywait, specifies how often and how long to try to get a lock on a locked object before issuing a locked object exception.</td>
</tr>
<tr>
<td>name</td>
<td>server_name</td>
<td>Specifies a name for this server instance. This name need not be unique; however the name may be used to lookup server information within the start-up configuration file.</td>
</tr>
<tr>
<td></td>
<td>see description</td>
<td>The value of this name is not case-sensitive. If not specified, a name will be created for the server based on the server type.</td>
</tr>
<tr>
<td>p or port</td>
<td>port_num</td>
<td>Tells the server to listen on port port_num.</td>
</tr>
<tr>
<td>pw or password</td>
<td>default_user_password</td>
<td>Used in conjunction with the user and anonymous switches, provides the password to use on an anonymous connection</td>
</tr>
<tr>
<td>persona</td>
<td>username</td>
<td>Specifies the Operating system username, which the process running the server will assume.</td>
</tr>
<tr>
<td></td>
<td>none</td>
<td>If not specified, persona will not be used. See Persona for more details.</td>
</tr>
<tr>
<td>relay</td>
<td>false</td>
<td>If specified true, designates that this server should relay poll requests to all active servers in its network community.</td>
</tr>
<tr>
<td>restrictAccess</td>
<td>false</td>
<td>Used in conjunction with allow, deny and other options to restrict access to designated databases, users and operations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This option should only be used within an XML formatted configuration file. See Restricting Server, Database and Operational Access for more details.</td>
</tr>
<tr>
<td>restrictSQL</td>
<td>sql_verb_list</td>
<td>Used to restrict allowable SQL statements to only those that start with the one of the verbs specified in the comma – separated verb list.</td>
</tr>
<tr>
<td></td>
<td>none</td>
<td>This option should only be used within an XML formatted configuration file. See Restricting SQL Statements for more details.</td>
</tr>
<tr>
<td>retainRdbSQLState</td>
<td>false</td>
<td>Since release 7.3.2.0.0 If specified true, designates that this server should retain the SQLState values returned by Rdb and pass them unchanged to the client. The default behaviour is to alter the SQLState values returned under some circumstances, to a generic “S1000” state.</td>
</tr>
<tr>
<td>srv.bindTimeout</td>
<td>timeout</td>
<td>Sets the timeout, in milliseconds, on waiting for a database connection to complete. If the database fails to connect within this time, an exception will be raised.</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td>A value of zero (0) means unlimited timeout.</td>
</tr>
<tr>
<td>srv.cliStartup</td>
<td>file_specification</td>
<td>Specifies the start-up batch or command file that will be used to execute any CLI statements the server issues.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If not specified, edb$jdbc_home:rdbjdbc_execcli.com will be used. See Server Command Procedures for more details.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>srv.idleTimeout timeout</td>
<td>0</td>
<td>Sets the maximum time, in milliseconds, the server will wait for a new client connection request. If no new connection is made within the timeout period, the server will be closed down due to inactivity. A value of zero (0) means unlimited idle time allowed. See Server Inactivity Timeout for more details.</td>
</tr>
<tr>
<td>srv.mcBasePort base_port</td>
<td>5517</td>
<td>Specifies the base port number that will be used for multicast operations. A value of zero (0) will disable multicast operations.</td>
</tr>
<tr>
<td>srv.mcGroupIP group_ip</td>
<td>239.192.1.1</td>
<td>Specifies the multicast IP group within which this server will participate.</td>
</tr>
<tr>
<td>srv.networkKeepAlive</td>
<td>false</td>
<td>If specified true, the socket used to connect to the client will have SoKeepAlive enabled. See your socket documentation for more information on SoKeepAlive (TCP option SO_KEEPALIVE).</td>
</tr>
<tr>
<td>srv.onStartCmd command</td>
<td>none</td>
<td>Specifies a DCL command statement that should be executed prior to starting up a server. The specified command will only be executed if the server is started using the controller or by a Pool server. See On Start Commands for more details.</td>
</tr>
<tr>
<td>srv.password server_password</td>
<td>none</td>
<td>Specifies an additional password that clients need to provide before they may use the server for database connections. See Further server access protection for more details.</td>
</tr>
<tr>
<td>srv.showPoll</td>
<td>false</td>
<td>If specified true, information about POLL requests received should be traced, if server action tracing has been enabled. See Trace for further information.</td>
</tr>
</tbody>
</table>
| srv.startup file_specification | see description | Specifies the start-up batch or command file that will be used by the controller to start the process for this server. If not specified, 
\[rdbjdk_home\]:\rdbjdbc_startsrv.com will be used. See Server Command Procedures for more details. |
| tl or tracelevel trace_level | 0       | Sets the trace level for debugging purposes. See Trace for further information. |
| transaction transaction_option | none  | Since release 7.3.4.0.4 Specifies the default transaction behaviour for all connections using this server. The value autofetch is the only transaction option recognized and specifies that transactions should be auto-committed when the server sends FETCHSIZE groups of records back to the client. See the section Default Transaction for more information on the autofetch transaction option. |
| tracelocal                   | false   | If specified true, only local server base tracing should be enabled. If this option is set, any tracelevel values specified by a client connection will not affect the trace level of the server components. |
| trywait wait_time            | 10      | Specifies the time in milliseconds to wait between lock tries. This switch, used in conjunction with mastries and lockwait, specifies how often
Table 4.1: Server Configuration Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type server_type</td>
<td>RdbThinSrv</td>
<td>Specifies the server type of this server. Valid values are:</td>
</tr>
<tr>
<td>u or user default_user_name</td>
<td>none</td>
<td>Used in conjunction with the password and anonymous switches, provides the username to use on an anonymous connection.</td>
</tr>
<tr>
<td>url connection_URL</td>
<td>none</td>
<td>Specifies the node IP and port this server will run on. This switch overrides any port switch. The format of the &lt;connection URL&gt; is //&lt;node&gt;:&lt;port&gt;/</td>
</tr>
</tbody>
</table>

The following server configuration options may only be used in XML-formatted configuration:

<allow database="database-name"/>

Specifies the name of a database to which this server will allow access. This is used in conjunction with the restrictAccess option. The named database should also be described in the same configuration file. A separate allowDatabase option should be used for each database to which this server will allow access. Note: this form of the allow database option is only available release 7.3.2.0.0 Oracle JDBC for Rdb and later. See Restricting Database Access for more details.

<allow IP="ip-mask"/>

Specifies the IPs this server will allow access from. This is used in conjunction with the restrictAccess option. A separate allowIP option should be used for each IP or IP group from which this server will allow access. Note: The allow IP option is only available option is only available release 7.3.2.0.0 Oracle JDBC for Rdb and later. See Restricting IP Access for more details.

<allow privuser="user-name"/>

Specifies the usernames to which this server will allow special access. This is used in conjunction with options such as the allowAccessToCL option. A separate allowPrivUser option should be used for each username to which this server will allow special access to. Note: this form of the allow privuser option is only available release 7.3.2.0.0 Oracle JDBC for Rdb and later.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;allow user=&quot;user-name&quot;&gt; none</td>
<td>Specifies the usernames to which this server will allow database access. This is used in conjunction with the restrictAccess option. A separate allowUser option should be used for each user to which this server will allow database access. This option should only be used within an XML formatted configuration file. Note: this form of the allow user option is only available release 7.3.2.0.0 Oracle JDBC for Rdb and later. See Restricting User Access for more details.</td>
<td></td>
</tr>
<tr>
<td>&lt;allowDatabase name=&quot;database-name&quot;&gt; none</td>
<td>Specifies the name of a database to which this server will allow access. This is used in conjunction with the restrictAccess option. The named database should also be described in the same configuration file. A separate allowDatabase option should be used for each database to which this server will allow access. See Restricting Database Access for more details.</td>
<td></td>
</tr>
<tr>
<td>&lt;allowIP IP=&quot;ip-mask&quot;&gt; none</td>
<td>Specifies the IPs this server will allow access from. This is used in conjunction with the restrictAccess option. A separate allowIP option should be used for each IP or IP group from which this server will allow access. Note: The allow IP option is only available release 7.3.2.0.0 Oracle JDBC for Rdb and later. See Restricting IP Access for more details.</td>
<td></td>
</tr>
<tr>
<td>&lt;allowPrivUser name=&quot;user-name&quot;&gt; none</td>
<td>Specifies the usernames to which this server will allow special access. This is used in conjunction with options such as the allowAccessToCL option. A separate allowPrivUser option should be used for each username to which this server will allow special access to. See Privileged Users for more details.</td>
<td></td>
</tr>
<tr>
<td>&lt;allowUser name=&quot;user-name&quot;&gt; none</td>
<td>Specifies the usernames to which this server will allow database access. This is used in conjunction with the restrictAccess option. A separate allowUser option should be used for each user to which this server will allow database access. This option should only be used within an XML formatted configuration file. See Restricting User Access for more details.</td>
<td></td>
</tr>
<tr>
<td>&lt;deny IP=&quot;ip-mask&quot;&gt; none</td>
<td>Specifies the IPs from which this server will deny access. This is used in conjunction with the restrictAccess option. Since release 7.3.2.0.0</td>
<td></td>
</tr>
</tbody>
</table>
### 4.2 Multi-Process Server Configuration Options

In addition to the options shown in Server Configuration Options, the following configuration options may be used on the command line or in configuration files in conjunction with multi-process servers:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxFreeExecutors</td>
<td>0</td>
<td>Specifies the maximum number of free (unused) executor processes that may be maintained while the server is running.</td>
</tr>
<tr>
<td>minFreeExecutors</td>
<td>0</td>
<td>Specifies the minimum number of free (unused) executor processes that should be maintained during executor cleanup due to excess idle time, or when the executor reuse is set to “none”.</td>
</tr>
<tr>
<td>prestartedExecutors</td>
<td>0</td>
<td>Specifies the number of executor process to start up when the multi-process server starts.</td>
</tr>
</tbody>
</table>

See Multi-Process Server Configuration Options for additional options that may be used with multi-process servers.

See Pool Server Configuration Options for the options that may be used with Pool servers.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sharedMem size_in_KB</td>
<td>1024</td>
<td>Specifies the amount of global shared memory (in KB) that should be allocated by the server.</td>
</tr>
<tr>
<td>srv.execPrefix prefix</td>
<td>see description</td>
<td>Specifies the prefix to use for executor names. If not specified, a standard prefix based on server name will be used. See Executor Naming for more details.</td>
</tr>
<tr>
<td>srv.execStartup file_specification</td>
<td>see description</td>
<td>Specifies the start-up batch or command file that will be used to start the subprocess for each client connection. If not specified, rdb$jdbc_home:rdbjdbc_startexec.com will be used. See Server Command Procedures for more details.</td>
</tr>
<tr>
<td>srv.execBalance balance</td>
<td>0</td>
<td>Since release 7.3.2.0.0 Sets the executor balancing to be used. A value of zero (0) means FIFO. See Executor Balancing for more details.</td>
</tr>
<tr>
<td>srv.execReuse reuse</td>
<td>0</td>
<td>Since release 7.3.2.0.0 Sets the executor reuse to be used. A value of zero (0) means “Serial” reuse. See Executor Reuse for more details.</td>
</tr>
<tr>
<td>srv.execTimeout timeout</td>
<td>0</td>
<td>Sets the timeout, in milliseconds, that an unused executor process can remain idle in the free executor queue before being terminated. A value of zero (0) means unlimited timeout.</td>
</tr>
<tr>
<td>srv.lostExecSweep wait_time</td>
<td>30000</td>
<td>Since release 7.3.1.0.0 Specifies the time, in milliseconds, to wait before checking for lost executor processes again. The default is 30 seconds. A value of zero (0) will disable lost executor sweeps.</td>
</tr>
<tr>
<td>srv.mpMaxTries maximum_tries</td>
<td>500</td>
<td>Specifies the number of times the server should try to synchronize handshake with executor before giving up.</td>
</tr>
<tr>
<td>srv.mpTryWait wait_time</td>
<td>10</td>
<td>Specifies the time in milliseconds to wait between server/executor handshake synchronization tries.</td>
</tr>
<tr>
<td>srv.onExecStartCmd command</td>
<td>none</td>
<td>Specifies a DCL command statement that should be executed prior to starting up an executor. See On Start Commands for more details.</td>
</tr>
<tr>
<td>srv.usecreprc</td>
<td>false</td>
<td>Since release 7.3.4.1.2 If true, JDBC will use SYS$CREPRC to create processes as detached. If false (the default), JDBC will use internal JAVA methods to create subprocesses. See Executor Process Startup for more details.</td>
</tr>
</tbody>
</table>

See Executor Maintenance for more information on executor housekeeping carried out by the multi-process server.

### 4.3 Pool Server Configuration Options

The valid configuration options that may be used with a Pool server can be found in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cfg or configfile configuration_filename</td>
<td>none</td>
<td>The file specification of a configuration file where server attributes may be found.</td>
</tr>
</tbody>
</table>
Attributes set in this configuration file may be overridden by setting the same attribute at the command line level.

If the file extension is XML, the configuration parameters are held in a XML format.

By default no configuration file is used. See Configuration Files for more details.

controlpass control_password none

Specifies the password that control users must use to be able to issue control commands on this server instance.

log or logfile file_specification console

Specifies the file specification of the log file for this server. If trace is enabled, the trace messages will be written to this file instead of the console.

By default trace messages will be written to the console.

node node none

Specifies the node on which the thin server number <n> resides.

This option is not valid for use in XML-formatted configuration files.

poolserver none

Specifies that the server should act as a Pool server.

This is a mandatory option if used on the command line or a non-XML formatted configuration file.

poolsize pool_size none

Specifies the number of thin servers that will be specified.

This is a mandatory option if used on the command line or a non-XML formatted configuration file.

port port_num none

Specifies the port for the thin server number <n> in server list.

This option is not valid for use in XML-formatted configuration files.

p or port port_num

Tells the Pool server to listen on port port_num.

srv.balance balance_type or balance_keyword Default

Specifies the server pool balancing to use. The option value may be a numeric literal or a keyword.

See Server Pool Balancing for more details.

srv.keepAliveTimer seconds 60

Sets the time, in seconds, of the duration between Pool server checks for non-running pooled servers that have autoRestart enabled.

See Oracle JDBC for Rdb Pool Server for more details.

crv.mcBasePort base_port 5517

Specifies the base port number that will be used for multicast operations.

A value of zero (0) will disable multicast operations.

crv.mcGroupIP group_ip 239.192.1.1

Specifies the multicast IP group within which this server will participate.

crv.password server_password none

Specifies an additional password that clients need to provide before they may use the server for database connections.

See Further server access protection for more details.

crv.useLogicalIPs true

Only Valid for Pool servers.

Specifies that the server should not translate named IP values to IP addresses.
The valid configuration options that may be used in conjunction with a Pool server, and used only within an XML-formatted configuration file, can be found in the following table:

Table 4.3 - Pool Server Configuration Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>pooledservername</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As there may be a number of servers listed in the server pool, Oracle advises to use the configuration file to specify these options.

If you are using a standard configuration file, the number of servers in the pool is specified by the poolsize option. In the case of an XML-formatted configuration file, the number of servers in the pool will be the same as the number of PooledServer subsections within the server definition.

Each server participating in the pool must have both a node and a port id specified for it.

See Configuration Files for examples of configuring a Pool server.

### 4.4 Manager Server Configuration Options

The valid configuration options that may be used with a manager server can be found in the following table:

Table 4.4 - Manager Server Configuration Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>cfg or configfile</td>
<td>none</td>
</tr>
<tr>
<td>configuration_filename</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>controlpass</td>
<td>none</td>
</tr>
<tr>
<td>control_password</td>
<td></td>
</tr>
<tr>
<td>log or logfile</td>
<td>console</td>
</tr>
<tr>
<td>file_specification</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

See Configuration Files for more information on this password.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p or port ( port_num )</td>
<td>1701</td>
<td>Tells the server to listen on port ( port_num ).</td>
</tr>
<tr>
<td>srv.keepAliveTimer ( seconds )</td>
<td>60</td>
<td>Sets the time, in seconds, of the duration between manager server checks for non-runners that have autoRestart enabled. See Oracle JDBC for Rdb Manager Server for more details.</td>
</tr>
<tr>
<td>srv.keepAliveWait ( seconds )</td>
<td>60</td>
<td>Sets the time, in seconds, the manager server will wait for a newly started server to confirm it has started correctly, before raising a failed server event. See Oracle JDBC for Rdb Manager Server for more details.</td>
</tr>
<tr>
<td>srv.mcBasePort ( base_port )</td>
<td>5517</td>
<td>Specifies the base port number that will be used for multicast operations. A value of zero (0) will disable multicast operations.</td>
</tr>
<tr>
<td>srv.mcGroupIP ( group_ip )</td>
<td>239.192.1.1</td>
<td>Specifies the multicast IP group within which this server will participate.</td>
</tr>
<tr>
<td>tl or tracelevel ( trace_level )</td>
<td>0</td>
<td>Sets the trace level for debugging purposes. See Trace for further information.</td>
</tr>
</tbody>
</table>
| type \( server\_type \)  | RdbManSrv | Specifies the server type of this server. Valid values are:  
  • RdbManSrv - Manager server.  
  • RdbManSrvSSL - Manager server using SSL for communication. |
| url \( connection\_URL \)  | none    | Specifies the node IP and port this server will run on. This switch overrides any \( port\) switch. |

See Configuration Files for examples of configuring a manager server.

### 4.5 Configuration Files

Instead of setting the switches on the command line, you can specify a configuration file that details the settings.

Two formats of configuration files are recognized:

- Standard Java Properties load file
- XML-formatted file

#### 4.5.1 Standard Properties File

The following section describes the use of configuration file formatted as a standard Java Properties load file. See XML Formatted Configuration File for details on using an XML-formatted configuration file.

Most of the server configuration options as specified in configuration options tables can be used but with the following changes:

- Each keyword requires a value, even those that do not have values on the command-line; these options are considered Booleans and thus should have the appropriate \texttt{true} value.
- Each keyword must be separated from its value by an equals sign (=)

The \texttt{–cfg} switch on the command line allows you to specify the file specification of this configuration file:

```
$java –jar rdb$jdbc_home:rdbthinsrv.jar –cfg thinsrv.cfg
```

**Example**

Java style comments and empty lines may be included in the file, for example:

```
// configuration file for our thin server

// the default port for the thin server is 1701 but we
// want it to listen on another port
```
In addition, the configuration file for a Pool server should contain information about the list of servers to which it may delegate connection requests, for example:

```xml
<config>
    // configuration file for Pool server
    // the default port for the Pool server is 1702
    port=1702
    // show is a Pool server and the poolsize
    // (number of subservient servers)
    poolserver=true
    poolsize=4
    // now add the servers
    node1=MYNODE1
    port1=1704
    node2=MYNODE1
    port2=1705
    node3=MYNODE1
    port3=1706
    node4=MYNODE2
    port4=1704
</config>
```

### 4.5.2 XML-Formatted Configuration File

Instead of setting the switches on the command line, you can specify an XML-formatted configuration file that details the settings of these switches. The XML-formatted configuration file allows a greater number of configuration options to be specified than the standard CFG file and is the recommended configuration file format.

The XML-formatted configuration file differs from the standard CFG file in that it may contain information about multiple servers in the same configuration file. Each server is specified within a separate server section and must be given a unique name. This name is used to get default configuration information about the server on server start-up, as well as how a server may be identified on your system and within the controller interface.

The `-cfg` switch on the command line allows you to specify the file specification of this file.

The server configuration options as specified in configuration options tables can be used but with the following changes:

- Each keyword requires a value, even those that do not have values on the command line. These options are considered Boolean values and thus should have the appropriate `true` value.
- Each keyword must be separated from its value by an equals sign (=).
- All option values must be enclosed in double quotation marks.

The configuration document is a hierarchical XML object. Each keyword must be placed within its appropriate section or subsection.

Multiple servers may be specified within the same configuration file but each server must have a unique name.

The format of the contents of the configuration file is XML V1.0.

**Format**

```
$java ... -cfg <config file>.xml
```

**Example**

```
<?xml version = "1.0"?>
<!--Configuration file for Rdb Thin JDBC Drivers and Servers -->
<config>
```
<SERVRS><!--
<DEFAULT server characteristics-->  
<server  
    name="DEFAULT"  
    type="RdbThinSrv"  
    url="/\047localhost:1701/"  
    maxClients="-1"  
    srv.bindTimeout="1000"  
    srv.idleTimeout="0"  
    srv.mcBasePort="5517"  
    srv.mcGroupId="239.192.1.1"  
    tracelevel = "0"

    url="/\047localhost:1705/"  
    autoStart="true"  
    maxClients="10"  
    maxFreeExecutors="10"  
    prestartedExecutors="10"  
    sharedMem="10240" />  

<server  
    name="rdbpool"  
    type="RdbThinSrvPool"  
    url="/\047localhost:1702/" />  

<server  
    name="srvssl1forRdb"  
    type="RdbThinSrvSSL"  
    url="/\047localhost:1709/" />  

<server  
    name="rdbman"  
    type="RdbManSrv"  
    url="/\047localhost:2060/" />
-->
The XML-formatted configuration file is an XML document that is composed of several sections and sub-sections.

Description of the sections and sub-sections within an XML-formatted configuration file is now presented:

- Config Section
- Session Section
- Databases Section
- Database Section
- Events Section
- Event Section
- Servers Section
- Server Section
- Pooled Server Subsection
- Allow Database Subsection
- Allow IP Subsection
- Allow User Subsection
- EnableEvents Subsection
- Deny IP Subsection
- Deny SQL Subsection

4.5.2.1 Config Section

This section covers the entire configuration settings and contains the specific configuration sections as described below.

Format

```
<config>
  [ session section ]
  [ databases section ]
  [ servers section ]
  [ events section ]
<config>
```

4.5.2.2 Session Section

This section describes session characteristics for an interactive session. Information within the session section is currently only used by the Oracle JDBC for Rdb controller. You can specify information such as passwords and user names that may be used when you start up a controller session.

If it exists, the session named DEFAULT will be used to setup the default session characteristics.

These session properties provide an alternate way of specifying options you may have otherwise supplied on the command line during controller startup.

Format

```
<session
  [ session property ]...
/
```

Options

Valid properties for the session section can be seen in the following table:

<table>
<thead>
<tr>
<th>Table 4.5-1: Session Section Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option</strong></td>
</tr>
<tr>
<td>controlPass</td>
</tr>
</tbody>
</table>

Note: This password can be a plain-text or obfuscated password created using the obfuscate command. You should not use an obfuscated password created using the digest command, as the server will not recognize the password.
<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlUser</td>
<td>none</td>
<td>User name to use on control connections.</td>
</tr>
<tr>
<td>password</td>
<td>none</td>
<td>Currently this has the same function as controlPass, however if both are present, controlPass will take precedence.</td>
</tr>
</tbody>
</table>

**Note:** This password can be a plain-text or obfuscated password created using the `obfuscate` command.

You should not use an obfuscated password created using the `digest` command as the server will not recognize the password.

See [Password Obfuscation in Server Configuration Files](#) for more details.

<table>
<thead>
<tr>
<th>option</th>
<th>default</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Name for this session description; must be <code>DEFAULT</code>.</td>
</tr>
<tr>
<td>user</td>
<td>none</td>
<td>User name to use on connection.</td>
</tr>
<tr>
<td>tracelevel</td>
<td>0</td>
<td>The sessions default trace level.</td>
</tr>
<tr>
<td>srv.mcBasePort</td>
<td>5517</td>
<td>Specifies the base port number that will be used for multicast operations.</td>
</tr>
<tr>
<td>srv.mcGroupIP</td>
<td>239.192.1.1</td>
<td>Specifies the multicast IP group that will be used for multicast operations.</td>
</tr>
<tr>
<td>ssl.*</td>
<td>none</td>
<td>Specifies SSL configuration information for the session that may be used to connect to SSL-enabled thin servers. See <a href="#">Using SSL</a> for more information.</td>
</tr>
</tbody>
</table>

**Example**

```xml
<session
    name="DEFAULT"
    controlPass="jdbc_control"
    user="jdbc_user"
    password="jdbc_control"
    srv.mcBasePort="5517"
    srv.mcGroupIP="239.192.1.1"
/>```

**Note:**

1. The session properties `srv.mcBasePort` and `srv.mcGroupIP` specify the multicast attributes that should be used for polling servers. Only those servers participating in the specified multicast group will respond to any poll requests issued by the controller.
2. Although the user and control passwords may be stored in plain-text format in the configuration file as shown in the example above, this may be contrary to your organization's security policy. Oracle recommends not to store plain-text passwords in your configuration files, instead the appropriate command line switches should be used to provide the password.
3. User passwords and control passwords used within the session section of the configuration file may be stored as obfuscated values created using the `Obfuscate` command. Control passwords associated with servers may also be specified in the server section of the configuration file as obfuscated values created using the `Digest` command.

### 4.5.2.3 Databases Section

This section specifies one or more database sections.

**Format**

```xml
<databases>
    [ database section ]...
</databases>```

### 4.5.2.4 Database Section

This section specifies a named database with the given properties.

**Format**

```xml
<database>
    [ database property ]...
</database>```
Valid properties for the database section can be seen in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>The name by which the Oracle JDBC for Rdb drivers may recognize this database. This name is required and must be unique within the databases section of this configuration file.</td>
</tr>
<tr>
<td>url</td>
<td>none</td>
<td>The url that may be used to access this database.</td>
</tr>
<tr>
<td>driver</td>
<td>none</td>
<td>The class path of the preferred JDBC driver that may be used to access this database.</td>
</tr>
<tr>
<td>URLPrefix</td>
<td>none</td>
<td>The prefix that needs to be added to the url above to provide a complete JDBC Connection URL.</td>
</tr>
</tbody>
</table>

4.5.2.5 Events Section
Since release 7.3.1.0.0

This section specifies one or more event sections.

Format

```
<events>
  [ event section ]...
</events>
```

4.5.2.6 Event Section

This section specifies a named event with the given properties.

Format

```
<event>
  [ event property ]...
</event>
```

Options

Valid properties for the event section can be seen in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>The name by which the Oracle JDBC for Rdb servers may recognize this event. This name is required and must be unique within the events section of this configuration file.</td>
</tr>
<tr>
<td>type</td>
<td>none</td>
<td>The type or category of the event. See Event criteria for more details.</td>
</tr>
<tr>
<td>watch</td>
<td>none</td>
<td>The criteria that should be watched. The watch criteria depends on the event type. See Event criteria for more details.</td>
</tr>
<tr>
<td>pattern</td>
<td>none</td>
<td>The pattern that should be used to filter the event watch criteria. The pattern is a Java regular expression that will be used to match the watched criteria. See Event criteria for more details.</td>
</tr>
<tr>
<td>threshold</td>
<td>Max</td>
<td>The actual value that has to be met, exceeded, or near to trigger a threshold event. See Event criteria for more details.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>deviation</td>
<td>none</td>
<td>The allowed deviation that the watched criteria can have before the event will be triggered. See Event criteria for more details.</td>
</tr>
<tr>
<td>testFor</td>
<td>none</td>
<td>Criteria condition to test for. See Event criteria for more details.</td>
</tr>
<tr>
<td>message</td>
<td>none</td>
<td>This is the customized message that will be logged when this event is triggered.</td>
</tr>
</tbody>
</table>

Example

```xml
<!–Rdb events -->
<events>
  <event
    name = "NO_TABLE"
    type = "EXCEPTION"
    watch = "SYSERROR"
    pattern = ".*RELNOTDEF.*"
    message = "Problem with table " />
  <event
    name = "Near Max"
    type = "THRESHOLD"
    watch = "NUMUSERS"
    deviation="-3"
    message = "The number of users nearing maximum allowed"
  />
</events>
```

Details on using the various event properties may be found in Defining and Enabling Events.

4.5.2.7 Servers Section

This section specifies one or more server property sections.

Format

```xml
<servers>
  [ server section ]...
</servers>
```

4.5.2.8 Server Section

This section specifies one or more properties to assign to this server. See Server Configuration for details on the properties that may be set.

Format

```xml
<server
  <property="value"/>

or

<server
  <property="value"/>
  [ pooled server subsection ]...
  [ allow database subsection ]...
  [ allow IP subsection ]...
  [ allow user subsection ]...
  [ enabled event subsection ]...
  [ deny IP subsection ]...
  [ deny SQL subsection ]...
</server>
```

Example 1

A standard thin server called serv1 listening on port 1799 could be described using the following Server Property section:

```xml
<server
  name="serv1"
  type="RdbThinSrv"
  url="//localhost:1799/"
  logfile="myLogs:serv1.log"
/>
```

Remarks

Default server characteristics for server configuration can be specified so that options need not be repeated within the specific server configuration sections. Default server options may be specified by declaring a server section with a name of DEFAULT or DEFAULTSSL:
name="DEFAULT"
type="RdbThinSrv"
url="/localhost:1701/"
maxClients="-1"
srv.bindTimeout="0"
srv.idleTimeout="0"
srv.mcBasePort="5517"
srv.mcGroupIP="239.1.1.1"
autoStart="false"
controlUser="jdbc_user"
controlPass="0x811B15F866179583EB3C96751585B843"

The DEFAULT and DEFAULTSSL server definitions should only be used to define the default server characteristics and are not intended to represent actual server instances that can be started by the controller or Pool servers.

These default server properties will be assigned to each server found defined after them in the configuration file unless explicitly overridden in the specific server subsection.

The placement of the DEFAULT and DEFAULTSSL server sections within the configuration file is important. Only those servers defined in sections that occur after these default definitions will have these default characteristics. Any server section specified prior to the default server sections will not get these default characteristics. Oracle recommends that these two sections be the first two server sections within your configuration file.

If subsections such as Pooled Server or Allowed Database are required, then the second format for a Server section must be used.

Example 2

```
<server
    name="rdbpool"
    type="RdbThinSrvPool"
    url="/localhost:1702/"
>
    <pooledServer name="srv1forRdb"/>
    <pooledServer name="srv2forRdb"/>
    <pooledServer name="srvMPforRdb"/>
</server>
```

4.5.2.9 Pooled Server Subsection

This subsection specifies a server that will take part in the Pool server's server pool, and is valid only when used within an RdbThinSrvPool server declaration. The declared server name must reference a server already named in this configuration file. Multiple PooledServer subsections may be present in a single server declaration. The set of pooledServers provided will make up the pool of servers that the Pool server may try to access.

Format

```
<pooledServer name="declared server"/>
```

Example

```
<server
    name="rdbpool"
    type="RdbThinSrvPool"
    url="/localhost:1702/"
>
    <pooledServer name="srv1forRdb"/>
    <pooledServer name="srv2forRdb"/>
    <pooledServer name="srvMPforRdb"/>
</server>
```

4.5.2.10 Allow Database Subsection

This subsection specifies the database that clients using the server may access, and is only valid when used within a server declaration. The declared database name must either reference a database already named in the database section of this configuration file, or must be a valid database file specification or logical name. Multiple AllowDatabase subsections may be present in a single server declaration. For database access to be restricted the server attribute restrictAccess must be set to true. See the section Restricting Database Access for more details.

Format

```
<allowDatabase name="db specification"/>
```

Alternatively, from release 7.3.2.0.0 onwards:
Example

<server>
    <allowDatabase name="mf_pers"/>
    <allowDatabase name="disk1:[databases]customers"/>
</server>

4.5.2.11  Allow IP Subsection

Since release 7.3.2.0.0

This subsection specifies the IPs that may be allowed to access this server, and is only valid when used within a server declaration.

The declared IP must be a valid IPv4 dot-decimal formatted IP string, or a Java regular expression based on the same standard IPv4 dot-decimal notation.

Multiple AllowIP subsections may be present in a single server declaration.

For IP access to be restricted the server attribute restrictAccess must be set to true.

This feature is only available when using Oracle JDBC for Rdb release 7.3.2.0.0 and later.

See the section Restricting IP Access for more details.

Format

<allowIP IP="IP allowed" />

or

<allow IP="IP allowed" />

Example

<server>
    <allow IP ="170.0.0.1"/>
    <allow IP ="170\0.0.0.1.(5-7][8-9])"/>
</server>

4.5.2.12  Allow User Subsection

This subsection specifies the usernames the server will allow access to, and is only valid when used within a server declaration.

The declared username must be a valid username recognized by Rdb. The matching of usernames by the server for this level of restriction is not case-sensitive.

Multiple AllowUser subsections may be present in a single server declaration.

For user access to be restricted the server attribute restrictAccess must be set to true.

See the section Restricting User Access for more details.

Format

<allowUser name="username" />

Alternatively, from release 7.3.2.0.0 onwards:

Format

<allow user="username" />

Example

<server>
    <allowUser name="smith"/>
    <allowUser name="jones"/>
</server>
### 4.5.2.13 EnableEvents Subsection

*Since release 7.3.1.0.0*

This subsection specifies the events the server should log, and is only valid when used within a server declaration.

Multiple enableEvent subsections may be present in a single server declaration.

See Event Logging and Notification for more details.

**Format**

```
<enableEvent name="event name" />
```

**Example**

```
<server
    name="srv2"
    type="RdbThinSrv"
    url="/localhost:1701/"
>
    <enableEvent name="BAD_TABLE"/>
    <enableEvent name="DENIED_SQL"/>
</server>
```

The name provided in the enableEvent must match a valid Event specified in the Events Section of the same configuration file.

### 4.5.2.14 Deny IP Subsection

*Since release 7.3.2.0.0*

This subsection specifies the IPs that may be denied to access this server, and is only valid when used within a server declaration.

The declared IP must be a valid IPv4 dot-decimal formatted IP string, or a Java regular expression based on the same standard IPv4 dot-decimal notation.

Multiple DenyIP subsections may be present in a single server declaration.

For IP access to be restricted the server attribute restrictAccess must be set to `true`.

This feature is only available when using Oracle JDBC for Rdb release 7.3.2.0.0 and later.

See the section Restricting IP Access for more details.

**Format**

```
<denyIP IP="IP denied" />
```

**Example**

```
<server
    name="srv2restrict"
    type="RdbThinSrv"
    url="/localhost:1701/"
    restrictAccess="true"
>
    <deny IP="170.0.0.1"/>
    <deny IP="170.0.0.2"/>
</server>
```

### 4.5.2.15 Deny SQL Subsection

*Since release 7.3.1.0.0*

This subsection specifies the SQL statement that should be denied by the server, and is only valid when used within a server declaration.

Multiple Deny subsections may be present in a single server declaration.

See Restricting SQL Statements for more details.

**Format**

```
<deny SQL="sql pattern" />
```

**Example**

```
<server
    name="srv2"
    type="RdbThinSrv"
    url="/localhost:1701/"
>
    <deny SQL =" (?i).*select.*jobs.* ">
</server>
```
4.5.3 Using filenames in the configuration file

A number of attributes within the configuration file sections require the specification of a filename, for example:

- `cfg=<filename>`
- `log=<filename>`
- `srv.execStartup=<filename>`
- `srv.startup=<filename>`

The filename must be a valid OpenVMS file specification that may contain a full or partial file path and may include logical names.

You must ensure that, if logical names are used, they are available to the context within which the server will be started, and that the file is accessible by the VMS user that starts up the server.

If a server defined in the configuration will be started up using the controller, as a pooled server by a Pool server, or by Oracle SQL/Services, a detached process will be created for the server and the `LOGINOUT.EXE` will be run to ensure a valid process environment under which Java and Oracle Rdb can be accessed.

Because the `LOGINOUT.EXE` program is run, any file specification using relative file paths must be relative to the login directory of the invoker, otherwise a full file specification must be used.

Contents
Secure Sockets Layer (SSL) was developed to provide security for Web traffic, including confidentiality, message integrity, and authentication. SSL achieves this through the use of cryptography, digital signatures, and certificates.

Oracle JDBC for Rdb servers and thin clients may use SSL for communication over TCP/IP. SSL allows an SSL-enabled server to authenticate itself to an SSL-enabled client, allows the client to authenticate itself to the server, and allows both machines to establish an encrypted connection.

Before trying to use SSL with the thin driver, you should familiarize yourself with general Java security and SSL concepts. Please refer to your Java documentation for general information on SSL and Java Security.

The following sections provide SSL information specific to using SSL with the thin driver and assume a basic understanding of Java Security and SSL:

• SSL Configuration
• SSL and the Controller
• SSL Configuration Options

5.1 SSL Configuration

Information about SSL connection characteristics must be provided to both the client and server, and in order for a communication channel to be established, both the server and client must agree on the SSL security characteristics.

In addition, it is important that both the client and the server have the same security certificate for authorization. The following sections detail how to provide SSL characteristics in a client connection request and to an SSL-enabled Oracle JDBC for Rdb server:

• Client SSL Configuration
• Server SSL Configuration

5.1.1 Client SSL Configuration

The client application must specify its SSL characteristics during its connection request to the thin driver. The simplest way of doing this is by providing extra SSL information in the properties block that is passed to the DriverManager.getConnection() method.

The SSL information provides information such as where to find the appropriate certificate for SSL connections and what context and protocols should be used to carry out the SSL handshake during connection set-up.

Example 1

Properties info = new Properties();
info.put("user", user);
info.put("password", password);
info.put("tracelevel", traceLevel);
info.put("ssl", "true");
info.put("ssl.default", "false");
info.put("ssl.context", "TLS");
info.put("ssl.keyManagerFactory", "SunX509");
info.put("ssl.keyStoreType", "jks");
info.put("ssl.keyStore", "rdbjdbccli.kst");
info.put("ssl.keyStorePassword", "CHANGETHIS");
info.put("ssl.keyStorePassword", "CHANGETHIS");
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1755/my_db_dir:pers", info);

Remarks
The properties block must have the property ssl set to true for SSL connections to be attempted.

In addition, the SSL characteristics can be specified explicitly as properties, or you may use ssl.default set to true to request that the default SSL characteristics for your system should be used.

Example 2

Properties info = new Properties();
info.put("user", user);
info.put("password", password);
info.put("tracelevel", traceLevel);
info.put("ssl", "true");
info.put("ssl.default", "true");
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1755/my_db_dir:pers", info);

Remarks
See SSL configuration options for details of the ssl.* options.

For an SSL connection to be made, the appropriate certificate for the server to which you are trying to attach should be in the keystore you have designated in the SSL properties for the connection.
If no certificate is found the following exception will be raised:

javax.net.ssl.SSLException: No available certificate corresponds to the SSL cipher suites, which are enabled.

See your Java Security documentation for more information on certificates.

5.1.2 Server SSL Configuration

An SSL-enabled server must also be provided with SSL configuration information. This is usually provided within the server section for the named server in an XML-based configuration file.

To indicate that the server should be SSL-enabled, the server must be defined as one of the following SSL server types:

- RdbThinSrvSSL
- RdbThinSrvMPSSL
- RdbThinSrvPoolSSL
- RdbManSrvSSL

Example 1

```xml
<server
    name="MYSSL"
    type="RdbThinSrvSSL"
    ssl.default="false"
    ssl.context="TLS"
    ssl.keyManagerFactory="SunX509"
    ssl.keyStoreType="jks"
    ssl.keyStore="rdbjdbcsrv.kst"
    ssl.keyStorePassword="CHANGETHIS"
    ssl.trustStore="rdbjdbcsrv.kst"
    ssl.trustStorePassword="CHANGETHIS"
/>```

Remarks

If you wish to define a number of SSL-enabled servers with the same SSL characteristics, then you can use the special DEFAULTSSL server definition to define the default characteristics. Each subsequent server definition that has one of the SSL server types will use these characteristics, unless explicitly overridden in the server definition.

Example 2

```xml
<server
    name="DEFAULTSSL"
    type="RdbThinSrvSSL"
    ssl.default="false"
    ssl.context="TLS"
    ssl.keyManagerFactory="SunX509"
    ssl.keyStoreType="jks"
    ssl.keyStore="rdbjdbcsrv.kst"
    ssl.keyStorePassword="CHANGETHIS"
    ssl.trustStore="rdbjdbcsrv.kst"
    ssl.trustStorePassword="CHANGETHIS"
/>```

Remarks

If a Pool server is SSL-enabled, for security reasons it will only communicate with pooled servers within its pool that are also SSL-enabled. Non-SSL-enabled pooled servers within the pool will be ignored and will not be considered candidates for redirection of connection requests.

See SSL Configuration Options for details of these options.

5.2 SSL and the Controller

All connections made to SSL-enabled servers must be made using SSL connections. This also includes the controller.

If the controller will be used to manage SSL-enabled servers, then the controller session must also have the correct SSL information to make the secure connection to the server.
You can specify the SSL information that the controller uses for connecting to SSL-enabled thin servers by starting the controller using an XML-formatted configuration file that has the appropriate SSL information in its SESSION section.

Example

```xml
<session
  name="DEFAULT"
  controlPass="jdbc_user"
  user="cts1"
  password="jdbc_user"
  tracelevel="0"
  srv.mcBasePort="5518"
  srv.mcGroupIP="239.192.1.2"
  ssl.default="false"
  ssl.context="TLS"
  ssl.keyManagerFactory="SunX509"
  ssl.keyStoreType="jks"
  ssl.keyStore="rdbjdbccli.kst"
  ssl.keyStorePassword="CHANGETHIS"
  ssl.trustStore="rdbjdbccli.kst"
  ssl.trustStorePassword="CHANGETHIS"
/>
```

Remarks

This is the same SSL information that you would have provided for a client SSL configuration as described in Client SSL configuration.

If this information is provided, the controller will use the SSL configuration to connect to any server that responds to a poll request as an SSL-enabled server.

5.3 SSL Configuration Options

The various SSL configuration options that may be set can be found in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl.default</td>
<td>false</td>
<td>If specified, indicates that the default SSL socket factory should be used to create an SSL socket.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default SSL socket factory can be changed by setting the value of the &quot;ssl.ServerSocketFactory.provider&quot; security property (in the Java security properties file) to the desired class.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All other ssl.* configuration options will be ignored, if ssl.default is specified and set to true.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If ssl.default is not specified, or specified as false, then the values of the following ssl.* properties should be used to create an SSL socket factory.</td>
</tr>
<tr>
<td>ssl.context</td>
<td>none</td>
<td>Indicates the SSL context to use, for example &quot;TLS&quot;.</td>
</tr>
<tr>
<td>keyManagerFactory</td>
<td>none</td>
<td>Indicates the keymanager factory to use, for example &quot;SunX509&quot;.</td>
</tr>
<tr>
<td>keyStoreType</td>
<td>none</td>
<td>Indicates the type of the key store, for example &quot;:jks&quot;.</td>
</tr>
<tr>
<td>keyStore</td>
<td>none</td>
<td>Indicates the filename of the keystore.</td>
</tr>
<tr>
<td>keyStorePassword</td>
<td>none</td>
<td>Indicates the password for the keystore.</td>
</tr>
<tr>
<td>trustStore</td>
<td>none</td>
<td>Indicates the filename of the trust store.</td>
</tr>
<tr>
<td>trustStorePassword</td>
<td>none</td>
<td>Indicates the password of the trust store.</td>
</tr>
</tbody>
</table>

5.4 Using Self-Signed Certificates for Testing

The following code is an example that may be used to build and copy certificates that may be used for SSL communications where the client and server are on OpenVMS nodes that have Java environments already set up.

Note:

A copy of this code can be found in the JDBC installation directory within the file BUILD_CERTS_TEMPLATE.COM

Information such as the keystore and password should be changed appropriately for your own situation.

```bash
$! The following should be done on the Server node
$ write sys$output "Generating the Server KeyStore in file
rdbjdbcsrv.kst"
```
$ keytool -genkey -alias rdbjdbc-sv -dname "CN=Jim Murray, OU=Rdb Engineering, O=Oracle, c=US" -keypass "CHANGETHIS" -storepass "CHANGETHIS" -KeyStore rdbjdbcsrv.kst
$!
$write sys$output "Exporting the certificate from keystore to external file server.cer
$ keytool -export -alias rdbjdbc-sv -storepass "CHANGETHIS" -file server.cer -keystore rdbjdbcsrv.kst
$!
$write sys$output "Generating the Client KeyStore in file rdbjdbccli.kst
$ keytool -genkey -alias rdbjdbc-cl -dname "CN=Rdbjdbc Client, OU=X, O=Y, L=Z, S=XY, C=YZ" -keyalg RSA -keypass "CHANGETHIS" -storepass "CHANGETHIS" -keystore rdbjdbccli.kst
$!
$write sys$output "Exporting the certificate from keystore to external file client.cer
$ keytool -export -alias rdbjdbc-cl -storepass "CHANGETHIS" -file client.cer -keystore rdbjdbccli.kst
$!
$write sys$output "Importing Client’s certificate into Server’s keystore
$ keytool -import -v -trustcacerts -alias rdbjdbc -file client.cer -keystore rdbjdbcsrv.kst -keypass "CHANGETHIS" -storepass "CHANGETHIS" yes
$!
$write sys$output "Importing Server’s certificate into Client’s keystore
$ keytool -import -v -trustcacerts -alias rdbjdbc -file server.cer -keystore rdbjdbccli.kst -keypass "CHANGETHIS" -storepass "CHANGETHIS" yes

The keytool command should work as shown above on most operating systems that have Java installed.

Once the keystores have been set up, as long as you have setup the SSL properties correctly for the client and the server as shown in previous sections, you can use SSL for client/server communication within the thin driver.

**Note:** It is important to use double quotes to maintain values such as passwords exactly as you specify them in the server or client SSL connection configuration properties.
Chapter 6
Oracle JDBC for Rdb Controller

The Oracle JDBC for Rdb controller (here-on referred to as the controller) allows basic management of Oracle JDBC for Rdb servers.

Contained in the rdbthincontrol.jar file, this application allows local and remote password-protected server management operations to be carried out on a thin server or Pool server. These operations can include showing the clients that are currently connected, stopping client threads, and starting and stopping thin servers.

The controller can be run either in interactive mode or single command mode. In interactive mode you typically connect to the server you wish to manage and then issue the management requests. When you are finished using the controller, you can issue the exit command to terminate the image.

In single command mode, you provide command line switches to tell the controller what action has to be performed. When the action is complete, the controller image will terminate.

The controller is typically used in conjunction with an XML-formatted configuration file that provides information about the Oracle JDBC for Rdb servers running on your system.

In addition, the configuration file may provide session information such as the broadcast port information to use when doing poll operations. See Configuration Files for more information about configuration files.

The controller may be used to start and stop servers, as well as other operations pertaining to servers and connected clients. In addition, the controller may be used to show the current status of Oracle JDBC for Rdb servers running throughout your network.

Below is a sample session using the controller in interactive mode:

Example

rdbthincontrol> show stored servers
Stored server info
RDB$NODE : localhost
RDB$PORT : 1702
RDB$STATUS : not available
RDB$SERVER_NAME : SRV2
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : not available
RDB$SERVER_SHR_VERSION : not available
RDB$SERVER_PID : not available
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS : -1

RDB$NODE : localhost
RDB$PORT : 1701
RDB$STATUS : not available
RDB$SERVER_NAME : SRV1
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : not available
RDB$SERVER_SHR_VERSION : not available
RDB$SERVER_PID : not available
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS : -1
rdbthincontrol> start server srv1
Starting server ...
RDB$NODE : 138.1.14.91
RDB$PORT : 1701
RDB$STATUS : Idle
RDB$SERVER_NAME : srv1
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : T7.2-510 20070109 B719
RDB$SERVER_SHR_VERSION : T7.2-510 20061221 B6CL
RDB$SERVER_PID : 0x20238378(539198328)
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0

rdbthincontrol> start server srv1
Starting server ...
RDB$NODE : 138.1.14.91
RDB$PORT : 1701
RDB$STATUS : Idle
RDB$SERVER_NAME : srv1
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : T7.2-510 20070109 B719
RDB$SERVER_SHR_VERSION : T7.2-510 20061221 B6CL
RDB$SERVER_PID : 0x20238378(539198328)
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0

57
The following sections detail how to run the controller and carry out various server and client control functions on active servers within your network:

- Running the Controller
- Connecting to Servers
- Control Password
- Multicast Polling
- Server Matching
- Server Operations
- Client Operations

6.1 Running the Controller

The controller allows basic management of Oracle JDBC for Rdb servers. The controller can be run from the OpenVMS DCL command line either in single command mode or as a command line interface:

```
RDB$MAX_CLIENTS    : -1
RDB$TRACE_LEVEL    : 0
RDB$LOG_FILE       : rdbjdbclog
RDB$RESTRICT_ACCESS: false
rdbthincontrol> poll
Polling servers ... 
srv1(0) //138.1.14.91:1701/ (0x20238378<539198328>)
rdbthincontrol> start server srv2
Starting server ...
.
RDB$NODE           : 138.1.14.91
RDB$PORT           : 1702
RDB$STATUS         : Idle
RDB$SERVER_NAME    : srv2
RDB$SERVER_TYPE    : RdbThinSrv
RDB$SERVER_VERSION : T7.2-510 20070109 B719
RDB$SERVER_SHR_VERSION : T7.2-510 20061221 B6CL
RDB$SERVER_PID     : 0x2033137C(540218236)
RDB$ALLOWS_ANON    : false
RDB$ALLOWS_BYPASS  : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS    : -1
RDB$TRACE_LEVEL    : 0
RDB$LOG_FILE       : rdbjdbclog
RDB$RESTRICT_ACCESS: false
rdbthincontrol> poll
Polling servers ... 
srv2(0) //138.1.14.91:1702/ (0x2033137C<540218236>)
srv1(0) //138.1.14.91:1701/ (0x20238378<539198328>)
rdbthincontrol> show active servers
Active server info
RDB$NODE           : 138.1.14.91
RDB$PORT           : 1702
RDB$STATUS         : Idle
RDB$SERVER_NAME    : srv2
RDB$SERVER_TYPE    : RdbThinSrv
RDB$SERVER_VERSION : T7.2-510 20070109 B719
RDB$SERVER_SHR_VERSION : T7.2-510 20061221 B6CL
RDB$SERVER_PID     : 0x2033137C(540218236)
RDB$ALLOWS_ANON    : false
RDB$ALLOWS_BYPASS  : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS    : -1
RDB$TRACE_LEVEL    : 0
RDB$LOG_FILE       : rdbjdbclog
RDB$RESTRICT_ACCESS: false
rdbthincontrol> stop all servers
Successfully stopped Thin Server : srv1 (//138.1.14.91:1701/)
Successfully stopped Thin Server : srv2 (//138.1.14.91:1702/)
rdbthincontrol> poll
Polling servers ...
rdbthincontrol> exit
```
For the controller to be able to manage an Oracle JDBC for Rdb server the server must have a control password.

Remarks
Valid <option>s can be found in Table 6.1-1.
Valid <command_keyword>s can be found in Table 6.1-2.

See Server Configuration Options for more details on specifying the control password.

### Table 6.1-1: Controller Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-active</td>
<td>false</td>
<td>Used in conjunction with a command_keyword to specify that the action applies to only active designated entities.</td>
</tr>
<tr>
<td>-all</td>
<td>n/a</td>
<td>Used in conjunction with a command_keyword to specify that the action applies to all designated entities.</td>
</tr>
<tr>
<td>-configfile or -cfg</td>
<td>none</td>
<td>The file specification of a configuration file where session and server attributes may be found.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Attributes set in this configuration file may be overridden by setting the same attribute at the command line level. See Configuration Files for more details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>By default no configuration file is used.</td>
</tr>
<tr>
<td>-controlpass &lt;control password&gt;</td>
<td>none</td>
<td>Specifies the control password to use when connecting to servers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This password takes precedence over any password option provided on the same command line.</td>
</tr>
<tr>
<td>-n or -node &lt;node&gt;</td>
<td>none</td>
<td>Specifies the node where the server to be connected to is running.</td>
</tr>
<tr>
<td>-name &lt;server name &gt;</td>
<td>none</td>
<td>Specifies a name for the server. The name is used to lookup server information within the start-up configuration file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The value of this name is not case-sensitive.</td>
</tr>
<tr>
<td>-oem</td>
<td>n/a</td>
<td>Used by OEM to indicate that the return status and messages should be formatted for OEM usage.</td>
</tr>
<tr>
<td>-password or -pw &lt;password&gt;</td>
<td>none</td>
<td>Specifies the password to send to the thin server when requesting a control connection.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If a controlpass option is also found on the same command line the controlpass option will take precedence.</td>
</tr>
<tr>
<td>-pollTimeout &lt;timeout&gt;</td>
<td>2000</td>
<td>Specifies the time, in milliseconds, that the controller should wait for POLL replies from servers. See Polling Servers for more information.</td>
</tr>
<tr>
<td>-port or -p &lt;port_num&gt;</td>
<td>none</td>
<td>Specifies the port on which the server to be connected to is listening.</td>
</tr>
<tr>
<td>-srvargs &lt;server_arguments&gt;</td>
<td>none</td>
<td>Additional arguments to be passed on the connection URL when connecting to the server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example: @tracelevel=-1</td>
</tr>
<tr>
<td>-srv.mcBasePort &lt;base_port&gt;</td>
<td>5517</td>
<td>Specifies the base port number that will be used for multicast operations.</td>
</tr>
<tr>
<td>-srv.mcGroupIP &lt;group_ip&gt;</td>
<td>239.192.1.1</td>
<td>Specifies the multicast IP group within which this server will participate.</td>
</tr>
</tbody>
</table>
| -stored                 | n/a     | Used in conjunction with a command_keyword to specify that the action applies to the stored designated entities as found in the XML configuration file.
Table 6.1-2: Controller Command Keywords

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-tracelevel or -tl &lt;trace_level&gt;</td>
<td>Specifies the default tracelevel for the session. The value zero (0) means no tracing.</td>
</tr>
<tr>
<td>-user or -u &lt;user_name&gt;</td>
<td>Specifies the username to use for connection to the server.</td>
</tr>
<tr>
<td>-url &lt;connection URL&gt;</td>
<td>Specifies the node IP and port of the server to connect. This switch overrides any port and node switch specified. The format of the &lt;connection URL&gt; is //&lt;node&gt;:&lt;port&gt;/</td>
</tr>
</tbody>
</table>

Note: A number of these options may also be specified in a session section of the XML-formatted configuration file used to start an interactive controller session. See Session Section within XML Formatted Configuration File for more details.

Table 6.1-2: Controller Command Keywords

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-poll</td>
<td>Sends a poll request out to locate active servers. See Polling Servers for more information.</td>
</tr>
<tr>
<td>-startserver</td>
<td>Starts the server as specified by the other options given on the command line. See Starting Servers for more information.</td>
</tr>
<tr>
<td>-openserver</td>
<td>Opens the server as specified by the other options given on the command line. See Opening Servers for more information.</td>
</tr>
<tr>
<td>-closeserver</td>
<td>Closes the server as specified by the other options given on the command line. See Closing Servers for more information.</td>
</tr>
<tr>
<td>-showserver</td>
<td>Issues the Show Server command that gets server information from the connected server. See Showing Servers for more information.</td>
</tr>
<tr>
<td>-showclients</td>
<td>Issues the Show Clients command, which gets client information from the connected server. See Showing Clients for more information.</td>
</tr>
<tr>
<td>-stopserver</td>
<td>Stops the server as specified by the other options given on the command line. See Stopping Servers for more information.</td>
</tr>
<tr>
<td>-stopclient &lt;client_id&gt;</td>
<td>Issues the Stop Client command which requests the connected server to terminate the specified client thread. The &lt;client_id&gt; is an id of a client as displayed by the Show Clients command. See Stopping Clients for more information. There is no default value for &lt;client_id&gt;.</td>
</tr>
</tbody>
</table>

If the controller is invoked with the appropriate connect information and one of command keywords, the controller will issue the desired request to the server, optionally display the results, and terminate immediately.

If more than one command keyword is present, only one will be issued using the precedence as shown in the preceding table.

Example
An example of issuing command keyword to the controller:

$java -jar rdb$jdbc_home:rdbthincontrol.jar -u jan -controlpass mpass -node nd1 -port 1701 -stopserver

6.1.2 Controller Command Line

If no command keyword is used on the controller invocation, the application will go into command line prompt mode allowing multiple commands to be issued.

If valid connection information is provided at the controller invocation (i.e. node, port, user and password), the controller will automatically attempt to connect to the specified server.

If a connection has not been established or a different server connection is required, then the Connect command can be issued at the control command line. See Connecting to Servers for more information.
If username and password are not provided on the connect command line, then the values of the configuration options when the controller was invoked will be used.

If a configuration file is specified, the configuration file session characteristics will be used. See Session Section within XML formatted Configuration File for more information on session characteristics.

Commands may be issued at the control command line either within the context of a server connection or outside the context of a specific server connection.

The commands that may be issued once a connection has been established to a server are discussed in Commands requiring server connection.

The commands that do not require a server connection are discussed in Commands Not requiring a server connection.

Format

$java -jar rdb$jdbc_home:rdbthincontrol.jar -cfg my_servers.xml

6.1.2.1 Commands requiring a server connection

Once a valid server connection has been established the commands shown in the following table may be issued.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close server</td>
<td>Closes the currently connected server. See Closing Servers for more details.</td>
</tr>
<tr>
<td>disconnect</td>
<td>Disconnects from the currently connected server.</td>
</tr>
<tr>
<td>open server</td>
<td>Opens the currently connected server. See Opening Servers for more details.</td>
</tr>
<tr>
<td>set logfile [filename]</td>
<td>Sets the logfile for the currently connected active server.</td>
</tr>
<tr>
<td></td>
<td>This may be used to redirect trace log message to a different log file, which will close the current log file. If [filename] is missing of is equal to the value OFF the current logfile is still closed and log messages will no longer be sent to the log file.</td>
</tr>
<tr>
<td>set default tracelevel &lt;int&gt;</td>
<td>Sets the default tracelevel on the currently connected active server.</td>
</tr>
<tr>
<td></td>
<td>This does not affect currently connected clients. Only clients connecting after the set default tracelevel is issued will be affected.</td>
</tr>
<tr>
<td>set tracelevel &lt;int&gt;</td>
<td>Sets the tracelevel on the currently connected active server.</td>
</tr>
<tr>
<td></td>
<td>This will set the trace level for all clients that are currently connected to the server. Clients connecting after the set is issued will not be affected.</td>
</tr>
<tr>
<td>show clients</td>
<td>Show all clients on the currently connected server. See Showing Clients for more details.</td>
</tr>
<tr>
<td>show server</td>
<td>Show the details of the currently connected server. See Showing Servers for more information.</td>
</tr>
<tr>
<td>stop client &lt;client_id&gt;</td>
<td>Stops the client matching the specified &lt;client_id&gt; on the currently connected server. See Stopping Clients for more details.</td>
</tr>
<tr>
<td>stop clients</td>
<td>Stops all clients on the currently connected server. See Stopping Clients for more details.</td>
</tr>
<tr>
<td>stop server</td>
<td>Stops the currently connected server.</td>
</tr>
<tr>
<td>watch [server]</td>
<td>Send trace logging from connected server to the current console. See Watching Servers for more details.</td>
</tr>
</tbody>
</table>

Example

$java -jar rdb$jdbc_home:rdbthincontrol.jar
rdbthincontrol> connect //localhost:1701/ jones mypassword
rdbthincontrol> show server
RDB$NODE : localhost
RDB$PORT : 1701
RDB$STATUS : Idle
RDB$SERVER_NAME : rdbthnsrv1
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : V7.1-300 20040624 B46N
RDB$SERVER_SHR_VERSION : V7.1-300 20040624 B46N
6.1.2.2 Commands not Requiring a Server Connection

A number of commands may be issued that do not require you to have a connection established, however, for all commands other than `poll` and `quit`, you will have to provide a username and control password which will be used to connect to the servers to obtain the required information.

The commands that do not require a server connection are listed in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>poll</code></td>
<td>Multicast Poll for responding servers. See <a href="#">Polling Servers</a> for more details.</td>
</tr>
<tr>
<td><code>set session controlpass &lt;pwd&gt;</code></td>
<td>Sets the sessions control password. See <a href="#">Control Password</a> for more information.</td>
</tr>
<tr>
<td><code>set default tracelevel &lt;int&gt;</code></td>
<td>Sets the default tracelevel on the identified active server. This does not affect currently connected clients. Only clients connecting after the set default tracelevel is issued will be affected.</td>
</tr>
<tr>
<td><code>set logfile &lt;filename&gt; &lt;server_ident&gt;</code></td>
<td>Sets the log file specification for the identified active server. If <code>&lt;filename&gt;</code> is the value <code>OFF</code> then the current log file will be closed and log messages will no longer be sent to the log file.</td>
</tr>
<tr>
<td><code>set polltimeout &lt;int&gt;</code></td>
<td>Sets the time, in milliseconds that the controller should wait for <code>POLL</code> replies from servers. See <a href="#">Polling Servers</a> for more information.</td>
</tr>
<tr>
<td><code>set tracelevel &lt;int&gt;</code></td>
<td>Sets the tracelevel on the identified active server. This will set the trace level for all clients that are currently connected to the server. Clients connecting after the set is issued will not be affected.</td>
</tr>
<tr>
<td><code>show active servers</code></td>
<td>Show information about servers. See <a href="#">Showing Servers</a> for more details.</td>
</tr>
<tr>
<td><code>show all servers</code></td>
<td>Shows information about clients on all responding servers. See <a href="#">Showing Clients</a> for more details.</td>
</tr>
<tr>
<td><code>show server &lt;server_ident&gt;</code></td>
<td>Shows information about clients on all responding servers. See <a href="#">Showing Clients</a> for more details.</td>
</tr>
<tr>
<td><code>show active clients</code></td>
<td>Shows information about clients with username <code>&lt;name&gt;</code> on all responding servers. See <a href="#">Showing Clients</a> for more details.</td>
</tr>
<tr>
<td><code>show all clients</code></td>
<td>Shows information about clients with username <code>&lt;name&gt;</code> on all responding servers. See <a href="#">Showing Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop active clients</code></td>
<td>Stops all clients on all responding servers. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop all clients</code></td>
<td>Stops all clients on all responding servers. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop active clients &lt;name&gt;</code></td>
<td>Stops all clients with username <code>&lt;name&gt;</code> on all responding servers. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop all clients &lt;name&gt;</code></td>
<td>Stops all clients with username <code>&lt;name&gt;</code> on all responding servers. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop active clients in &lt;database spec&gt;</code></td>
<td>Stops all clients on all responding servers if the client is currently connected to the specified database. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop all clients in &lt;database spec&gt;</code></td>
<td>Stops all clients on all responding servers if the client is currently connected to the specified database. See <a href="#">Stopping Clients</a> for more details.</td>
</tr>
<tr>
<td><code>stop active servers</code></td>
<td>Stops active servers. See <a href="#">Stopping Servers</a> for more details.</td>
</tr>
<tr>
<td><code>stop all servers</code></td>
<td>Stops active servers. See <a href="#">Stopping Servers</a> for more details.</td>
</tr>
<tr>
<td><code>open active servers</code></td>
<td>Opens active servers. See <a href="#">Opening Servers</a> for more details.</td>
</tr>
<tr>
<td><code>open all servers</code></td>
<td>Opens active servers. See <a href="#">Opening Servers</a> for more details.</td>
</tr>
<tr>
<td><code>close active servers</code></td>
<td>Closes active servers. See <a href="#">Closing Servers</a> for more details.</td>
</tr>
<tr>
<td><code>close all servers</code></td>
<td>Closes active servers. See <a href="#">Closing Servers</a> for more details.</td>
</tr>
<tr>
<td><code>watch [server] &lt;server_ident&gt;</code></td>
<td>Watches active servers. See <a href="#">Watching Servers</a> for more details.</td>
</tr>
</tbody>
</table>
quit or exit

Exits the controller application.

Example

```bash
$java -jar rdb$jdbc_home:rdbthincontrol.jar -user jones -
-controlpass jdbc_user
rdbthincontrol> show active servers
RDB$NODE : localhost
RDB$PORT : 1701
RDB$STATUS : Idle
RDB$SERVER_NAME : rdbthnsrv1
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : V7.1-300 20040624 B46N
RDB$SERVER_PID : 0x0B30 (2864)
RDB$ALLOW_ANON : false
RDB$ALLOW_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS : -1

RDB$NODE : localhost
RDB$PORT : 1711
RDB$STATUS : Idle
RDB$SERVER_NAME : myserver
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : V7.1-300 20040624 B46N
RDB$SERVER_PID : 0x0B88 (2952)
RDB$ALLOW_ANON : false
RDB$ALLOW_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS : -1
rdbthincontrol>
```

If a server does not recognize the provided control password, it will respond with a failure message:

```bash
rdbthincontrol> show active servers
Failed to connect <CONTROL>
No Rdb Thin Server connection has been established
Unable to connect to server //localhost:1701/
Failed to connect <CONTROL>
No Rdb Thin Server connection has been established
Unable to connect to server //localhost:1711/
rdbthincontrol>
```

Contents

6.2 Connecting to Servers

The majority of commands that can be issued from the controller require a valid control connection to be established with a server. If valid connection information is provided at the controller invocation (node, port, user and password), the controller will automatically attempt to connect to the specified server when the controller starts up.

If user and password are provided at the controller invocation, this information will be maintained for the entire controller session and will be used in subsequent connection request unless explicitly overridden on the command statement.

Commands will only be carried out on a server if a control connection has been established, which requires the correct control password to be provided during the connect request. See Control Password for more information of this password.

This control connection may be an explicit connection established for the session by using the Connect command or may be implicitly established if a command is issued to a server that requires control access to execute successfully. Many controller commands allow server connection information to be specified, indicating which server to apply the command. In addition, the connection information may provide a username and password to use for that server.

Format

```bash
<command> <server_connection>
```

The `<server_connection>` information is comprised of a server identification string and optional connection username and control password:

Format

```bash
<server_ident> [ <server_uid> ]
```

The `<server_ident>` string can be one of the following:

- Port ID - this is the same as issuing: //localhost:<port>/
- full URL with the format: //<node>:<port>/
- name of server as found in the configuration used to start the controller

The `<server_uid>` is:

```bash
<username> [ <password> ]
```
The <password> must match the control password of the server for the control connection to be carried out successfully.

If a username or password is not provided on the command line then the current session information is used.

This connection, once established, will be maintained until either an explicit Disconnect is issued, or a new connection is established to another server or the controller exits.

If an attempt is made to issue a controller command without a connection being established, then an error condition will be raised:

Example

rdbthincontrol> watch
No Rdb Thin Server connection has been established

If username and password are not provided on the connect command line, then the values of the appropriate configuration options set when the controller was invoked will be used.

If a configuration file is specified, the configuration file session characteristics will be used.

See Session Section within XML formatted Configuration File for more information on session characteristics.

6.2.1 Connect Command

If a connection has not been established, or the current connection has been disconnected, or a different server connection is required, then the Connect command can be issued at the control command line.

Format

connect [server] <server_connection>

This command connects to the server specified by the <server_connection> information.

Example

The following examples use the Connect command:

rdbthincontrol> connect //localhost:1701/ jones mypassword
rdbthincontrol> connect server 1701
rdbthincontrol> connect myServer jim xxxxx

Remarks

If username and password are not provided on the Connect command line, then the values entered in the configuration options when the controller was invoked will be used, or if a configuration file is specified, the configuration file session characteristics will be used. See Session Section within XML formatted Configuration File for more information on session characteristics.

6.2.2 Implicit Connection

A number of the control commands require a control connection to be established with the target server. If the target server is not currently connected, both explicitly provided connection information and session connection information may be used to attempt to establish a control connection.

Connection information may be provided on the command line along with the command, for example:

Example

rdbthincontrol> stop server //localhost:1701/ jones mypassword

Once an implicit connection is made, this connection will be established as the current session connection until overridden by another implicit or explicit connection.

6.3 Control Password

To carry out any operations on active servers or clients, you are required to provide a control password. This password must match the control password for that active server, otherwise, an exception will be raised and the operation will fail.

When you start up the controller you may provide a password as a command line option or in the session section of an XML-formatted Configuration file. If you provide both a password and a controlPass the controlPass will take precedence.

Example

rdbthincontrol> stop server myMPServer
Failed to connect <CONTROL>
No Rdb Thin Server connection has been established
Unable to connect to server //localhost:1788/

In addition the control password may be set for a session by using the Set Session ControlPass statement at the controller command line prompt.
rdbthincontrol> set session controlpass badpassword
rdbthincontrol> show server 1701
Failed to connect <CONTROL>
No Rdb Thin Server connection has been established
rdbthincontrol> set session controlpass mypassword
rdbthincontrol> show server 1701
RDB$NODE : 192.168.1.100
RDB$PORT : 1701
RDB$STATUS : Idle
RDB$SERVER_NAME : jimserv
RDB$SERVER_TYPE : RdbThinSrv
RDB$SERVER_VERSION : X7.1-301 20040713 B47C
RDB$SERVER_SHR_VERSION : X7.1-301 20040712 B47C
RDB$SERVER_PID : 0x1728(5928)
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
RDB$MAX_CLIENTS : -1

Note:
A session password or controlPass specified on the controller command line should not
start with the following strings:
• “0x” or
• “##”
A session password or controlPass specified in a configuration file starting with the
prefixes as designated above, will be considered to be a digested or obfuscated password.

Contents
6.4 Multicast Polling
The controller uses multicast polling to discover Oracle JDBC for Rdb servers that may be available
on the network.
Multicasting is a style of efficiently broadcasting data over a network connection to many
connected servers. Any server listening in to the multicast IP address will receive the data
packets that are broadcast, such as poll requests.
Oracle JDBC for Rdb servers use the Administrative Scoping range of addresses that allow easy
limiting of multicast transmission to well defined boundaries within your network.
Administrative Scoping is the restriction of multicast transport based on the address range of the
multicast group. It is defined by RFC 2365 “Administratively Scoped IP Multicast.” and is restricted to the
address range:
239.0.0.0 to 239.255.255.255
The IP address for server multicast polling should be chosen from within the following range:
239.192.0.0 to 239.192.255.255
This range is known as the IPv4 Organization Local Scope and has a subnet mask of 255.252.0.0. It
is intended for use by an entire organization setting multicast scopes privately for its own internal or
organizational use and allows up to 262,144 group addresses.
By default, Rdb servers use the multicast IP 239.192.1.1 with a base port of 5517.
Multicast Group IP addresses can be assigned to a server using the srv.mcGroupIP option within
a server configuration file or the server start-up command line.
The srv.mcBasePort option allows you to change the Multicast Base port.

Note:
When a server participates in a multicast group, as part of the standard multicast
protocol its presence in the group will be broadcast at regular intervals. This may
conflict with the network policy and procedures of your network administration.
Please consult your network manager to ensure that multicast polling is allowed on your
system. Your network manager may also allocate a specific IP address and Port range
that may be used by the Rdb Native Drivers, and you should change your server and
session configuration files to reflect these allocated addresses.
Setting the Multicast Base port to zero (0) will effectively disable multicast broadcast
and receipt for that server. This also means that the server will not respond to any POLL
requests issued by the Controller.

See Polling Servers for more details on how the controller may be used to POLL servers.

Contents
6.5 Server Matching
To allow the selectivity of servers when issuing controller commands, certain commands may take a server matching pattern.

The server matching pattern takes the form of a standard Java Regular Expression (REGEX) and may be used to select out those servers on the system that should either respond and/or carry out the required operation.

Note: In addition to the server matching criteria, only servers that are using the same Group IP will respond to controller command such as POLL. See Multicast Polling for more details.

Note: Currently the only controller command allowing server matching is the POLL command. See Polling Servers for more details.

Example 1

```
 rdbthincontrol> poll #type:RdbThinSrvPool#node:ALPHA.*
```

In this example, the server matching pattern refines the server selection for the POLL request to target only Pool servers currently running on nodes starting with names "ALPHA".

Format

The format of the server match pattern is:

```
[#<match type>:<match value>]*
```

where `<match type>` is one of:

- `type` - the type of server
- `name` - the server name
- `port` - the port the server is listening on
- `stat` - the state of the server
- `node` - the node the server is running on
- `vers` - the version JDBC the server is running

and `<match value>` depends on the `<match type>`. Some `<match type>`s will allow a regular expression pattern to match on. The following sections describe each of the `<match type>`s and their allowable `<match value>`s.

See your Java documentation for more information on Regular Expressions.

6.5.1 type match

The `<match type>` specifies the type of server that should respond. The following table shows the `<match value>`s allowed for a type match:

<table>
<thead>
<tr>
<th>Type name</th>
<th>Type code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RdbThinSrv</td>
<td>0</td>
<td>Standard thin server.</td>
</tr>
<tr>
<td>RdbThinSrvMP</td>
<td>1</td>
<td>Multi-process server.</td>
</tr>
<tr>
<td>RdbThinSrvSSL</td>
<td>2</td>
<td>Thin server using SSL for communication.</td>
</tr>
<tr>
<td>RdbThinSrvMPSSL</td>
<td>3</td>
<td>Multi-process server using SSL.</td>
</tr>
<tr>
<td>RdbThinSrvPool</td>
<td>4</td>
<td>Pool server.</td>
</tr>
<tr>
<td>RdbThinSrvPoolSSL</td>
<td>5</td>
<td>Pool server using SSL.</td>
</tr>
<tr>
<td>RdbManSrv</td>
<td>102</td>
<td>JDBC Manager server</td>
</tr>
<tr>
<td>RdbManSrvSSL</td>
<td>103</td>
<td>JDBC Manager server using SSL.</td>
</tr>
</tbody>
</table>

The `<match value>` for server type may be either an int value, representing the server type code as shown above, or a string value to match the server type name.

The `<match value>` may be a regular expression. Character case will be ignored.

Example 1

All SSL server types

```
 rdbthincontrol> poll #type:.*SSL
```

Example 2

All multi-process server types

```
 rdbthincontrol> poll #type:[13]
```

Example 3

Any multi-process server using SSL

```
 rdbthincontrol> poll #type:rdbthin srv/mpssl
```

6.5.2 name match

The name `<match type>` specifies the name of server that should respond. The `<match value>` may be a regular expression. Character casing will be ignored.

Example 1

All servers named "MY_MP_SRV"

```
 rdbthincontrol> poll #name:MY_MP_SRV
```
Example 2
All servers with names starting with "MP_", ending with "_SRV" and any 2 characters in between.
```
rdbthincontrol>poll #name:MP_.*_SRV
```

Example 3
All servers with names starting with "P_", ending with "_SRV" and 1 or more digits in between.
```
rdbthincontrol>poll #name:P_\(d+\)_SRV
```

6.5.3 port match

The `port <match type>` specifies the port numbers for server that should respond. The `<match value>` may be a regular expression.

Example 1
All servers listening on port 1701
```
rdbthincontrol>poll #port:1701
```

Example 2
All servers listening on port 1700 though 1709
```
rdbthincontrol>poll #port:170\d
```

6.5.4 stat match

The `stat <match type>` specifies only servers currently in the specified state should respond. The following table shows the `<match value>`s allowed for a `stat` match:

<table>
<thead>
<tr>
<th>Match Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABLE</td>
<td>The server is currently available and has at least one client connected.</td>
</tr>
<tr>
<td>BUSY</td>
<td>The server has the maximum number of clients connected. See <code>maxClients</code> server property.</td>
</tr>
<tr>
<td>CLOSED</td>
<td>The server is currently closed with no clients connected. See <code>Closing Servers</code>.</td>
</tr>
<tr>
<td>CLOSING</td>
<td>The server is currently closing but still has at least one client connected. See <code>Closing Servers</code>.</td>
</tr>
<tr>
<td>IDLE</td>
<td>The server is currently available and no clients connected.</td>
</tr>
</tbody>
</table>

The `<match value>` may be a regular expression. Character casing will be ignored.

Example 1
All idle servers
```
rdbthincontrol>poll #stat:idle
```

Example 2
All closed servers or servers in the process of closing
```
rdbthincontrol>poll #stat:clos.*
```

Example 3
All available servers irrespective of the number of clients connected
```
rdbthincontrol>poll #stat:IDLE|BUSY|AVAIL.*
```

6.5.5 node match

The `node <match type>` specifies that only servers running on the specified node(s) should respond. The `<match value>` may be a regular expression. Character casing will be ignored.

The `<match value>` pattern can represent either the name of the node or the IP address of the node.

Example 1
All servers running on node ALPHA1
```
rdbthincontrol>poll #node:ALPHA1
```

Example 2
All servers running on node ALPHA1, ALPHA2 and ALPHA3
```
rdbthincontrol>poll #node:ALPHA[123]
```

Example 3
All servers running in the sub-network 192.169.1.*
```
rdbthincontrol>poll #node:192.169.1.(\d+)
```

6.5.6 vers match
The `<match type>` specifies that only servers running under the specified Oracle JDBC for Rdb version should respond.

The `<match value>` may be a regular expression. Character casing will be ignored.

The `<match value>` pattern may optionally include the "V" prefix for the version.

The `<match value>` pattern strings ",", "."," and "ALL" are handled as special patterns and indicate that ALL versions should matched. This wildcard version specification may be used to allow prior-version servers to respond to controller command containing match selectivity. See Handling prior version Servers for more details.

Example 1
All servers with release 7.3.0.0.0 Oracle JDBC for Rdb

```
rdbthincontrol>poll #vers:73
```

Example 2
All servers running on node ALPHA1 including prior-version servers

```
rdbthincontrol>poll #vers:ALL#node:ALPHA1
```

6.5.7 Handling Servers From Prior Releases

Server matching relies on special handling of controller command by the servers that is only available in servers from release 7.3.0.0.0 Oracle JDBC for Rdb and later. This handling ensures that only those servers that match the selection criteria will carry out the operations requested.

If your network has prior-version JDBC servers running, while these servers may respond to standard control requests such as POLL, they may not respond to the control statements containing matching patterns introduced in release 7.3.0.0. For example, assuming the network has several 7.3.x.x servers and one 7.2.x.x server, named "V72SRV", running, the standard POLL request will discover all of the servers:

```
rdbthincontrol> poll
Polling servers ...
mpx(1) //192.168.1.2:1899/ (0xC6C<3180>) node = froggy2
rdbthnsrv1(0) //192.168.1.2:1701/ (0x9A8<2472>) node = froggy2
rdbthnsrv2(0) //192.168.1.2:1702/ (0xB30<2864>) node = froggy2
v72srv(0) //192.168.1.2:1800/ (0xC10<3088>) node = froggy2
```

But a POLL request with matching criteria will not:

```
rdbthincontrol> poll #node:192.168.1.\d+
Polling servers (using qualifiers : #node:192.168.1.\d+ ) ...
mpx(1) //192.168.1.2:1899/ (0xC6C<3180>) node = froggy2
rdbthnsrv1(0) //192.168.1.2:1701/ (0x9A8<2472>) node = froggy2
rdbthnsrv2(0) //192.168.1.2:1702/ (0xB30<2864>) node = froggy2
```

If match criteria is required and prior version servers are present, then the `VERS` match condition set to ALL may be used to indicate to the controller that matching should be done by the controller, rather than the servers. This will allow prior version servers to respond correctly:

```
rdbthincontrol> poll #node:192.168.1.\d+\#vers:all
Polling servers (using qualifiers : #node:192.168.1.\d+\#vers:all ) ...
mpx(1) //192.168.1.2:1899/ (0xC6C<3180>) node = froggy2
rdbthnsrv1(0) //192.168.1.2:1701/ (0x9A8<2472>) node = froggy2
rdbthnsrv2(0) //192.168.1.2:1702/ (0xB30<2864>) node = froggy2
v72srv(0) //192.168.1.2:1800/ (0xC10<3088>) node = froggy2
```

6.6 Server Operations

This section details the operations you may carry out on servers using the controller both interactively and in command mode.

The following sub-sections describe:

- Closing Servers
- Opening Servers
- Showing Servers
- Starting Servers
- Stopping Servers
- Watching Servers
- Watching Events
- Poling Servers
- Showing Executors

Note:

The examples in this section assume that Java has been set up and the following DCL symbol has been set in the environment.

```
$ thincontrol := "java" -jar rdb5.jar@bome:0000:thincontrol.jar -
cfg ny_servers.xml -controlpass "MySecretPassword"
```
The configuration file contents used for these examples may be seen in Sample configuration file MY_SERVERS.XML.

Server Matching may be used in conjunction with the following server commands to target specific servers or groups of servers on your network.

6.6.1 Closing Servers

Active servers may be closed using the controller. You must provide a valid control password for the server.

Closing a server sets its maxClients attribute to zero (0) thus preventing any further connections to be made. Already established connections are not affected.

You may issue an open command later to re-open a closed server, which will reestablish the maxClients value for the server back to the value it was prior to closing. See Opening Servers for more details.

Only those servers where the control password matches the control session control password will be closed.

6.6.1.1 Interactive mode

The interactive control commands available to close servers can be seen in the following table:

Table 6.6-Interactive Close Server

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close active servers</td>
<td>Closes all responding servers. Keywords all and active in this context are considered synonyms.</td>
</tr>
<tr>
<td>close all servers</td>
<td>Closes the currently connected server.</td>
</tr>
<tr>
<td>close server &lt;server_connection&gt;</td>
<td>Closes the active server specified by the server connection information. See Connecting to Servers for more information.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> close server myserver
rdbthincontrol> close server //prod_node:1766/
rdbthincontrol> close server 1701
rdbthincontrol> close active server
```

6.6.1.2 Command mode

The command mode commands available to close servers can be seen in the following table:

Table 6.6-Command Mode Close Server

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-closeServer</td>
<td>-name</td>
<td>-active</td>
<td>-in</td>
<td>Close the server as specified by other command line options.</td>
</tr>
<tr>
<td>-closeServer -active or -all</td>
<td>-node</td>
<td>-all</td>
<td>-using</td>
<td>Close all servers that are responding to the multicast poll request.</td>
</tr>
<tr>
<td>-closeServer</td>
<td>-name</td>
<td>-node</td>
<td>-port</td>
<td>-URL</td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

Example

```
$ thincontrol -closeServer -url //prod_node:1766/
$ thincontrol -closeServer -port 1701 -node localhost
$ thincontrol -closeServer -active
$ thincontrol -closeServer -name myserver
```

6.6.2 Opening Servers

Active servers may be opened using the controller. You must provide a valid control password for the server.

Opening a server allows new client connections to be made using that server.

You may issue an open command to re-open a closed server, which will reestablish the maxClients value for the server back to the value it was prior to closing.
6.6.2.1 Interactive mode

The control commands available to open servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>open active servers</td>
<td>Opens all responding servers.</td>
</tr>
<tr>
<td>open all servers</td>
<td>Opens the currently connected server.</td>
</tr>
<tr>
<td>open server &lt;server_connection&gt;</td>
<td>Opens the active server specified by the server connection information. See Connecting to Servers for more information.</td>
</tr>
</tbody>
</table>

Example:

```
rdbthincontrol> open server
rdbthincontrol> open server myserv
rdbthincontrol> open server //prod_node:1766/
rdbthincontrol> open server 1701
rdbthincontrol> open all servers
rdbthincontrol> open server //prod_node:1766/ fred mypass
```

6.6.2.2 Command mode

The command mode commands available to open servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-openServer</td>
<td>-name</td>
<td>-active</td>
<td>-in</td>
<td>Opens the server as specified by other command line options.</td>
</tr>
<tr>
<td>-openServer -active or -all</td>
<td>-node</td>
<td>-all</td>
<td>-using</td>
<td>Open all servers that are responding to the multicast poll request.</td>
</tr>
<tr>
<td>-openServer -all</td>
<td>-port</td>
<td>-using</td>
<td>-URL</td>
<td></td>
</tr>
<tr>
<td>show active servers</td>
<td></td>
<td></td>
<td></td>
<td>Shows all servers that are responding to the multicast poll request.</td>
</tr>
<tr>
<td>show all servers</td>
<td></td>
<td></td>
<td></td>
<td>Shows active servers as well as the server definitions as found in the configuration file used to start the controller.</td>
</tr>
<tr>
<td>show stored servers</td>
<td></td>
<td></td>
<td></td>
<td>Shows the server definitions as found in the configuration file used to start the controller.</td>
</tr>
<tr>
<td>show server</td>
<td></td>
<td></td>
<td></td>
<td>Shows information about the currently connected server.</td>
</tr>
<tr>
<td>show server &lt;server_connection&gt;</td>
<td></td>
<td></td>
<td></td>
<td>Shows information about the active server specified by the server connection information. See Connecting to Servers for more information.</td>
</tr>
</tbody>
</table>

Example:

```
$ thincontrol -openServer -url //prod_node:1766/
$ thincontrol -openServer -port 1701 -node localhost
$ thincontrol -openServer -active
$ thincontrol -openServer -name myserver
```

6.6.3 Showing Servers

Information about active and known servers may be displayed using the controller. You must provide a valid control password for the server before information will be displayed.

If showing all or active servers only those servers where the control password matches the control session control password will have information displayed.

All server definitions as stored in the configuration file will be displayed when showing stored or all servers irrespective of the control password.

6.6.3.1 Interactive mode

The control commands available to show servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show active servers</td>
<td>Show all servers that are responding to the multicast poll request.</td>
</tr>
<tr>
<td>show all servers</td>
<td>Shows active servers as well as the server definitions as found in the configuration file used to start the controller.</td>
</tr>
<tr>
<td>show stored servers</td>
<td>Shows the server definitions as found in the configuration file used to start the controller.</td>
</tr>
<tr>
<td>show server</td>
<td>Shows information about the currently connected server.</td>
</tr>
<tr>
<td>show server &lt;server_connection&gt;</td>
<td>Shows information about the active server specified by the server connection information. See Connecting to Servers for more information.</td>
</tr>
</tbody>
</table>
Example

```bash
$ thincontrol -showServer -url //prod_node:1766/
$ thincontrol -showServer -port 1701 -node localhost
$ thincontrol -showServer -active
$ thincontrol -showServer -all
$ thincontrol -showServer -stored
$ thincontrol -showServer -name myserver
```

### 6.6.3.2 Command mode

The command mode commands available to show servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-showServer</td>
<td>-name</td>
<td>-active</td>
<td>-all</td>
<td>Shows the server as specified by other command line options.</td>
</tr>
<tr>
<td>-showServer</td>
<td>-active</td>
<td>-name</td>
<td>-node</td>
<td>Show all servers that are responding to the multicast poll request.</td>
</tr>
<tr>
<td>-showServer</td>
<td>-all</td>
<td>-name</td>
<td>-node</td>
<td>Shows active servers as well as the server definitions as found in the configuration file used to start the controller.</td>
</tr>
<tr>
<td>-showServer</td>
<td>-stored</td>
<td>-name</td>
<td>-node</td>
<td>Shows the server definitions as found in the configuration file used to start the controller.</td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

**Note:** If multiple conflicting keywords are found on the one command line only one action will be taken and the following precedence is used:

- `-all`
- `-active`
- `-stored`
- specified server

### Information displayed in Show Server

When the `show server` command is executed, the following information about the server is displayed:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$NODE</td>
<td>The node the server is running on.</td>
</tr>
<tr>
<td>RDB$PORT</td>
<td>The TCP/IP port the server is listening on.</td>
</tr>
<tr>
<td>RDB$STATUS</td>
<td>The current status of the server.</td>
</tr>
<tr>
<td>RDB$SERVER_NAME</td>
<td>The name of the server.</td>
</tr>
<tr>
<td>RDB$SERVER_TYPE</td>
<td>The type of server.</td>
</tr>
<tr>
<td>RDB$SERVER_VERSION</td>
<td>The version information for the server JAR file used. Format &quot;Release release# build# internalCheckId&quot;.</td>
</tr>
<tr>
<td>RDB$SERVER_SHR_VERSION</td>
<td>The version of the JDBC shared images used. Format &quot;Release release# build# internalCheckId&quot;.</td>
</tr>
<tr>
<td>RDB$SERVER_PID</td>
<td>The process identification of the server process. Format &quot;hexadecimal PID (decimal PID)&quot;.</td>
</tr>
<tr>
<td>RDB$ALLOW_ANON</td>
<td>If <code>true</code>, the server allows anonymous connections.</td>
</tr>
</tbody>
</table>
Attribute | Description
--- | ---
RDB$ALLOWS_BYPASS | If true, the server will use BYPASS during database connection setup. See BYPASS Privilege.
RDB$NUMBER_OF_CLIENTS | The number of non-control client connections currently using the server.
RDB$MAX_CLIENTS | The maximum number of non-control client connections the server will allow.
RDB$TRACE_LEVEL | The current trace level for the server.
RDB$LOG_FILE | The log file currently being used.
RDB$RESTRICT_ACCESS | If true, access is restricted to this server.
RDB$CAST_INFO | Multicast information. Format “Group IP:Base port”
RDB$START_TIMESTAMP | Timestamp when the server was started.
RDB$CFG_FILE | The server configuration file.

In addition, if the connected server is multi-process then the following attributes will also be displayed:

Table 6.6—Additional Multi-Process Server Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$NUMBER_OF_FREE_EXECUTORS</td>
<td>The number of free executor processes.</td>
</tr>
<tr>
<td>RDB$MAX_FREE_EXECUTORS</td>
<td>The maximum number of free executor process that the server will maintain.</td>
</tr>
<tr>
<td>RDB$SHARED_MEMORY</td>
<td>The amount of shared memory (bytes) allocated by the server.</td>
</tr>
<tr>
<td>RDB$FREE_SHARED_MEMORY</td>
<td>The amount of shared memory (bytes) allocated but not used.</td>
</tr>
<tr>
<td>RDB$SEG_STRINGS</td>
<td>The amount of shared memory (bytes) used by segmented strings (blobs).</td>
</tr>
<tr>
<td>RDB$NUMBER_OF_CHUNKS</td>
<td>The number of free chunks of shared memory available for use.</td>
</tr>
<tr>
<td>RDB$LARGEST CHUNK</td>
<td>The amount of memory (bytes) of the largest memory chunk available.</td>
</tr>
<tr>
<td>RDB$NUMBER_OF_BUSY_EXECUTORS</td>
<td>The number of executor processes currently allocated to active connections.</td>
</tr>
<tr>
<td>RDB$PAGEFILE_QUOTA</td>
<td>Server process JPI$_PGFLQUOTA value.</td>
</tr>
<tr>
<td>RDB$PAGEFILE_COUNT</td>
<td>Server process JPI$_PAGFILCNT value.</td>
</tr>
<tr>
<td>RDB$GLOBPAGE_COUNT</td>
<td>Server process JPI$_GPGCNT value.</td>
</tr>
<tr>
<td>RDB$MS_COUNT</td>
<td>Server process JPI$_PPGCNT value.</td>
</tr>
<tr>
<td>RDB$PAGEBLI_COUNT</td>
<td>Server process JPI$_APTCNT value.</td>
</tr>
<tr>
<td>RDB$PAGE_FAULTS</td>
<td>Server process JPI$_PAGEFLTS value.</td>
</tr>
<tr>
<td>RDB$CPU_TIME</td>
<td>Server process JPI$_CPUTIM value.</td>
</tr>
</tbody>
</table>

Note: The format and contents of the show server display may change in future releases of Oracle JDBC for Rdb.

Example

```sql
rdbthincontrol> connect 1804
rdbthincontrol> show server
RDB$NODE : 192.168.1.100
RDB$PORT : 1804
RDB$STATUS : Idle
RDB$SERVER_NAME : mppool2
RDB$SERVER_TYPE : RdbThinSrvPool
RDB$SERVER_VERSION : Release 7.3.2.0.5 20130625 BD6Q
RDB$SERVER_SHR_VERSION : Release 7.3.2.0.5 20130625 BD6P
RDB$SERVER_PID : 0x22A7DF71(581267057)
RDB$ALLOWS_ANON : false
RDB$ALLOWS_BYPASS : false
RDB$NUMBER_OF_CLIENTS : 0
```
6.6.4 Starting Servers

Servers may be started using the controller.

If the server specifies a node or URL that is not the same as the node the controller is running on you must use the VIA command qualifier otherwise an exception will be raised.

6.6.4.1 Interactive mode

The control commands available to start servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start all servers</td>
<td>Starts all autostart servers found in the XML-formatted configuration file used when invoking the controller.</td>
</tr>
<tr>
<td>Start server</td>
<td>Starts a server of type RdbThinSrv on the local host with all default characteristics.</td>
</tr>
<tr>
<td>Start server &lt;port id&gt;</td>
<td>Starts a server of type RdbThinSrv listening on the designated port on the local host with default remaining characteristics.</td>
</tr>
<tr>
<td>Start server &lt;name&gt;</td>
<td>Starts the server that matches the &lt;name&gt; provided. See XML formatted Configuration File for more information on named server definitions.</td>
</tr>
<tr>
<td>Start server &lt;name&gt; via &lt;server_connection&gt;</td>
<td>Starts the server that matches the &lt;name&gt; provided, by forwarding the request to the manager server specified by &lt;server_connection&gt;.</td>
</tr>
</tbody>
</table>

Example

rdbthincontrol> start server myserver
rdbthincontrol> start server 1799
rdbthincontrol> start server all
rdbthincontrol> start server serv1 via manag1

6.6.4.2 Command mode

The command mode commands available to start servers can be seen in the following table:
Table 6.6 Command Mode Start Server

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-startServer</td>
<td>-name</td>
<td>-active</td>
<td>Starts the server as specified by other command line options.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td>-all</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td>-using</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td>-in</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-startServer -all</td>
<td>-name</td>
<td>-active or -all</td>
<td>Starts all autostart servers found in the XML-formatted configuration file used when invoking the controller.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td>-using</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td>-in</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

Note:
There is no command mode equivalence of the “start server via” interactive node command.

Example

$ thincontrol -startServer -port 1701 -node localhost
$ thincontrol -startServer -name myserv
$ thincontrol -startServer -all

6.6.5 Stopping Servers

Active servers may be stopped using the controller. You must provide a valid control password for the server.

Only those servers where the control password matches the control session control password will be stopped.

Note:
Stopping a server will forcibly terminate all database connections on that server and does not wait for client transaction completion.

Consider using the Close Server command first, to stop further client connections and then use the Stop Server command later when no clients are bound. See Closing Servers for more details.

You may use Show Server or Show Clients command to see if any clients are currently using the server. See Showing Servers for more details.

6.6.5.1 Interactive mode

The control commands available to stop servers can be seen in the following table:

Table 6.6.11 Interactive Stop Server

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stop active servers</td>
<td>Stops all responding servers. The keywords all and active in this context are considered synonyms.</td>
</tr>
<tr>
<td>stop all servers</td>
<td>Stops the currently connected server.</td>
</tr>
<tr>
<td>stop server</td>
<td>Stops the active server specified by the server connection information. See Connecting to servers for more information.</td>
</tr>
</tbody>
</table>

Example

rdthincontrol> stop server
rdthincontrol> stop server myserv
rdthincontrol> stop server //prod_node:1766/
rdthincontrol> stop server 1701
rdthincontrol> stop active servers
rdthincontrol> stop server //prod_node:1766/ fred mypass

6.6.5.2 Command mode

The command mode commands available to stop servers can be seen in the following table:

Table 6.6.12 Command Mode Stop Server

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-stopServer</td>
<td>-name</td>
<td>-active</td>
<td>Stops the server as specified by other command line options.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td>-all</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td>-using</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td>-in</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-stopServer -all</td>
<td>-name</td>
<td>-active or -all</td>
<td>Stops all responding servers.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td>-using</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td>-in</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.
6.6.6 Watching Servers

The trace output for an active server may be displayed on the controller console. You must provide a valid control password for the server to be able to watch its trace.

Only those servers where the control password matches the control session control password will be watched.

When you watch a server, all trace output from that server will also be sent to the current console running the controller.

The display of trace output messages occurs asynchronously with the command line interface. The same trace information will also be sent to the servers log file.

Note:
Because the server uses Java logger to log trace message to remote consoles such as the controller, the output from the server will be buffered prior to being sent across the network to the console. This means that the trace output may be displayed sporadically on the console as the buffer is first filled and then flushed.

6.6.6.1 Interactive mode

The control commands available to watch servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>watch [server]</td>
<td>Watch the currently connected server.</td>
</tr>
<tr>
<td>watch server &lt;server_connection&gt;</td>
<td>Watch the active server specified by the server connection information. See Connecting to servers for more information.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> watch server myserv
rdbthincontrol> watch server //prod_node:1766/
rdbthincontrol> watch server 1701 jack password1
rdbthincontrol> watch
```

6.6.6.2 Command mode

The command mode commands available to watch servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-watch</td>
<td>-name</td>
<td>-active</td>
<td>-all</td>
<td>Watches the server as specified by other command line options.</td>
</tr>
</tbody>
</table>

Example

```
$ thincontrol --port 1701 --node localhost --watch
$ thincontrol --cfg my_cfg.xml --name myserver --watch
```

6.6.7 Watching Events

**Since release 7.3.1.0.0**

Events logged output for an active server may be displayed on the controller console. You must provide a valid control password for the server to be able to watch for events.

When you watch for events on a server, all Events logged by that server will also be sent to the current console running the controller. The logged event output is in the form of XML-formatted messages.

The display of event output messages occurs asynchronously with the command line interface.

Note:
Because the server uses Java logger to log trace message to remote consoles such as the controller, the output from the server will be buffered prior to being sent across the network to the console. This means that the trace output may be displayed sporadically on the console as the buffer is first filled and then flushed.

See also Event Logging and Notification.
6.6.7.1 Interactive mode

The control commands available to watch events can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>watch events</td>
<td>Watch for events on the currently connected server.</td>
</tr>
<tr>
<td>watch events [on] &lt;server_connection&gt;</td>
<td>Watch for events on the active server specified by the server connection information. The keyword “ON” is optional. See Connecting to servers for more information.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> watch events myserv
rdbthincontrol> watch events //prod_node:1766/
rdbthincontrol> watch events on 1701 jack password1
rdbthincontrol> watch events
```

6.6.7.2 Command mode

The command mode commands available to watch events can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-watchEvents</td>
<td>-name</td>
<td>-active</td>
<td>-all</td>
<td>Watches events logged by the server as specified by other command line options.</td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td></td>
<td>-using</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td></td>
<td>-in</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example

```
$ thincontrol --port 1701 --node localhost --watchEvents
$ thincontrol --cfg my_cfg.xml -name myserver --watchEvents
```

6.6.8 Polling Servers

The poll command uses the multicast information to poll responding Oracle JDBC for Rdb servers:

Each available server will respond with information about which node and port it is listening on. In addition the poll response identifies the Process ID the server is using on that node.

A control password is not required to use the poll command.

As the operation is a poll, the thin controller will wait a prescribed amount of time before displaying the responses from the poll request. The pollTimeout attribute specifies the amount of time in milliseconds that the controller should wait for a reply on the receiving socket. If no reply is received within that period of time the poll operation is deemed complete and the responding servers will be sorted and listed.

The default value for the pollTimeout attribute is 2000 milliseconds (2 seconds).

If the network or the servers are very busy it is possible that a server may not respond within the default time, if this is the case the timeout may be increased by specifying a larger value for pollTimeout attribute in either the command line or the session section of the configuration file used when invoking the controller.

The pollTimeout attribute may also be set within a controller session using the Set command on the controller command line.

6.6.8.1 Interactive mode

The control commands available to poll servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>poll</td>
<td>Poll active servers.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> poll
Polling servers ...
i73spregtestsrv(5) //111.137.33.8:2505/ {0x23E38538<602125624>} node = alfred
i73sslregtstsrv(2) //111.137.32.212:2503/ {0x2400FF7E<604045182>} node = victoria
i73sslregtstsrv(2) //111.137.33.8:2503/ {0x23E3CC2A<602131498>} node = alfred regtestsrv_a71(0) //111.137.32.1850/ {0x2026C201<539410945>} node = spencer
rdbthincontrol>
```
6.6.8.2 Command mode

The command mode commands available to poll servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>poll</td>
<td>-active</td>
<td>-all</td>
<td>-name</td>
<td>Poll active servers.</td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td>-port</td>
<td>-URL</td>
<td></td>
</tr>
<tr>
<td></td>
<td>-using</td>
<td></td>
<td>-in</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 6.6-18 Command Mode Poll Server

Example

$ thincontrol -poll

6.6.9 Poll Sub-commands

Starting with release 7.3.0.1.0, the controller will allow subcommands to be issued during a POLL request.

When a listening server receives a POLL request it may optionally carry-out a sub-command sent to it within the POLL request message.

There is currently only one recognized POLL sub-command:

- Reopenlogs

Note:
The POLL sub-command functionality is only available when using the thin controller JAR from release 7.3.0.1.0 (or above). Only release 7.3.0.1.0 (or above) servers will accept a POLL sub-command.

6.6.9.1 Reopenlogs Sub-command

The reopenlogs subcommand tells the listening server to re-open its log files allowing the prior version of the files to be read or copied.

Due to a restriction within Java on OpenVMS, log files opened by a JDBC server cannot be read or copied while the log files are currently being used by the server, thus to see the contents of these files they must first be closed by the server process.

On receiving this sub-command, the server will flush out its log stream, and then close its currently opened log files. It will then create a new version of the log files using the same file names.

6.6.9.2 Interactive mode

The control commands available to poll servers can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>poll reopenlogs</td>
<td>Poll active servers and request the log files to be re-opened.</td>
</tr>
</tbody>
</table>

Example

rdbthincontrol> poll reopenlogs
Polling servers ... 
regtestsrv_a71(0) //111.137.177:1850/ (0x2026C201<539410945>) node = spencer
rdbthincontrol> poll reopenlogs #name:regtestsrv_a71
Polling servers (using qualifiers : #name:regtestsrv_a71) ... 
regtestsrv_a71(0) //111.137.177:1850/ (0x2026C201<539410945>) node = spencer

6.6.9.3 Command mode

The command mode commands available to poll servers can be seen in the following table:
Table 6.6 - Command Mode Poll reopenlogs

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>poll reopenlogs</td>
<td></td>
<td></td>
<td>-active</td>
<td>Poll active servers and request the log files to be re-opened.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-all</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-name</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-node</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-port</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-URL</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-using</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>-ls</td>
<td></td>
</tr>
</tbody>
</table>

Example

$ thincontrol -poll reopenlogs
$ thincontrol -poll reopenlogs #name:MY_MP_SRV

6.6.10 Showing Executors

Since release 7.3.2.0.0

Information about executors within the currently connected multi-process server may be displayed using the controller.

6.6.10.1 Interactive mode

The control commands available to show executors can be seen in following table:

Table 6.6.21 Interactive Show Executors

<table>
<thead>
<tr>
<th>Command</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show executors</td>
<td></td>
<td></td>
<td>Shows all executors used by the currently connected server.</td>
</tr>
</tbody>
</table>

Example

rdbthincontrol> show executors

6.6.10.2 Command mode

The command mode commands available to show executors can be seen in following table:

Table 6.6.22 Command Mode Show Executors

<table>
<thead>
<tr>
<th>Command</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showexecutors</td>
<td>-active</td>
<td>-all</td>
<td>Show executors on the currently connected server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>If present will be used to establish a connection to a server.</td>
</tr>
<tr>
<td></td>
<td>-name</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-node</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-URL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

Example

$ thincontrol -showexecutors -port 1701 -node mynode

6.6.10.3 Information displayed in Show Executors

When the show executors command is executed, information about each executor is displayed as a list of attributes:

Table 6.6.23 Show Executors Display Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$EXECUTOR_NAME</td>
<td>Internal unique JDBC executor name allocated to each new executor.</td>
</tr>
<tr>
<td>RDB$PID</td>
<td>Show the OpenVMS process ID of the executor process.</td>
</tr>
<tr>
<td>RDB$STATE</td>
<td>Current state of the executor.</td>
</tr>
<tr>
<td>RDB$NUM_STMTS</td>
<td>The number of open and compiled SQL statements.</td>
</tr>
<tr>
<td>RDB$NUM_CURSORS</td>
<td>The number of cursors allocated.</td>
</tr>
<tr>
<td>RDB$MEM_SQLDAS</td>
<td>The amount of shared memory (bytes) used by SQLDA structures.</td>
</tr>
<tr>
<td>RDB$MEM_BUFFERS</td>
<td>The amount of shared memory (bytes) used by buffers.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RDB$MEM_SEG_STRINGS</td>
<td>The amount of shared memory (bytes) used by segmented strings (blobs).</td>
</tr>
<tr>
<td>RDB$MEM_NUM_FREE_CHUNKS</td>
<td>The number of free chunks of shared memory available for use.</td>
</tr>
<tr>
<td>RDB$MEM_LARGEST_CHUNK</td>
<td>The amount of memory (bytes) of the largest memory chunk available.</td>
</tr>
<tr>
<td>RDB$MEM_TOTAL_FREE</td>
<td>The amount of shared memory (bytes) allocated to this executor and still free.</td>
</tr>
<tr>
<td>RDB$MEM_PAGEFILE_QUOTA</td>
<td>Executor process JPI$_PGFLQUOTA value.</td>
</tr>
<tr>
<td>RDB$MEM_PAGEFILE_COUNT</td>
<td>Executor process JPI$_PAGFILECNT value.</td>
</tr>
<tr>
<td>RDB$MEM_GLOBPAGE_COUNT</td>
<td>Executor process JPI$_GPGCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_WS_COUNT</td>
<td>Executor process JPI$_PPGCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_PAGETBL_COUNT</td>
<td>Executor process JPI$_APTCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_PAGE_FAULTS</td>
<td>Executor process JPI$_PAGEFLTS value.</td>
</tr>
<tr>
<td>RDB$MEM_CPU_TIME</td>
<td>Executor process JPI$_CPUTIM value.</td>
</tr>
</tbody>
</table>

Note: The format and contents of the show executors display may change in future releases of Oracle JDBC for Rdb.

Example

```
rdbthincontrol> show executors
//localhost:1799/ is currently running 1 executor
RDB$EXECUTOR_NAME       : JDBCDEV00000001
RDB$PID                 : 0x22A7DF71(581427057)
RDB$STATE               : Client 00000004 connected
raid1:jdbc.regtest.721!mf_personnel as murray
RDB$NUM_STMTS           : 1
RDB$NUM_CURSORS         : 0
RDB$MEM_SQLDAS          : 139496
RDB$MEM_BUFFERS         : 0
RDB$MEM_SEG_STRINGS     : 0
RDB$MEM_NUM_FREE_CHUNKS : 2
RDB$MEM_LARGEST_CHUNK   : 165008
RDB$MEM_TOTAL_FREE      : 165800
RDB$MEM_PAGEFILE_QUOTA  : 718750
RDB$MEM_PAGEFILE_COUNT  : 576751
RDB$MEM_GLOBPAGE_COUNT  : 945
RDB$MEM_WS_COUNT        : 2070
RDB$MEM_PAGETBL_COUNT   : 0
RDB$MEM_PAGE_FAULTS     : 39
RDB$MEM_CPU_TIME        : 55
rdbthincontrol>
```

6.6.11 Showing Server Pool

Information about pooled servers being maintained by the currently connected pool server may be displayed using the controller.

6.6.11.1 Interactive mode

The control commands available to show pooled servers can be seen in following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show serverpool</td>
<td>Shows all pooled servers maintained by the currently connected pool server.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> show serverpool
```

6.6.11.2 Command mode

The command mode commands available to show server pools can be seen in following table:
Table 6.6 Command Mode Show Clients

<table>
<thead>
<tr>
<th>Command</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-showserverpool</td>
<td>-active</td>
<td>-name</td>
<td>Show pooled servers maintained by the currently connected server.</td>
</tr>
<tr>
<td></td>
<td>-all</td>
<td>-node</td>
<td>If present will be used to establish a connection to a server.</td>
</tr>
<tr>
<td></td>
<td>-port</td>
<td>-URL</td>
<td></td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

Example

```
$ thincontrol –showserverpool –port 1701 –node mynode
```

6.6.11.3 Information displayed in Show ServerPool

When the `show serverpool` command is executed, information about each pooled server is displayed as a list of attributes:

Table 6.6-26 Show Executors Display Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDBSERVER_NAME</td>
<td>Server name.</td>
</tr>
<tr>
<td>RDB$URL</td>
<td>URL of the server. Format “//node:port/”</td>
</tr>
<tr>
<td>RDB$PID</td>
<td>The process identification of the server process. Format “hexadecimal PID (decimal PID)”.</td>
</tr>
<tr>
<td>RDB$VERSION</td>
<td>The version information for the server JAR file used. Format “Release release# build#”.</td>
</tr>
<tr>
<td>RDB$MAX_CLIENTS</td>
<td>Maximum number of non-control client connections allowed by server.</td>
</tr>
<tr>
<td>RDB$NUM_CLIENTS</td>
<td>Current number non-control client connections.</td>
</tr>
<tr>
<td>RDB$STATE</td>
<td>Current state of the pooled server. Possible values: RUNNING – pooled server available, NOT RESPONDING – pooled server not responding to poll server status request.</td>
</tr>
</tbody>
</table>

Example

```
rdbthincontrol> connect 1804
rdbthincontrol> show serverpool
Server Pool controlled by //localhost:1804/ contains 3 servers:
RDBSERVER_NAME : srv1MP
RDB$URL         : //localhost:1881/
RDB$PID         : 5804
RDB$VERSION     : 73205:20130626
RDB$MAX_CLIENTS : 10
RDB$NUM_CLIENTS : 0
RDB$STATE       : RUNNING
RDBSERVER_NAME : srv2MP
RDB$URL         : //localhost:1882/
RDB$PID         : 5032
RDB$VERSION     : 73205:20130626
RDB$MAX_CLIENTS : 10
RDB$NUM_CLIENTS : 0
RDB$STATE       : RUNNING
RDBSERVER_NAME : srv3MP
RDB$URL         : //localhost:1883/
RDB$PID         : 5960
RDB$VERSION     : 73205:20130626
RDB$MAX_CLIENTS : 10
RDB$NUM_CLIENTS : 0
RDB$STATE       : RUNNING
```

```
rdbthincontrol>
```

6.7 Client Operations

6.7.1 Showing Clients
Clients will only be displayed for those servers where the control password matches the control session control password.

### 6.7.1 Interactive mode

The control commands available to show clients can be seen in following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show active clients show all clients</td>
<td>Shows all clients on responding servers.</td>
</tr>
<tr>
<td>show active clients &lt;name&gt; show all clients &lt;name&gt;</td>
<td>Shows all clients with username &lt;name&gt; on responding servers.</td>
</tr>
<tr>
<td>show active clients in &lt;database_spec&gt; show all clients in &lt;database_spec&gt;</td>
<td>Shows all clients currently connected to the specified database on all responding servers.</td>
</tr>
<tr>
<td>show clients</td>
<td>Shows all clients in the currently connected server.</td>
</tr>
<tr>
<td>show clients in &lt;database_spec&gt;</td>
<td>Shows all clients currently connected to the specified database on the currently connected server.</td>
</tr>
</tbody>
</table>

#### Example

```
rdbthincontrol> show active clients
rdbthincontrol> show all clients fred
rdbthincontrol> show clients
erdbthincontrol> show clients in disk1:[dbc]pers
erdbthincontrol> show all clients in disk1:[dbc]pers
```

### 6.7.1.2 Command mode

The command mode commands available to show clients can be seen in following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Required options</th>
<th>Additional options</th>
<th>Ignored options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-showClient &lt;client id&gt; &lt;active&gt; -all</td>
<td>-name</td>
<td>-node -port -URL -using &lt;user&gt;</td>
<td>Show specified client on the currently connected server.</td>
<td></td>
</tr>
<tr>
<td>-showClients</td>
<td>-name</td>
<td>-node -port -URL -using &lt;user&gt;</td>
<td>Show all clients on the currently connected server.</td>
<td></td>
</tr>
<tr>
<td>-in &lt;database_spec&gt;</td>
<td>-name</td>
<td>-node -port -URL -using &lt;user&gt;</td>
<td>Show all clients connected to &lt;database_spec&gt; on the currently connected server.</td>
<td></td>
</tr>
<tr>
<td>-showClients -all or -active</td>
<td>-name</td>
<td>-node -port -URL -using &lt;user&gt;</td>
<td>Show all clients on all responding servers.</td>
<td></td>
</tr>
<tr>
<td>-in &lt;database_spec&gt;</td>
<td>-name</td>
<td>-node -port -URL -using &lt;user&gt;</td>
<td>Show all clients connected to &lt;database_spec&gt; on all responding servers.</td>
<td></td>
</tr>
</tbody>
</table>

Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.

#### Example

```
$ thincontrol -showclients -all
$ thincontrol -showclients -port 1701 -node mynode
$ thincontrol -showclients -all -in db_dir:personnel
$ thincontrol -showclients -all -using murray
```

### 6.7.1.3 Information displayed in Show Client
When the `show client` command is executed, information about each client that matches any selection criteria provided is displayed as a list of attributes:

### Table 6.7.3 Show Clients display attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$CLIENT_ID</td>
<td>Internal unique JDBC client id allocated to each new connection request. An asterisk (*) suffix indicates your current control connection.</td>
</tr>
<tr>
<td>RDB$URL</td>
<td>The database specification component of the URL provided by the client connection. If this is a control connection the following string will be displayed: &quot;&lt;CONTROL CONNECTION&gt;&quot;.</td>
</tr>
<tr>
<td>RDB$USER</td>
<td>The username used by this client. In addition, if an application name has been provided for this connection (using the &quot;@app&quot; connection option) it will be displayed in parenthesis after the username. See Connection Options for more information on the use of the &quot;@app&quot; option. If this is a control connection the following string will be displayed: &quot;&lt;control&gt;&quot;.</td>
</tr>
<tr>
<td>RDB$IP</td>
<td>The IP of the source of the connection request. Format &quot;node:port&quot;.</td>
</tr>
<tr>
<td>RDB$PID</td>
<td>The identification of the thread this client is using on the server. Format &quot;hexadecimal PID:THREAD_ID (decimal PID:THREAD_ID)&quot;. If this is a control connection only the PID portion will be displayed.</td>
</tr>
<tr>
<td>RDB$PID_AT_EXECUTOR</td>
<td>The process identification of the executor this client is using. Format &quot;hexadecimal PID (decimal PID)&quot;. If the server is not multi-process, this attribute indicates the process identification of the server and the unique connection number allocated to this connection. Format &quot;hexadecimal PID:CONNECT_ID (decimal PID:CONNECT_ID)&quot;.</td>
</tr>
<tr>
<td>RDB$LAST_SQL</td>
<td>The last SQL statement (if any) issued by the client.</td>
</tr>
<tr>
<td>RDB$LAST_ACTION</td>
<td>The last action issued by client. Format &quot;timestamp : action&quot;.</td>
</tr>
<tr>
<td>RDB$LAST_EXCEPTION</td>
<td>The last exception (if any) raised on this client request within the server.</td>
</tr>
<tr>
<td>RDB$TIME_SINCE_LAST_ACTION</td>
<td>The amount of time elapsed since the last action recorded for this client on the server. Format &quot;days hours:minutes&quot;.</td>
</tr>
<tr>
<td>RDB$MINUTES_SINCE_LAST_ACTION</td>
<td>The amount of time elapsed in minutes since the last action recorded for this client on the server. Format “minutes”.</td>
</tr>
<tr>
<td>RDB$LAST_OPEN</td>
<td>Timestamp of the last connection made by this client.</td>
</tr>
<tr>
<td>RDB$PID_AT_DB</td>
<td>Since release 7.3.2.0.2 The process identification of the internal Rdb Stream this client is using. Format “hexadecimal PID: decimal STREAM_ID”. This is the same PID format used by other Rdb facilities such as RMU to uniquely identify client connections within the database. The Rdb stream information is only available if the client has connected to a database within an Rdb environment of Oracle Rdb release 7.2.5.0.0 or above, and the JDBC server used is release 7.3.2.0.2 or above.</td>
</tr>
</tbody>
</table>

In addition, if the connected server is multi-process then the following attributes will also be displayed for each client’s executor process (control connections will have all values set to zero (0)):

### Table 6.7.4 Additional Multi-Process Server Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$NUM_STMTS</td>
<td>The number of open and compiled SQL statements.</td>
</tr>
<tr>
<td>RDB$NUM_CURSORS</td>
<td>The number of cursors allocated.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RDB$MEM_SQLDAS</td>
<td>The amount of shared memory (bytes) used by SQLDA structures.</td>
</tr>
<tr>
<td>RDB$MEM_BUFFERS</td>
<td>The amount of shared memory (bytes) used by buffers.</td>
</tr>
<tr>
<td>RDB$MEM_SEG_STRINGS</td>
<td>The amount of shared memory (bytes) used by segmented strings (blobs).</td>
</tr>
<tr>
<td>RDB$MEM_NUM_FREE_CHUNKS</td>
<td>The number of free chunks of shared memory available for use.</td>
</tr>
<tr>
<td>RDB$MEM_LARGEST_CHUNK</td>
<td>The amount of memory (bytes) of the largest memory chunk available.</td>
</tr>
<tr>
<td>RDB$MEM_TOTAL_FREE</td>
<td>The amount of shared memory (bytes) allocated to this executor and still free.</td>
</tr>
<tr>
<td>RDB$MEM_PAGEFILE_QUOTA</td>
<td>Executor process JP$PGFLQUOTA value.</td>
</tr>
<tr>
<td>RDB$MEM_PAGEFILE_COUNT</td>
<td>Executor process JP$PAGFILCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_GLOBPAGE_COUNT</td>
<td>Executor process JP$PGGCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_WS_COUNT</td>
<td>Executor process JP$PPGCNT value.</td>
</tr>
<tr>
<td>RDB$MEM_PAGEFAULTS</td>
<td>Executor process JP$PAGEFLTS value.</td>
</tr>
<tr>
<td>RDB$MEM_CPU_TIME</td>
<td>Executor process JP$CPUTIM value.</td>
</tr>
</tbody>
</table>

Note: The format and contents of the show clients display may change in future releases of Oracle JDBC for Rdb.

Example

```
xdbthincontrol> show clients
RDB$CLIENT_ID : 00000002*
RDB$URL       : <CONTROL CONNECTION>
RDB$USER      : <control>
RDB$IP        : 127.0.0.1:62799
RDB$PID       : 0x22A57736(581269302)
RDB$PID_AT_EXECUTOR : 0x22A51437:1(581243959:1)
RDB$LAST_EXCEPTION : 0
RDB$TIME_SINCE_LAST_ACTION : 0 01:46
RDB$MINUTES_SINCE_LAST_ACTION : 106
RDB$LAST_OPEN : 0
RDB$PID_AT_DB  : 0
RDB$NUM_STMTS  : 0
RDB$NUM_CURSORS : 0
RDB$MEM_SQLDAS : 0
RDB$MEM_BUFFERS : 0
RDB$MEM_SEG_STRINGS : 0
RDB$MEM_NUM_FREE_CHUNKS : 0
RDB$MEM_LARGEST_CHUNK : 0
RDB$MEM_TOTAL_FREE : 0
RDB$MEM_PAGEFILE_QUOTA : 0
RDB$MEM_PAGEFILE_COUNT : 0
RDB$MEM_GLOBPAGE_COUNT : 0
RDB$MEM WS_COUNT : 0
RDB$MEM_PAGEFAULTS : 0
RDB$MEM_CPU_TIME : 0
```
6.7.2 Stopping Clients

Clients within active servers may be stopped using the controller. You must provide a valid control password for the server.

Clients will only be stopped in those servers where the control password matches the control session control password.

If a database file specification is used, only those clients current connected to that database will be stopped. The database file specification must match exactly, ignoring character case, to that shown in the show clients output.

Note:
Stopping a client will forcibly terminate all database connections on that server for that client and does not wait for client transaction completion.

You may use the show clients command to see clients that are currently using the server. See Showing Clients for more details.

In the following command, if <client_id> is provided, it must match a client id returned by the show clients command. Leading zeroes (0) may be left off the <client_id>.

6.7.2.1 Interactive mode

The control commands available to stop clients can be seen in the following table:

<table>
<thead>
<tr>
<th>Command (Interactive) Stop Clients</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stop active clients</td>
<td>Stops all clients on responding servers.</td>
</tr>
<tr>
<td>stop all clients</td>
<td></td>
</tr>
<tr>
<td>stop active clients &lt;name&gt;</td>
<td>Stops all clients with user name &lt;name&gt; on responding servers.</td>
</tr>
<tr>
<td>stop all clients &lt;name&gt;</td>
<td></td>
</tr>
<tr>
<td>stop active clients in &lt;database_spec&gt;</td>
<td>Stops all clients currently connected to the specified database on all responding servers.</td>
</tr>
<tr>
<td>stop all clients in &lt;database_spec&gt;</td>
<td></td>
</tr>
<tr>
<td>stop clients &lt;database_spec&gt;</td>
<td>Stops all clients currently connected server that are currently connected to the specified database.</td>
</tr>
<tr>
<td>stop client &lt;client_id&gt;</td>
<td>Stops the specified client on the currently connected server.</td>
</tr>
</tbody>
</table>

Example:

```
rdbthincontrol> stop active clients
rdbthincontrol> stop all clients fred
rdbthincontrol> stop clients
rdbthincontrol> stop client 0000000A
```

6.7.2.2 Command mode

The command mode commands available to stop clients can be seen in the following table:

<table>
<thead>
<tr>
<th>Command (Command Mode) Stop Clients</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-stopClient &lt;client_id&gt;</td>
<td>Stops specified client on the currently connected server.</td>
</tr>
<tr>
<td>-active -all &lt;user&gt;</td>
<td>If present will be used to establish a connection to a server.</td>
</tr>
<tr>
<td>-name -node -port -URL -using &lt;user&gt;</td>
<td>If present specifies that only users using the username &lt;user&gt; should be stopped.</td>
</tr>
<tr>
<td>-stopClients &lt;database_spec&gt;</td>
<td>Stops all clients on the currently connected server.</td>
</tr>
<tr>
<td>-name -node -port -URL -using &lt;user&gt;</td>
<td>If present will be used to establish a connection to a server.</td>
</tr>
<tr>
<td>-in &lt;database_spec&gt;</td>
<td>If present specifies that only users using the username &lt;user&gt; should be stopped.</td>
</tr>
<tr>
<td>-all</td>
<td>If present specifies that only users connected to</td>
</tr>
</tbody>
</table>
**Qualifiers specified in the Ignored Options column are silently ignored if present on the Command line.**

### Example

```bash
$ thincontrol -stopClient 0000000A
$ thincontrol -stopClients -all
$ thincontrol -stopClients -active -in db_dir:mf_personnel
$ thincontrol -stopClients -all -using murray
$ thincontrol -stopClients -port 1701 -node mynode -using murray
```

### Contents

#### 6.8 Other Commands

The Controller has several commands that are neither server nor client operations:

- digest
- obfuscate

#### 6.8.1 Digest

**Digest** will create a non-reversible obfuscated control password to be used in configuration files. See obfuscating **Control Passwords** for more details.

##### 6.8.1.1 Interactive mode

The control command available to obfuscate control passwords can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>digest &lt;plain text pwd&gt;</td>
<td>Obfuscates the control password using digest.</td>
</tr>
</tbody>
</table>

**Example**

```bash
rdthincontrol> digest thisismypassword
digest : 0x31435008693CE6976F45DEDC5532E2C1
```

##### 6.8.1.2 Command mode

The command mode commands available to obfuscate user passwords can be seen in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-digest &lt;plain text pwd&gt;</td>
<td>Obfuscates the control password using digest.</td>
</tr>
</tbody>
</table>

**Example**

```bash
$ java -jar rdthincontrol.jar -digest "MySecretPassword"
digest : 0x7315A012ECAD1059A3634F8EBE1347846
```

**Note:**

If double quotation characters are not used to surround the plain text password DCL may, depending on your environment, force the value to all lower case or all upper case which may differ from the original.

#### 6.8.2 Obfuscate

**Obfuscate** will create a reversible obfuscated user password to be used in configuration files. See obfuscating **User Passwords** for more details.

##### 6.8.2.1 Interactive mode

The control command available to obfuscate user passwords can be seen in the following table:
Table 6.8 - Interactive Mode Obfuscate

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obfuscate &lt;plain text pwd&gt;</td>
<td>Obfuscates the user password.</td>
</tr>
</tbody>
</table>

Example

```
rbthincontrol> obfuscate mypassword
obfuscation: ##016BA4158E5884C8D6EAFE71697D4DC9483417DA0BA1
```

6.8.2.2 Command mode

The command mode commands available to obfuscate user passwords can be seen in following table:

Table 6.8 - Command Mode Obfuscate

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obfuscate &lt;plain text pwd&gt;</td>
<td>Obfuscates the user password.</td>
</tr>
</tbody>
</table>

Example

```
$ thincontrol -obfuscate "mypassword"
obfuscation: ##0145A4158E5884C8D6EAFE71697D4DC9483417DA0BA1
```

Note:

If double quotation characters are not used to surround the plain text password DCL may, depending on your environment, force the value to all lower case or all upper case which may differ from the original.

Chapter 7
Oracle SQL/Services and Oracle JDBC for Rdb Servers

The Oracle SQL/Services management command line may be used to start and stop servers using the new dispatcher protocol called JDBC available in Oracle SQL/Services V7.1.6 and later.

Currently the Oracle SQL/Services interface to Oracle JDBC for Rdb Servers is minimal and may only be used to start and stop a JDBC dispatcher which in turn will start or stop the associated Oracle JDBC for Rdb server.

Starting an Oracle JDBC for Rdb server using Oracle SQL/Services involves the following steps:

1. Create an SQL/Services Dispatcher with the protocol JDBC.
   See Creating an Oracle SQL/Services JDBC Dispatcher.
2. Associate the JDBC Dispatcher with an Oracle JDBC for Rdb server.
   See Associating an Oracle SQL/Services JDBC Dispatcher to a Server.
3. Start the JDBC dispatcher.
   See Starting a JDBC Dispatcher.

In order for the dispatcher to start a server, the dispatcher must determine the name and type of the server, as well as the command procedures and configuration files to use during startup.

The following sections show how these determinations are carried out.

A1.3 Sample Setup, Starting an Oracle JDBC for Rdb thin server from Oracle SQL/Services, provides a working example on creating a JDBC dispatcher and its server associations.

7.1 JDBC Dispatcher

A new SQL/Services dispatcher protocol of JDBC was introduced in release 7.1.6 of Oracle SQL/Services. This dispatcher type allows you to create JDBC dispatchers that may be associated with Oracle JDBC for Rdb servers.

7.1.1 Creating an Oracle SQL/Services JDBC Dispatcher

To be able to start and stop Oracle JDBC for Rdb servers using Oracle SQL/Services, a dispatcher with protocol JDBC must be defined using the Oracle SQL/Services management console. You must provide the new dispatcher with a unique name and network port. It is important to ensure that the use of the PORT_ID is unique as the port provided will be used by the associated Oracle JDBC for Rdb server and only one server at a time may listen on a single TCPIP port.

Format
CREATE DISPATCHER <dispatcher name> NETWORK_PORT TCPIP PORT_ID <port> PROTOCOL JDBC;

Where:
• <dispatcher name> is a unique name for this dispatcher instance
• <port> is the port number the associated server will listen on

Example
$ MCR SQLSRV_MANAGE72
SQLSRV> CONNECT SERVER;
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1880 PROTOCOL JDBC;
SQLSRV> SHOW DISPATCHER;
Dispatcher JDBC_DISP
  State: UNKNOWN
  Autostart: on
  Max connections: 100 clients
  Idx User Timeout: <none>
  Max client buffer size: 5000 bytes
  Network Ports: (State) (Protocol)
  TCP/IP port 1880 Unknown JDBC clients
  Log path: SYS$MANAGER:
  Dump path: SYS$MANAGER:

Caution:
The Oracle SQL/Services Management GUI (unsupported software) does not recognize dispatchers of the type JDBC. This means that you will no longer be able to use the GUI once a JDBC dispatcher has been defined.

7.1.2 Associating an Oracle SQL/Services JDBC Dispatcher to a Server

Each Oracle SQL/Services JDBC dispatcher must be associated with an Oracle JDBC for Rdb server.

Since release 7.3.5.0.0

The simplest way to associate a JDBC server to a dispatcher, is to provide a JDBC server entry in the default JDBC configuration file named the same as the SQL/Services dispatcher.
7.1.2.1 Associating Server Characteristics using Dispatcher Name

The name chosen for the JDBC Dispatcher may be used as the name of the JDBC server that is started when the dispatcher is started.

By default, on dispatcher startup, SQL/Services will look in the default JDBC configuration file, RDB$JDBC_COM:RDBJDBCCFG.XML for a JDBC server named the same as the dispatcher name. If found this will be the server that the dispatcher will start up. For example, given the dispatcher name JDBC_DISP, you might create the following RDB$JDBC_COM:RDBJDBCCFG.XML file:

```xml
<?xml version = '1.0'?>
<!- Configuration file for Rdb Thin JDBC Drivers/Servers -->
<config>
  <!- SERVERS -->
  <server>
    <server name="DEFAULT" type="RdbThinSrv" url="//localhost:1701/" maxClients="-1" srv.bindTimeout="0" srv.idleTimeout="0" srv.mdbasePort="9520" srv.mogroupID="239.192.1.10" autoStart="false" controlUser="jdbc_user" controlPass="0x811B15F866179583EB3C96751585B843" cfo="rdb$jdbc_com:jdbc:mysql://localhost:3306" srv.startup="rdb$jdbc_home:jdbc_startsrv.com" srv.onStartCmd="@rdb$jdbc_com:rdbjdbc_sqs_onstartup.com"
    ...
</server>
</servers>
</config>
```

If you choose not to use the default configuration file, you may create a server specific configuration file RDB$JDBC_COM:<dispatcher name>_CFG.XML, for example, RDB$JDBC_COM:JDBC_DISP_CFG.XML.

Note: To ensure that SQL/Services and JDBC correctly associates server usage, you should make sure that the URL and PORT characteristics of the server in the configuration file match up with the PORT_ID chosen for the JDBC dispatcher.

If your system relies on legacy behaviour and expects that the associated JDBC server be named SQS<port>, you may disable the use of the dispatcher name association by deassigning the RDB$JDBC_SQS_USE_DISPNAME system logical name that will be setup if you executed the JDBC startup command procedure suggested during JDBC installation. By default this is a system/exec based logical name so to deassign the logical name use:

```bash
$ deassign/system/exec RDB$JDBC_SQS_USE_DISPNAME
```

7.1.3 Legacy Behaviour – Using the PORT_ID

The PORT_ID specifies the TCP/IP port that can be used by the Oracle JDBC for Rdb server and is used by the dispatcher start up procedures to determine information about the associated server.

In addition to which port the server will listen on, the PORT_ID may be used by the dispatcher to determine:

- What type of Oracle JDBC for Rdb server to start.
- The name that will be given to this server.
- What configuration file to use for this server.
- Any DCL command to run during the server startup procedure.

The overloading of the use of the PORT_ID by the JDBC dispatcher is necessary as the amount of information stored for a JDBC dispatcher is minimal keeping it in line with the information stored for other SQL/Services Dispatcher types.

In the process of determining the server attributes the dispatcher may try to translate the following logical names:

- RDB$JDBC_SQSNAM_<port>
- RDB$JDBC_SQSCFG_<port>
- RDB$JDBC_SQSCMD_<port>
- RDB$JDBC_SQSTYPE_<port>
In the above logical names the `<port>` will be substituted by the PORT_ID of the JDBC dispatcher prior to logical name translation.

If no such logical names exist, the dispatcher will then use alternate methods to provide the server with a name and will to try to locate a suitable command procedure and configuration file. The following sections detail how these determinations are carried out.

When determining the server information required to correctly start the associated Oracle JDBC for Rdb server, the dispatcher will carry out the following steps in the order specified:

1. First the dispatcher will create a name for the server.
2. Any DCL command required to be executed during server start up is then determined.
3. The file specification of the configuration file to provide to the server is then determined.
4. The server type for the server is then determined.

If you have not set up specific criteria for the JDBC server as detailed in the following sections, these defaults will be used:

1. The server name will be SQS<port>.
2. The standard JDBC server startup command procedure, `RDB$JDBC_HOME:RDBJDBC_STARTSRV.COM` will be executed.
3. The configuration file `RDB$JDBC_COM:RDBJDBCCFG.XML` will be used.
4. The server type will be designated as POOL.
5. If JAV A is not setup system-wide then JAVA Release 8.0 will be selected.
6. If Rdb has not been setup for the server process, then Rdb V7.3 will be selected.
7. If running on A64 and JAVA 8.0 or later is available then 64 Bit JDBC servers will be used.

### 7.1.3.1 Determining the server name

A server name is required as it may be used by the server start up procedure to locate properties from its configuration file. The name used will determine various characteristics of the started server.

In addition the server name will be used as the OpenVMS process name and will determine the naming of any associated executors if the server is a multi-process server.

The server name is also used in creating log and temporary files during the running of the server.

The PORT_ID is used to determine the name of the Oracle JDBC for Rdb server using the following precedence:

1. If the logical name `RDB$JDBC_SQSNAM_<port>` exists then it is translated to provide the server name
2. If the logical name does not exist the server name will be `SQS<port>`

#### Example 1

Logical name not defined:

```
$ show log RDB$JDBC_SQSNAM_1888  
%SHOW-S-NOTRAN, no translation for logical name RDB$JDBC_SQSNAM_1888  
$ MCR SQLSRV_MANAGE72  
SQLSRV> CONNECT SERVER;  
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;  
```

This will create a server named `SQS1888`.

#### Example 2

Logical name defined:

```
$ DEFINE/SYSTEM RDB$JDBC_SQSNAM_1888 MY_POOL_SRV  
$ MCR SQLSRV_MANAGE72  
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;  
```

This will create a server named `MY_POOL_SRV`.

### 7.1.3.2 Determining extra DCL commands for use during start-up

During the invocation of a JDBC server, the following DCL command procedure is executed:

`RDB$JDBC_HOME:RDBJDBC_STARTSRV.COM`

This is the standard startup command procedure used by Oracle JDBC for Rdb and was created for you during the installation of the Oracle JDBC for Rdb product.

This command procedure will setup some environmental elements and then execute a Java command to start the server. A discrete dispatcher process will be set up by the SQL/Services START DISPATCHER command and the Java command will be run under this process context.

The `RDBJDBC_STARTSRV` command procedure will try to locate and execute any specific setup command procedures you may have designated for its use. This is done prior to the procedure executing the Java command that will ultimately start the server instance.

The PORT_ID is used to determine the name of an Open VMS DCL command procedure that may be invoked containing your system and environmental setup procedures. The file specification of the command procedure is determined using the following precedence:

1. If the logical name `RDB$JDBC_SQSCMD_<port>` exists then it is translated to provide the command procedure file specification
2. If the logical name does not exist the dispatcher will try to locate and execute the file `rdb$jdbc_home:rdbjdbc_sqs_onStartup.com`
3. If this file does not exists the dispatcher will try to locate and execute the file `rdb$jdbc_home:rdbjdbc_sqs_onStartup.com`

89
Example 1

Logical name not defined and file rdb$jdbc_com:rdbjdbc_sqs_onStartup.com does exist:

```
$ show log RDB$JDBC_SQSCMD_1888
%SHOW-S-NOTRAN, no translation for logical name RDB$JDBC_SQSCMD_1888
$ MCR SQLSRV_MANAGE72
$SQLSRV> CONNECT SERVER;
$SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
The file RDB$JDBC_COM:RDBJDBC_SQS_ONSTARTUP.COM will be executed.
```

Example 2

Logical name defined:

```
$ DEFINE/SYSTEM RDB$JDBC_SQSCMD_1888 RDB$JDBC_COM:MY_SRV1888_ONSTART.COM
$ MCR SQLSRV_MANAGE72
$SQLSRV> CONNECT SERVER;
$SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
The file RDB$JDBC_COM:MY_SRV1888_ONSTART.COM will be executed.
```

7.1.3.3 Determining the server configuration file

The PORT_ID is also used to determine the configuration file to use on server startup. This file can be a CFG or an XML-formatted configuration file and is used to provide information to the server about what characteristics it should use when running. See Configuration Files for more details on the use of configuration files.

You may choose to provide a separate configuration file for the server associated with each JDBC dispatcher, or you may choose to use a single XML-formatted configuration file containing the server attributes for all your servers.

The appropriate configuration file is determined by the dispatcher by trying to translate the logical name RDB$JDBC_SQSCFG_<port> where PORT_ID is substituted for <port> prior to logical name translation. If the logical name is not there then the dispatcher will try use a configuration file from the JDBC system directories.

The following is the precedence for this file search:

1. The file pointed to by the RDB$JDBC_SQSCFG_<port> logical name if it exists.
2. RDB$JDBC_COM:<server name>_CFG.XML where the server name as determined in previous steps is substituted for <server_name>
3. RDB$JDBC_COM:SQLSRV_JDBC_SERVER_CFG.XML
4. RDB$JDBC_COM:RDBJDBCCFG.XML

Example 1

Logical name not defined and file RDB$JDBC_COM:SQLSRV_JDBC_SERVER_CFG.XML does exist:

```
$ show log RDB$JDBC_SQSCFG_1888
%SHOW-S-NOTRAN, no translation for logical name RDB$JDBC_SQSCFG_1888
$ MCR SQLSRV_MANAGE72
$SQLSRV> CONNECT SERVER;
$SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
The file RDB$JDBC_COM:SQLSRV_JDBC_SERVER_CFG.XML will be used.
```

Example 2

Logical name defined:

```
$ DEFINE/SYSTEM RDB$JDBC_SQSCFG_1888 RDB$JDBC_COM:MY_SRV1888_CFG.XML
$ MCR SQLSRV_MANAGE72
$SQLSRV> CONNECT SERVER;
$SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
The file RDB$JDBC_COM:MY_SRV1888_CFG.XML will be used.
```

7.1.3.4 Determining Server Type

During the startup of the server associated with the Oracle SQL/Services JDBC dispatcher, the type of the server to startup also needs to be determined.

The server type will be used by the dispatcher to determine the appropriate JDBC JAR file to use when invoking the server. The server type will also used to determine other server attributes that have to be set for a successful instantiation of a server process.

The dispatcher will use the PORT_ID to try to identify the appropriate JDBC server type to start.

There are four types of Oracle JDBC for RdB servers recognized by Oracle SQL/Services:

- **POOL** - a Pool server i.e. type="RdbThinSrvPool"
- **MP** - a multi-process server i.e. type="RdbThinSrvMP"
- **STD** - a standard thin server i.e. type="RdbThinSrv"
- **MAN** - a manager server i.e. type="RdbManSrv"

When the dispatcher determines the server type, the following steps are used:

1. If the logical name RDB$JDBC_SQSTYPE_<port> exists, it is translated to provide the server type. The translated logical name must be one of the valid server types as shown above.
2. If the logical name does not exist the server type will be **POOL**.
Note:
As the dispatcher cannot currently use the server name to determine the server type, it is important that this logical name be correctly setup if the type of the server to start is not a POOL server i.e. type="RdbThinSrvPool". If this is not correctly set the wrong JDBC JAR file may be used and the server may fail to start correctly. The log files associated with the server, usually written to the directory RDB\JDBC_LOGS will show the start-up failure and the reason for the failure.

Example 1
Logical name not defined:

```sql
$ show log RDB\JDBC\SQSTYPE_1888
SHOW-S-NOTRAN, no translation for logical name RDB\JDBC\SQSTYPE_1888
$ MCR SQLSRV_MANAGE72
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
```

This will create a server with type RdbThinSrvPool.

Example 2
Logical name defined:

```sql
$ DEFINE/SYSTEM RDB\JDBC\SQSTYPE_1888 MP
$ MCR SQLSRV_MANAGE72
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 1888 PROTOCOL JDBC;
```

This will create a server with type RdbThinSrvMP.

Example 3
Logical name defined:

```sql
$ DEFINE/SYSTEM RDB\JDBC\SQSTYPE_2070 MAN
$ MCR SQLSRV_MANAGE72
SQLSRV> CREATE DISPATCHER JDBC_DISP NETWORK_PORT TCPIP PORT_ID 2070 PROTOCOL JDBC;
```

This will create a server with type RdbManSrv.

Contents

7.1.4 Starting a JDBC Dispatcher

Once you have defined a JDBC dispatcher, it can be started like any other Oracle SQL/Services dispatcher:

Example

```sql
SQLSRV> start dispatcher jdbc_disp;
SQLSRV> show disp jdbc_disp;
```

The Oracle SQL/Services monitor will attempt to start the server associated this dispatcher.
If the dispatcher fails to start, the SQL/Services server should contain an error entry for this event in the server’s log file:

```
---
EVENT BEGIN: EVENT_LOG ------------------------
Tue Jan 24 16:36:18.880 2017
---
%SQLSRV-I-EVENT_LOG, event logged at line 8704 in file CMD.C;1
%SQLSRV-E-FLOBDISPUNAVAIL, Dispatcher process JDBC_DISP00I failed
%SQLSRV-I-LOGFILE, Log file : SYS$SYSROOT:[SYSMGR]\SQS_MYNODE_JDBC_DISP00I73.LOG;
Dump file: SYS$SYSROOT:[SYSMGR]\SQS_MYNODE_JDBC_DISP00I73.DMP;
---
EVENT END: EVENT_LOG ------------------------
---
```

```
$ type SYS$SYSROOT:[SYSMGR]\SQS_MYNODE_JDBC_SRV\MCH_0073.LOG;
```

---EVENT BEGIN: EVENT_LOG ------------------------
Tue Jan 24 16:36:18.880 2017---
SQLSRV-E-LOGFILE, Log file located at line 8704 in file CMD.C;1
SQLSRV-E-FLOBDISPUNAVAIL, Dispatcher process JDBC_DISP00I failed
SQLSRV-E-LOGFILE, Log file : SYS$SYSROOT:[SYSMGR]\SQS_MYNODE_JDBC_DISP00I73.LOG;
---EVENT END: EVENT_LOG ------------------------
Tue Jan 24 16:36:18.880 2017---
```
The dispatcher events are written to the SYSSMANAGER directory in a log file named:

SYS$MANAGER:SQS_<nodename>_JDBC_DISP<nnnnn>.LOG

The <nodename> depends on the node the dispatcher is started up on. The <nnnnn> is the unique id given to this dispatcher instance by Oracle SQL/Services

For example:

SQS_MYNODE_JDBC_DISP00173.LOG

This log can be useful in determining why a dispatcher did not start up properly. For example if appropriate logical names have not been setup as specified in the installation of Oracle JDBC Drivers for Rdb then a message similar to the following may be found at the end of the log file:

$ @rdb$jdbc_home:rdbjdbc_startsrv SQS1880 "SQS" %DCL-OPENIN, error opening RDB$JDBC_HOME:[SYSMGR]\RDBJDBC_STARTSRV.COM; as input "RMS-F-DEV", error in device name or inappropriate device type for operation SYSTEM job terminated at 21-JAN-2017 16:36:18.880

Accounting information:
Served 2/0 count: 37 Peak working set size: 2272
Direct 1/0 count: 14 Peak virtual size: 173072
Page faults: 192 Mounted volumes: 0
Charged CPU time: 0 00:00:00.24 Elapsed time: 0 00:00:00.21

If it is not clear from the dispatcher log what may have caused the error you can define the logical name SQLSRV_JDBC_SERVER_STARTUP_VERIFY:

$define/sys SQLSRV_JDBC_SERVER_STARTUP_VERIFY "true"

This will enable DCL verify for the SQL/Services JDBC startup command procedure.

Once this logical name is defined try to start the dispatcher again. The dispatcher log should now show the DCL verify for the startup command procedure.

Check this trace information for the names of the configuration file and command procedures and other setup criteria used during the startup attempt.

7.1.5 Stopping a JDBC Dispatcher

The STOP DISPATCHER statement may be used to stop a running JDBC dispatcher.

Example

SQLSV> STOP DISPATCHER JDBC_DISP

This will also stop the associated Oracle JDBC for Rdb server.

If you have associated the dispatcher with a Pool server, and the pooled servers have autoStart enabled, then these pooled servers will also be shut down at this time.

See your Oracle SQL/Services documentation for more information on the Oracle SQL/Services management console.

Contents

7.2 Command Procedures used by Oracle SQL/Services

When a JDBC dispatcher is started, Oracle SQL/Services will use the OpenVMS command procedure SYS$MANAGER:SQLSRV_JDBC_SERVER_STARTUP<version>.COM

Since release 7.3.5.0.0

and

RDB$JDBC_HOME:SQLSRV_JDBC_SERVER_STARTUP_COMMON.COM

to start the server associated with a JDBC dispatcher.

As multiple versions of SQL/Services may be present on your system, the Oracle JDBC for Rdb installation provides multiple versions of the SQLSRV_JDBC_SERVER_STARTUP command procedure. The <version> of the command procedure determines the version of SQL/Services it is associated with, thus:

SYS$MANAGER:SQLSRV_JDBC_SERVER_STARTUP71.COM

will be the command procedure used by version 7.1 SQL/Services during the JDBC dispatcher startup.

These command procedures in turn execute the following command procedure:

RDB$JDBC_HOME:RDBJDBC_STARTSRV.COM

This enables you to have multiple versions of the Oracle JDBC for Rdb on your systems, each with potentially different startup requirements specified in the RDBJDBC_STARTSRV.COM. The logical name RDBS$JDBC_HOME in your SQL/Services environment may be used to select the specific version of the Oracle JDBC for Rdb it will use.
As the releases of Oracle JDBC for Rdb are independent of the releases of Oracle SQL/Services, the currently installed version of Oracle JDBC for Rdb may not have installed an appropriate SQL/Services JDBC Server command procedure for all SQL/Services versions installed on your system.

If this is the case, JDBC dispatchers will not start up correctly for the installed SQL/Services version.

To fix this problem you can simply copy an existing SQL/services JDBC Server command procedure within SYSSMANAGER: and alter the version number of its filename to reflect the SQL/Services version you are using.

7.2.1 JDBC Dispatcher Setup Procedure

In addition, an additional OpenVMS command procedure can be defined to set up environmental characteristics required for your system. This command procedure is located for use with this server using the following precedence:

1. the file pointed to by the logical name RDB$JDBC_SQSCMD_<port> if defined
2. RDB$JDBC_COM:RDBJDBC_SQS_ONSTARTUP.COM
3. RDB$JDBC_HOME:RDBJDBC_SQS_ONSTARTUP.COM

If command procedure is found on your system using this search list, this command procedure will be executed just prior to the server being invoked. You may use this command procedure and to setup environmental conditions for the server execution, for example:

```bash
$@sys$share:rdb$setver 71
$@sys$common:[java$141.com]JAVA$141_SETUP.COM
```

7.3 Using Pool Servers

Each JDBC dispatcher defined is related only to a single server. Use a Pool server if you require more than one server to be started for a single dispatcher.

By defining a pool of servers that the Pool server can use and enabling autoStart on each of these servers, a whole pool of servers can be started by starting a single dispatcher. See Pool Server Operation for more information on Pool servers.

The following example shows how you can define a dispatcher to start up a Pool server that will automatically start up three standard thin servers as part of its pool.

**Contents**

7.3.5.0.0

**Note:**

This example uses the default server naming, server type of POOL and a standard SQS_ONSTARTUP command procedure. No RDB$JDBC_SQS* logical names need be set up.

1. Define an Oracle SQL/Services dispatcher

```bash
$ MCR SQLSRV_MANAGE72
SQLSRV> connect server;
SQLSRV>
CREATE DISPATCHER POOL_DISP NETWORK_PORT TCPIP PORT_ID 1880 PROTOCOL JDBC;
```

2. Create a configuration file for this server in RDB$JDBC_COM:POOL_DISP_CFG.XML

```xml
<config>
  <servers>
    <server name="DEFAULT" type="RdbThinSrv" url="/localhost:1701/" maxClients="-1" srv.bindTimeout="0" srv.idleTimeout="0" srv.mcBasePort="5520" srv.mcGroupIP="239.192.1.10" autoStart="false" controlUser="jdbc_user" controlPass="0x811B15F866179583EB3C96751585B843" cfg="rdb$jdbc_com:sqlsrv_jdbc_server_cfg.xml" srv.startup="rdb$jdbc_home:rdbjdbc_startsrv.com" srv.onStartCmd="@rdb$jdbc_com:rdbjdbc_sqs_onstartup.com" />
    <server name="SQSrjs1" type="RdbThinSrv" url="/localhost:1891/" autoStart="true" maxClients="10" />
  </servers>
</config>
```
3. Create an onStartup command procedure that sets up the appropriate Rdb and Java versions for your system:

For example, RDB$JDBC_COM:RDBJDBC_SQS_ONSTARTUP.COM may contain:

```bash
$@sys$share:rdb$setver 73
$@sys$common:java$60.com:JAVA$60 SETUP.COM
```

4. Start the dispatcher

```bash
SQLSRV> start dispatcher pool_disp
```

Remarks

In this example the command procedure pointed to by default srv.onStartCmd in the XML configuration file happens to be the same as the one created as the SQS__ONSTARTUP command procedure. These do not have to be the same command procedure.

The Oracle SQL/Services JDBC dispatcher SQS__ONSTARTUP command procedure is used during the startup of the associated Pool server. The pooled servers that the Pool server starts, use the command procedure pointed to by the srv.onStartCmd switch.

Chapter 8
Performance

The overall performance of application access to an underlying relational database depends on a number of factors including:

- **Database performance including:**
  - Speed of query compilation
  - Efficiency of query optimization
  - Efficiency of record lookup using indexes
  - Efficiency of record retrieval
  - Performance of the underlying operating system and hardware

- **JDBC performance including:**
  - Efficiency of object creation and disposal
  - Efficiency of internal message protocols
  - Degree of buffering of data and metadata
  - Efficiency of the underlying subsystem used by the drivers and servers including the Java VM, operating system and hardware

- **Network performance including:**
  - The number of client/server message round-trips
  - The network “distance” between the client and server machines, the more hops taken between the two nodes, the longer the round-trip time
  - Size of network buffers and flush times
  - Overall performance of the network

- **Application performance including:**
  - Effective utilization of database and operating system resources
  - SQL statement reuse utilizing PreparedStatements
  - Use of data buffering by utilizing appropriate Fetchsize

Details on performance considerations for the underlying Rdb database system may be found in your Oracle Rdb documentation.

Details about performance and your network may be found in the appropriate documentation provided by your hardware and operating system vendors.

Details about Java VM and operating system performance may be found in documentation provided by your operating system vendors.

Details about performance consideration related to the use of Oracle JDBC for Rdb drivers and servers maybe be found in the following sub-sections and elsewhere in this document and the Oracle JDBC for Rdb Release Notes.

### 8.1 Performance Features

There are several features available in Oracle JDBC for Rdb to help improve the overall performance of your applications using the JDBC drivers and the efficiency and performance of the JDBC servers:

- **Fetchsize** may be used to improve the overall performance of record retrieval by reducing the number of network round-trips used to retrieve records.
- **Lockwait and Maxtries** may help overall concurrency and performance when using thin servers.
- **Inactivity timeouts** may be used to limit the number of resources tied-up by unused servers and inactive connections.
- **SQL statement caching** may be used to reduce the compilation and setup time of frequently used queries.
- **Results caching** may be used to improve record retrieval times by caching frequently used query results.

### 8.2 FetchSize

The `setFetchSize` methods in `Statement` and `ResultSet` allow you to set the record fetch size for server record retrieval. The `FetchSize` gives a hint to the server as to how many records to batch up and send over the network at one time.

Network I/O is very expensive, so the more data you can send in a single I/O the better the performance. If you do not explicitly change the default `FetchSize` by using the `FetchSize` option, the default is 100.

### 8.3 Lockwait and Maxtries

The standard thin server is a multi-threaded server that allows concurrent access to Oracle Rdb by many client processes. Within a single OpenVMS process, Oracle Rdb is single-threaded, thus the thin server has to synchronize client database activity.

Because database actions must be serialized, any action that might take a prolonged length of time may seriously impact the overall throughput of the server.

By default the server will wait indefinitely for a lock, however, in order to try to minimize the impact of one client thread on another you may specify the period of time the server should wait for a lock.
If this wait is not indefinite, any thread will wait for the specified amount of time trying to get a lock. If the lock is not granted control is returned to the server. By default, the server will then try to get a lock ten (10) times, waiting for the specified amount of time each time, before raising a locking exception.

Specifying a short wait duration, for example one (1) second, may help reduce the impact that one thread may have on another sibling thread.

The *lockwait* connection option or server option allows control of the duration of the wait for a lock, the minimum actual wait period being one (1) second, which is the minimum lock wait time supported by Rdb transactions. A *lockwait* of 0 is the same as starting up a transaction with *NOWAIT*. A *lockwait* of minus one (-1) is the same as starting up a transaction with *WAIT* without specifying a value, which causes the server to wait indefinitely.

The *maxtries* connection option or server option allows you to specify the maximum number of times the server will try to get a lock before giving up. The default *maxtries* value is 10.

The higher the value you assign to the *lockwait* switch, the more likely that a locked object may slow down all clients, so it is preferable to keep the lockwait at a minimum but increase the number of lock attempts appropriately.

### 8.3.1 Lockwait precedence

As well as being able to specify the lockwait either at the server level or at the connection level as shown above, Oracle Rdb allows you to specify a maximum lock wait for the process by using the RDM$BIND_LOCK_TIMEOUT_INTERVAL logical name. In addition a database-wide lock timeout value may be established using the LOCK TIMEOUT INTERVAL clause of the SQL CREATE DATABASE and SQL ALTER DATABASE statements.

The following describes the order of precedence observed when lockwait has been specified in more than one way.

1. A connection lockwait value as specified explicitly on the connection string will take precedence over the server lockwait value but only for that one connection.
2. An explicit lockwait set on either the server or connection will take precedence over the value set by the RDM$BIND_LOCK_TIMEOUT_INTERVAL logical name.
3. The database-wide lock timeout interval if specified will place an upper limit on the interval specified by the RDM$BIND_LOCK_TIMEOUT_INTERVAL logical name or the lockwait on both the server and connection.

**Example 1**

```
RDM$BIND_LOCK_TIMEOUT_INTERVAL = 10
server LOCKWAIT = 20
connection LOCKWAIT = 30
LOCK TIMEOUT INTERVAL not specified
```

Results in a lockwait of 30.

**Example 2**

```
RDM$BIND_LOCK_TIMEOUT_INTERVAL = 10
server LOCKWAIT = 20
connection LOCKWAIT = 30
LOCK TIMEOUT INTERVAL = 25
```

Results in a lockwait of 25.

**Example 3**

```
RDM$BIND_LOCK_TIMEOUT_INTERVAL = 10
server LOCKWAIT = 20
connection LOCKWAIT = 30
LOCK TIMEOUT INTERVAL = 35
```

Results in a lockwait of 30.

**Example 4**

```
RDM$BIND_LOCK_TIMEOUT_INTERVAL = 10
server LOCKWAIT = 20
connection LOCKWAIT not specified
LOCK TIMEOUT INTERVAL not specified
```

Results in a lockwait of 20.

**Example 5**

```
RDM$BIND_LOCK_TIMEOUT_INTERVAL = 10
server LOCKWAIT not specified
connection LOCKWAIT not specified
LOCK TIMEOUT INTERVAL = 25
```

Results in a lockwait of 10.

See your Oracle Rdb Documentation for more information on the use of the RDM$BIND_LOCK_TIMEOUT_INTERVAL logical name and the LOCK TIMEOUT INTERVAL clause.

### 8.4 Inactivity timeouts
8.4.1 Client connection timeout

The `-cli.idleTimeout` switch may be used to specify the amount of time in milliseconds that a connection may remain inactive before being closed down. The default value of 0 specifies that the time is indefinite, i.e. the connection will not timeout.

You may specify the client idle timeout as a server configuration option either in the server definition within an XML-formatted configuration file or as a command-line switch when starting a server.

Example

For example:

```
$ java -jar rdbthinsrv.jar -port 1701 -cli.idleTimeout 3600000
```

specifies that any client connection may remain idle for 1 hour before being terminated

or in the XML-formatted configuration file:

```
<server
  name="srv2forRdb"
  type="RdbThinSrv"
  url="/localhost:1708/"
  cli.idleTimeout="3600000"
/>
```

When a client is forcibly terminated by this timeout the following message will be logged in the server log:

```
oracle.rdb.jdbc.common.RdbException:
Client terminated due to inactivity
```

When specified as a server switch, the timeout will apply to all clients connected using that server.

You may also specify the client timeout as a qualifier on the connection string on the client-side application.

```
Connection conn = DriverManager.getConnection("jdbc:rdbthin://bravo:1701/my_db_dir:personnel@cli.idleTimeout=360000",user, pass);
```

When specified this way the timeout will only apply to this one connection.

If a non-zero `cli.idleTimeout` is specified in both the server configuration and as a connection qualifier, the lesser of the two values will be used for that connection.

Inactivity is determined by the lack of activity on the socket the server is listening to the client on, if no request is sent from the client for the specified amount of time, a timeout is deemed to have occurred.

If a client inactivity timeout occurs on a connection that is using a multi-process server executor, that executor will be terminated. Even though the connection will be correctly closed down after the timeout event, as it is unknown why there was no activity seen on the connection, the executor sub-process is deemed "unsafe" and consequently is terminated.

8.4.2 Server Inactivity Timeout

You can specify the amount of time that a server may remain idle before being closed down due to inactivity.

The `-srv.idleTimeout` switch may be used to specify the amount of time in milliseconds that a server may remain inactive before being closed down. The default value of 0 specifies that the time is indefinite, i.e. the server will not timeout.

You may specify the server idle timeout as a server configuration option either in the server definition within an XML-formatted configuration file or as a command-line switch when starting a server.

Example

For example:

```
$ java -jar rdbthinsrv.jar -port 1701 -srv.idleTimeout 3600000
```

specifies that the server may remain idle for 1 hour before being terminated

Or in the XML-formatted configuration file:

```
<server
  name="srv2forRdb"
  type="RdbThinSrv"
  url="/localhost:1708/"
  srv.idleTimeout="3600000"
/>
```

When server is terminated by this timeout the following message will be logged in the server log:
A server inactivity timeout will occur if, after the length of time specified, no new client connection is
data to that server, and there are current not connect clients.

In other words, the timeout period is started after each new connection. If the timeout expires and
there are current connections still using the server, the timeout period will be reset to start again.

Contents

8.5 SQL Statement Cache

When using the thin driver, performance may be improved by enabling SQL statement caching.

Whenever the thin driver needs to prepare a SQL statement, the statement must be sent over the
network to the server for Oracle Rdb to prepare the statement and to send back a list of columns or
parameters that the statement references.

If the same SQL statement is prepared repeatedly during a single connection, without SQL statement
caching the statement will be prepared and column information sent back each time. This can be time
consuming because it requires network traffic, the preparation of the statement, and getting the column
and parameter information. These steps can be a substantial part of the network I/O and performance
cost of the queries.

To help reduce this cost, the thin driver allows you to cache SQL statements so that if the exact same
SQL string is prepared more than once during a single connected session, the cost for retrieving
column information is only incurred once.

SQL statement caching can be enabled by using the sqlcache switch when you request a connection
either by placing the switch in the connection URL or using the information block that is passed in the
connect request.

Example

Set the sqlcache property of the Properties passed to the DriverManager.getConnection
method:

```java
Properties info = new Properties();
info.put("user", user);
info.put("password", pw);
info.put("sqlcache", 100);
conn = DriverManager.getConnection (connStr, info);
```

Or append @sqlcache to the database specification part of the connect URL:

```java
Connection conn = DriverManager.getConnection("jdbc:rdbthin://bravo:1701/"+
"my_db_dir:personnel@sqlcache=100",user, pass);
```

In addition a SET SQLCACHE statement can be executed.

```java
Stmt.executeUpdate("set sqlcache 100");
```

Remarks

The value specified with the sqlcache switch tells the thin driver how many SQL statements it can hold
concurrently in its cache. A value of 0 (the default) specifies that SQL statement caching be disabled.

Once the SQL statement cache is full for a given connection, the storing of a new statement will
remove the least commonly used statement from the cache.

Because SQL statements may be held in cache even after the user has closed the containing
java.sql.Statement, the query will still be registered as current by Oracle Rdb and may prevent actions
such as DROP TABLE from being done. In addition each concurrent statement that is held in cache may
take up memory on both the server and client side of the connection.

You can clean out the connection SQL cache by issuing a SET SQLCACHE statement with value 0 and
then issuing another SET SQLCACHE statement to reset the cache to the desired size.

Currently you cannot specify the removal of a specific SQL statement from cache.

Note:

SQL statement caching is a client-side action and is disabled by default. This feature is
only applicable to the thin driver. Using the SQL Statement cache property or using the
set sqlcache statement will be silently ignored by the native driver.

8.5.1 Caching Statement Handles

In addition to saving the network cost of retrieving column information, enabling SQL statement
handle caching may also improve application performance when used in conjunction with SQL
statement caching.

Similar to using the PreparedStatements, enabling statement handle caching allows the Thin driver to
re-use compiled Rdb statements which may improve the overall performance of retrieving results as
the statement does not have to be compiled again or the column information retrieved from the server.
SQL statement handling caching works for both Statements and PreparedStatements. If the exact SQL text is recognized as being prepared previously in the same connection context, and that Statement is no longer in use (i.e. the Statement or PreparedStatement has been closed) then, instead of sending down a request to the server to compile the query again, the driver will re-use the statement handle compiled by the previous request.

This is particularly effective where applications may be using connection pooling. As it cannot be guaranteed that the query they wish to use is available within the connection context of the pooled connection allocated to the connection request, the same PreparedStatements may have to be issued repeatedly within the same actual Rdb connection context. This redundant query compilation may be costly in terms of network traffic.

If SQL statement handle caching is enabled, PreparedStatements may be effectively re-used across serial re-use of a pooled connection, thus saving expensive network IO required for query recompilation.

Statement handle caching can be enabled by using the sqlcachePS switch when you request a connection either by placing the switch in the connection URL or using the information block that is passed in the connect request.

Example

Set the sqlcacheps property of the Properties passed to the DriverManager.getConnection method:

```
Properties info = new Properties();
info.put("user", user);
info.put("password", pw);
info.put("sqlcacheps", "true");
conn = DriverManager.getConnection (connStr, info);
```

Or append @sqlcacheps to the database specification part of the connect URL:

```
Connection conn = DriverManager.getConnection("jdbc:rdbthin://bravo:1701/"+
 "my_db_dir:personnel@sqlcacheps=true",user, pass);
```

In addition a SET SQLCACHES statement can be executed.

```
Stmt.executeUpdate("set sqlcacheps true");
```

Remarks

The value true specified for the sqlcacheps switch tells the thin driver to keep hold of Rdb statement handles and other statement information to re-use if exactly the same Statement SQL text is recognized. A value of false specifies that SQL statement handle caching be disabled.

SQL statement caching must be enabled for SQL statement handle caching to take place; if SQL statement caching is disabled (i.e. sqlcache having the value '0'), the sqlcacheps switch is ignored.

Enabling SQL statement handle caching by executing a SET SQLCACHES = TRUE statement will automatically clear out any the existing SQL statement that may already be cached to ensure that handles are being maintained for all cached statements.

Disabling SQL statement handle caching on by executing a SET SQLCACHES = FALSE statement will prevent any further statement handles being saved. Existing cached statements will still be available for reuse for query compilation but the associated statement handles will not be reused.

To release all the resources associated with holding statement handles in cache you must clear the SQL cache by issuing a set sqlcache 0 statement.

Note: SQL statement handle caching is a client-side action and is disabled by default. This feature is only applicable to the thin driver. The sqlcacheps switch will be silently ignored by the native driver, or if SQL statement caching is not enabled.

---

**Contents**

8.6 Results Cache

When using the thin driver, performance may be improved by enabling Results caching. Results caching will maintain ResultSet context across the life of a connection, allowing frequently used data to be cached and reused by subsequent identical queries within the same connection.

Results cache effectively takes a “snapshot” of the query results the first time a particular SQL query is executed within a connection.

Results caching can be enabled by using the resultscache switch when you request a connection either by placing the switch in the connection URL or using the information block that is passed in the connect request.

Example

Set the resultscache property of the Properties passed to the DriverManager.getConnection method:

```
Properties info = new Properties();
info.put("user", user);
info.put("password", pw);
```
info.put("resultscache", 10);

conn = DriverManager.getConnection (connStr, info);

Or append @resultscache to the database specification part of the connect URL:

Connection conn = DriverManager.getConnection("jdbc:rdbthin://bravo:1701/"+
"my_db_dir:personnel@resultscache=10", user, pass);

In addition a SET RESULTSCACHE statement can be executed.

Stmt.executeUpdate("set resultscache 10");

Remarks
The value specified with the sqlcache switch tells the thin driver how many SQL statements it can hold concurrently in its cache. A value of 0 (the default) specifies that results caching be disabled.

The Results cache may be cleared by clearing the SQL cache by issuing a SET SQLCACHE statement with value 0 and then issuing another SET SQLCACHE statement to reset the cache to the desired size.

Currently you cannot specify the removal of a specific SQL statement from cache.

Note:
SQL statement caching is a client-side action and is disabled by default. This feature is only applicable to the thin driver. Using the SQL Statement cache property or using the set sqlcache statement will be silently ignored by the native driver.
9.1 Event Logging

Oracle Rdb for JDBC servers may be setup to log specified events to a special event logger that can be monitored by either the Oracle JDBC for Rdb controller or a special application created by you or a third party.

JDBC servers use the standard Java logging facility to log enabled server events, and these events may be then monitored by local or remote applications that have enlisted with the server as log watchers.

The controller may be used to watch events notifications by using the WATCH EVENTS command. Alternatively you may choose to write your own application to handle event notifications, details on how this may be achieved may be found in the following sections.

An example on how you may use the controller to watch for events of thin servers may be seen in Watch Events using the Controller. The Controlled subsection Watching Events covers the syntax of the Watch Events command.

Notification of events using a sample event watcher application is covered in WatchEvent Sample Application.

But before events can be monitored they need to be defined in the XML configuration file used by the server, and then enabled for each server by designating by using enableEvent elements. See the following sections for more details.

9.2 Defining and Enabling Events.

Rdb Events are special events that are defined in the Events section of the XML configuration file. Once defined these events may be enabled on a server-by-server basis by designating one or more enableEvent elements within the server configuration section of the XML configuration file.

Enabled Events specified in a default server configuration will be enabled for all servers that inherit the default server characteristics.

Servers will only log events that have been enabled either explicitly in the server’s configuration or in a default server configuration inherited by the server.

The following is an example configuration file that defines and enables events:

```xml
<config>
  <connections>
    <servers>
      <!-- DEFAULT server characteristics-->
      <server
        name="DEFAULT"
        type="RdbThinSrv"
        url="/\localhost:1701/"
        maxClients="-1"
        srv.bindTimeout="9"
        srv.idleTimeout="9"
        srv.networkKeepAlive="true"
        srv.mcBasePort="5517"
        srv.mcGroupIP="239.192.1.1"
        autoStart="false"
        controlUser="jdbc_user"
        controlPass="0x811B15F866179583EB3C96751585B843"
        cfg="my.xml"
      >
        <allowPrivUser name = "owner"/>
        <enableEvent name = "denied_sql"/>
        <enableEvent name = "db_error"/>
        <enableEvent name = "syntax_error"/>
      </server>
      <!-- SERVERS -->
      <server
        name = "rdbthnsrv8"
        description = "My test server"
        type = "RdbThinSrv"
        url = "\localhost:1708/"
        allowAccessToCL = "true"
        allowAccessToRMU = "true"
        controluser = "jdbc_user"
        restrictAccess = "true"
        restrictSQL = "SELECT,SHOW"
      >
        <deny SQL = "\(?i\).*select.*jobs.*"/>
        <allowUser name = "jdbc_user"/>
      </server>
    </servers>
  </connections>
</config>
```
The following sections explain how to define and enable events.

9.2.1 Defining Events

Events are described by an event section within the XML configuration file which comprises of several attributes as seen in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deviation</td>
<td>The deviation criteria allowed. This attribute is only valid for threshold type events. See Deviation for more details.</td>
</tr>
<tr>
<td>message</td>
<td>A customized message to display in the event log when this event occurs. This attribute is valid for all event types.</td>
</tr>
<tr>
<td>name</td>
<td>The unique name of this event, this attribute must be provided for each event.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pattern</td>
<td>Pattern that should be matched, the pattern value should be in the form of a Java regular expression.</td>
</tr>
<tr>
<td></td>
<td>See your Java documentation for more information on Regular Expressions.</td>
</tr>
<tr>
<td>testFor</td>
<td>Test criteria to test for, see the testFor table below.</td>
</tr>
<tr>
<td>threshold</td>
<td>This is the actual value that has to be met, exceeded, or near to trigger a threshold event. See Threshold Event Threshold attribute for more information.</td>
</tr>
<tr>
<td>type</td>
<td>Type or category of event; valid type are specified in Event Types.</td>
</tr>
<tr>
<td>watch</td>
<td>The specific element to monitor, this will depend on the type of the event. Details of valid values to watch can be found under the appropriate event type subsection within the Event Types section.</td>
</tr>
</tbody>
</table>

### Example

```
<event
  name = "NO_TABLE"
  type = "EXCEPTION"
  watch = "SYSERROR"
  pattern = ".*RELNOTDEF.*"
  message = "Problem with table ">
</event>
```

The above event will be triggered when an exception is raised that contains the string “RELNOTDEF” in its message. Details of the format of the event configuration section may be found in Events Section.

Each event must have a unique name, and be valid type as specified in Event Types. The addition event criteria will depend on the type of the event and is covered under each event type in the following sections.

### 9.3 Event Types

Events fall into the following categories or types:

- **DENIAL** – triggered when an operation is denied by the server
- **EXCEPTION** – triggered when an exception is raised by the server or the underlying database system
- **THRESHOLD** – triggered when some threshold has been reached or about to be reached.
- **EVENT** – general purpose event notification

Depending on the type of the Event, additional criteria may be required within the event description to characterize the event that should be logged. The following sections detail the different event types and attributes used to define the event criteria.

### 9.3.1 Denial Events

A Denial event, that is, an event with the event type "DENIAL" is triggered when an operation is denied by the server.

The following event criteria may be used with this event type:

- **Name**
- **Message**
- **Watch**

#### Example

```
<event
  name = "DENIED_USER"
  type = "DENIAL"
  watch = "USER"
  message = "You are not allowed to access this server"
/>```

The above event will be triggered when a user attempt to login but is not in the `allowUser` list for this server.

#### 9.3.1.1 Denial Event Watch Attribute

The specific operation to monitor is specified by the `WATCH` attribute of the event and include:

- **USER** – will be triggered when the server raises a denied user exception when the user attempting to use the server is not found in the server’s `allowedUser` list.

---

103
• DB – will be triggered when the server raises a denied database exception when the user attempts to connect to a database that is not found in the server’s allowedDB list.

• IP – will be triggered when the server raises a denied IP exception when the user attempts to connect to a database from an IP that is not found in the server’s allowed IP list.

• AUTH – will be triggered if the username/password provided is refused by the underlying database system.

• SQL – will be triggered if an attempt to use a SQL statement that is either not in the restrictSQL list of the server or is found to match the deny SQL attribute of the server configuration. See Restricting SQL Statements for more details.

If no WATCH attribute is provided then the event will be triggered on the occurrence of any of the denial events listed above.

9.3.2 Exception Events

An Exception event, that is, an event with the event type “EXCEPTION” is triggered when an exception is raised by the server or the underlying database system.

The following event criteria may be used with this event type:

- Name
- Message
- Watch
- Pattern

Example

```xml
<event
    name = "NO_TABLE"
    type = "EXCEPTION"
    watch = "SYSERROR"
    pattern = ".*RELNOTDEF.*"
    message = "Problem with table " />
```

The above event will be triggered when an exception is raised that contains the string “RELNOTDEF” in its message.

9.3.2.1 Exception Event Watch Attribute

Exception types are specified by the WATCH attribute of the event and include:

- SYSERROR - any exception thrown

In addition a pattern may be specified that filters the exceptions to only those that match the given regular expression pattern. The matching pattern is specified using the PATTERN attribute.

9.3.2.2 Exception Event Pattern Attribute

A regular expression pattern may be used to filter the exceptions that should be notified as an event. If a pattern is specified for the event, then only those exceptions where the exception message matches the specified pattern will be logged as an event.

If no pattern is specified all exceptions will be logged for this exception event.

See your Java documentation for more information on Regular Expressions.

9.3.3 Threshold Events

A Threshold event, that is, an event with the event type “THRESHOLD” is triggered when the specified threshold is met or exceeded, or is within or not within the deviation provided.

The following event criteria may be used with this event type:

- Name
- Message
- Watch
- Threshold
- TestFor
- Deviation

The value that will be tested to see if a threshold has been triggered is specified in the Threshold attribute of the event. The threshold comparison style is determined by the testFor attribute. If a Deviation attribute is also specified, it is used in conjunction with the Threshold attribute to determine a triggering range or limit.

Note:

The testing for threshold events is only carried out during certain standard server operations, such as during the connection of a new client or during the disconnect of an existing connection. During the normal execution cycle of a server, the various thresholds may be exceeded, but an event is only raised if the triggering criteria are met at the time of the trigger test.
Example

```xml
<event
  name = "Atleast2"
  type = "THRESHOLD"
  watch = "NUMUSERS"
  threshold="2"
  message = "The number of users of this server is >= 2"
/>
```

The above event will be triggered when the number of users is equal to or exceeds 2.

### 9.3.3.1 Threshold Event Watch attribute

Threshold types are specified by the `WATCH` attribute of the event and include:

<table>
<thead>
<tr>
<th>Literal</th>
<th>Tested during</th>
<th>Max determined by</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumUsers</td>
<td>Connect</td>
<td>The number of current clients on the server.</td>
</tr>
<tr>
<td></td>
<td>Disconnect</td>
<td></td>
</tr>
<tr>
<td>FreeSharedMem</td>
<td>Connect</td>
<td>The amount of free global shared memory in bytes.</td>
</tr>
<tr>
<td></td>
<td>Disconnect</td>
<td></td>
</tr>
<tr>
<td>NumFreeExecs</td>
<td>Connect</td>
<td>The number of free executors.</td>
</tr>
<tr>
<td></td>
<td>Disconnect</td>
<td></td>
</tr>
</tbody>
</table>

The value that will be tested to see if a threshold has been triggered is specified in the `Threshold` attribute of the event. The threshold comparison style is determined by the `testFor` attribute. If a `Deviation` attribute is also specified it is used in conjunction with the `Threshold` attribute to determine a triggering range or limit.

An event is only raised if the triggering threshold is met at the time specified by the “Tested during” column in the above table. At all other times the watched criteria may come within trigger range without actually triggering an event. So, for example, `FreeSharedMem` events will be only raised if the triggering criteria is met during the Connect or Disconnect phase of a user connection.

### 9.3.3.2 Threshold Event Threshold attribute

The `Threshold` attribute can be an integer value or may be the literal "Min" or may start with the text literal "Max".

If a text literal with the value "Min" or starting with "Max" is used then the threshold value is predetermined by the server attribute that is appropriate:

<table>
<thead>
<tr>
<th>Literal</th>
<th>Watch</th>
<th>Threshold determined by</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxFreeExecs</td>
<td>&lt;any&gt;</td>
<td>The server's <code>maxfreeexecutors</code> attribute.</td>
</tr>
<tr>
<td>MaxUsers</td>
<td>&lt;any&gt;</td>
<td>The server's <code>maxClients</code> attribute.</td>
</tr>
<tr>
<td>MaxSharedMemory</td>
<td>&lt;any&gt;</td>
<td>The server's <code>sharedmem</code> attribute converted to the number of bytes.</td>
</tr>
<tr>
<td>Max</td>
<td>NumUsers</td>
<td>The server's <code>maxClients</code> attribute.</td>
</tr>
<tr>
<td></td>
<td>NumFreeExecs</td>
<td>The server's <code>maxfreeexecutors</code> attribute.</td>
</tr>
<tr>
<td></td>
<td>FreeSharedMem</td>
<td>The server's <code>sharedmem</code> attribute converted to the number of bytes.</td>
</tr>
<tr>
<td>Min</td>
<td>NumUsers</td>
<td>The server's <code>maxClients</code> attribute.</td>
</tr>
<tr>
<td></td>
<td>NumFreeExecs</td>
<td>The server's <code>maxfreeexecutors</code> attribute.</td>
</tr>
<tr>
<td></td>
<td>FreeSharedMem</td>
<td>The server's <code>sharedmem</code> attribute converted to the number of bytes.</td>
</tr>
</tbody>
</table>

( **Note:** See description below. )

The text literals shown above are not case sensitive. If the `Threshold` attribute is not specified then "Max" is assumed.

By default "Min" implies the value 0 and will be evaluated as such when used as a threshold check, however when used with the `Watch` values as specified in the table above, the literal “Min” takes on a special meaning:

1. If a % deviation is present then the absolute deviation is determined by applying the % deviation value against the appropriate threshold attribute as shown in the table above. In this case the positive value of the % deviation is always used, any sign (+/-) is discarded.
2. The threshold range is then determined as being from 0 to the value calculated in 1 above.

See [Threshold Event Watch attribute](#) for more information.
Example

In this example, if the server's shared memory is set to 100000 bytes, this event will trigger when the amount of free shared memory is in the range of 0 through 10000 bytes.

9.3.3.3 Threshold Event TestFor attribute

The testFor attribute determines the test used to set the threshold trigger:

<table>
<thead>
<tr>
<th>testFor</th>
<th>Alternatives</th>
<th>Trigger when watch is</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQL</td>
<td>=, ==, EQUAL</td>
<td>Equal to threshold.</td>
</tr>
<tr>
<td>NEQ</td>
<td>!=, &lt;&gt;, NOT EQUAL</td>
<td>Not Equal to threshold.</td>
</tr>
<tr>
<td>LSS</td>
<td>&lt;, LESS</td>
<td>Less than threshold.</td>
</tr>
<tr>
<td>GTR</td>
<td>&gt;, GREATER</td>
<td>Greater than threshold.</td>
</tr>
<tr>
<td>LEQ</td>
<td>&lt;=, LESS OR EQUAL</td>
<td>Less than or equal to threshold.</td>
</tr>
<tr>
<td>GEQ</td>
<td>&gt;=, GREATER OR EQUAL</td>
<td>Greater than or equal to threshold.</td>
</tr>
<tr>
<td>WITHIN</td>
<td></td>
<td>Within the deviation of threshold.</td>
</tr>
<tr>
<td>NOT WITHIN</td>
<td></td>
<td>Not within the deviation of threshold.</td>
</tr>
</tbody>
</table>

The value of the testFor attribute may be the keyword as show in the testFor column above, or one of the alternate literals as shown in the Alternative column.

If neither a testFor nor a Deviation value is specified in the Event attribute list the testFor will default to GEQ.

If a Deviation value is specified but no testFor the testFor will default to WITHIN.

9.3.3.4 Threshold Event Deviation attribute

If a Deviation value is specified and a testFor value other than WITHIN or NOT WITHIN is specified then the Deviation is used to modify the Threshold value.

If a testFor value is not specified or the value of WITHIN or NOT WITHIN is specified, the deviation is used to produce a value range to be tested. The range is inclusive, that is, the range limit values will be considered as being included in the testing criteria.

The Deviation value may be signed or unsigned and may be an absolute or a percentage value using the following format:

Format

```
[+ | -] value [%]
```

If a sign operator prefix is used the value will be used to modify the Threshold value appropriately.

If a testFor value is not specified or the value of WITHIN or NOT WITHIN is specified then if a plus (+) operator is present the trigger range will be assumed to be from the threshold value to the threshold incremented by the value. If a minus(-) operator is present the range will be assumed to be from the threshold minus the value to the threshold value. If neither a plus (+) operator nor a minus(-) operator is present then the range will be the threshold +/- the value;

If a percent (%) operator is present a percentage value rather than an absolute value and will be used to modify the Threshold value.

Example1

```
<event
  name = "NearExhausted"
  type = "THRESHOLD"
  watch = "FREESHAREDMEM"
  threshold = "MAX"
  deviation = "-90%"
  testFor = "LSS"
  message = " Global shared memory is almost Exhausted !"
/> 
```

This event will trigger when the amount of free shared memory is less than 10% of the maximum allocated by the server.

Example2

```
<event
  name = "NearExhausted"
  type = "THRESHOLD"
/> 
```
This event will trigger when the free shared memory is less than or equal to 10% of the maximum allocated by the server. Note: This is actually a range test for values falling in the range 0 to 10% of the maximum free shared memory, inclusive.

Example 3

```xml
<event
  name = "Check Max Free Executors"
  type = "THRESHOLD"
  watch = "NUMUSERS"
  threshold = "MAXFREEEXECSES"
  deviation = "2"
  testFor = "WITHIN"
  message = "Consider increasing number of free executors"
 />
<event
  name = "Emphatic Check Max Free Executors"
  type = "THRESHOLD"
  watch = "NUMUSERS"
  threshold = "MAXFREEEXECSES"
  deviation = "+2"
  testFor = "GTR"
  message = "INCREASE the number of free executors NOW!"
 />
```

Event “Check Max Free Executors” will trigger if the current number of users changes to be within ±2 of the maximum number of free executors set for the server.

If the number of users is more than 2 above the max free executors the event “Emphatic Check Max Free Executors” will be triggered instead.

9.3.4 General Events

A general event, that is, an event with the event type “EVENT” is triggered when the specified event or operation is noted by the server.

The following event criteria may be used with this event type:

- Name
- Message
- Watch

Example

```xml
<event
  name = "Connect event"
  type = "EVENT"
  watch = "CONN_DISCON"
  message = "Connect or Disconnect occurred"
 />
```

The above event will be triggered whenever a connection is made or is disconnected.

9.3.4.1 General Event Watch attribute

The server event types are specified by the `WATCH` attribute of the event and include:

- Conn_Discon – log whenever a connection is made or is disconnected.

4. Watch Events using the Controller.

The controller may be used to watch for events happening on a JDBC server.

The Watch Events command tells the controller to enlist as an event listener with the specified server. All events then logged by the server will be displayed by the thin controller as XML-formatted events:

```
rdbthincontrol> watch events 1708
rdbthincontrol> logger:1540://100.191.133.64:1708/>rdbthinsrv8 :
logger:1540://100.191.133.64:1708/>INFO: <event> <seq>0</seq> <timestamp>2011-11-14 12:29:29.120</timestamp> <type>13</type> <name>CONNECT</name> <source>
```

Contents

4. Watch Events using the Controller.
See Watching Events for the syntax of the Controller Watch Events command.

Contents

9.5 WatchEvent Sample Application.

During installation the WatchEvent sample application will be installed in your JDBC installation directory. This application, deployed as a Java jar, can be run to watch for Rdb events being raised by the JDBC servers.

This sample application may be used as a template to help you develop your own Event notification application.

If you have not used this application before please carry out the steps described in the following sections:

9.5.1 WatchEvent Sample Application Setup

The WatchEvent.jar file contains a sample application that may be modified to carry out your own operations when a JDBC server event is received.

You may run the application unchanged on systems that run Java and have Java/Swing enabled by carrying out the following steps:

Step 1 Copy the WatchEvent.jar file to your desired system host

The WatchEvent.jar is a Java/Swing based application jar file that may be run on any system where JRE Version 1.6 or higher is running and that has Java/Swing enabled.
During installation of JDBC the WatchEvent.jar file will be copied to the JDBC installation directory. If you have carried out the advised post installation steps this directory will be pointed to by the logical name RDB$JDBC_HOME.

Copy this jar file to the system you wish to run on. Make sure that any file copy application you use copies the file in binary format otherwise it may not work correctly on the destination system.

As well as containing the Java application, the jar file contains the following source files that may be extracted and used:

- WatchEvents.java – the source for this application
- WatchEvents.cfg – a sample configuration file
- Event.xsl – a sample XSLT stylesheet

Various JAR and ZIP file explorer applications are available that allow the extraction of components from Java jar files, please consult your system documentation or the Internet for a tool you may use on your chosen host system.

Inline comments within the WatchEvents.java source file should help you use the source as an example of how to write your own JDBC notification application.

These three source files may be tailored or modified to suit your own requirements. How these files may be modified and used is discussed in the following sections.

Step 2 Optionally create or modify the configuration file

The jar file contains a sample configuration file, WatchEvent.cfg, that may be extracted and modified to suit your specific requirements. This configuration file is formatted as a standard Java properties file and contains the application configuration properties that are used to determine the behaviour of the application.

The default configuration file contains the following:

```
# WatchEvents configuration file
user  = jdbc_user
pw    = jdbc_user
server= localhost:1701
loggerport = 1555
XSL   = Event.xsl
display = 0
```

The following properties may be used:

<table>
<thead>
<tr>
<th>WatchEvent Configuration Properties</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>display</td>
<td>0</td>
<td>The type of display to use:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = display each message within its own individual modal dialog box.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = append formatted event information to the WatchEvent application’s main dialog box.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>-1 = display each message on the console running the WatchEvent application.</td>
</tr>
<tr>
<td>loggerport</td>
<td>1555</td>
<td>The port to be used for the remote logging.</td>
</tr>
<tr>
<td>pw</td>
<td>jdbc_user</td>
<td>The control password for the server you will be watching.</td>
</tr>
<tr>
<td>server</td>
<td>localhost:1701</td>
<td>The url (host:port) of the server.</td>
</tr>
<tr>
<td>user</td>
<td>jdbc_user</td>
<td>The control user name for the server you will be watching.</td>
</tr>
<tr>
<td>XSL</td>
<td>Event.xsl</td>
<td>The XSLT stylesheet file used to format the event XML input message received. See below for more details.</td>
</tr>
</tbody>
</table>

If you use a tailored configuration file you should make sure that the application can use it when it is invoked.

By default the application will look for the configuration file named WatchEvents.cfg in the same directory that the application jar file is invoked from.

If you wish to change the configuration file name or change its location you will have to provide the configuration switch `-CFG` on the command line used to invoke the application, for example:

```
java -jar WatchEvents.jar -CFG c:\mydir\my_own_config.cfg
```

If no configuration file is found, or if a property is not specified in the configuration file, then the default settings described in the table above will be used.
Step 2 Optionally create or modify the event XSLT stylesheet file

The XSL property of the configuration file specifies an XSLT stylesheet file that should be used to format the event messages received from the server.

The event messages are XML documents that contain information about the event raised.

You may change how this information is displayed by changing the default XSL file contents or by specifying your own stylesheet. See XSLT for more information on how to use stylesheets.

The sample XSLT stylesheet Event.xsl may be extracted from the application jar and modified to suit your own setup.

The application will try to locate a valid XSL stylesheet using the following search precedence:

1. the file described by the XSL property switch if provided on the command line
2. the file described by the XSL property switch if provided in the configuration file
3. the file Event.xsl if it exists in the same directory containing the application jar file
4. the file xmlout.xsl if it exists in the same directory containing the application jar file
5. Event.xsl if it exists inside WatchEvents.jar

If no stylesheet is found then the raw XML information will be displayed.

9.5.2 Invoking the WatchEvent Sample Application.

Once correctly setup, the application can be invoked using the standard Java executable jar invocation:

```
java -jar WatchEvents.jar
```

The invocation command line may also contain configuration switches using the same configuration properties as shown in the WatchEvent Configuration Properties table above by preceding the configuration property name with a hyphen (-) and adding the property value after it separated by a blank space, for example:

```
java -jar WatchEvents.jar -pw mysecret -XSL demo.xsl
```

Any property not specified will be set to the default value as specified in the WatchEvent Configuration Properties table.
Chapter 10
Other Features

10.1 Anonymous Usernames

By default, the thin driver disallows blank usernames to be passed to it during database connection. A valid username for that database must be used. If the client attempts to connect to the database using a blank username the following exception will be raised:

```
rdb.RdbException: Io exception : Io exception :
in <rdbjdbcsrv:connect>
```

The following server configuration option can be used to change this behavior:

- `anonymous`

Use this option tells to allow anonymous connections (that is, where the username is blank) to the Oracle JDBC for Rdb thin server, for example:

```
$ java -jar rdbthinsrv.jar -anonymous
```

In addition, if anonymous connections are allowed, you can specify the default username and password to use on an anonymous connection by using the following options:

- `username <username>`
- `password <password>`

```
Example

$ java -jar rdbthinsrv.jar -anonymous -username fred -password "jones"
```

10.2 BYPASS Privilege

Privilege checking on Oracle Rdb uses the layered method. Sometimes it is not obvious how privilege checking obtains its results:

- The first pass at privilege checking occurs at an object identifier level, asking if this entity has the right to do this action to this object. If access is denied at this level a series of cascading attempts are made to try to get the privilege.

- After the object protection is checked, the entity's privilege at the database is checked. If the entity has been granted `DBADM` it will be allowed to carry out the operation even if it does not have the explicit privilege such as `CREATE`. This privilege is a kind of catch all much like `BYPASS` on OpenVMS.

- If the entity still has not been granted the privilege at the database level, the OpenVMS privileges for the OpenVMS user that the application is running under are checked.

- If that use r has the appropriate level of privilege, they are then granted the action on the object.

This means that privilege checking within Oracle JDBC for Rdb server not only depends on the privilege assigned to the connection user within the database, but also on the privilege of the OpenVMS user that started the server application (the Executor).

```
Note:
The Executor is the standard term used for the OpenVMS user under which the application is executing. This should not be confused with the "executor" processes used in conjunction with JDBC multi-process servers.
```

This allows you to set up a privileged server that has access to data that the user may not have. In other words, you can restrict user access to data in the database if and only if they come through the Oracle JDBC for Rdb server; they do not have access directly.

If you wish restricted access, grant restricted access only to the Executor and set minimum privileges. Then grant the appropriate rights to connection users so that they will have the required access. If they do not have the rights and the Executor does not have the rights, access is denied. If the user does have the right even though the Executor does not, access is allowed.

Within the thin server the `BYPASS` and `SYSPRV` privileges are disabled by default. The user will only get the privileges he has been granted and will not inherit privileges from the executor.

If the server is required to run with `BYPASS` privilege, thus allowing less privileged users access to the database objects, you should use the `--bypass` option.

10.2.1 BYPASS and Multi-Process Servers

When you use a JDBC multi-process server a separate executor process is used to carry out the database operations. This executor process inherits the privileges and authorization characteristics from the server process that started it.
Thus the information as described above applies to the executor processes in exactly the same manner as described for the server process.

### 10.2.2 Rights Identifiers

When using OpenVMS rights identifiers to restrict access to a database and its objects you should ensure that the database security option has been set on the Rdb database to enable PERSONA checking.

By default Rdb databases created or restored prior to Oracle Rdb release 7.3.1.0. will not have the security PERSONA feature enabled by default. If this feature is not enabled Rdb will not take into account any OpenVMS rights identifiers of the connecting username when determining access and authorization.

See the `ALTER DATABASE ... SECURITY IS EXTERNAL (PERSONA SUPPORT IS ENABLED)` option in the Oracle Rdb SQL Reference Manual Volume 2 for more details on how to change your older databases to enable PERSONA for Rdb security checking.

#### Note:

Rdb PERSONA checking is different to the Persona option used by JDBC servers. Please see your Oracle Rdb documentation for more information on PERSONA.

### 10.3 Persona

When an Oracle JDBC for Rdb thin server is running, it assumes the default privileges and identifiers of the user that started the server process. Similarly, when a SQL Services JDBC Dispatcher starts a server, the server will inherit the privileges and identifiers of the SQL/Services dispatcher process.

You can change this behaviour by specifying a persona value in the server definition for the server in the XML-formatted configuration file, or by using the persona switch on the command line when starting up the server.

When started with a persona, the server process will inherit its privileges and identifiers from the named persona.

BYPASS and SYSPRV privileges are still disabled by default, see BYPASS Privilege for more details.

To start a server with a specific persona, you will need to be logged into an account that has IMPERSONATE privilege and read access to the system authorization database.

The persona value associated with the server must be a valid OpenVMS persona on the system you are running the server on.

See Server Configuration Options for the format of the Persona option.

#### 10.3.1 Persona and Server Operations

When persona is used with a server, you should ensure that the persona used has appropriate access to the JDBC command procedures and JDBC log directories. This is especially important if you use persona with a Pool server or a multi-process server.

Before a server carries out any other operation it will assume the persona provided and then by default disable BYPASS (see BYPASS Privilege). So from that time on the server is operating under the persona supplied and will be restricted to the rights and authorization given to that persona.

When persona is used both the multi-process server and the Pool server will need to have read/execute/write access to the RDB$JDBC_COM directory and read/write access to the RDB$JDBC_LOG directory.

By default the installation of the JDBC drivers will create these directories on your installation destination directory and set the access to both these directories to world READ/EXECUTE. You will have to alter the file protection on these directories and grant WRITE access to the persona.

If you have redirected these logical names to another directory you must ensure that the persona has the read/write access to these directories.

See File and Directory access Requirements for more details.

### 10.4 Default Transaction

The type of transaction the Oracle JDBC for Rdb drivers start up when a transaction is required depends on a number of conditions:

- Whether AUTOCOMMIT is enabled
- The verb of the SQL statement to be executed
- The default transaction type specified on connection using the connection option `transaction`
- The setting of the transaction types in the connection if changed by methods such as `Connection.setReadOnly()` and `Connection.setTransactionIsolation()`.

Contents
Immediately after the connection has been made, JDBC will start the default transaction in anticipation of subsequent operations on the database. By default this will be a READ ONLY transaction. If you do not wish to have a transaction started at this stage you may defer the start of the transaction by using either READONLYDEFER or READWRITEDEFER on the connection string transaction option. See Connection Options for more details.

When AUTOCOMMIT is disabled, the type of transaction started will depend on whether the connection has been set read-only and whether a default transaction type has been specified on the connection using a connection switch. By default, a READ_WRITE_SERIALIZABLE transaction will be started if AUTOCOMMIT is turned off and no other method has been called to change the default transaction type.

If the setting of the transaction type in the connection is MANUAL this default behaviour changes. Setting transactions to MANUAL indicates that the client will take responsibility for the start of transactions. The drivers will no longer start transactions, however, if AUTOCOMMIT is enabled, the driver will still commit transactions appropriately.

When transactions are set to MANUAL and the first operation after a connection or after a transaction termination is not SET TRANSACTION, Oracle Rdb will start a transaction on behalf of the client. Please see the Oracle Rdb documentation for information on the default transaction mechanism provided by SQL.

10.4.1 Autocommit Transaction Duration

Since release 7.3.4.0.4

When AUTOCOMMIT is enabled, JDBC will automatically commit transactions at the end of the execution of a statement.

Sometimes during long-duration client-side read operations it may be advantageous to commit the current transaction more frequently, to prevent the read-only transaction from locking out other database operations.

For example, when using SQLDeveloper to read through Rdb records using Oracle JDBC for Rdb, records are delivered to the client application in groups, where the number of records in a record group depends on the FETCHSIZE specified for the statement or session. As you scroll down a list of records, the application may request the next group of records from the server. This may mean that if you have not finished scrolling through all the records in the retrieval set, there may still be a transaction outstanding on the database and while you may be past the current record group, the transaction is still active on the server waiting for the rest of the records to be requested. If you leave the browse window open for an extended duration, this could cause read-only transaction lockouts on the database.

JDBC allows you to specify that transactions should be auto-committed each time the server sends a FETCHSIZE number of records back to the client. This means that while the client is browsing the current group of records, that no transaction will be outstanding on the server. The TRANSACTION option AUTOFETCH may be used to inform JDBC that auto-commit is required each time the server sends FETCHSIZE groups of records. In addition the TRANSACTION option AUTOREADFETCH not only causes an auto-commit to be done on each record group send, but also tells JDBC to start a Read-Only transaction by default.

See your JDBC documentation on FETCHSIZE and how to specify the number of records to retrieve during client/server fetch operations. The application you are using may also have documentation on how to specify the FETCHSIZE when using JDBC drivers.

10.5 Executor Sub-process used with the Rdb Native driver

To improve multi-threaded concurrent access to the database while using the Rdb Native driver, you may specify that separate sub-process executors should be started for each connection request.

By default all database operations within a standard Rdb Native driver instance are carried out synchronously, within a single OpenVMS process. This synchronization is required as Rdb will only let one thread carry out a database operation at a time. This may limit the general concurrency that may be seen if you are using the Rdb Native driver within a multi-threaded environment.

To improve concurrency in a multi-threaded environment you can request the Rdb Native driver to start-up a separate executor for the database connection.

To start a separate executor for the connection you need to specify the multiprocess switch on connection URL you use for your database connection.

Since release 7.3.4.2.3

Alternatively you could set the multiprocess option to the value spawn to achieve the same results:

If no specific behaviour has been specified, by default the Oracle JDBC for Rdb drivers will start in AUTOCOMMIT mode and will start up a READ_WRITE SERIALizable transaction if the SQL statement requires a read-write transaction, for example, INSERT or UPDATE. If the statement does not require a read-write transaction, a READ ONLY transaction is started.
As a separate sub-process is created for each connection made, output written by the executor process to SYS$OUTPUT and SYS$ERROR will be redirected to log files specific to that sub-process. You should ensure that your process has write access to the log directory RDB$JDBC_LOGS.

10.5.1 Starting a Detached Executor Process

Since release 7.3.4.2.3

By default, when requested, the native driver will start a separate sub-process to run the executor image within. If you wish the driver to use a detached process instead of a sub-process, you may specify this by giving the multiprocess connection string switch the value detached:

```java
Connection conn = DriverManager.getConnection(
    "jdbc:rdbNative:my_db_dir:pers@multiprocess=detached", user, pass);
```

This tells the driver to create a separate process that will run the standard loginout.exe on startup.

10.5.2 Setting an Alternative ExecStartup Command Procedure

Similar to the MP Server, after the executor process is created, to start the executor image the native driver uses an OpenVMS DCL command procedure. By default this is:

```
rdb$jdbc_home:rdbjdbc_startexec.com
```

As the executor process does have its own environment it may be necessary for you to include environmental setup commands specific to your database environment. For example if you run multiple versions of Rdb on your system you may have to setup the environment to choose the correct Rdb version to use prior to the executor image being invoked.

You may choose to add these environment setup commands to the default JDBC executor startup command procedure, but if you do so you should be reminded that this command procedure may be replaced if you reinstall JDBC on your system.

Thus Oracle recommends that you do not alter the standard command procedure. Instead, you should create a copy of it, make your changes and rename this copy for your own use. To tell the driver to use this modified command procedure add a `srv.execStartup` specification to the connection string:

```java
Connection conn = DriverManager.getConnection(
    "jdbc:rdbNative:my_db_dir:pers@multiprocess=true" +
    "@srv.execStartup=my_dir:my_startexec.com", user, pass);
```

10.5.3 Setting Maximum Handshake Tries and Wait Duration

When the main process starts an executor process a handshake protocol is established between the two processes to allow them to carry out subsequent inter-process communication.

The main process will attempt 100 times in quick succession to establish the handshake, and then, by default, will try 500 more times with a delay of 10 ms between each try.

On some systems where the workload is heavy and particularly on single-cpu systems it is possible that after the sub-process is created the main process may attempt to establish the communication unsuccessfully. Depending on process and thread scheduling it is possible that the maximum number of attempts to establish handshake may occur before the sub-process is scheduled for execution.

On these systems you may wish to increase the number of attempts at handshake or the duration to wait between handshake attempts to prevent the premature aborting of the driver-executor connection. You may use the `handshakeTries` and `handshakeWait` options on the connection string to change these values.

See Connection Options for more details.

Contents

10.6 JDBC Hint Methods

Several methods in the JDBC classes are considered to provide hints to the drivers or underlying database system and do not have to be strictly observed. Many existing drivers silently ignore these methods.

To allow compatibility with other drivers, you may specify that optional hint methods be ignored by using the `usehints` connection switch:

```java
@usehints=false
```

This setting tells the Oracle JDBC for Rdb drivers to ignore hint methods.

By default the Oracle JDBC for Rdb drivers will observe hint methods.

The following methods are perceived as non-mandatory hints:

- `Connection.setReadOnly()`
- `ResultSet.setFetchDirection()`
- `ResultSet.setFetchSize()`
- `Statement.setFetchDirection()`
- `Statement.setFetchSize()`
10.7 Logging and Tracing

Exceptions, informational and warning messages are written to the server’s log file, if one has been specified.

In addition, when a server is started with a non-zero tracelevel, trace messages are also written to the server’s log file.

The server’s log file is generally found within the RDB$JDBC_LOGS directory, but server configuration attributes may be used to point to any directory that the server process has write access to.

If an exception is raised within the context of an executor process then the exception message will be logged to one of the executors log files, usually also found in the RDB$JDBC_LOGS directory.

If no log file is specified for a server, these messages are written to the System.out channel of the process within which the server is running.

The log file server configuration attribute is generally an absolute or relative file specification of where to write log messages. If the file specification is relative then it will be relative to the default directory from which the server process was invoked.

The log file specification may also be a special pattern, in which case certain key character sequences may be used in conjunction with normal ASCII filename characters to specify the automatic creation of the log file name. See Logfile Pattern for details on log filename pattern characters.

In addition to logging to a log file, certain events and other messages can also be logged using the standard Java Logging facilities.

By default Java Logging is turned off. See your Java JDK 1.4.1 for information on the Java Logger.

10.7.1 Logfile Pattern.

The following table shows the pattern character sequences that may be used in logfile patterns:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;%d&quot;</td>
<td>Replace with a compressed date/time value.</td>
</tr>
<tr>
<td>&quot;%g&quot;</td>
<td>Replace with a generation number to distinguish rotated logs. If no &quot;%g&quot; field has been specified and the file count is greater than one, then a generation number will be added to the end of the generated filename.</td>
</tr>
<tr>
<td>&quot;%m&quot;</td>
<td>Replace with the current process id (PID) of the server.</td>
</tr>
<tr>
<td>&quot;%n&quot;</td>
<td>Replace with the node name.</td>
</tr>
<tr>
<td>&quot;%p&quot;</td>
<td>Replace with the server name.</td>
</tr>
<tr>
<td>&quot;%u&quot;</td>
<td>Replace with a unique number to resolve conflicts.</td>
</tr>
<tr>
<td>&quot;%%&quot;</td>
<td>Translates to a single percent sign &quot;%&quot;.</td>
</tr>
</tbody>
</table>

Example:

Given the following entries in the configuration file:

```xml
<server
    name="DEFAULT"
    type="RdbThinSrv"
    url="/localhost:1701/"
    log="%n_%d.log"
/>

<server
    name="TESTSRV"
    tracelevel="-1"
    port = "1899"
/>
```

When TESTSRV server is started on the date October 30, 2012 it will log trace messages and exceptions to the file:

RDB$JDBC_LOGS:TESTSRV_CAUH3G1.LOG
Currently the method `Statement.cancel()` is not supported in the Oracle JDBC for Rdb drivers. If an application calls this method the driver will raise the following Exception:

```
oracle.rdb.jdbc.common.RdbException: Unsupported feature
<Statement.cancel>
```

In applications and application servers that expect this feature to be present, the raising of this exception may cause problems with the application functionality or may lead to excessive messages being written to the application log file.

If your application does not depend on the statement cancellation to actually take effect, and that failure to cancel can be safely ignored, you may specify the `ignoreStatementCancel` switch of the connection URL:

```
Connection conn = DriverManager.getConnection(
    "jdbc:rdbNative:my_db_dir:pers@ignoreStatementCancel=true",
    user, pass);
```

### 10.9 Server Name

Each server may be given its own name that may be used to identify a server within the controller and to look up configuration information. The name of a server may be used to identify configuration setting within an XML-formatted configuration file on server start up.

**Example 1**

For example given the following entry in `MY_CFG.XML` file:

```
<servers>
  <server
    name="myMPServer"
    type="RdbThinSrvMP"
    url="/localhost:1788/"
  />
</servers>
```

and the following command line statement:

```
$ java -jar rdbthinsrv.jar -cfg MY_CFG.XML -name myMPServer
```

A multi-process server with the name `myMPServer` will be started up on localhost listening to port 1788.

Names of servers within an XML-formatted configuration file must be unique as it is by name alone that server characteristics are searched for within the configuration file. Note that on OpenVMS character case is not significant in name matching.

The following two special server names may be used, `DEFAULT` and `DEFAULTSSL`, within the XML-formatted configuration file.

The server characteristics defined in the `DEFAULT` server will be used to provide the base configuration information for all servers, but any of these characteristics can be over-ridden either by command line switches or by characteristics defined within the specified named server in the configuration file.

**Example 2**

For example given the following server entry in `MY_CFG.XML` file:

```
<servers>
  <server
    name = "DEFAULT"
    type = "RdbThinSrv"
    url = "//localhost:1755/"
    maxClients="-1"
  />
  <server
    name="myServer"
    maxClients="10"
  />
</servers>
```

and the following command line statement:

```
$ java -jar rdbthinsrv.jar -cfg MY_CFG.XML -name "myServer"
```

A thin server with the name `myServer` will be started up on localhost listening to port 1755 with `maxClients = 10`.

The server characteristics within the `DEFAULTSSL` server will be used to provide base SSL information for `RdbThinSrvSSL` type servers.
Example 3

If an XML-formatted configuration file is used, a server is not found that matches the name provided on the command line, and a DEFAULT server definition is provided, then the DEFAULT server characteristics will be used for that server.

For example given the following server entry in MY_CFG.XML file:

```xml
<servers>
  <server
    name = "DEFAULT"
    type = "RdbThinSrv"
    url = "//localhost:1799/"
    maxClients=1
  />
</servers>
```

and the following command line statement:

```
$ java -jar rdbthinsrv.jar -cfg MY_CFG.XML -name "myServer"
```

A thin server with the name myServer will be started up on localhost listening to port 1799 with unlimited maxClients.

10.10 Named Databases

The XML-formatted configuration file allows the specification of known named databases, allowing the Oracle JDBC for Rdb servers the ability to recognize alternate names for databases served on the node the server is running on.

Similar to logical names and JNDI name spaces, the use of alternate names allows the separation of the name the client uses for the database and the actual file specification of the database.

Before requesting Oracle Rdb connect to a database, the thin server will check its list of known databases for a match against the file specification portion on the given Connection URL. If one matches, then the file specification portion of the URL property of the named database will be used to provide the connection database specification.

Example

For example, given the following named database:

```xml
<database
  name="mf_pers"
  url="//localhost:1701/disk1:[databases]mf_personnel"
  driver="oracle.rdb.jdbc.rdbThin.Driver"
  URLPrefix="jdbc:rdbThin:"
/>
```

And the following connection statement:

```
Connection conn = DriverManager.getConnection( "jdbc:rdbThin://bravo:1701/mf_pers",user, pass);
```

The client will be connected to the Oracle Rdb database

```
disk1:[databases]mf_personnel.rdb
```

During the translation of the named database, the node and port part of the URL within the named database definition is discarded.

Named databases may also be used to restrict database access within the server. See Restricting Database Access for more information on this feature.

The list of named databases may be made available for client application access if the server configuration option allowShowDatabases is set to true. See Getting a List of Known Databases from Server for more details.

10.11 On Start Commands

There are three startup command attributes that may be specified in the XML-formatted configuration file server section: srv.onStartCmd, srv.onExecStartCmd and srv.onCliStartCmd.

These options allow the specification of DCL command that should be executed just prior to the start up of a server or executor.

Note:

The srv.onStartCmd, srv.onExecStartCmd and the srv.onCliStartCmd point to a command that will be execute on start up of the server, executor or CLI invocation. If the command is to invoke a DCL command procedure you must also include the DCL invocation symbol @ in the command line.

10.11.1 srv.onStartCmd
This option specifies a DCL command to be executed prior to the invocation of the specified thin server. It must be a valid OpenVMS DCL command and must be valid within the context of the server process created by the controller or Pool server.

If multiple DCL commands are required then they should be placed within a DCL command procedure, which in turn should be made available to the environment under which the controller or Pool server runs. Oracle recommends that these command procedures be placed within the rdb$jdbc_com directory and the file protection set to allow the controller or Pool server execute access.

Example 1

For example, if your system requires a specific setup to be run to set your Java environment and Oracle Rdb environment, you may create a command procedure similar to the following example.

Create rdb$jdbc_com:our_setup.com containing
$$sys$share:rdb$setver 71
$$sys$common:[java$141.com]JAVA$141_SETUP.COM

and provide a pointer to this command procedure in the srv.onStartCmd option

<server
name="srv2forRdb"
type="RdbThinSrv"
url="/localhost:1708/"
srv.onStartCmd="rdb$jdbc_com:our_setup.com"/>

Care should be taken when providing commands for the server process to execute using this property. These commands will be executed prior to the invocation of the Java statement that starts the actual server instance. As detached OpenVMS processes will be used to run the server you must ensure that all the necessary symbols and logical names are available for the server's use within the detached process.

In particular if you redefine the standard RDB$JDBC_* logical names within your set-up to use a private version of Oracle JDBC for Rdb, you must ensure that appropriate JAR file and images are available and executable within the detached process server environment.

Example 2

For example, care should be taken in how the logical names are specified. The following redefinition may appear to point the logical name to the current default directory:

$define rdb$jdbc_home []

However this logical name will be translated during the creation of the temporary command procedure that will be used to start the server, which in this case as only the directory has been specified, the disk or device will default to the current device of the login directory of the detached process, which might not be the same device as you expected. This may prevent the server process form correctly starting.

If you need to redefine a logical name to the current default directory you can use the $f$environment DCL lexical function:

$define rdb$jdbc_home 'f$environment("DEFAULT")

This will set both the default device and directory.

If problems are found with starting a server process you can look for new log files in the RDB$JDBC_LOGS directory which may provide some information on any errors found.

Caution:
Do not use the SET VERIFY command within these command procedures. As the method Runtime.exec() may be used by the servers to create processes, the use of the SET VERIFY command within the command procedure may hang the server. This is a documented limitation of using Runtime.exec() on Open VMS Java. The logical name JAVA$EXEC_TRACE is available to help debug Runtime.exec() calls on OpenVMS. Refer to the OpenVMS Java documentation for more details.

Note:
The srv.onStartCmd command is only used by the controller or Pool server to start a server. If the server is started by any other means, neither the server startup command procedure nor any commands in the srv.onStartCmd server attribute will be executed.

10.11.2 srv.onExecStartCmd

This option specifies a DCL command to be executed prior to the invocation of an executor by a multi-process server. It must be a valid OpenVMS DCL command and must be valid within the context of the multi-process server process.

If multiple DCL commands are required, then they should be placed within a DCL command procedure, which in turn should be made available to the environment under which the server runs. It is recommended that these command procedures should be placed within the rdb$jdbc_com directory and the file protection set so that the server can access them.

Example

For example, if your system requires a specific setup to be run to set your Oracle Rdb environment, you may create a command procedure similar to the following example.

Create rdb$jdbc_com:our_exec_setup.com containing
$$sys$share:rdb$setver 7.1
<server
  name="MPsrv2forRdb"
  type="RdbThinSrvMP"
  url="/localhost:1788/"
  srv.onExecStartCmd="@rdb$jdbc_com:our_exec_setup.com"
/>

Caution:
Do not use the SET VERIFY command within these command procedures. As the method Runtime.exec() may be used by the servers to create processes, the use of the SET VERIFY command within the command procedure may hang the server. This is a documented limitation of using Runtime.exec() on Open VMS Java. The logical name JAVA$EXEC_TRACE is available to help debug Runtime.exec() calls on OpenVMS. Refer to the OpenVMS Java documentation for more details.

10.11.3 srv.onCliStartCmd

This option specifies a DCL command to be executed prior to the invocation of a CLI statement by a JDBC server. It must be a valid OpenVMS DCL command and must be valid within the context of the server process.

If multiple DCL commands are required, then they should be placed within a DCL command procedure, which in turn should be made available to the environment under which the server runs. It is recommended that these command procedures should be placed within the rdb$jdbc_com directory and the file protection set so that the server can access them.

Example
For example, if your system requires a specific setup to be run to set your Oracle Rdb environment, you may create a command procedure similar to the following example.

Create rdb$jdbc_com:our_cli_setup.com

$@sys$share:rdb$setver 7.1
and provide a pointer to this command procedure in the srv.onCliStartCmd option

<server
  name="MPsrv2forRdb"
  type="RdbThinSrvMP"
  url="/localhost:1788/"
  srv.onCliStartCmd="@rdb$jdbc_com:our_cli_setup.com"
/>

Caution:
Do not use the SET VERIFY command within these command procedures. As the method Runtime.exec() may be used by the servers to create processes, the use of the SET VERIFY command within the command procedure may hang the server. This is a documented limitation of using Runtime.exec() on Open VMS Java. The logical name JAVA$EXEC_TRACE is available to help debug Runtime.exec() calls on OpenVMS. Refer to the OpenVMS Java documentation for more details.

Contents
10.12 Password Obfuscation in Server Configuration Files

There are two types of passwords that may be stored in the server configuration files

• control passwords
• user passwords

In addition, two types of obfuscated passwords are allowed in server configuration files:

• Obfuscations produced by the digest command which is an allowed form for control passwords
• Obfuscations produced by the obfuscate command which is an allowed form of obfuscation of user passwords

The main difference in the obfuscation produced by these two commands is that digest uses one-way algorithms where as obfuscate uses reversible algorithms.

10.12.1 Control Passwords

To help prevent an unauthorized user from controlling server operations such as closing down a running server, a control password should be assigned to each server on startup. This password must be used whenever server control operations are carried out using the Oracle JDBC for Rdb Server Control interface.

To ensure better security of these control passwords, the server configuration file may contain the server control password in an obfuscated form. You can obtain an obfuscated password for a control password by using the digest statement in the Controller.

Example 1
rdbthincontrol> digest thisismypassword
digest: 0x31435008693CE6976F45DDEC5532E2C1
The value can then be used in the configuration file where you would have normally provided a plain text control password.

Example 2

```java
<server
  name="RdbThinSrv1707"
  type="RdbThinSrvMP"
  url="/localhost:1707/"
  srv.execStartup="mystartup"
  controlUser="jdbc_user"
  controlPass="0x811B15F866179583EB3C96751585B843"
/>
```

This value must be copied exactly as returned by the `digest` command.

The plain text password conversion to its obfuscated form is case-sensitive, so the same word or phrase but with different character casing will produce a different digested form.

Passwords are case sensitive so you must ensure that the value of the password used in plain text and in it digested form match exactly character by character including case.

This is particularly important if a password is used on the DCL command line. If double quotation characters are not used to surround the plain text password DCL may, depending on your environment, force the value to all lower case or all uppercase which may differ from the original.

Example 3

For example when `~digest` is used in command mode make sure the value is enclosed in double quotations:

```java
$ java -jar rdbthincontrol.jar -digest "MySecretPassword"
```

This value must be copied exactly as returned by the `digest` command.

Passwords are case sensitive so you must ensure that the value of the password used in plain text and in its digested form match exactly character by character including case. This is particularly important if a password is used on the DCL command line. If double quotation characters are not used to surround the plain text password DCL may, depending on your environment, force the value to all lower case or all uppercase which may differ from the original.

Example 3

The value of the obfuscated form of the password will change every time the `obfuscate` command is used:

```java
rdbthincontrol> obfuscate mypassword
```

The value can then be used in the configuration file where you would have normally provided a plain text user password.

Example 2

```java
<server
  name="RdbThinSrv1701"
  type="RdbThinSrv"
  url="/localhost:1701/"
  anonymous = "true"
  User="jdbc_user"
  Password="##016BA4158E5884C8D6EAEFE71697D4DC9483417DA0BA1"
/>
```

This value must be copied exactly as returned by the `obfuscate` command.

The plain-text password conversion to its obfuscated form is case-sensitive, so the same word or phrase but with different character casing will produce a different obfuscated form.

Passwords are case sensitive so you must ensure that the value of the password used in plain text and in it digested form match exactly character by character including case.

This is particularly important if a password is used on the DCL command line. If double quotation characters are not used to surround the plain text password DCL may, depending on your environment, force the value to all lower case or all uppercase which may differ from the original.

The value of the obfuscated form of the password will change every time the `obfuscate` command is used:

Example 3

```
rdbthincontrol> obfuscate mypassword
```

The value can then be used in the configuration file where you would have normally provided a plain text control password.
Note:
Obfuscated user passwords are only valid when used in conjunction with a session or server definition in a configuration file or as a server start up command line configuration option. Any user password used in a connection statement must be in plain text form.

See also: **Obfuscate** in the section Oracle JDBC for Rdb Controller.

## 10.13 Restricting Server, Database and Operational Access

In addition to the standard Rdb authorization checking that is carried out during the connection to a database using a thin server, the databases accessed, the operations attempted and the usernames allowed may be restricted at the server level.

The following sub-sections detail how access to a thin server and its served databases may be intentionally restricted.

### 10.13.1 Restricting Database Access

You may restrict connections made via a server to only those databases specified as allowed databases.

This may be done by setting the `restrictAccess` property for the server in the configuration file and then providing a list of databases that may be accessed using `allowDatabase` subsections.

**Example**

```xml
<server name="srv2restrict" type="RdbThinSrv" url="//localhost:1701/"
 restrictAccess="true">
 <allowDatabase name="mf_pers"/>
 <allowDatabase name="disk1:[databases]customers"/>
</server>
```

The name value of an `allowDatabase` subsection may be either the name of a database already declared within the same configuration file, or the database file specification portion of a connection URL.

If a client is using a server with restricted access, then the file specification portion of the JDBC Connection URL used must match one of the names within the allowed database subsections. No file expansions or logical name translations are done on the Connection URL before the server checks these names against the allowed databases, so it is important that, apart from the variations in case, the names be exactly as specified in the allowed database subsections.

If the server `restrictAccess` property is `true` and there is at least one `allowDatabase` subsection specified then the server will allow access to only those databases specified.

If the server `restrictAccess` property is `false` or not specified or if no `allowDatabase` subsection is specified for the server then no database restrictions will be applied.

The `allowDatabase` subsections are also inherited from both the “DEFAULT” and, if appropriate, the “DEFAULTSSL” server definition.

Thus, the list of allowed databases will be the combination of the allowed database list present in the “DEFAULT” and the list within the specific server’s definition. If the server uses SSL, the database list within “DEFAULTSSL” is also included.

**Example 1**

For example given the above server description of a server running on the node `bravo`:

```java
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1701/mf_pers",user, pass);
will be allowed.
```

**Example 2**

```java
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1701/MF_Pers",user, pass);
will be allowed because character case in the database specification is not significant.
```

**Example 3**

```java
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1701/disk1:[databases]customers",user, pass);
will be allowed.
```

**Example 4**

```java
Connection conn = DriverManager.getConnection("jdbc:rdbThin://bravo:1701/disk1:[databases]customers.rdb", user, pass);
will NOT be allowed due to the extra ".rdb".
```

**Example 5**

```java
Connection conn = DriverManager.getConnection(
```
10.13.2 Restricting User Access

When using a thin server, Rdb authorization checking is carried out during the connection to the database. Rdb will check the username and password provided to determine the authorization access for the given user.

In addition you may further restrict which users may use the server by setting the restrictAccess property for the server in the configuration file and then providing a list of usernames that will be restricted using allow or deny User subsections.

Example

```
<server
  name="srv2restrict"
  type="RdbThinSrv"
  url="/localhost:1701/"
  restrictAccess="true">
  <allow user="jdbc_user"/>
  <allow user="APP.*"/>
  <deny user="APP_M1"/>
</server>
```

The name value of an allow or deny User subsection must be a valid Rdb username, the keyword "owner" or a be a valid Java regular expression.

If a client is using a server with restricted access, the username used by the originating client request will be checked against the allow and/or deny lists to see if the server will accept the connection.

If the server restrictAccess property is true and there is at least one allow user or deny user subsection specified then the server will allow access to only those users that match any of the allow users specified but do not match any deny user specified for that server.

If the server restrictAccess property is true and there are no allow user subsections specified but there is at least one deny user subsection specified then the server will deny access to usernames that match any of the deny users specified for that server.

If the server restrictAccess property is false or not specified, or if no allow user or deny user subsections are specified for the server then no username restrictions will be applied.

The allow user and deny user subsections are also inherited from both the "DEFAULT" and, if appropriate, the "DEFAULTSSL" server definition. Thus, the list of usernames to be considered will be the combination of the username list present in the "DEFAULT" and the list within the specific server's definition. If the server uses SSL, the username list within "DEFAULTSSL" is also included.

As any username within the restriction lists may be a standard username value or a Java regular expression, the server determines the style of match to apply to each list entry by looking at the user pattern of that entry.

If the username pattern contains any standard Java regular expression control characters, other than asterisk (*), it will be considered a regular expression.

If you plan to use Java regular expression for matching usernames, it is important to note that prior to restriction checking, the username provided for the server connection attempt will have leading, trailing and embedded space characters removed and remaining characters converted to lowercase.

Since release 7.3.4.0.0

The keyword "owner" informs JDBC to use the OpenVMS username of the account under which the server was started.

10.13.3 Restricting IP Access

Since release 7.3.2.0.0

You may restrict client access to a JDBC server by specifying sets of IP addresses that indicate who will be allowed or denied access to making a connection using the server.

This may be done by setting the restrictAccess property for the server in the configuration file and then providing one or more IPs using allow or deny subsections.

Example 1

```
<server
  name="srv2restrict"
  type="RdbThinSrv"
  url="/localhost:1701/"
  restrictAccess="true">
  <allow IP = "100.1.1.1|1[0-9][0-9]|1[0-9][0-9]|1[0-9]">
```
The value of an allow or deny IP subsection may be either a numerical IPv4 address presented in the standard dot-Decimal notation or may be a Java regular expression based on the same standard IPv4 dot-Decimal notation.

Note:

IPv4 addresses are 32 bit values that are canonically represented in a dot-Decimal notation, which consists of 4 decimal numbers (segments), each ranging from 0 through 255, separated by dots. For example: 100.1.1.3.

If a client is using a server with restricted access, the IP of the originating client request will be checked against the allow and/or deny lists to see if the server will accept the connection.

If the server restrictAccess property is true and there is at least one allow IP or deny IP subsection specified then the server will allow access to only those IPs that match any of the allow IPs specified but do not match any deny IP specified for that server.

If the server restrictAccess property is true and there are no allow IP subsections specified but there is at least one deny IP subsection specified then the server will deny access to IPs that match any of the deny IPs specified for that server.

If the server restrictAccess property is false or not specified, or if no allow IP or deny IP subsections are specified for the server then no IP restrictions will be applied.

The allow IP and deny IP subsections are also inherited from both the “DEFAULT” and, if appropriate, the “DEFAULTSSL” server definition. Thus, the list of IPs to be considered will be the combination of the IP list present in the “DEFAULT” and the list within the specific server’s definition. If the server uses SSL, the IP list within “DEFAULTSSL” is also included.

As any IP within the restriction lists may be a full or partial IPv4 dot-Decimal value or a Java regular expression, the server determines the style of match to apply to each list entry by looking at the IP pattern of that entry.

If the IP pattern contains any standard Java regular expression control characters, other than period (.) or asterisk (*), it will be considered a regular expression. Remember, if you are using a regular expression, you should to escape any dot separators present in the IP pattern otherwise they will be used as a character wildcards.

If only numeric characters and periods are found in the pattern, the IP will be matched using standard string equality matching.

Example 2

Take care when applying restrictions to client connections made from the same host as the JDBC server is running, you should provide a local network IP value:

```
<server
  name="srv2restrict"
  type="RdbThinSrv"
  url="/100.1.1.1:1701/"
  restrictAccess="true">
  <allow IP = "100.1.1.1"/>
  <allow IP = "127.0.0.1"/>
</server>
```

In the above example, only client applications running on the same node as the server will be allowed access.

Note:

If the client connection is made from the same node the server is running on, the network socket connection may be using the local network range 127.0.*.*. This may depend on how your network has been setup.

If this is the case then you may have to provide both the local network IP and the full network IP in the allow or deny IP lists.

The IP masks used in the restriction lists are matched as simple strings, even when Java regular expressions are used. No translation of IPs or conversion to/from canonical form is done. Thus, in Example 2 above, even though "100.1.1.1" and "127.0.0.1" may be two designations of the same network node they are considered discrete IP values when the JDBC server applies IP restriction testing. Hence, both designations should be provided in the restriction lists.

Example 3

Groups of IPs may be specified by providing partial IP values by specifying from 1 to 3 leading IP segments. The missing segments will be considered as matching the full range of the segment values i.e. 0 through 255. In this way groups of IPs may be represented by a single partial IP value, for example:

```
<allow IP = "100.1.1" />
```

The above IP property tells the server to allow IP values 100.1.1.0 through 100.1.1.255.
Example 4

Similarly,

<allow IP = "100.0" />

tells the server to allow IP values 100.0.0.0 through 100.0.255.255.

Example 5

Groups of IPs may be specified by providing from 1 to 3 leading IP segments and using asterisk
wildcard characters, "*", in the remaining trailing segments. The wildcard segments will be
considered as matching the full range of the segment values i.e. 0 through 255. In this way groups of
IPS may be represented by a wildcard IP value, for example:

<allow IP = "100.3.*.*" />

The above IP property tells the server to allow IP values 100.3.0.0 through 100.3.255.255.

Example 6

Alternatively, IP groups may be specified by providing an appropriate Java regular expression:

<deny IP = "100\..0\..0\..(25[0-5]|2[0-4][0-9]|1[0-9][0-9]|[1-9][0-9]|0)/"/>

Tells the server to deny any IP in the range 100.0.0.0 through 100.0.0.255

Note:

IPv4 addresses may be subject to change during rerouting of connections through your
TCP/IP network. Care should be taken to determine the appropriate IP address or address
ranges that client applications may be connecting from, taking into account any IP
translations or reassignments. Because IP addresses may be subject to change, Oracle
recommends that you should not rely solely on IP addresses for server access restrictions.
You should also consider, additionally using other restriction criteria such as user
restrictions or server passwords to ensure tighter access security.

Server restrictions do not remove the need to ensure correct authorization and control
access on each of the database that may be accessed. Server restrictions are meant to
enhance the security provided by the underlying standard Rdb database authorization and
access control security measures, and not replace them.

10.13.4 Privileged Users Access

Users may be granted a “Privileged User” status when accessing a JDBC server. Privileged users may
be allowed to carry out operations on the server or the server’s host that would not normally be
granted, for example, access to the command line.

A user is designated “privileged” by having their username specified within an allowPrivUser
configuration option for that server, for example:

Example

<server
    name="srv2"
    type="RdbThinSrv"
    url="/localhost:1701/">
    <allowPrivUser name="jdbc_user"/>
    <allowPrivUser name="owner"/>
</server>

The name value of an allowPrivUser subsection must be a valid Rdb username or the keyword
"owner".

The keyword “owner” informs JDBC to accept the OpenVMS username of the account under which
the server was started as a valid privileged user.

Normal OpenVMS authorization and privilege checking is still carried out on all operations executed
by a privileged user. The username/password provided for the database connection will be used for
authorization checking by OpenVMS.

Note:

Control users that have successfully connected to the server using a control connection are
automatically considered “Privileged User”s.

10.13.5 Access to the Command Line

Users may be granted access to execute command line operations on the host that the server is
executing on.

If the user has been granted access, the server may execute OpenVMS DCL commands on the server’s
host system on behalf of the user. The commands are executed in a separate logonout session
established specifically for command line access.
During the execution of the DCL command, messages that are written to either SYS$OUTPUT or SYS$ERROR will be relayed back to the client application.

Enabling command line access for a server requires two server configuration options:

1. The server must have Command Line access enabled by having the server configuration option allowAccessToCL set to true, see Server Configuration Options for more details.
2. The user must be a designated “Privileged User”; see Privileged Users for more details.

The following example shows that both “jdbc_user” and “smith” will be allowed command line access when using srv1.

Example

```xml
<server
  name = "srv1"
  type = "RdbThinSrv"
  url = "//localhost:1701/
  autoStart="true"
  allowAccessToCL = "true">
  <allowPrivUser name = "jdbc_user"/>
  <allowPrivUser name = "smith"/>
</server>
```

Command line access is carried out by the server within a separate process using special command procedures. See CLI Startup Command Procedure for more details.

Command line access is only available when using certain applications such the SQLDeveloper Addin for Rdb and is used to provide the ability to execute RMU and other operations required by the SQLDeveloper application.

This command line access feature is currently not available for general application use.

10.13.6 Access to the Server Root

Since release 7.3.4.0.0

Users may be granted access to the server root in order to carry out operations that do not require a bind to an Rdb database.

If the user has been granted access, the server may execute commands such as CREATE and DROP database on behalf of the user.

Server root access is enabled by setting the server configuration option allowAccessToRoot to either of the following values:

- “true”- allows all users access to server root
- “priv”- allows only privilege users access to server root

By default server root access is disabled. Access may also be disabled by explicitly setting the allowAccessToRoot server configuration option to false.

If allowAccessToRoot is set to “priv” then the user must be a designated “Privileged User” before root access is allowed, see Privileged Users for more details.

Example

```xml
<server
  name = "srv1"
  type = "RdbThinSrv"
  url = "//localhost:1701/
  allowAccessToRoot = "priv">
  <allowPrivUser name = "jdbc_user"/>
  <allowPrivUser name = "smith"/>
</server>
```

In this example only the users “jdbc_user” and “smith” will be allowed access to the server root.

10.13.7 Create and Drop Database Entitlement

Since release 7.3.4.0.0

Users may be granted the ability to create or drop databases on the host that the server is executing on.

If the user has been granted access, the server may execute CREATE and DROP database command on behalf of the user.

Enabling CREATE and DROP database access for a server require the setting of the following server configuration options:

- allowAccessToRoot
- allowCreateDatabase
- allowDropDatabase

Normal Oracle Rdb and OpenVMS authorization and privilege checking are still carried out on all operations executed by the user after being granted create and drop database access by the JDBC
server. The username/password provided for the server root connection will be used for authorization checking.

Note:
Control users that have successfully connected to the server using a control connection are automatically considered “Privileged User”.

The following sections provide more detail on the granting of CREATE and DROP database access.

10.13.7.1 Create Database Entitlement

New database creation access is enabled by setting the server configuration option allowCreateDatabase to either of the following values:

- “true” - allows all users access to create databases
- “priv” - allows only privilege users access to create databases

In addition, access to the server root must also be enabled, thus in order for a user to be able to create new databases, the server must have the following configuration options set:

1. The server must have server root access enabled by having the server configuration option allowAccessToRoot set to either the value true or the value "priv", see Access to the Server Root for more details.
2. The server must have database create access enabled by having the server configuration option allowCreateDatabase set to the value true or the value "priv", if the creation of new databases should be allowed.
3. If either server configuration option allowAccessToRoot or allowCreateDatabase is set to the value "priv", then the user must be a designated “Privileged User” before being allowed to carry out the operation, see Privileged Users for more details.

The following example shows that both “jdbc_user” and “smith” will be allowed to create new databases when using srv1.

```xml
<server
  name = "srv1"
  type = "RdbThinSrv"
  url = "//localhost:1701/"
  allowAccessToRoot = "true"
  allowCreateDatabase = "priv">
  <allowPrivUser name = "jdbc_user"/>
  <allowPrivUser name = "smith"/>
</server>
```

Once granted access to the operation by the server, normal Oracle Rdb and OpenVMS authorization and privilege checking will still be carried out at the time of the command execution.

See the section Create Database for more information.

10.13.7.2 Drop Database Entitlement

The dropping of existing databases is enabled by setting the server configuration option allowDropDatabase to either of the following values:

- “true” - allows all users access to drop databases
- “priv” - allows only privilege users access to drop databases

In addition, access to the server root must also be enabled, thus in order for a user to be able to drop a database, the server must have the following configuration options set:

1. The server must have server root access enabled by having the server configuration option allowAccessToRoot set to either the value true or the value "priv", see Access to the Server Root for more details.
2. The server must have database drop access enabled by having the server configuration option allowDropDatabase set to the value true or the value "priv", if the dropping of existing databases should be allowed.
3. If either server configuration option allowAccessToRoot or allowDropDatabase is set to the value "priv", then the user must be a designated “Privileged User” before being allowed to carry out the operation, see Privileged Users for more details.

The following example shows that both “jdbc_user” and “jones” will be allowed to use drop database when served by srv1.

```xml
<server
  name = "srv1"
  type = "RdbThinSrv"
  url = "//localhost:1701/"
  allowAccessToRoot = "priv"
  allowDropDatabase = "priv">
  <allowPrivUser name = "jdbc_user"/>
  <allowPrivUser name = "jones"/>
</server>
```

Once granted access to the operation by the server, normal Oracle Rdb and OpenVMS authorization and privilege checking will still be carried out at the time of the command execution.

See the section Dropping an Existing Database for more information.
Further server access protection

In addition to restricting the databases accessed and the users allowed to use the server, a server may also be protected using a server password.

This may be done by setting the \texttt{srv.password} property for the server in the configuration file. This password may be either a plain text password or an obfuscated password value.

Oracle recommends not to store password in your configuration file, however if you choose to store them then an obfuscated from should be used. You may use the \texttt{digest} or \texttt{obfuscate} functions within the Controller application to generate an obfuscated password that is suitable to use with the \texttt{srv.password} property. See \texttt{Password Obfuscation in Server Configuration Files} for more details.

To make a successful connection to a database using a password-protected server the client connection properties must also provide either the plain text value of the password or an obfuscated value produced using the Controller application \texttt{obfuscate} command, on the client connection request.

The connection attribute \texttt{"srv.password"} is used to provide the password on the connection request. This attribute may be specified as part of the connection string or within the \texttt{"info"} properties list provided to the \texttt{DriverManager.getConnection} method.

\begin{itemize}
\item \textbf{Note:} If the plain text password contains the character \texttt{"@"} then you must use an obfuscated password as the \texttt{"@"} may cause problems with internal JDBC parsing.
\end{itemize}

Example

\begin{verbatim}
<server
    name="srv2restrict"
    type="RdbThinSrv"
    url="//localhost:1701/"
    srv.password="0x811B15F866179583EB3C96751585B843"
/>
\end{verbatim}

In this example, an obfuscated password is used which matches the plain text password \texttt{"jdbc_user"}.

To connect to a database using this server the client must provide a \texttt{@srv.password} value on the connection request and the password can be a plain text password that matched the one specified for the server:

\begin{verbatim}
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://bravo:1755/+
    "my_db_dir:pers@srv.password=jdbc_user",user, pass);
\end{verbatim}

Alternatively and preferred, you may use an obfuscated password:

\begin{verbatim}
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://bravo:1755/+
    "my_db_dir:pers@srv.password="+
    "##013F5615A403E4384B7D0FEFE71696B4DCC", user, pass);
\end{verbatim}

Restricting SQL Statements

\textbf{Since release 7.3.1.0.0}

You may restrict SQL statements executed via a server to only those specified by providing a list of restricted verbs and/or by providing a denied SQL statement pattern.

This may be done by providing a list of SQL verbs that may be allowed using the server’s \texttt{restrictSQL} attribute. Alternatively, or in addition to, you may provide a Java Regular Expression (REGEX) pattern in a \texttt{deny SQL} attribute that will be used to determine if the SQL statement should be denied.

The \texttt{restrictSQL} attribute takes a comma separated list of verbs that will be accepted by the server, if the SQL statement text starts with a verb that is not in this list it will be denied. This verb check is not case-sensitive.

The \texttt{deny SQL} attribute of the server is also used to determine if the SQL statement attempted will be allowed, if the SQL statement text matches the specified regular expression pattern it will be denied.

The \texttt{restrictSQL} attribute if present overrides any \texttt{restrictSQL} attribute that may be inherited from the default server definition.

However, the \texttt{deny SQL} attributes may also be inherited from the default server specification. The resultant denial list is the combination of the attributes from both the default server and the specific server definition.

\begin{itemize}
\item \textbf{Note:}
\end{itemize}
A Java regular expression is case-sensitive by default, however you may use the in-line modifier (\i) to make the pattern case-insensitive. See your Java documentation for more information on using Java regular expressions.

Example

```xml
<server
    name="srv2restrict"
    type="RdbThinSrv"
    url="/localhost:1701/"
>
    restrictSQL = "SELECT,SHOW"

    <deny SQL = "(?i).*select.*jobs.*="/n
</server>
```

In the above example, allowable SQL statements must start with either "SELECT" or "SHOW" and cannot contain the combination of "SELECT" and "JOBS", otherwise the SQL statement will be denied by the server. In this example the tests for verb restriction and statement denial are both case-insensitive.

The restrictSQL or deny SQL attributes of the server will be used to determine if the SQL statement will be allowed.

If no restrictSQL or deny SQL attributes are specified then no SQL restrictions will be applied by the server.

Note:
Even if the server allows the SQL statement to proceed, the underlying database system may still restrict the statement depending on ACLs and other database specific criteria.

The restrictSQL or deny SQL attributes allow some level of checking to be placed on queries being processed by JDBC, however they are not a substitute for correct security procedures and controls being in-place on the underlying databases.

You should refer to your Rdb documentation on database security and restricting access to tables and contents.
Caution:
Do not use the `SET VERIFY` command within these command procedures. As the method
`Runtime.exec()` may be used by the servers to create processes, the use of the `SET VERIFY`
command within the command procedure may hang the server. This is a documented limitation of
using `Runtime.exec()` on Open VMS Java. The logical name `JAVA$EXEC_TRACE` is available
to help debug `Runtime.exec()` calls on OpenVMS. Refer to the OpenVMS Java documentation
for more details.

Note: If the only changes required are environmental setup, Oracle recommends that instead of
altering the start-up command procedures, the server attribute `srv.onStartCmd`,
`srv.onExecStartCmd` or `srv.onCliStartCmd` should be considered. See On
Start Commands for more details.

10.15.1 Server Startup Command Procedure
The controller uses the server startup command procedure to start a thin server.
The `srv.startup` option within the server section of an XML-formatted configuration file may be
used to specify the file specification of the command procedure that should be used to start that server.
Example
For example:

```
<server
  name="srv2forRdb"
  type="RdbThinSrv"
  url="/localhost:1708/"
  autoStart="true"
  logfile="rdb$jdbc_logs:srv2forRdb.log"
  srv.startup="rdb$jdbc_com:our_customized_startsrv.com"
/>
```

During the driver kit installation the command procedure `rdbjdbc_startsrv.com` is placed in
the `rdb$jdbc_home` directory. This file will be used by default for server start up using the
controller and Pool servers.
The `DEFAULT` server provided in the default configuration file RDBJDBCCFG.XML specifies this
command procedure.

```
srv.startup="rdb$jdbc_home:rdbjdbc_startsrv.com"
```

You can choose to change this default command procedure to customize for your system settings, or
you can create a new customized procedure and change the configuration file so that servers use this
new file. However Oracle recommends that you use the `srv.onStartCmd` server attribute instead.
See `srv.onStartCmd` for more information.

Caution:
Do not use the SET VERIFY command within these command procedures. As the method
`Runtime.exec()` may be used by the servers to create processes, the use of the SET VERIFY
command within the command procedure may hang the server. This is a documented limitation of
using `Runtime.exec()` on Open VMS Java. The logical name `JAVA$EXEC_TRACE` is available
to help debug `Runtime.exec()` calls on OpenVMS. Refer to the OpenVMS Java documentation
for more details.

Note: The server startup command procedure is only used by the controller or Pool server to
start a thin server; if the server is started by any other means neither the server startup
command procedure nor any commands in the `srv.onStartCmd` server attribute will
be executed.

10.15.2 Executor Startup Command Procedure
The multi-process server uses the executor startup command procedure to start an executor process for
a client connection.
You can use the `srv.execStartup` option to specify the file specification of the command
procedure that should be used to start executors by a multi-process server.
Example
For example:

```
<server
  name="MPsrv2forRdb"
  type="RdbThinSrvMP"
  url="/localhost:1788/"
  srv.execStartup="rdb$jdbc_com:our_customized_startexec.com"
/>
```

You can choose to change this default command procedure to customize for your system settings, or
you can create a new customized procedure and change the configuration file so that servers use this
new file. However Oracle recommends that you use the `srv.onExecStartCmd` server attribute instead. See `srv.onExecStartCmd` for more information.
Caution: Do not use the SET VERIFY command within these command procedures. As the method Runtime.exec() may be used by the servers to create processes, the use of the SET VERIFY command within the command procedure may hang the server. This is a documented limitation of using Runtime.exec() on Open VMS Java. The logical name JAVA$EXEC_TRACE is available to help debug Runtime.exec() calls on OpenVMS. Refer to the OpenVMS Java documentation for more details.

The srv.execStartup and srv.onExecStartCmd options are only valid within the XML-Formatted configuration file server section for a multi-process server.

10.15.3 CLI Startup Command Procedure

The JDBC server uses the CLI startup command procedure to execute any CLI statements it is required to issue on behalf of a client.

If the server attribute allowAccessToCLI is set to true, clients may issue CLI statements to execute OpenVMS DCL commands in the context of the running server.

You can use the srv.cliStartup option to specify the file specification of the command procedure that should be used to execute the CLI commands.

Example

For example:

```xml
<server name="Srv2forRdb" type="RdbThinSrv" url="//localhost:1777/"
    srv.cliStartup="rdb$jdbc_com:our_customized_cli.com"/>
```

You can choose to change this default command procedure to customize for your system settings, or you can create a new customized procedure and change the configuration file so that servers use this new file. However Oracle recommends that you use the srv.onCliStartCmd server attribute instead. See srv.onCliStartCmd for more information.

Caution: Do not use the SET VERIFY command within these command procedures. As the method Runtime.exec() may be used by the servers to create processes, the use of the SET VERIFY command within the command procedure may hang the server. This is a documented limitation of using Runtime.exec() on Open VMS Java. The logical name JAVA$EXEC_TRACE is available to help debug Runtime.exec() calls on OpenVMS. Refer to the OpenVMS Java documentation for more details.

The srv.execStartup and srv.onExecStartCmd options are only valid within the XML-Formatted configuration file server section for a multi-process server.

10.16 Server/Client Protocol Checking

To ensure that the protocol between the Oracle JDBC for Rdb thin driver and servers correctly align, the Oracle JDBC for Rdb servers check versioning information transmitted by the client. This allows the quick trapping of problems that may occur because of a mismatch between the server instance and the thin driver.

Example

The following is an example of the type of error message that will be seen if the client and server mismatch:

```
oracle.rdb.jdbc.common.RdbException: Io exception :
 Io exception : Server Protocol error : received 1 : expected 2
 @rdb.Client.FetchBlobSeg
```

To prevent these protocol errors, all the Oracle JDBC for Rdb driver JAR files should be replaced at the same time whenever a new kit is installed.

To check that the server/clients instances match enable @tracelevel=-1 on the connection URL for your client application. See Trace for more details.

Near the start of the log there will be messages indicating the instance values for both the client and the server. If these two numbers do not match then protocol errors are likely.

An example of the log messages showing Instance information:

```sh
>> main ThinConnect@3.setTraceLevel msg : Rdb
nativeInstance=20030508
>> main ThinConnect@3.setTraceLevel msg : Rdb
serverInstance=20030508
```

10.17 Using OpenVMS FailSAFE IP.
OpenVMS FailSAFE IP may be using in conjunction with Oracle JDBC for Rdb thin driver and servers. During failover, FailSAFE IP will redirect the existing Oracle JDBC for Rdb client/server IP connections to the standby service.

If the failover service exists on the same node as the failed service, the connections should continue to be viable transparently.

If however, the failover service is on another node, then as Rdb connections cannot be transferred between processes, the failover will not be transparent. The thin driver should receive a socket exception on the failed TCP/IP port, as the original service is no longer available.

Note that server socket exceptions will only be raised on a connection if there is a network read or write outstanding. If the driver is currently idle and not carrying out a read or write on the socket to the server, no exception will be raised. Subsequent operations on that connection by the driver will however raise the socket exception.

The socket exception will be passed through to the application wrapped in an SQLException. It is then up to the application to catch the exception and to clean up its environment and if applicable establish a new Connection to the driver.

Depending on where the client is running it is possible that the client operating system may not raise a SocketException even if a read or write is pending. On these systems it is possible for the client connection to be held in limbo waiting for a read or write to complete.

To help reduce the impact of possible hangs due to the failure of the socket subsystem to raise the correct socket exception, a timeout may be placed on network read/writes. If the read/write does not complete within the designated time an exception will be raised.

Care should be taken in setting this timeout value as longer-duration database operations such as statement compilation may delay the server sending back its results. The client-side will have a socket read waiting on the return of the results, which could timeout if this duration is set too short in relation to the performance of your system and database software. Oracle recommends that if used, this timeout value should be set to a large value (in the order of several minutes) if you suspect that query operations on the server side may take some time.

See networkTimeout in Connection Options for more details on network read and write timeout.

### Contents

#### 10.18 Attaching to Multiple Databases in the Same Connection

Oracle Rdb allows the application programmer to attach to multiple databases using the same connection context. Starting with Version 7.3 of Oracle JDBC for Rdb, this feature is also available to developers using the Oracle JDBC for Rdb drivers.

Both the Native and Thin Driver classes have Oracle Rdb-specific extensions allowing the developer to attach more databases to an existing Connection.

**Example**

```java
String dbUrl = "jdbc:rdbThin://localhost:1701/db_dir:DB_one";
String user = "jdbc_user";
String pwd = "jdbc_user";

Connection dbConnection = DriverManager.getConnection(dbUrl, user, pwd);
dbConnection.setAutoCommit(false);
oracle.rdb.jdbc.rdbThin.Driver d = (oracle.rdb.jdbc.rdbThin.Driver)DriverManager.getDriver(dbUrl);

dbConnection2 = d.attach("db_dir:DBtwo","MYDB2",user,pwd,dbConnection);
Statement s1 = dbConnection.createStatement();
// first declare a transaction
s1.execute("declare transaction read only");
.. ..
s1.execute("commit");
.. ..
dbConnection2.close();
dbConnection.close();
```

The `attach()` methods in the Oracle JDBC for Rdb drivers allow the developer to attach another database to an existing Connection. The following conditions should be noted:

- Autocommit must be disabled prior to attaching a second database and should remain disabled until the connections have been closed.
- Each attach must provide a unique alias for Oracle Rdb to use.
- Transaction must be handled manually.

---

131
Transactions must be declared or set manually prior to executing any SQL statement. Rdb transactions must be finalized manually prior to disconnecting from the databases. Rdb transaction handling when multiple databases are attached is more complex than single database connections. See the Oracle Rdb documentation for other limitations and conditions applying to multiple database attaches.

See attach() Public Method in the Driver class for more information on attach().

Contents

10.19 Shutdown Thread

During the normal shutdown of a multi-threaded application on OpenVMS, the shutdown will wait on all children threads of the application to terminate before the shutdown will be finalized.

If for any reason a thread still remains running, the shutdown of the application will stall indefinitely until the thread terminates.

Normal Java class finalizers are not run during application shutdown and so class finalizer cannot be used to ensure that subordinate threads are correctly terminated during shutdown.

When the multi-process option is used with the JDBC Native Driver, each connection made by the user application will create its own thread to execute under. This thread is correctly terminated when the connection Disconnect is called.

If one or more application connections are not closed prior to shutting down the application, the application will hang during shutdown waiting for these connections to terminate. Thus the developer should ensure that all connections made using the multi-process Native Driver during the application are correctly disconnected prior to terminating the application.

Starting with release 7.3.0.0.0 the Oracle JDBC for Rdb drivers will create a shutdown thread when they are initially invoked. The purpose of this thread is to use the shutdown-hook feature provided by OpenVMS that will execute the thread at shutdown. The shutdown thread will ensure that any connection left open by the application will be correctly disconnected prior to the application shutdown proceeding, thus preventing application hangs at shutdown.

The application developer does not need to change any code for this shutdown feature to be enabled, as long as the application is using release 7.3.0.0.0 (or later) JDBC driver libraries the shutdown hook will be in place.

Contents

10.20 Getting a List of Known Databases from Server

Databases known to servers may be listed within the databases section of the server configuration file.

This list of known databases is made available to the client application utilizing the Oracle JDBC for Rdb thin driver by using either:

- Show Databases SQL statement or the
- getDatabases() method

A list of known databases will be returned to the caller only if the server configuration option allowShowDatabases has been set to true for the connected server. See Server Configuration Options for more details on this option.

10.20.1 Show Databases SQL statement

The Oracle JDBC for Rdb thin driver will allow the following SQL syntax extension in the SQL text of a Statement or PreparedStatement:

```
SHOW DATABASES
```

This syntax is specific to the Oracle JDBC for Rdb thin driver and is not passed through to the underlying database system. On recognizing this SQL statement, the driver will create a ResultSet that will contain a list of databases known to the connected thin server.

Example

```java
Connection conn = DriverManager.getConnection(dbUrl, user, pwd);
Statement sc = conn.createStatement();
ResultSet rs = sc.executeQuery("show databases");
while (rs.next()) {
    System.out.println(rs.getString("RDB$DATABASE_NAME") + " : " + rs.getString("RDB$DESCRIPTION");
}
rs.close();
sc.close();
conn.close();
```

See attach() Public Method in the Driver class for more information on attach().
10.20.2 getDatabases()

The Oracle JDBC for Rdb thin driver has a JDBC extension method, `getDatabases()` that may be used to return a list of databases known to a server.

Unlike the `SHOW DATABASES` SQL statement, the `getDatabases()` method does not require a connection to a database prior to being called. The `getDatabases()` takes a single parameter, the URL to the server that will be interrogated.

Example

```java
Hashtable h = oracle.rdb.jdbc.rdbThin.Driver.getDatabases("//localhost:1701/");
if (h != null) {
    Enumeration e = h.keys();
    while (e.hasMoreElements()) {
        String key = (String)e.nextElement();
        log(key + " : " + h.get(key));
    }
}
```

See the Driver class extension `getDatabases() Public Static Method` for more information.

10.21 Create and Drop Database

Since release 7.3.4.0.0

The Oracle JDBC for Rdb drivers and servers allow the creation of new Rdb databases and the dropping of existing Rdb databases.

A special JDBC connection is required for CREATE/DROP database operations, this connection, called a server root, is made to the JDBC server itself, rather than to a database instance.

Rdb database may be created or dropped by executing a JDBC Statement against the server root connection. The JDBC Statement SQL text may contain the standard Oracle Rdb SQL create or drop database syntax. As with other SQL statements when using the JDBC drivers, all syntactic keywords must not be abbreviated.

10.21.1 Server Root

Normally, JDBC thin connections are made to database instances using the JDBC server, that is, you must provide the details of both the server instance and the database file specification when specifying the connection URL.

However when creating or dropping databases, the connection needs to be made to the server itself rather than having the server bind to an existing database. To facilitate this, the JDBC thin drivers will allow connections to be made directly to a JDBC server; the term server root is used for such a connection.

To connect to the server root, instead of providing a database file specification in the connection URL you must use the following URL clause:

```
@ROOT=TRUE
```

Example

```java
Properties info = new Properties();
info.put("user", user);
info.put("password", pw);
info.put("tracelevel", -1);
String connStr = "/mynode:1701/@root=true";
conn = DriverManager.getConnection(connStr, info);
```

You must still provide a valid username and password to the `getConnection()` method, this information will be used by the server to:

- validate that you have access to the server root
- be used in the underlying SQL CREATE/DROP statements sent to Rdb

10.21.2 Server Configuration Requirements

By default JDBC servers will not allow access to server root. To allow user access you must enable root access in the server configuration section of the XML-based configuration file used by the server.
The server configuration option allowAccessToRoot is used to control root access. If the server’s allowAccessToRoot option is not specified it will be inherited from default server and if not specified for the default server, access will be denied.

See Access to the Server Root and Create and Drop Database Entitlement for more details.

10.21.3 Create Database

The create database operation is controlled by the connected server as well as Rdb and OpenVMS. In addition to having server root access you will require create database access to be granted by the server. In addition the username used in the server root connection will need to have the appropriate Rdb and OpenVMS authorizations necessary for database creation. See Create and Drop Database Entitlement for more information on create database entitlement and see your Oracle Rdb documentation for create database authorization requirements.

Once connected to the server root, and you have been allowed CREATE database database access, new databases may be created by executing JDBC Statements containing valid Rdb SQL create database syntax.

Example 1

```java
Statement stmt = conn.createStatement();
stmt.execute("create database filename 'my_db'";
```

Full file specifications may be used when declaring the database filename. If a directory or device specification is not provided then the database will be created relative to the default directory of the connected server if using the JDBC thin driver, or relative to your current default directory if using the JDBC native driver.

You may provide an ALIAS for the database in the create statement, however the alias value ‘RDB$DBHANDLE’ is specifically disallowed and JDBC will throw an exception if this value is used.

You may also provide a username and password within the SQL text to establish the ownership of the database:

Example 2

```java
Statement stmt = conn.createStatement();
stmt.execute("create database filename 'my_db' user 'my_username' using 'my_password'");
```

If you do not provide a username directly in the SQL text, the username and password provided in the server root connection will be used.

10.21.3.1 Overwriting Existing Databases

As OpenVMS allows multiple versions of files, by default, the execution of the create database statement will create a new version of the database if one already exists for the file specification provided. JDBC will not throw an exception if the database already exists.

You may specify that JDBC should only create the database if it does not already exist. In addition to the standard Oracle Rdb SQL syntax, JDBC will also accept the following clause:

```
IF NOT EXISTS
```

Example

```java
Statement stmt = conn.createStatement();
stmt.execute("create database filename 'my_db' if not exists);
```

If a database already exists matching the provided file specification, the create statement will be silently ignored.

This clause may be inserted anywhere after the database keyword;

Examples

```
"create database filename 'my_db' if not exists"
"create database if not exists filename 'my_db'
"create database alias 'mydb' if not exists filename 'my_db'"
```

10.21.4 Drop Database

The drop database operation is controlled by the connected server as well as Rdb and OpenVMS. In addition to having server root access you will require drop database access to be granted by the server. In addition the username used will need to have the appropriate Rdb and OpenVMS authorizations necessary for database creation. See Create and Drop Database Entitlement for more information on drop database entitlement and see your Oracle Rdb documentation for drop database authorization requirements.

Once connected to the server root, and you have been allowed drop database access, existing databases may be dropped by executing JDBC Statements containing valid Rdb SQL drop database syntax.

Example

```java
Statement stmt = conn.createStatement();
stmt.execute("drop database filename 'my_db'");
```
Full file specifications may be used when declaring the database filename, if a directory or device specification is not provided then the database will be searched for relative to the default directory of the connected server if using the JDBC thin driver, or relative to your current default directory if using the JDBC native driver.

Note:  Rdb will not allow a database to be dropped if there are any users currently bound to the database.  You should ensure that no active connections are currently bound to the database prior to issuing the drop database statement.

10.21.4.1 If Exists Clause
If you issue a drop database on a database file specification for a file that does not exist, Rdb will raise an exception.

To prevent an exception being raised, in addition to the standard Oracle Rdb SQL syntax you may use the following clause:

IF EXISTS

If a database does not exist matching the provided file specification, the drop statement will be silently ignored. This clause may be inserted anywhere after the database keyword;

Examples
"drop database filename 'my_db' if exists"
"drop database if exists filename 'my_db'"

10.22 Trace
Trace provides tracing of method calls and other debug information within the Oracle JDBC for Rdb drivers and servers. See Trace Values for valid trace level values.

The trace level value may be a signed decimal or a Java-style hexadecimal literal.

By default, trace output is written to the normal JDBC DriverManager.PrintWriter. You can override the default by using one of the following settings:

rdb.Debug.setLogStream(PrintStream ps)
rdb.Debug.setLogWriter(PrintWriter pw)

Example
The following example shows how to override the default:

rdb.Debug.setLogStream(new PrintStream(
    new FileOutputStream("mylog.log")));

If trace is enabled and the DriverManager.PrintWriter is not currently defined a PrintWriter for System.out is defined for you.

10.22.1 Setting tracelevel
Trace of JDBC operations may be enabled using one of the following methods:

• tracelevel property
• tracelevel switch
• tracelevel option
• Doracle.rdb.jdbc.tracelevel system option
• Set tracelevel

Details of these methods can be found in the following sections.

10.22.1.1 Tracelevel Property
Tracing can be enabled by setting the tracelevel property of the Properties passed to the DriverManager.getConnection method to the appropriate value:

Example
Properties info = new Properties();
info.put("user", user);
info.put("password", pw);
info.put("tracelevel", -1);
conn = DriverManager.getConnection (connStr, info);

See Connection Options for more details.

10.22.1.2 Tracelevel Switch
Using the tracelevel switch when starting a server can enable tracing:

Example
$java -jar rdbjdbc_home:rdbservman.jar -cfg thinsrv.cfg -tracelevel -1
10.22.1.3 Trace Level Option

Placing the `tracelevel` option in the server definition within an XML-Formatted configuration file can enable tracing.

Example

```xml
<server name="mypoolserver"
        type="RdbThinSrvPool"
        traceLevel="-1"
        url="/"localhost:1702/">
  <pooledServer name="srv1forRdb"/>
  <pooledServer name="srv2forRdb"/>
</server>
```

See Server Configuration for more details.

10.22.1.4 Trace Level System Property

Using the `Rdb��统` property `Doracle.rdb.jdbc.tracelevel` when invoking your application or Rdb server can enable tracing.

Example

```bash
$java Doracle.rdb.jdbc.tracelevel=-1 my_application
```

See Oracle JDBC for Rdb System Properties for more details.

10.22.1.5 Set Trace Level statement

Using the `SET TRACELEVEL` command in the controller can enable tracing.

Example

```bash
$java -jar rdb$jdbc_home:rdbthincontrol.jar
rdbthincontrol> connect //localhost:1701/ jones mypassword
rdbthincontrol> set tracelevel –1
```

See Controller Command Line for more details.

10.22.2 Abbreviated form of tracelevel

The abbreviated form for the `traceLevel` keyword, "tl", may also be used in the same manner.

10.22.3 Trace Values

The value passed to `trace` is actually a 32bit flag mask. Each bit set determines what will be traced, as shown in the following table.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Hexadecimal Value</th>
<th>Decimal Value</th>
<th>Traces</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0x00000001</td>

10.23 File and Directory access Requirements

There are certain file and directory access requirements that must be met to successfully use Oracle JDBC for Rdb servers, drivers and the controller.

The controller and servers require access to the directories pointed to by the following logical names:
During installation a command procedure will be created for you that you can use to set up these logical names for your system pointing to the installation directory. It is your decision whether to add these logical names to your startup command procedure or require some other mechanism such as a login setup command procedure to set these up for JDBC users.

The logical names may be placed in any of your logical name tables, the normal OpenVMS logical translation precedence will be followed when any of the JDBC components try to access files using these logical names. This allows you to have system-wide, group level or private copies of the JDBC kits each using their own set of directories.

It is important that the appropriate access be granted to users that require to startup servers or use the JDBC jar files. During installation the three directories will be created under the installation directory, and be given the following protection.

This allows the world read/execute access to all the directories and contents. If this does not comply with your organizational requirements then you should alter these protections appropriately.

Users of the controller, or those that startup servers manually will also require WRITE access to both the RDB$JDBC_COM and RDB$JDBC_LOGS directory to successfully startup servers, as the server process needs to be able to write log and temporary files to these directories.

If a server is started up using the SQL/Services JDBC dispatcher then the account under which the dispatcher runs needs WRITE access to these directories.

If you redirect these logical names to other directories you must ensure that the file and directory protections comply with the above requirements.

If persona is used with servers then you must ensure that the persona has the appropriate access rights as described above.

Contents
Chapter 11
JDBC Extensions for Oracle Rdb

The following sections provide information on features that are extensions to the JDBC standard provided by Oracle JDBC for Rdb.

The following Oracle JDBC for Rdb classes have been enhanced:

- Blob Class
- Driver Class
- ResultSet Class

In addition to enhancements made to classes, developers using Oracle JDBC for Rdb drivers may use extended SQL syntax within Statement and PreparedStatement SQL text:

- SET
- SHOW DATABASES

11.1 Blob Class

Class
oracle.rdb.jdbc.common.Blob

An additional public method has been added to Blob:

- setSegSeparator()

Note:
The maximum size of a blob segment supported by Oracle Rdb today is 65535. The Oracle JDBC for Rdb drivers will correctly handle segments up to this maximum size.

There is no limit on the number of segments that can be stored for a single Blob, however, as the drivers materialize the blob into internal byte arrays. The correct handling of very large blobs in this version of the Oracle JDBC for Rdb drivers is limited to the free memory that is available to the Java environment.

11.1.1 setSegSeparator() Public Method

Declaration
// Additional method
public void setSegSeparator(java.lang.String separator)

Parameters

- separator

The separator string to use between segments. A null or empty string will clear the separator value.

Remarks

To enable limited formatting of data returned from Oracle Rdb segmented strings, an additional public method has been added to oracle.rdb.jdbc.common.Blob that allows the specification of a separator string value to be inserted between segments when the segmented string is converted to a JDBC blob object.

The separator can be cleared by passing either a null object or empty String as the parameter to setSegSeparator().

Example

The following code segment shows how to add a newline break between segments.

```java
import oracle.rdb.jdbc.common.Blob;

ResultSet rs = s.executeQuery("select resume from resumes where employee_id = '00164'");
rs.next();
Blob bl = (Blob)rs.getBlob(1);
bl.setSegSeparator("\n");
byte[] bytes = bl.getBytes(1,9999);
String st1 = new String(bytes);
System.out.println("resume : " + st1);
```

11.2 Driver Class

Class
oracle.rdb.jdbc.rdbThin.Driver
or
An additional public method has been added to both Oracle JDBC for Rdb driver classes:

- attach() Public Method (overloaded)
- getDatabase() Public Static Method

### 11.2.1 attach() Public Method

The attach() method allows another database to be attached within the same Connection context. Databases that are attached within the same connection may take part in the same SQL compound statement.

**Overload List:**

- attach( String, java.util.Properties, java.sql.Connection)
  - Attach the database using the provided properties to the given connection.
- attach( String, String, String, String, java.sql.Connection)
  - Attach the database using the provided alias, username and password to the given connection.

#### 11.2.1.1 attach( String, java.util.Properties, java.sql.Connection)

**Declaration**

```java
// Additional method
public void attach( String url, java.util.Properties info, java.sql.Connection parent )
```

**Parameters**

- `url`
  - The URL of the database to attach.
- `info`
  - Properties for the new database attach.
- `parent`
  - The parent connection the database should be attached to.

**Remarks**

The `url` string must contain the specification of the database to attach to. Any driver prefix, for example, "jdbc:rdbThin:", node and/or port supplied in the `url` string will be disregarded.

See Oracle Rdb Database URL Specification Used with the Oracle JDBC for Rdb native driver and Oracle Rdb Database URL Specification Used with the Oracle Rdb thin driver for more information on specifying a URL.

The `info` properties object should contain at least the alias, username and password used for the database attach. See Connection Options for more details on using the connection properties object.

In addition:

- Autocommit must be disabled prior to attaching a second database and should remain disabled until the connections have been closed.
- Each attach must provide a unique `alias` for Oracle Rdb to use.
- See the Oracle Rdb documentation for other limitations and conditions applying to multiple database attaches.

**Example**

```java
String dbUrl = "jdbc:rdbThin://localhost:1701/db_dir:DB_one";
Properties info = new Properties();
info.setProperty("user", "jdbc_user");
info.setProperty("password", "jdbc_user");
Connection dbConnection = DriverManager.getConnection(dbUrl, info);
info.setProperty("alias", "MYDB2");
dbConnection.setAutoCommit(false);
oracle.rdb.jdbc.rdbThin.Driver d = (oracle.rdb.jdbc.rdbThin.Driver)DriverManager.getDriver(dbUrl);
dbConnection2 = d.attach("db_dir:DBtwo", info, dbConnection);
```

#### 11.2.1.2 attach( String, String, String, String, java.sql.Connection)

**Declaration**

```java
// Additional method
public void attach( String url, String alias, String username, String password, oracle.rdb.jdbc.common.Connection parent )
```

**Parameters**

- `url`
  - The URL of the database to attach.
- `alias`
  - The alias to use for the database.
• **username**
  The username to use to attach.

• **password**
  The password to use to attach.

• **parent**
  The parent connection the database should be attached to.

**Remarks**
The URL string must contain the specification of the database to attach to. Any driver prefix, for example "jdbc:rdbThin:“, server and port supplied in the URL string will be disregarded.

See [Oracle Rdb Database URL Specification Used with the Oracle JDBC for Rdb native driver](#) and [Oracle Rdb Database URL Specification Used with the Oracle Rdb thin driver](#) for more information on specifying a URL.

In addition:

• Autocommit must be disabled prior to attaching a second database and should remain disabled until the connections have been closed.

• Each attach must provide a unique alias for Oracle Rdb to use.

• See the Oracle Rdb documentation for other limitations and conditions applying to multiple database attaches.

**Example**

```java
String dbUrl = "jdbc:rdbThin://localhost:1701/db_dir:DB_one";
String user = "jdbc_user";
String pwd = "jdbc_user";

Connection dbConnection = DriverManager.getConnection(dbUrl, user, pwd);

dbConnection.setAutoCommit(false);

oracle.rdb.jdbc.rdbThin.Driver d = (oracle.rdb.jdbc.rdbThin.Driver)DriverManager.getDriver(dbUrl);

dbConnection2 = d.attach("db_dir:DBtwo","MYDB2", user, pwd, dbConnection);
```

### 11.2.2 `getDatabases()` Public Static Method

The Oracle JDBC for Rdb thin driver static method `getDatabases()` returns a list of databases known to the specified thin server.

**Declaration**

```java
public static Hashtable getDatabases(String serverUrl)
```

**Parameters**

- **serverUrl** – a string containing a partial connection URL containing just the node and port components of the server in the format: "/<node>:<port>/"

This static method is available only in the Oracle JDBC for Rdb thin driver. It returns a `Hashtable` containing the list of databases known to the specified server.

Each key in this `Hashtable` contains the name of a database as found in the Databases section of the configuration file used during the server's invocation. The value associated with the `Hashtable` key contains the description of the database.

**Example**

```java
Hashtable h = oracle.rdb.jdbc.rdbThin.Driver.getDatabases("/localhost:1701/");
if (h != null) {
    Enumeration e = h.keys();
    while (e.hasMoreElements()) {
        String key = (String)e.nextElement();
        log(key + " : " + h.get(key));
    }
}
```

### 11.3 ResultSet Class

**Class**

```java
oracle.rdb.jdbc.common.ResultSet
```

A semantic enhancement has been made to an existing public method

- `getBytes()` – all overloaded methods
11.3.1 getBytes() Public Method

The JDBC standard limits the use of the all the overloaded getBytes() methods for access to BINARY, VARBINARY and LONGVARBINARY data only. The Oracle JDBC for Rdb drivers relax this limitation and will attempt to return byte arrays for all valid SQL data types using these methods.

Using getBytes() on:

- CHAR and VARCHAR columns will return the raw data as returned by Rdb to the driver.
- Numeric columns will be returned in their Rdb native format as a big-endian array of bytes.
- DATE, and TIME will be returned as 64 bit big-endian array of bytes.

11.4 Extended SQL Syntax - SET

In addition to the standard SQL SET statements allowable in dynamic SQL, the Oracle JDBC for Rdb drivers will recognize driver specific SET statements as specified below.

Format

- `SET TRACELeVEL <trace_level>` Sets the trace level, see Trace for more information.
- `SET SQLCACHE <sqlcache_size>` Sets the SQL statement cache size to the specified value. A value of 0 disables SQL statement caching.

The SET statements can be issued as a SQL statement in the following methods:

- `java.sql.Statement.execute`
- `java.sql.Statement.executeUpdate`
- `java.sql.Statement.executeQuery`

These SET statements will not be sent down to the underlying database system.

Example

```java
Statement stmt = conn.createStatement();
stmt.execute("set sqlcache 10");
```

11.5 Extended SQL Syntax – SHOW DATABASES

The Oracle JDBC for Rdb Thin driver allows the developer to retrieve the list of known databases from a connected server.

Format

`SHOW DATABASES`

The SHOW DATABASES statement is captured by the Thin driver, which will return a ResultSet containing a row for each database that is known to the connected thin server. A known database is any database specified in the server XML-formatted configuration file Databases Section of the configuration file used during start up of the server. As this is a SQL statement, a valid Connection to a database on the server is required before the SHOW DATABASES statement can be executed. The SHOW DATABASES statement will not be sent down to the underlying database system.

The ResultSet returned by the SHOW DATABASES statement contains one row for each database known, and each row contains the following columns:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDB$DATABASE_NAME</td>
<td>string</td>
<td>The name given to the database in the server configuration file.</td>
</tr>
<tr>
<td>RDB$DESCRIPTION</td>
<td>string</td>
<td>Description of the database in the server configuration file.</td>
</tr>
</tbody>
</table>

The value of the RDB$DATABASE_NAME column may be used as the database file specification component of a URL string for Connections made to this server.

Example

```java
Connection conn = DriverManager.getConnection(
    "jdbc:rdbThin://localhost:1701/" + dbnam,
    user, pwd);
```

---

[114]
During the preconditioning of SQL queries for use within JDBC, the JDBC drivers may add extra SQL syntax to the provided query in order to return dbkeys for future potential record access by the driver.

Although JDBC attempts to ensure that the additional text is valid for the statement, there may be some rare cases where the retrieval of dbkeys from the query is not possible, in which case JDBC may raise a SQL syntax exception during statement processing.

You may explicitly tell JDBC not to add this additional code by using the "[nodbk]" escape to the start of the SQL text of your statement, for example:

```java
PreparedStatement ps = connection.prepareStatement("[nodbk]SELECT EMPLOYEES.EMPLOYEE_ID, S1.SALARY_START, S2.SALARY_START FROM EMPLOYEES, SALARY_HISTORY S1, SALARY_HISTORY S2 ..."
```

If JDBC sees this escape value, no additional dbkey clause(s) will be added.

A side-effect of this is that JDBC will not be able to carry out internal operations on the retrieved data that require JDBC knowing the dbkey of the records involved. An example of such an operation is the retrieval of BLOB (Segmented string) data from a table which requires JDBC to obtain the dbkey of each record to re-establish context of the record when it execute the internal segmented string retrieval subqueries.

You may also turn off the addition of the extra dbkey clause(s) to all queries connection-wide by using the "@suppressAddingDbkey=true" connection switch. See Connection Options for more details.
Chapter 12
Other Information

12.1 Disallowed Dynamic SQL Statements

Because JDBC has its own connection protocol, the following dynamic SQL statements will raise an exception if they are executed from a Statement or PreparedStatement:

- SET CONNECT
- CONNECT
- DISCONNECT

12.2 Sample Setup, Starting and Using an Oracle JDBC for Rdb thin server.

This section describes step by step how you can start a simple JDBC server and use it to access a database on your system.

1. Install Oracle JDBC for Rdb on the database server.
2. Decide on the versions of Rdb and Java you wish to use on the server.
3. Setup server-side configuration files and command procedures.
4. Start the Oracle JDBC for Rdb thin server.
5. Install Oracle JDBC for Rdb thin driver on your client machine.
6. Write you application using the JDBC API.
7. Run your applications.

You may choose to start-up a server by either:

- Invoking the rdbthinsrv JAR directly at the DCL command line. See Starting a Thin Server from the Command Line.
- By creating and starting a JDBC Dispatcher in SQL/Services. See Starting a Thin Server from Oracle SQL/Services.
- Or by using the Oracle JDBC for Rdb controller. See Starting a Thin Server from the Oracle JDBC for Rdb controller.

In this walk-through we will use the controller to maintain the servers. It is important that the command procedures used during the start-up of a server from the controller be correctly specified thus details of the appropriate command procedures will be provided below.

Step 1 Install Oracle JDBC for Rdb

The Oracle JDBC for Rdb Release Notes describe the steps required to install Oracle JDBC for Rdb. These steps should be followed to install the product on the OpenVMS node that will be used as server for you Oracle Rdb database.

The server machine requires Java to be installed prior to installing the Oracle JDBC for Rdb kit.

Once you have installed the kit you must set up your system so that it can use the JDBC kit. Several configuration files may have to be created or altered. Details of these steps follow.

Step 2 Decide on the versions of Rdb and Java

The Oracle JDBC for Rdb Release Notes will tell you the minimum versions of Rdb and Java supported by Oracle JDBC for Rdb. You may however have several versions of both Rdb and Java on your server, that meet the minimum requirements.

When the thin servers run they will need to have the environment they are running within set up so that the correct version of Rdb and Java will be used depending on your organization requirements, and which Oracle Rdb databases you wish the thin servers to access.

If you do have multiple versions of Rdb on your system, it is important that the server runs within the correct version of Rdb for the databases it will access. The Rdb environment is set up at the process level and cannot be changed for that server while the server is actually running. This means that a single running instance of a thin server may only be able to access databases for a single Rdb version.

If you try to connect to a database that does not match the version of Rdb you have set up for the thin server execution instance you will get an exception similar to:

```
SQLException: Failed to connect : in <rdbjdbcsrv:connect failure>
%RDB-F-WRONG_ODS, the on-disk structure of the database file is not supported by this version
-RODS-F-ROOTMAJVER, database format 71.0 is not compatible with software version 72.1:81000
```

You may have different version of Java on your system as well. In addition you can choose different Java VMs to run under. The VM version and type must be decided for a single thin server instances as once Java has been invoked and the server is running it cannot be changed for that server instance.

Both Rdb and Java provide mechanisms by which you can set up your environment for a specific version or variant. The Rdb version set up and the Java VM set up may be carried out manually by you prior to invoking a thin server from the DCL command line.
Alternatively there are ways of providing the appropriate set up during the thin server start-up when you choose to start the server using SQL/Services JDBC Dispatcher or by using the controller. An example of this type of set up can be seen in the steps that follow.

For the purpose of this walkthrough we will assume the following:

- Integrity server machine running OpenVMS
- Oracle Rdb release 7.2.x.x.x
- JAVA 6.0 (1.6.0)

**Step 3 Setup server-side configuration files and command procedures**

Oracle JDBC for Rdb uses various command procedures to carry out server operations and set up its environment. These command procedures may have to be altered to suit your organizational and operational needs.

You may be required to:

- Modify RDBJDBC_STARTUP.COM
- Add an invocation RDBJDBC_STARTUP.COM from your system startup procedure
- Create a XML-formatted configuration file for your server definitions
- Create a server set up command procedure

In addition Oracle recommends that XML-Formatted configuration files should be used to maintain server and other information. These configuration file will have to be created by you. An example of a server configuration file may be found below and in the Sample configuration file MY_SERVERS.XML.

**RDBJDBC_STARTUP.COM**

During installation a file called RDBJDBC_STARTUP.COM will be created in the installation directory. This command procedure may be used to set up the required system wide logical names for Oracle JDBC for Rdb to function correctly. You may choose to use this command procedure with or without changes to set up the JDBC environment.

If the JDBC servers and drivers are to be used system wide then system logical names should be used. In this case it may be appropriate to add the RDBJDBC_STARTUP.COM command procedure to your system startup procedure.

If you only require private use then JOB level logical names should be used, in which case the RDBJDBC_STARTUP.COM may be copied and/or modified to change the logicals to JOB level. Each user of the Oracle JDBC for Rdb on your server system will then need to invoke this startup procedure prior to carrying out operations such as controller actions, starting or stopping or accessing the thin servers.

The RDBJDBC_STARTUP.COM file provides logical names that will be used by the Oracle JDBC for Rdb components to locate JARS, images and command procedures and where to write log and temporary files. See the Oracle JDBC for Rdb Release Notes for more information on this command procedure and the JDBC specific logical names.

The steps that follow assume that the appropriate logical names have been set up and are available for use by you and Oracle JDBC for Rdb.

**Server Configuration File**

Server, session and connection options may be added individually on the DCL command line when you invoke a server or the controller, but it may be more convenient to place these options in a configuration file and then use this configuration file when you carry out server operations.

See *Configuration Files* for more information on what may be contained in the configurations files and the format of the data within the file. Oracle recommends using the XML-formatted form of the configuration files as it does allow greater flexibility of option specification and allows more than one server definition to be defined in a single configuration file.

Since release 7.3.3.0.0

During installation a generic configuration file RDBJDBCCFG_TEMPLATE.XML will be copied to the RDB$JDBC_HOME directory. Also during installation, if the RDB$JDBC_COM directory does not already contain a file named RDBJDBCCFG.XML, the contents of the configuration template file will be used to create this file.

**Note:** The RDBJDBCCFG_TEMPLATE.XML found in the RDB$JDBC_HOME directory will be replaced each time you install Oracle JDBC for Rdb, however, any existing RDBJDBCCFG.XML file found in the RDB$JDBC_COM directory will not be replaced. Oracle recommends to use RDB$JDBC_HOME:RDBJDBCCFG_TEMPLATE.XML only as a template file and not to use this file in production.

You may use the configuration template file as a basis of your server configuration file. The configuration file provides information to Oracle JDBC for Rdb about the various servers you may be running. In addition it provides session information for users of the controller.

**Note:** The Oracle SQL/Services JDBC dispatcher uses a search list to locate the configuration file to use on server start up. If no other appropriate configuration file is found, the file RDBJDBCCFG.XML in RDB$JDBC_COM will be used.
We have also chosen to place configuration and any other site specific files in the RDB$JDBC_COM directory, mainly as this is a standard Oracle JDBC for Rdb directory and the logical name should be already set up for us at the system level. The files may be placed anywhere on your system, as long as the controller and server processes can access them. Remember that a server process will be started up in much the same way as a normal login to the system, so it is important that any logical names used in the file specification be available to that process. The easiest way to ensure this is to have OpenVMS system wide logical names. In addition a control password, MySecretPassword has been chosen for control access to the servers. Although the controlpass can be stored in its plain text form in the configuration file, Oracle recommends that you use the obfuscated form in the server characteristics section. But make sure that you are consistent with the casing of the password as passwords are case-sensitive The controller may be used to provide this obfuscated password, but make sure that you keep the casing correct by placing double quotations around the password phrase if you use the controller in command mode.

Example

```
$ java -jar rdbsjcontrol.jar -digest "MySecretPassword"
Digest : 0x7315A012ECAD1059A3634F8BE1347846
```

See Password Obfuscation in Server Configuration Files for more details.

The new configuration file called MY_CFG.XML:

```xml
<?xml version = '1.0'?>
<!-- Configuration file for MY servers -->
<config>
  <!-- SESSION -->
  <session
    name="DEFAULT"
    tracelevel="0"
    srv.mcBasePort="5517"
    srv.mcGroupIP="239.192.1.1"
/>

  <!-- SERVERS -->
  <servers>
    <!-- DEFAULT server characteristics-->
    <server
      name="DEFAULT"
      type="RdbThinSrv"
      url="/localhost:1701/"
      maxClients="-1"
      srv.bindTimeout="1000"
      srv.idleTimeout="0"
      srv.mcBasePort="5517"
      srv.mcGroupIP="239.192.1.1"
      tracelevel = "0"
      autostart = "false"
      autorestart = "false"
      restrictAccess = "false"
      anonymous = "false"
      bypass = "false"
      tracelevel = "0"
      relay = "false"
      srv.startup="@rdb$jdbc_com:my_setup.com"
    />

    <!--My new server -->
    <server
      name="MY_SRV"
      controlUser="GROUND_CONTROL"
      controlPass="0x7315A012ECAD1059A3634F8BE1347846"
      type="RdbThinSrv"
      url="/localhost:1888/"
      cfg="rdb$jdbc_com:my_cfg.xml"
      srv.onStartCmd="@rdb$jdbc_com:my_setup.com"
    />
  </servers>
</config>
```

Note:
The server definition for MY_SRV is fairly minimal allowing most of the DEFAULT characteristics to inherit. Also that the session section is used to ensure that the broadcast IP the controller will check will be the same as the server uses.

RDB$JDBC_HOME:RDB$JDBC_STARTSRV.COM

The default server properties in MY_CFG.XML sets the server configuration file used by the server by using the srv.startup property:
This file is used by the controller during the start-up of a detached OpenVMS process that the server will run within. In most situations the default command procedure, rdb$jdbc_home:rdbjdbc_startsrv.com created during installation, can be used without change.

Sever Setup Command Procedure

During server start-up any DCL command specified on srv.onStartCmd for the server, will be executed prior to the server class being invoked. So this a good place to carry out system specific and version specific set up procedures.

Note that as this properties is an executable DCL command, the @ character is required so that the command procedure is correctly invoked.

Example

my_setup.com

@@SYS$LIBRARY:RDB$SETVER 72
@@sys$common:([java$60.com]JAVA$60_SETUP.COM
$define/job MY_DB_DIR sys$common:([DBS]

These commands ensure that the environment is correct for the server process to access a V7.2 Oracle Rdb database using the Java 6.0.

Step 4 Start the Oracle JDBC for Rdb thin server

Now that set up and configuration files are created in place the controller may be used to start the server. The configuration file containing the server definitions is used as a parameter to the DCL command line invoking the controller. In the example we use command mode -startServer to start the server

Example

$ JAVA -JAR RDBTHINCONTROL.JAR -CFG RDB$JDBC_COM:MY_CFG.XML -CONTROLPASS "MySecretPassword" -STARTSERVER -NAME MY_SRV.

RDB$NODE: 138.1.14.91
RDB$PORT: 1888
RDB$STATUS: Idle
RDB$SERVER_NAME: srv1
RDB$SERVER_TYPE: RdbThinSrv
RDB$SERVER_VERSION: V7.3-000 20100101 BA11
RDB$SERVER_SHR_VERSION: V7.3-000 20100101 BA11
RDB$SERVER_PID: 0x2030DA4D(540072525)
RDB$ALLOWS_ANON: false
RDB$ALLOWS_BYPASS: false
RDB$NUMBER_OF_CLIENTS: 0
RDB$MAX_CLIENTS: -1
RDB$TRACE_LEVEL: 0
RDB$RESTRICT_ACCESS: false

In the example we provided both the configuration file to use and the control password. The controlpass could have been set in plain text in the configuration session section, but Oracle does not recommend placing plain text passwords in plain text files. Note also that the password is enclosed in double quotation marks to prevent case changing.

Step 5 Install the Oracle JDBC for Rdb thin driver on your client machine.

Once the Oracle JDBC for Rdb kit is installed on you OpenVMS server machine you must copy the thin driver component to the machine on which you will be running your application. This machine will also need to have Java installed.

The client-side components of the thin driver are contained in the RDBTHIN.JAR file.

A file transfer program such as FTP may be used to copy this JAR file to your client machine. Remember to ensure that a binary mode transfer is done as JARs are binary files.

You should place the JAR in an appropriate directory on your client machine. This may depend on how you will ultimately use the JDBC drivers and on the application and development systems you will be using on your client machine. See your application or development environment documentation on where JDBC drivers should be placed.

You should ensure that the RDBTHIN driver jar is part of your CLASSPATH so that Java will be able to load it when your application requests it.

Starting with Oracle JDBC for Rdb Release 7.3.5.0.0 you must choose the appropriate driver jar to use depending on the JAVA version you will be using and what JDBC features you require to use.
Depending on the client system there will be methods by which you can include the driver JAR as part of the Java command when running your application, in which case the JAR does not have to be placed in the CLASSPATH environmental variable.

**Example**
For example, in MSDOS, Java allows the use of `-cp` switch to specify classpath elements

```bash
dos> java -cp .;rdbThin.jar my_app
```

**Note:** JAR files are binary files so you should ensure that the transfer utility copies the JAR file in binary mode.

---

**Step 6 Write your application using the JDBC API**

The following is a simple application that tests that you have installed JDBC and carried out any set up correctly. This example is based on RdbJdbcCheckup.java from the installation and assumes that the Rdb server node has an IP of 555.1.14.91 and that the thin server we will use, the one we started earlier, is listening on port 1888.

**Example**

```java
/*
 * This sample can be used to check the JDBC installation.
 * Just run it and provide the connect information. It will
 * select "Hello World" from the database.
 */

// You need to import the java.sql package to use JDBC import java.sql.*;

// We import java.io to be able to read from the command line import java.io.*;

class my_app {
    static BufferedReader in;
    public static void main(String args[])
    throws SQLException, IOException, Exception {
        String driverConStr = "jdbc:rdbThin://555.1.14.91:1888/";
in = new BufferedReader(new InputStreamReader(System.in));
        Class.forName("oracle.rdb.jdbc.rdbThin.Driver");
        // Prompt the user for connect information
System.out.println("Please enter information to test connection" +
" to the database");
String user; String password; String database;
user = readEntry("user: ");
int slash_index = user.indexOf('/');
if (slash_index != -1) {
    password = user.substring(slash_index + 1);
    user = user.substring(0, slash_index);
} else
    password = readEntry("password: ");

database = readEntry("database: ");
System.out.print("Connecting to the database...");
System.out.flush();
System.out.println("Connecting...");
Connection conn = DriverManager.getConnection( driverConStr + database, user, password);
System.out.println("connected.");
Statement stmt = conn.createStatement();
// Do the SQL "Hello World" thing
ResultSet rset = stmt.executeQuery("select 'Hello World' from rdb$database");
while (rset.next())
    System.out.println(rset.getString(1));
System.out.println("connected.");
    // Create a statement
System.out.println(rset.getString(1));
System.out.println("connected.");
    // close the result set, the statement and connect
rset.close();
stmt.close();
conn.close();
}

// Utility function to read a line from standard input
static String readEntry(String prompt)
```

---

147
Step 7 Run your application

With the server started you can run the sample application and provide the thin server connection information

Example

The following example assumes an Oracle Rdb database personnel in MY_DB_DIR

$java –cp .;rdb$jdbc_home:rdbThin.jar "my_ap"

Please enter information to test connection to the database
user: my_name
password: my_password
database: my_db_dir:personnel
Connecting to the database...Connecting...
connected.
Hello World
Your JDBC installation is correct.

12.3 Sample Setup, Starting an Oracle JDBC for Rdb thin server from Oracle SQL/Services.

The following sections describe step by step how you can setup and start a simple JDBC server using Oracle SQL/Services.

Basically you have to:

1. Decide on the versions of Rdb and Java you wish to use on the server
2. Setup server-side configuration files and command procedures
3. Create a JDBC dispatcher in SQL/Services
4. Associate configuration and setup files
5. Start the JDBC dispatcher

See Chapter 7 Oracle SQL/Services and Oracle JDBC for Rdb Servers for more information on these operations.

Step 1 Decide on the versions of Rdb and Java

This step is basically the same as Step 2 Decide on the versions of Rdb and Java, as covered in Sample Setup, Starting and Using an Oracle JDBC for Rdb thin server.

Step 2 Setup server-side configuration files and command procedures

For the server to start correctly a command procedure and a configuration file have to be created.

The following two files must be created:

• The Server Configuration file
• The Server Setup file

You may use a XML configuration file to store the server definitions for you server. In addition you should provide a command procedure to set up the Rdb and Java environments correctly for this server. This environment setup may also be done as part of the setup of dispatcher environment in SQL/Services, but for the purpose of this example, we shall create our own setup procedure.

Server Configuration File

As limited information can be passed to the server at the command line, most of the server characteristics for a JDBC Dispatcher server can be placed in a configuration file.

See Configuration Files for more information on what may be contained in the configurations files and the format of the data within the file. Oracle recommends using the XML-formatted form of the configuration files as it does allow greater flexibility of option specification and allows more than one server definition to be defined in a single configuration file.

During installation a generic configuration file RDBJDBCCFG_TEMPLATE.XML will be copied to the RDB$JDBC_HOME directory. Also during installation, if the RDB$JDBC_HOME directory does not already contain a file named RDBJDBCCFG.XML, the contents of the configuration template file will be used to create this file.
You may use the configuration template file as a basis of your server configuration file. The configuration file provides information to Oracle JDBC for Rdb about the various servers you may be running. In addition it provides session information for users of the controller.

Note: The Oracle SQL/Services JDBC dispatcher uses a search list to locate the configuration file to use on server start up. If no other appropriate configuration file is found, the file RDBJDBCCFG.XML in RDB$JDBC_HOME will be used.

For this walkthrough we have decided to create the definition for a thin server called SQS1888 listening on port 1888. The generic configuration file was copied and changed to add this information.

We have also chosen to place configuration and any other site specific files in the RDB$JDBC_COM directory, mainly as this is a standard Oracle JDBC for Rdb directory and the logical name should be already set up for us at the system level. The files may be placed anywhere on your system, as long as the controller and server processes can access them. Remember that a server process will be started up in much the same way as a normal login to the system, so it is important that any logical names used in the file specification be available to that process. The easiest way to ensure this is to have system wide logical names.

In addition a control password, MySecretPassword has been chosen for control access to the servers.

Although the controlpass can be stored in its plain text form in the configuration file, Oracle recommends that you use the obfuscated form in the server characteristics section. But make sure that you are consistent with the casing of the password as passwords are case-sensitive.

The controller may be used to provide this obfuscated password, but make sure that you keep the casing correct by placing double quotations around the password phrase if you use the controller in command mode.

Example

```java
$ java -jar rdthincontrol.jar -digest "MySecretPassword"
digest : 0x7315A012ECAD1059A3634F8BEB1347846
```

See Password Obfuscation in Server Configuration Files for more details.

We have chosen to create a configuration file using one of the standard file specification used by the dispatcher when searching for configuration files. See Determining the server configuration file on how the dispatcher locates a configuration file to use.

As the port used by the server will be 1888 we will create a new configuration file called SQS1888_CFG.XML and place it in RDB$JDBC_COM directory:

```
<?xml version = '1.0'?>
<config>
  <session
    name="DEFAULT"
    tracelevel="0"
    srv.mcBasePort="5517"
    srv.mcGroupIP="239.192.1.1"
  />
  <servers>
    <server
      name="SQS1888"
      controlUser="SQS_CONTROL"
      controlPass="0x7315A012ECAD1059A3634F8BEB1347846"
    />
```

```
</config>
</config>
</config>
```
**Note:**

The server definition for **SQS1888** is fairly minimal allowing most of the **DEFAULT** characteristics to inherit. Also that the session section is used to ensure that the broadcast IP the controller will check will be the same as the server uses.

---

**Server Setup File**

The JDBC dispatcher may require environmental setup for Java and the correct Oracle Rdb version to run. This setup can be done in a command procedure that will be executed just prior to starting the actual server image.

As the setup is fairly generic we have decided to create the file

```
RDB$JDBC_SQS_ONSTARTUP.COM and place it in��DB$JDBC_COM directory. By default, this file will be used by the dispatcher whenever a server has to be started. **JDBC Dispatcher Setup Procedure** describes the use of a setup command procedure for the dispatcher.
```

**Example**

```
$ type RDB$JDBC_COM:RDB$JDBC_SQS_ONSTARTUP.COM
$@SYS$LIBRARY:RDB$SETVER 72
$@sys$common:[java$60.com]JAVA$60_SETUP.COM
$define/job MY_DB_DIR sys$common:[DBS]
```

These commands ensure that the environment is correct for the server process to access a V7.2 Oracle Rdb database using JAVA Hotspot VM, which is the default in Java 6.0.

In addition we have added a JOB level logical name that may be used in database file specifications on the JDBC Connection URL.

**Step 3. Create a JDBC dispatcher in SQL/Services**

Now that the configuration file and setup procedure have been created and moved to the appropriate directory we can now create a JDBC Dispatcher. We will use 1888 as the **PORT_ID** as this will be the key value used by the dispatcher to locate the necessary files for server-up.

```
$ MCR SQLSRV_MANAGE72
SQLSRV> CONNECT SERVER;
SQLSRV> CREATE DISPATCHER MY_JDBC_DISP NETWORK_PORT TCP/IP PORT_ID 1888 PROTOCOL JDBC;
SQLSRV> SHOW DISPATCHER;
```

```
Dispatcher MY_JDBC_DISP
State: UNKNOWN
Autostart: on
Max connects: 100 clients
Idle [User Timeout]: <none>
Max client buffer size: 5000 bytes
Network Ports: (State) (Protocol)
TCP/IP port 1888 Unknown JDBC clients
Log path: SYS$MNGER: Unknown
Dump path: SYS$MNGER:
```

**Step 4. Associate configuration and setup files**

Next we must associate the server configuration and setup files with this dispatcher.

As we chose to use standard configuration file names, the dispatcher will make the following associations automatically and we need take no further action to make this happen.

Given the **PORT_ID** of 1888:

- **server name = SQS1888**
- **configuration file = RDB$JDBC_COM:SQS1888_CFG.XML**
- **setup file = RDB$JDBC_COM:RDB$JDBC_SQS_ONSTARTUP.COM**

If we had chosen not to use standard naming then we would have had to set up logical names to point to the appropriate files. See **Associating an Oracle SQL/Services JDBC Dispatcher to a Server** for more details.

However, we still need to tell the dispatcher what type of server it will be starting so we have to create the appropriate logical name. For simplicity we shall place this logical name in the **SYSTEM** logical name table. See **Determining Server Type** for information on server type associations.

```
$DEFINE/SYSTEM RDB$JDBC_SQSTYPE_1888 STD
```

If we had chosen to start up a Pool server we would not have needed to create this logical name as this is the default server type used by the JDBC dispatcher, but as the server type is a normal thin server we must inform the dispatcher of this fact using the logical name.

---
Step 5 Start the JDBC dispatcher

Now that the configuration files are in place and any logical names used by the dispatcher have been defined we can now use the SQL/Services manager to start the JDBC dispatcher.

```
SQLSRV> start dispatcher my_jdbc_disp;
SQLSRV> show disp my_jdbc_disp;
Dispatcher MY_JDBC_DISP
State: STARTING
Autostart: on
Max connects: 100 clients
Idle User Timeout: <none>
Max client buffer size: 5000 bytes
Network Ports: (State) (Protocol)
TCP/IP port 1888 Inactive JDBC clients
Log path: SYS$MANAGER:
Dump path: SYS$MANAGER:
SQLSRV>
```

```
SQLSRV> show disp my_jdbc_disp;
Dispatcher MY_JDBC_DISP
State: RUNNING
Autostart: on
Max connects: 100 clients
Idle User Timeout: <none>
Max client buffer size: 5000 bytes
Network Ports: (State) (Protocol)
TCP/IP port 1888 Inactive JDBC clients
Log path: SYS$MANAGER:
Dump path: SYS$MANAGER:
```

```
Log File: SYS$SYSROOT:[SYSMGR]SQS_DECADB_JDBC_DISP08091.LOG;
Dump File: SYS$SYSROOT:[SYSMGR]SQS_DECADB_JDBC_DISP080.DMP;
```

See your Oracle SQL/Services documentation and Starting a JDBC Dispatcher for more details on starting a dispatcher.

If the server starts up correctly you should be able to use the server from any JDBC client using the Oracle JDBC for Rdb thin driver.

You may also use the controller to check that the server is actually running:

```
$ java -jar rdb$jdbc_home:rdbthincontrol.jar -
--cfg RDB$JDBC_COM:SQS1888_CFG.XML
--controlpass "MySecretPassword"
--name SQS1888 --showServer
```

12.4 Sample configuration file MY_SERVERS.XML

```
<?xml version = "1.0"?>
<!--Configuration file for Rdb Thin JDBC Drivers/Servers -->
<config>
  <!--SESSION -->
  <session
    name="fred"
    user="jdcb_user"
    tracelevel="0"
    srv.mcBasePort="5517"
    srv.mcGroupIP="239.192.1.1"
  />

  <!--SERVERS -->
  <!--DEFAULT server characteristics.-->  
  <!--NOTE control password is the obfuscated form of "MySecretPassword" -->
  <server
    name="DEFAULT"
    type="RdbThinSrv"
    url="/\localhost:1701/"
    maxClients="1"
    srv.bindTimeout="1000"
    srv.idleTimeout="0"
    srv.mcBasePort="5517"
    srv.mcGroupIP="239.192.1.1"
    tracelevel = "0"
    autostart = "false"
    autorestart = "false"
    restrictAccess = "false"
    anonymous = "false"
    bypass = "false"
    tracelocale = "false"
    relay = "false"
    controlUser="control_user"
    controlPass="0x7315A012ECAD1059A3634F8BE1347846"
    cfg="rdb$jdbc_com:rdbjdbc_startexec.com"
    srv.execStartup="rdb$jdbc_home:rdbjdbc_startexec.com"
    srv.startup="rdb$jdbc_home:rdbjdbc_startsrv.com"
    sharedmem = "0"
    ssl.default="true"
  >
```
